The directed *ortho* metalation – palladium catalyzed cross coupling connection. A general regiospecific route to 9-phenanthrols and phenanthrenes. Exploratory further metalation

Jian-min Fu and Victor Snieckus

Abstract: A new general and regiospecific synthesis of 9-phenanthrols (**1** + **2** → **3** → **4**, Scheme 1, Table 1) proceeding by a Directed *ortho* Metalation (DoM), Suzuki–Miyaura cross coupling, and a new LDA-mediated Directed remote Metalation sequence is described. The facile Pd-catalyzed hydrogenolysis of the phenanthrols **4** into the corresponding phenanthrenes **5** via their triflates **18** translates the original DoM regioselectivity also into a general synthesis of phenanthrenes (Table 2). Further DoM (**19** → **20, 21; 24** → **25**), cross coupling (**20c** → **23**), as well as oxidation – ring contraction (**4b, 4f** → **28a, 28b**) chemistry of phenanthrene derivatives is reported.

Key words: 9-phenanthrols, directed ortho metalation, Suzuki cross coupling, synthesis.

Résumé : On décrit une nouvelle synthèse, générale et régiospécifique, des 9-phénanthrols (**1** + **2** → **3** → **4** du tableau 1) par une séquence impliquant une réaction de métallation orientée vers la position *ortho* (DoM), un couplage croisé de Suzuki–Miyaura et une nouvelle métallation à distance orientée à l'aide de LDA. La transformation des phénanthrols (**4**) en phénanthrènes correspondants (**5**) qui se fait facilement par hydrogénolyse catalysée par le palladium des triflates (**18**) reflète la régiosélectivité de la réaction de DoM initiale en une synthèse générale des phénanthrènes (Tableau 2). On rapporte aussi d'autres réactions de DoM (**19** → **20; 21; 24** → **25**), de couplages croisés (**20c** → **23**) ainsi que la chimie de l'oxydation et de la contraction de cycle (**4b**, **4f** → **28a, 28b**) de dérivés du phénanthrène.

Mots clés : 9-phénanthrols, métallation orientée en ortho, couplage croisé de Suzuki, synthèse.

Introduction

Within the last decade, rapid and regioselective access of polysubstituted aromatics, an endeavor of special significance in the pharmaceutical industry, has been facilitated by the development of the Directed *ortho* Metalation (DoM) reaction (1). This strategy, which oftimes overcomes issues of harsh conditions and lack of regiocontrol inherent in the classical aromatic electrophilic subsitution reactions, has been extensively pursued for a variety of Directed Metalation Group (DMG) – bearing benzenes; significantly less attention has been given to exploration of DoM in more highly condensed aromatics. To take the simple step to greater complexity, naphthalene DoM chemistry has been scantily studied (2) and only sporadic reports have appeared in more highly fused aromatic systems (3). In the course of work aimed to generalize the synthetic link between DoM and the Suzuki–Miyaura Pd-catalyzed cross coupling reaction (4), the 2-carboxamido-2′-methyl biaryls **3** (Scheme 1) were prepared from partners **1** and **2** (5). At this point, stimulated by the delineation of the Complex Induced Proximity Effect (CIPE) concept (6), which was rewarded by the discovery of the LDA-mediated conversion of biaryl amides **6** into fluorenones **7** (7), we tested the conjecture that deprotonation of the vinylogously acidic 2′-methyl hydrogen in **3** would result in cyclization to 9-phenanthrols **4**, a process which, as for the conversion **6** → **7**, may be termed Directed remote Metalation (DreM).

Herein we report full details (8) of the successful verification and generalization of this reaction for the regiospecific construction of 9-phenanthrols **4**, their facile conversion into the corresponding phenanthrenes **5**, and selected further DoM, Suzuki–Miyaura cross coupling, and oxidation – ring contraction reactions of phenanthrene derivatives. Phenanthrenes

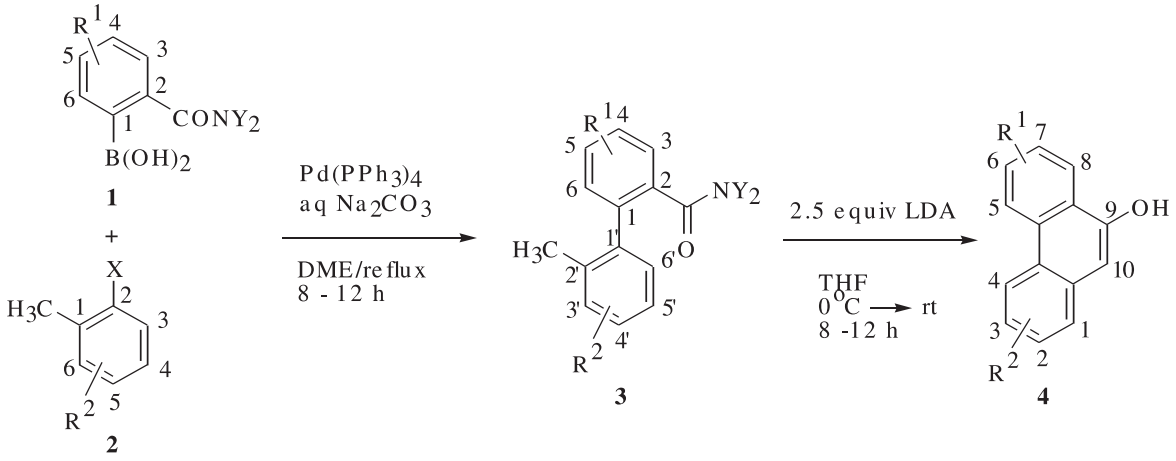
(9) represent an ambivalent class of substances which, on the one hand, are carcinogens found in the environment (10) and, on the other, natural products exhibiting potential for treatment of carcinomas and other disease states (11). Classical syntheses for phenanthrenes (12), e.g., ring annulations (13); carbocyclic ring expansion (14); intramolecular cyclization (15); and intermolecular cycloaddition (16), normally are long and laborious; inherently limited by availability of starting materials for more than trivial substitution patterns; and lack well-defined regiocontrol elements. The new carbanionic protocol (**3** → **4** → **5**) reported herein enjoys the advantages of the regiospecificity of DoM for the construction of benzamide boronic acids **1**, the ready availability of both **1** and **2** from materials of commerce, and the efficacy of the Suzuki–Miyaura reaction.

Synthesis of 2′-methylbiaryl-2-carboxamides 3 and conversion into 9-pheanthrols 4 (Table 1)

The requisite benzamide boronic acids **1** for the coupling reaction were prepared by standard *ortho*-lithiation (*s*-BuLi/TMEDA/–78°C/THF/1h) of the corresponding *N*,*N*-diethyl or *N*,*N*-diisopropyl benzamides followed by quenching with trimethyl borate and acidic workup. The boronic acids, usually obtained as fluffy solids, were not purified but directly subjected, as the excessive reactant (1.4 equiv) to the Suzuki–Miyaura cross coupling reaction (17*a*) with mainly bromo toluenes **2,** using a slightly modified procedure (DME as solvent) (17*b*, *c*). Ethanol was added as cosolvent as required for some insoluble boronic acids. Product biaryls **3** were obtained in good to excellent yields (Table 1) from coupling of unsubstituted (most entries) and methoxy (entries 3–5, 7) benzamide boronic acids **1** with 2-bromotoluenes **2** containing Cl (entries 5, 6) and electron withdrawing carboxamido (entries 8–10) and nitro (entries 11–15) groups.

The advantage of the greater reactivity of 2-iodotoluenes and choice of solvent is evident in sterically demanding cross coupling reactions. Thus, while coupling of **1e** with 2-bromotoluene (**2a**) (Scheme 2) gave **3g** in 23% (DME) and 5% (PhH) yields respectively, the corresponding iodotoluene **2c** afforded the product **3g** in 78% yield, optimized in DME.



Consideration of pK_a data (LDA pK_a = 36 (18), 4-methylbiphenyl pK_a > 40.2 (18, 19)) and the admittedly minor vinylogous acidity effect on the methyl hydrogens in the twisted biaryl **3a** provided the expectation that equilibrium concentrations of anion **8** will be formed (Scheme 3), triggered by a CIPE from amide – LDA coordination. Subsequent cyclization to the tetrahedral intermediate **9** is ultimately driven by aromatization to **11** which could occur indirectly, via elimination to the ketone **10** or, more likely, by direct elimination. Both paths would require a second equivalent of LDA to drive the equilibrium to completion. In congruence with this hypothesis in practice, treatment of the substrate **3a** with 1 equiv. of LDA at –78°C or at 0°C followed by warming to rt overnight gave 9-phenanthrol (**4a**) in only 50–58% yield, together with recovered starting material **3a** (~40%). However, using 2.5 equiv of LDA afforded 9-phenanthrol (**4a**) in 92% isolated yield.

With these general conditions established, the directed remote metalation – cyclization reaction to 9-phenanthrols was then extended to other biaryl substrates (Table 1). The absence of an amide steric effect is apparent from the fact that the *N*,*N*-diisopropyl amide **3b** underwent cyclization to give 9-phenanthrol (**4a**) in comparable high yield (entry 2) to that achieved starting with the *N*,*N*-diethyl amide **3a**. Methoxy, chloro, and carboxamido substituted phenanthrols were

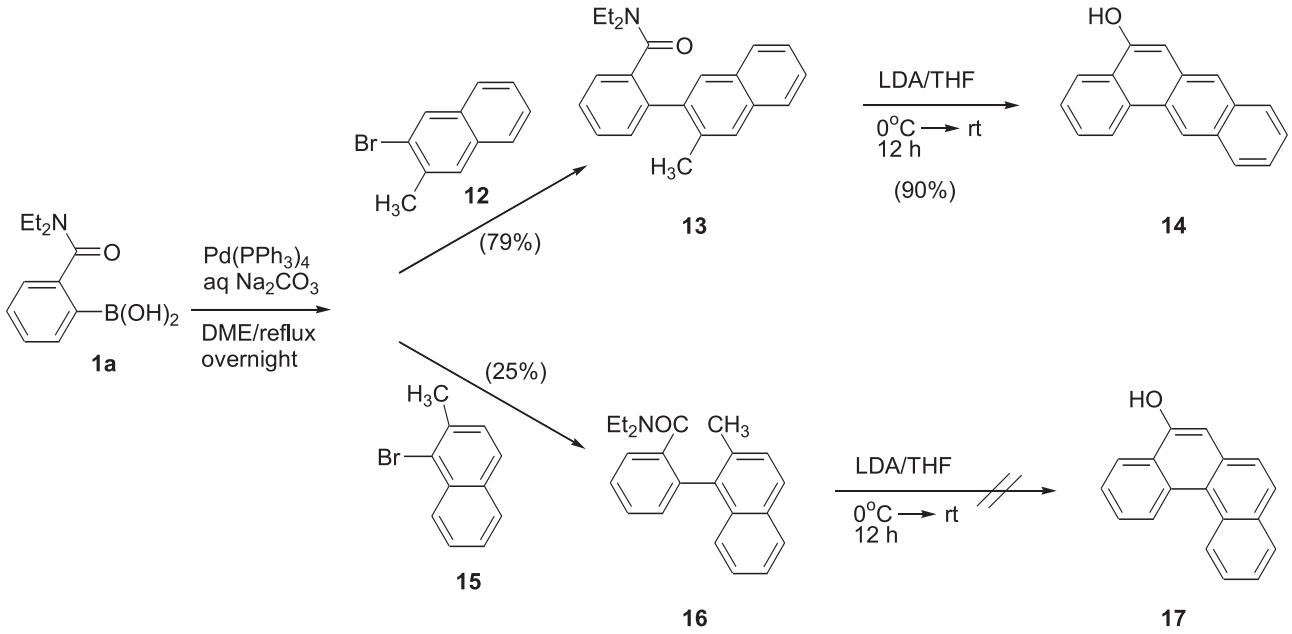
prepared in good yields (entries 3–10). The requirement of 2 equiv. of LDA for optimum yields was also ascertained in the case of 8-methoxy-9-phenanthrol (**4b**) (entry 3), formed in 92% yield compared to 63% when 1 equiv. of LDA was used. Nitro substituted biaryls failed to cyclize (entries 11–15). Although LDA addition to the THF solutions of these biaryls resulted in color changes from yellow to purple, aqueous workup led to decoloration and recovery of starting materials or decomposed products. These results may be due to the onset of single electron transfer processes between the nitrobiaryl (electron acceptor) (20) and LDA (electron donor) (21) partners. Use of bases which are successful in the Reissert indole synthesis involving 2-nitrotoluene deprotonation (e.g., NaH, KO*t*-Bu) (22) also failed to give nitro-substituted 9-phenanthrols. The characterization of some 9-phenanthrols required derivatization to acetate and (or) triflate due to their instability, as evidenced by brown discoloration after flash chromatography.



The potential value of the DreM-based 9-phenanthrol synthesis for the construction of more highly condensed polycyclic aromatics was tested on two selected cases **13** and **16** (Scheme 4) which were prepared from the cross coupling of **1a** with isomeric methyl bromonapthalenes **12** and **15** respectively. While **13** underwent LDA-mediated

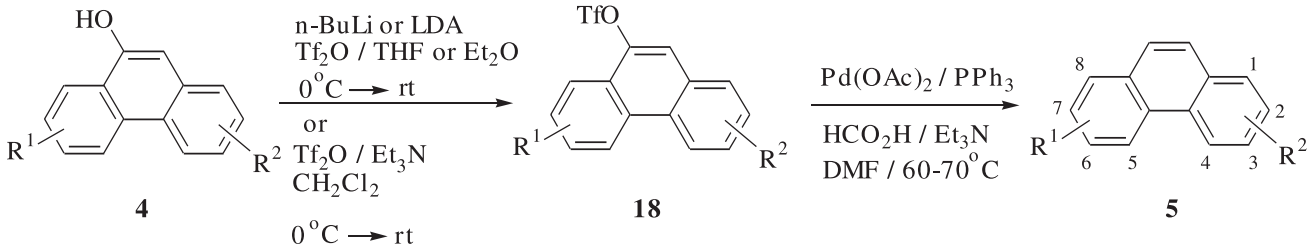
Scheme 4.

cyclization to 5-hydroxy benz[*c*]anthracene (**14**) in excellent yield, **16** failed to give the expected 10-hydroxy benz[*c*]phenanthrene (**17**) even under vigorous conditions (4 equiv of LDA in refluxing THF; quantitative recovery of **16**). The latter result, already foreshadowed by low yield in the cross coupling reaction to **16**, may be rationalized by a peri-hydrogen effect which inhibits achievement of the angle required for the non-linear (23) approach of carbanion to amide carbonyl or in the planarization needed for the tetrahedral intermediate corresponding to **9**.



The 9-phenanthrol to phenanthrene conversion (4 → 18 → 5)

To establish a general regiospecific phenanthrene synthesis based on the DreM protocol, the Pd-catalyzed hydrogenolysis of aryl triflates, independently discovered by three groups (24, 25) was adapted. Thus remarkably stable phenanthryl triflates **18** (Table 2), obtained by treatment of the corresponding phenanthrols **4** with *n*-BuLi or LDA

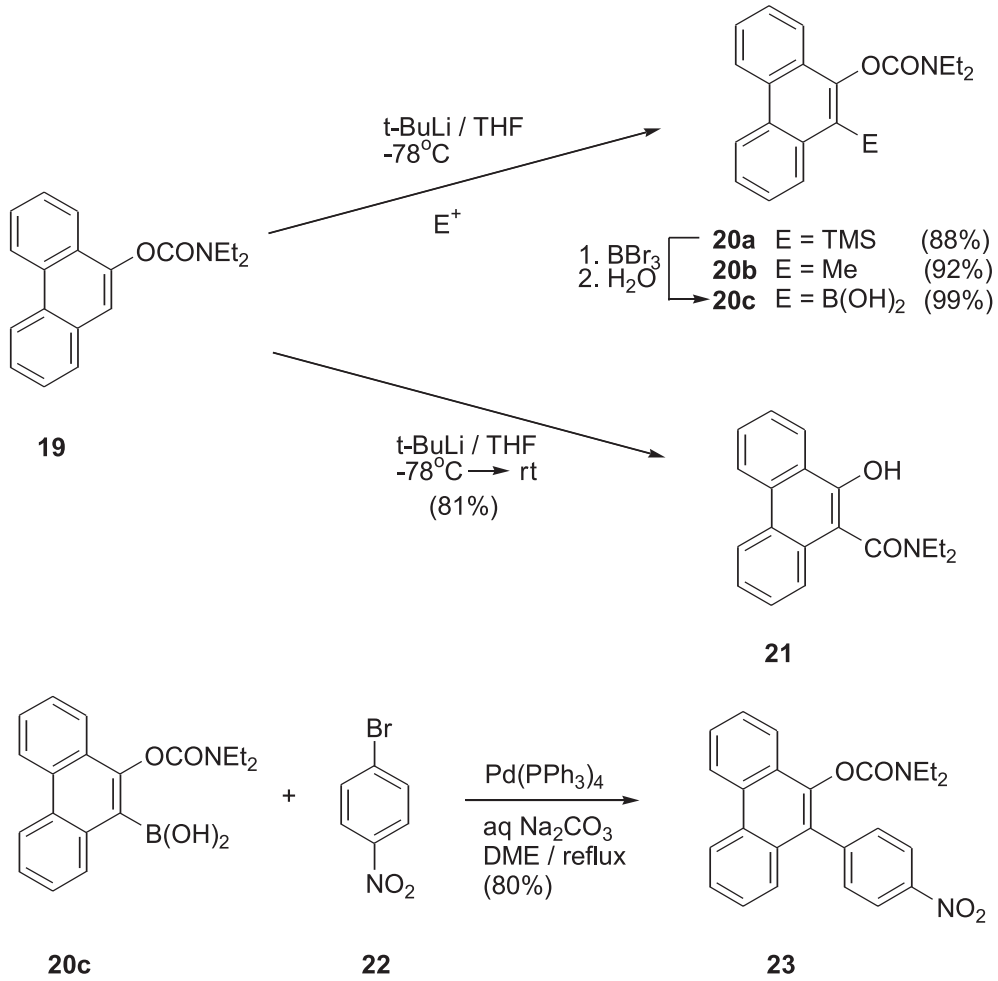
followed by triflic anhydride (24*a*) or by triethyl amine – triflic anhydride, (26) were subjected to reaction with $Pd(OAc)_2$ and PPh_3 in DMF followed by addition of Et_3N and formic acid to afford phenanthrenes **5** in good to excellent yields. The overall route to phenanthrenes, **1 + 2** → **3** → **4** → **18** → **5** constitutes a general, efficient, regiospecific, and convenient process which is expected to compete favorably with known methods for the preparation of this class of aromatic hydrocarbons. For example, the phenanthrene **5b** and **5e** were obtained in 57% and 47% overall yield respectively compared to ~10% overall yield for both compounds by the Stobbe condensation involving the intramolecular cyclization reaction as the key step (27).

DoM and other reactions of 9-phenanthrols

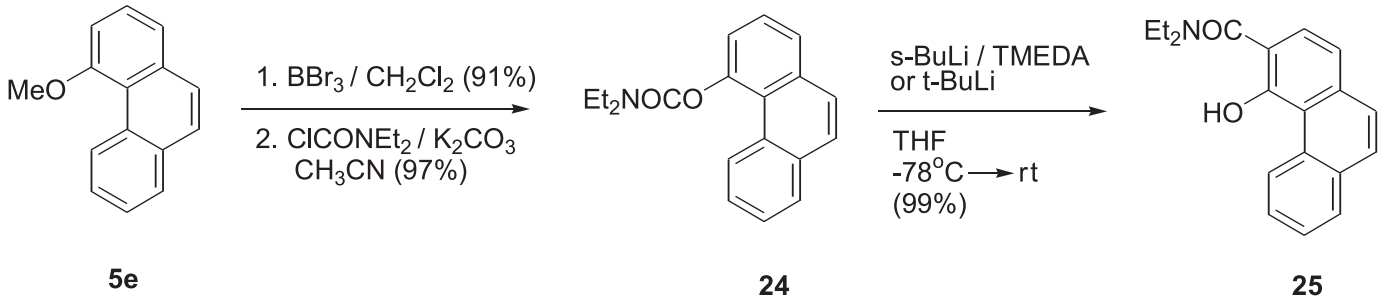
To explore phenanthrene C_{10} – DoM paths, the *N*,*N*-diethyl 9-phenanthryl *O*-carbamate **19** (Scheme 5) was prepared from the corresponding phenanthrol (**4a**) ($ClCONEt_2$/pyridine/reflux). When subjected to the standard metalation (*s*-BuLi/TMEDA/THF/–78°C/1 h) – silylation sequence, **19** afforded product **20a** in <44% yields; however, under *t*-BuLi metalation conditions, **20a** was obtained in 88% yield. Using these conditions, the 10-methyl phenanthrene **20b** was also prepared and exclusion of electrophile allowed the anionic Fries rearrangement (28) to proceed smoothly to give compound **21** in excellent yield. Treatment of the 9-TMS phenanthrene **20a** with BBr_3 resulted in ipso borodesilylation (29) to cleanly produce the corresponding boronic acid **20c** which underwent smooth palladium catalyzed cross coupling with 4-nitrobromobenzene (**22**) to furnish the biaryl **23** in good yield (80%). This sequence of potential generality presents an alternate route to Suzuki–Miyaura cross coupling partners which allows a C-H site *ortho* to a DMG to remain in a holding pattern as the TMS masked derivative and to be subsequently exposed by an regioselective ipso process.

In further examination of DoM chemistry of the phenanthrene nucleus (3), the available *N*,*N*-diethyl amides **5f** and **5g** (Table 2) were subjected to the standard metalation conditions followed by quenching with TMSCl. In each case, an inseparable mixture of the TMS isomers was obtained thus rendering this reaction of limited synthetic value. On the other hand, the phenanthryl-4-*O*-carbamate **24**, prepared from 4-methoxyphenanthrene (**5e**) by demethylation with BBr_3 and carbamoylation (Scheme 6), gave, upon metalation with either *s*-BuLi and TMEDA, or *t*-BuLi in THF at –78°C and warming to rt, the anionic Fries rearrangement (28) product **25** in quantitative yield. Attempts to trap the incipient *ortho* lithiated species with electrophiles such as TMSCl led also mainly to the formation of **25** (80%), thus suggesting a rapid migration presumably resulting from steric relief of the carbamate – C_5- peri – hydrogen interaction. These restricted observations suggest that phenanthrenes are substrates for profitable DoM and cross coupling chemistry, e.g., after phenol protection in **25**, further metalation may be contemplated.



The known facile oxidation of 9-phenanthrols into 9,10-phenanthroquinones (30) and the potential for a benzil-benzilic acid rearrangement (31) in the latter invited the development of a ring-contraction route to fluorenones (32). In this pursuit, 9-phenanthrols **4b** and **4f** (Scheme 7) were oxidized by bubbling oxygen into a DMF solution containing a catalytic amount of salcomine (33) to give the methoxy phenanthroquinones **26a** and **26b** in quantitative yields. Treatment with 2 M potassium hydroxide at 90°C provided mixtures of the benzil – benzilic acid rearrangement products **27** (major) together with fluorenones **28** (minor) which, without separation, were treated with lead tetraacetate (34), to afford the fluorenones **28** in excellent overall yields. Through this simple sequence, a synthetic conduit from phenanthrene to fluorenone aromatics is established.

Conclusions



A new general 9-phenanthrol synthesis proceeding by a Directed *ortho* Metalation (DoM) – Suzuki–Miyaura – Directed remote Metalation (DreM) sequence (**1 + 2** → **3** → **4**, Table 1) has been demonstrated. It posits advantages of inherent regiospecificity (DoM), brevity, mild conditions, and starting material availability. Furthermore, it serves as a relay for a regioselective synthesis of the corresponding

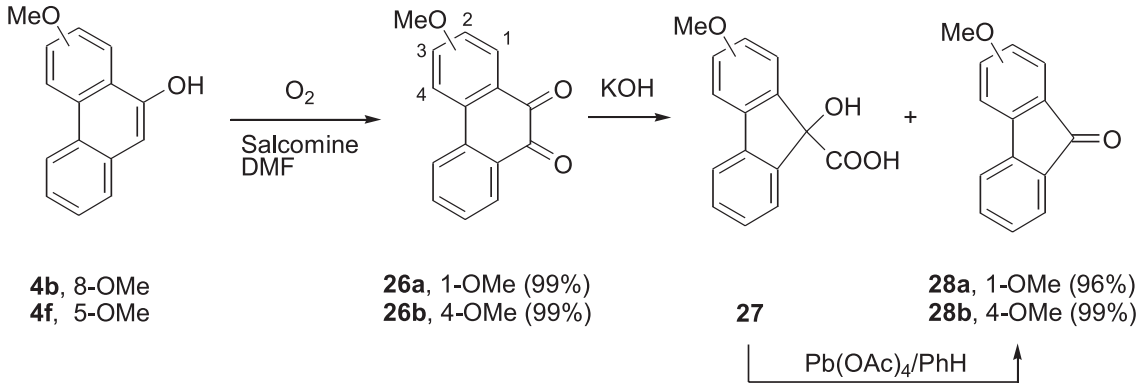
Scheme 5.

Scheme 6.

phenanthrenes by a Pd-catalyzed hydrogenolysis of the intermediate triflates (**4** → **18** → **5**, Table 2). These results together with additional exploratory DoM, cross coupling, and oxidation-rearrangement chemistry (Schemes 5–7) suggest considerable opportunity for the regiospecific construction of polysubstituted phenanthrene derivatives according to protocols elaborated herein which will compete favorably with or supercede classical methodologies.



Experimental section

General

Flash chromatography was carried out using Merck silica gel 60 (0.04–0.06 mm) purchased from BDH Chem. Co. Canada with EtOAc–hexane as eluent unless otherwise specified. Analytical thin layer chromatography (TLC) was performed using Merck precoated silica gel 60F-254 sheets. Melting points were determined using a Buchi model SMP-20 instrument and are uncorrected. IR spectra were recorded

© 2000 NRC Canada

Scheme 7.

on a Perkin-Elmer 983 IR spectrophotometer neat between NaCl plates, in $CHCl_3$ solution, Nujol, or KBr plate form. ^{1}H NMR and ^{13}C NMR spectra were recorded on AC-200 or AM-250 spectrometers in $CDCl_3$ solution using tetramethylsilane as internal standard unless otherwise specified. Mass spectra and HRMS were determined by Dr. R. Smith, McMaster University, Hamilton, Ontario, Canada, using VG 7070F or Varian spectrometers in EI mode unless otherwise specified. Elemental analysis were performed by Galbraith Laboratories, Knoxville, Tennessee. All dry solvents used were purified according to Perrin (35). Tetrahydrofuran, dimethoxyethane and diethyl ether were distilled from sodium-benzophenone ketyl under nitrogen immediately prior to use. Solutions of *n*-BuLi (hexane), *s*-BuLi (cyclohexane), and *t*-BuLi (pentane) were purchased from Aldrich Chemical Co. They were stored in resealable containers, and titrated periodically against 2,5-dimethoxybenzyl alcohol. *N*,*N*,*N′*,*N′*-Tetramethylethylenediamine (TMEDA) was dried over and distilled from CaH_2 before use. Lithium diisopropylamide (LDA) was always prepared before reactions by stirring a 1:1 mixture of diisopropylamine and *n*-BuLi at 0°C for 10 min (36). All commercial materials were purchased from Aldrich Chemical Co. or Lancaster Synthesis Ltd. Tetrakis(triphenylphosphine)palladium (0) was prepared following a literature procedure (37). All reactions were carried out under N_2 or Ar atmosphere unless otherwise specified. The –78°C temperature designated is approximate as achieved by a dry ice – acetone bath. The phrase "normal workup" means the addition of saturated aqueous NH_4Cl solution to the reaction mixture followed by CH_2Cl_2 extraction, drying over Na_2SO_4, filtration, and evaporation of the filtrate in vacuo to afford the crude product.

Synthesis of tertiary benzamides

The tertiary benzamides were prepared using the procedure described by Hall (38) from the reactions of corresponding carboxylic acids with $SOCl_2$ followed by treatment with an excess of the appropriate amines.

N,N-*Diethyl 3-methyl-4-bromobenzamide* (***2d***): bp: 120–122°C (0.02 mm). Lit. (39): bp 154°C (0.05 mm).

N,N-*Diethyl 3-bromo-4-methylbenzamide* (***2e***): mp 53–55°C (hexane); IR (KBr) 1617 cm^{-1}; ^{1}H NMR δ 1.05–1.30 (br, 6 H), 2.41 (s, 3 H), 3.20–3.60 (2 br, 4 H), 7.18–7.27 (m, 2 H), 7.54 (s, 1 H); MS *m*/*e* (rel intensity) 270 (M^+ + 2 – 1, 16), 268 (M^+ – 1, 14), 199 (34), 197 (35). Anal. calcd. for $C_{12}H_{16}BrNO$: C 53.35, H 5.97, N 5.19; found: C 53.55, H 5.96, N 5.14.

General procedure for the preparation of benzamide boronic acids (1) (method A)

A solution of the benzamide (1.00 mmol), dissolved in anhydrous THF (2 mL) was added dropwise to a stirred solution of a 1:1 *s*-BuLi–TMEDA complex or *t*-BuLi (1.10 mmol) in anhydrous THF (3 mL) at –78°C. The resulting mixture was stirred at –78°C for 1 h (unless otherwise specified), treated with an excess (4.0 mmol) of $B(OMe)_3$ and the whole was allowed to warm to room temperature overnight (8–12 h). A few drops of saturated aqueous NH_4Cl solution were added and the mixture was acidified with 2 M HCl until pH 5–6. After THF was removed in vacuo, the aqueous mixture was subjected to normal workup to afford the crude product.

*2-(*N,N-*Diethylcarboxamido)phenylboronic acid* (***1a***): According to method A, to a solution of *N*,*N*-diethyl benzamide (9.91 g, 56.74 mmol), *s*-BuLi (48.4 mL of 1.27 M solution, 61.5 mmol), and TMEDA (9.3 mL, 7.15 g, 61.5 mmol) in THF, was added $B(OMe)_3$ (25.4 mL, 23.25 g, 223.7 mmol). Acidification with 2 M HCl to pH 5–6 followed by normal workup afforded 11.63 g (94%) of **1a** as a fluffy solid which was used in cross coupling reactions without further purification.

*2-(*N,N-*Diisopropylcarboxamido)phenylboronic acid* (***1b***): According to method A, to a solution of *N*,*N*-diisopropyl benzamide (12.32 g, 60.0 mmol), *s*-BuLi (52.8 mL of 1.25 M solution, 66.0 mmol), and TMEDA (9.96 mL, 7.67 g, 66.0 mmol) in THF was added $B(OMe)_3$ (27.3 mL, 24.94 g, 240.0 mmol). Acidification with 2 M HCl to pH 5–6 followed by normal workup afforded 14.65 g (98%) of **1b** which was used in cross coupling reactions without further purification.

*3-Methoxy-2-(*N,N-*diethylcarboxamido)phenylboronic acid* (***1c***): According to method A, to a solution of *N*,*N*-diethyl 2-methoxybenzamide (6.22 g, 30.0 mmol), *s*-BuLi (25.4 mL of 1.30 M solution, 33.0 mmol), and TMEDA (5.0 mL, 3.85 g, 33.0 mmol) in THF, was added $B(OMe)_3$ (10.2 mL, 9.35 g, 90.0 mmol). Acidification with 2 M HCl to pH 5–6 followed

© 2000 NRC Canada

by normal workup afforded 7.31 g (97%) of **1c** which was used in cross coupling reactions without further purification.

*5-Methoxy-2-(*N,N-*diethylcarboxamido)phenylboronic acid (**1d**)*: According to method A, to a solution of *N*,*N*-diethyl 4-methoxybenzamide (3.40 g, 16.4 mmol), *s*-BuLi (14.0 mL of 1.29 M solution, 18.1 mmol), and TMEDA (2.7 mL, 2.01 g, 18.1 mmol) was added $B(OMe)_3$ (7.5 mL, 6.85 g, 65.7 mmol). Acidification with 2 M HCI to pH 5–6 followed by normal workup afforded 4.08 g (99%) of **1d**, which was used in cross coupling reactions without further purification.

*6-Methoxy-2-(*N,N-*diethylcarboxamido)phenylboronic acid (**1e**)*: According to method A, to a solution of *N*,*N*-diethyl 3-methoxybenzamide (2.07 g, 10.0 mmol), *s*-BuLi (8.7 mL of 1.27 M solution, 11.0 mmol), and TMEDA (1.66 mL, 1.28 g, 11.0 mmol) was added $B(OMe)_3$ (4.5 mL, 4.16 g, 40.0 mmol) at –78°C. The resulting mixture was stirred at –40°C for 4 h, quenched with saturated aqueous NH_4Cl solution at –40°C, and allowed to warm to rt over 1 h. Acidification with 2 M HCl to pH 5–6 and normal workup afforded 2.34 g (96%) of **1e** which was used in cross coupling reactions without further purification.

General procedure for the preparation of 2-methylbiaryl-2-carboxamides (3) (method B)

A mixture of $Pd(PPh_3)_4$ (0.04 mmol) and aryl halide or aryl triflate (1 mmol) in DME (3 mL) was stirred at rt for 10 min. The solution of benzamide boronic acid (**1**) (1.4 mmol) in DME (2 mL) was added. For insoluble boronic acids, a mixture of DME and a minimum amount of EtOH was used. 2 M aqueous Na_2CO_3 solution (3 mL) was added and the resulting mixture was refluxed overnight (8–12 h), cooled to rt and subjected to filtration. The filtrate was treated according to normal workup to afford the crude product.

N,N-*Diethyl 2′-methylbiphenyl-2-carboxamide (**3a**)*: According to method B, 2-bromotoluene (1.71 g, 10.0 mmol) was coupled with 2-(*N*,*N*-diethylcarboxamido)phenylboronic acid (3.01 g, 14.0 mmol) in the presence of $Pd(PPh_3)_4$ (0.462 g, 0.40 mmol). Normal workup followed by flash chromatography (1:2) afforded 2.31 g (87%) of **3a**: mp 67–68°C (hexane), (lit. (40) bp 130–135°C (0.05 mm)); IR ($CHCl_3$) 1620 cm^{-1}; ^1H NMR δ 0.65–0.71 (t, *J* = 7.1 Hz, 3 H), 0.90 (br, 3 H), 2.20 (s, 3 H), 2.60–3.90 (m, 4 H), 7.10–7.50 (m, 8 H).

N,N-*diisopropyl 2′-methylbiphenyl-2-carboxamide (**3b**)*: According to method B, 2-bromotoluene (1.04 g, 6.12 mmol) was coupled with 2-(*N*,*N*-diisopropylcarboxamido)phenylboronic acid (2.13 g, 8.56 mmol) in the presence of $Pd(PPh_3)_4$ (0.353 g, 0.31 mmol). Normal workup followed by flash chromatography (1:2) afforded 1.46 g (81%) of **3b**: mp 93–94°C (hexane); IR ($CHCl_3$) 1618 cm^{-1}; ^1H NMR δ 0.40–0.80 (br, 3 H), 0.97–1.00 (d, *J* = 6.3 Hz, 3 H), 1.04–1.07 (d, *J* = 6.8 Hz, 3 H), 1.46–1.49 (d, *J* = 6.8 Hz, 3 H), 2.23 (s, 3 H), 3.40–3.70 (br, 2 H), 7.12–7.41 (m, 8 H); MS *m*/*e* (rel intensity) 295 (M^+, 7), 252 (17), 195 (100), 165 (25). Anal. calcd. for $C_{20}H_{25}NO$: C 81.31, H 8.53, N 4.74; found: C 80.98, H 8.61, N 4.66.

N,N-*Diethyl 3-methoxy-2′-methylbiphenyl-2-carboxamide (**3c**)*: According to method B, 2-bromotoluene (2.05 g, 12.0 mmol) was coupled with 3-methoxy-2-(*N*,*N*-diethylcarboxamido)phenylboronic acid (4.23 g, 17.0 mmol) in the presence of $Pd(PPh_3)_4$ (0.555 g, 0.48 mmol). Normal workup followed by flash chromatography (1:1) afforded 3.02 g (85%) of **3c**: mp 90–91°C (cyclohexane); IR ($CHC1_3$) 1616 cm^{-1}; ^1H NMR δ 0.58–0.63 (t, *J* = 7.1 Hz, 3 H), 0.80–1.10 (br, 3 H), 2.20 (s, 3 H), 2.70–3.83 (m, 4 H), 3.86 (s, 3 H), 6.89–6.93 (dd, *J* = 7.6, 0.7 Hz, 1 H), 7.18–7.36 (m, 6 H); MS *m*/*e* (rel intensity) 297 (M^+, 1), 225 (100), 224 (32). General procedure for the synthesis of 9-phenanthrols (4) (method C)

To a freshly prepared solution of LDA (2.50 mmol) in THF (8 mL) at 0°C was added a solution of 2′-methylbiaryl-2-carboxamide (1.00 mmol) in THF (2 mL). The resulting mixture was stirred at rt for 3–12 h to give a brown or black solution that went colorless upon quenching with a few drops of aqueous NH_4Cl solution. This reaction mixture was acidified (2 M HCl) to pH 5–6 and the whole was evaporated to dryness in vacuo. Normal workup followed by flash chromatography afforded the desired product.

When, due to instability, 9-phenanthrol products required conversion into their acetate derivatives, these were prepared by stirring the 9-phenanthrols in acetic anhydride at rt overnight followed by evaporation to dryness in vacuo, normal workup, and flash chromatography.

*9-Phenanthrol (**4a**)*: According to method C treatment of *N,N*-diethyl 2′-methylbiphenyl-2-carboxamide (1.01 g, 4.1 mmol) with LDA (9.03 mmol) for 3 h followed by acidification, normal workup and flash chromatography (1:1) afforded 0.74 g (92%) of **4a**: mp 151–152°C (PhH) (lit. (41) mp 149–152°C); ^{1}H NMR spectrum was identical with that of authentic material (Aldrich Chem. Co.). Under similar conditions, treatment of the diisopropyl amide **3b,** (0.74 g, 2.5 mmol) with LDA (6.25 mmol) for 3 h followed by acidification, normal workup and flash chromatography (1:1) afforded 0.48 g (98%) of **4a** whose physical and spectroscopic properties were identical with those of the material obtained above.

*8-Methoxy-9-phenanthrol (**4b**)*: According to method C treatment of *N,N*-diethyl 3-methoxy-2′-methylbiphenyl-2-carboxamide (1.49 g, 5.0 mmol) with LDA (12.50 mmol) for 3 h followed by acidification, normal workup and flash chromatography (1:1) afforded 1.03 g (92%) of **4b**: mp 133–134°C (cyclohexane); IR ($CHC1_3$) 3387 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ 4.08 (s, 3 H), 7.05 (s, 1 H), 7.24–7.27 (d, *J* = 7.9 Hz, 1 H), 7.39–7.46 (m, 1 H), 7.49–7.55 (ddd, *J* = 8.0, 7.0, 1.1 Hz, 1 H), 7.60–7.66 (dd, *J* = 8.2, 8.2 Hz, 1 H), 7.71–7.75 (dd, *J* = 8.0, 1.2 Hz, 1 H), 8.43–8.46 (d, *J* = 8.2 Hz, 1 H), 8.61–8.64 (d, *J* = 8.2 Hz, 1 H), 9.60 (s, 1 H); MS *m*/*e* (rel intensity) 224 (M^+, 74), 181 (100), 152 (43). Anal. calcd. for $C_{15}H_{12}O_2$: C 80.34, H 5.39; found: C 80.32, H 5.50.

*6-Methoxy-9-phenanthrol (**4c**)*: According to method C treatment of *N,N*-diethyl 5-methoxy-2′-methylbiphenyl-2-carboxamide (1.81 g, 6.1 mmol) with LDA (15.25 mmol) for 6 h followed by acidification, normal workup and flash chromatography (1:1) afforded 1.21 g (88%) of **4c** which was characterized as its *triflate* **18c** (see below).

*2-Chloro-6-methoxy-9-phenanthrol (**4d**)*: According to method C treatment of *N,N*-diethyl 5-methoxy-2′-methyl- 4′-chlorobiphenyl-2-carboxamide (0.84 g, 2.5 mmol) with LDA (6.30 mmol) for 3 h followed by acidification, normal workup and flash chromatography (1:2) afforded 0.60 g (93%) of **4d**: mp 164–167°C (hexane–CH_2Cl_2); IR ($CHC1_3$) 3333 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ 3.98 (s, 3 H), 6.91 (s, 1 H), 7.25–7.30 (dd, *J* = 9.0, 2.4 Hz, 1 H), 7.35–7.39 (dd, *J* = 8.9, 2.2 Hz, 1 H), 7.80–7.81 (d, *J* = 2.2 Hz, 1 H), 8.11–8.12 (d, *J* = 2.4 Hz, 1 H), 8.15–8.18 (d, *J* = 9.0 Hz, 1 H), 8.67–8.71 (d, *J* = 8.9 Hz, 1 H), 10.46 (s, 1 H); MS m/*e* (rel intensity) 260 (M^+, 35), 258 (M^+, 100), 217 (14), 215 (41), 195 (13) which, due to instability, was converted into its *acetate*: mp 151–152°C (hexane); IR (KBr) 1747 cm^{-1}; ^{1}H NMR δ 2.48 (s, 3 H), 4.01 (s, 3 H), 7.25–7.29 (dd, *J* = 9.0, 2.3 Hz, 1 H), 7.30 (s, 1 H), 7.51–7.55 (dd, *J* = 8.9, 2.0 Hz, 1 H), 7.78–7.79 (d, *J* = 2.0 Hz, 1 H), 7.84–7.88 (d, *J* = 9.0 Hz, 1 H), 7.96–7.97 (d, *J* = 2.3 Hz, 1 H), 8.45–8.49 (d, *J* = 8.9 Hz, 1 H); MS *m*/*e* (rel intensity) 302 (M^+, 5), 300 (M^+, 16), 260 (34), 259 (17), 258 (100), 215 (31), 186 (16), 152 (26). Anal. calcd. for $C_{17}H_{l3}ClO_3$: C 67.90, H 4.36; found: C 67.97, H 4.34.

*2-Chloro-9-phenanthrol (**4e**)*: According to method C treatment of *N,N*-diethyl 2′-methyl-4′-chlorobiphenyl-2-carboxamide (0.60 g, 2.0 mmol) with LDA (5.00 mmol) for 1 h followed by acidification, normal workup and flash chromatography (1:1) afforded 0.44 g (96%) of **4e**: ^{1}H NMR (DMSO-d_6) δ 7.06 (s, 1 H), 7.40–7.44 (dd, *J* = 8.8, 2.3 Hz, 1 H), 7.62–7.75 (m, 2 H), 7.85–7.86 (d, *J* = 2.3 Hz, 1 H), 8.24–8.27 (m, 1 H), 8.66–8.70 (d, *J* = 8.8 Hz, 1 H), 8.73–8.76 (m, 1 H) which, due to instability, was converted into its *triflate* **18d** (see below).

*5-Methoxy-9-phenanthrol (**4f**)*: According to method C treatment of *N,N*-diethyl 6-methoxy-2′-methylbiphenyl-2-carboxamide (0.69 g, 2.3 mmol) with LDA (5.75 mmol) overnight followed by acidification, normal workup and flash chromatography (1:1) afforded 0.47 g (92%) of **4f** which was characterized as its *acetate*: mp 75–77°C (hexane–CH_2Cl_2); IR ($CHC1_3$) 1759 cm^{-1}; ^{1}H NMR δ 2.49 (s, 3 H), 4.14 (s, 3 H), 7.19–7.26 (m, 2 H), 7.54–7.66 (m, 4 H), 7.82–7.85 (m, 1 H), 9.62–9.65 (m, 1 H); MS *m*/*e* (rel intensity) 266 (M^+, 24), 224 (100) and its *triflate* **18e** (see below).

*2-(*N,N-*Diethylcarboxamido)-9-phenanthrol (**4g**)*: According to method C treatment of *N,N*-diethyl 2′-methyl-4′-(*N,N*-diethylcarboxamido)biphenyl-2-carboxamide (1.46 g, 4.0 mmol) with LDA (10.0 mmol) for 3 h followed by acidification, normal workup and flash chromatography (EtOAc) afforded 0.92 g (78%) of **4g**: mp 217–219°C (EtOAc); IR ($CHC1_3$) 1626 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ 1.10–1.20 (br, 6 H), 3.20–3.70 (br, 4 H), 7.13 (s, 1 H), 7.34–7.39 (dd, *J* = 8.5, 1.6 Hz, 1 H), 7.62–7.76 (m, 3 H), 8.23–8.30 (dd, *J* = 8.1, 1.0 Hz, 1 H), 8.68–8.72 (d, *J* = 8.5 Hz, 1 H), 8.76–8.83 (m, 1 H), 10.46 (s, 1 H); MS *m*/*e* (rel intensity) 293 (M^+, 27), 221 (53); HRMS calcd. for $C_{19}H_{19}NO_2$: 293.1417; found: 293.1409.

*3-(*N,N-*Diethylcarboxamido)-9-phenanthrol (**4h**)*: According to method C treatment of *N,N*-diethyl 2′-methyl-5′- (*N,N*-diethylcarboxamido)biphenyl-2-carboxamide (3.11 g, 8.5 mmol) with LDA (21.2 mmol) for 10 min at 0°C resulted in a gray yellow turbid mixture which was quenched with saturated NH_4Cl solution at 0°C. Acidification to pH 5–6, removal of THF in vacuo, and filtration afforded 1.67 g of a **4h** as a colorless solid. Normal workup of the aqueous filtrate followed by flash chromatography (EtOAc) afforded additional product (0.63 g) for a combined yield 2.30 g (92%) of **4h**: mp 255–257°C (MeOH); IR (KBr) 3390, 1623 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ 1.00–1.30 (br, 6 H),

General procedure for the synthesis of 9-phenanthrol triflates (18) (method D)

A solution of the 9-phenanthrol (1.0 mmol) at <0°C in Et_2O (10 mL) or THF (5 mL) was treated with *n*-BuLi or LDA (1.10 mmol), the mixture was stirred for 5 min and treated with triflic anhydride (1.1 mmol). The resulting mixture was allowed to warm to rt overnight, treated with a few drops of aqueous NH_4Cl solution and the whole was evaporated to dryness in vacuo. Normal workup followed by flash chromatography afforded the product.

*Phenanthren-9-yl trifluoromethanesulfonate (**18a**)*: According to method D, to a solution of 9-phenanthrol (1.17 g, 6.0 mmol) and *n*-BuLi (4.7 mL of 1.55 M solution, 7.2 mmol) in Et_2O at 0°C was added triflic anhydride (1.21 mL, 2.03 g, 7.2 mmol). Normal workup followed by flash chromatography (1:1) afforded 1.45 g (80%) of **18a**: bp 114–116°C (0.01 mm); IR (neat) 1412, 1211, 1135 cm^{-1}; ^1H NMR δ 7.60–7.79 (m, 5 H), 7.86–7.90 (dd, J = 7.7, 1.4 Hz, 1 H), 8.11–8.16 (m, 1 H), 8.62–8.71 (m, 2 H); MS *m*/*e* (rel intensity) 326 (M^+, 28), 193 (47), 165 (100); HRMS calcd. for $C_{15}H_9F_3O_3S$: 326.0225; found: 326.0227.

*8-Methoxyphenanthren-9-yl trifluoromethanesulfonate (**18b**)*: According to method D, to a solution of 8-methoxy- 9-phenanthrol (0.46 g, 2.1 mmol) and *n*-BuLi (1.65 mL of 1.50 M solution, 2.5 mmol) in Et_2O was added at 0°C triflic anhydride (0.42 mL, 0.70 g, 2.5 mmol). Normal workup followed by flash chromatography (1:2) afforded 0.55 g (75%) of **18b**: mp 149–151°C (hexane); IR (KBr) 1418, 1219, 1142 cm^{-1}; ^1H NMR δ 4.05 (s, 3 H), 7.13–7.16 (d, J = 8.5 Hz, 1 H), 7.56 (s, 1 H), 7.61–7.73 (m, 3 H), 7.84–7.88 (dd, J = 7.3, 1.8 Hz, 1 H), 8.32–8.35 (d, J = 8.5 Hz, 1 H), 8.62–8.65 (d, J = 8.0 Hz, 1 H); MS *m*/*e* (rel intensity), 356 (M^+, 31), 223 (29), 195 (47), 165 (100), 152 (32), 149 (27); HRMS calcd. for $C_{16}H_{11}F_3O_4S$: 356.0330; found: 356.0342.

*6-Methoxyphenanthren-9-yl trifluoromethanesulfonate (**18c**)*: According to method D, to a solution of 6-methoxy-9-phenanthrol (1.21 g, 5.4 mmol) and LDA (6.50 mmol) in THF was added triflic anhydride (1.09 mL, 1.83 g, 6.5 mmol) at 0°C. Normal workup followed by flash chromatography (1:2) afforded 1.26 g (65%) of **18c**: mp 68–70°C (hexane); IR ($CHC1_3$) 1406, 1224, 1135 cm^{-1}; ^1H NMR δ 4.04 (s, 3 H), 7.34–7.39 (dd, J = 9.0, 2.4 Hz, 1 H), 7.59 (s, 1 H), 7.61–7.74 (m, 2 H), 7.86–7.91 (m, 1 H), 8.05–8.09 (m, 2 H), 8.65–8.61 (m, 1 H); MS *m*/*e* (rel intensity) 356 (M^+, 28), 195 (100), 152 (32); HRMS calcd. for $C_{16}H_{11}F_3O_4S$: 356.0330; found: 356.0330.

*2-Chlorophenanthren-9-yl trifluoromethanesultonate (**18d**)*: According to method D, to a solution of 2-chloro-9-phenanthrol (0.457 g, 2.0 mmol) and *n*-Buli (1.63 mL of 1.55 M solution, 2.4 mmol) in THF was added at 0°C triflic anhydride (0.42 mL, 0.712 g, 2.40 mmol). Normal workup followed by flash chromatography (1:1) afforded 0.65 g (90%) of **18d**: mp 119.5–121°C (hexane); IR ($CHC1_3$) 1423, 1229, 1140 cm^{-1}; ^1H NMR δ 7.66–7.86 (m, 4 H), 7.91–7.92 (d, J = 2.2 Hz, 1 H), 8.13–8.19 (m, 1 H), 8.59–8.63 (d, J = 8.0 Hz, 1 H), 8.65–8.75 (dd, J = 8.0, 2.2 Hz, 1 H); MS *m*/*e* (rel intensity) 362 (M^+, 12), 360 (M^+, 32), 229 (17), 227 (47), 201 (34), 199 (100), 163 (26), 149 (29); HRMS calcd. for $C_{15}H_8F_3ClO_3S$: 359.9835; found: 359.9835.

*5-Methoxyphenanthren-9-yl trifluoromethanesulfonate (**18e**)*: According to method D, to a solution of 5-methoxy-9-phenanthrol (0.72 g, 3.2 mmol) and *n*-BuLi (2.36 mL of 1.50 M solution, 3.54 mmol) in THF was added triflic anhydride (0.65 mL, 1.09 g, 3.9 mmol) at –40°C. The resulting solution was warmed to –20°C, quenched with a saturated aqueous NH_4Cl solution, and the reaction mixture was allowed to warm to rt. Normal workup followed by flash chromatography (1:2) afforded 0.82 g (71%) of **18e**: mp

106–107°C (hexane); IR ($CHC1_3$) 1418, 1226, 1138 cm^{-1}; ^1H NMR δ 4.17 (s, 3 H), 7.27–7.30 (d, *J* = 7.9 Hz, 1 H). 7.60–7.83 (m, 5 H), 7.88–7.91 (dd, *J* = 7.6, 1.5 Hz, 1 H), 9.65–9.68 (d, *J* = 8.4 Hz, 1 H); MS *m*/*e* (rel intensity) 356 (M^+, 39), 223 (54), 195 (100), 152 (57); HRMS calcd. for $C_{16}H_{11}F_3O_4S$: 356.0330; found: 356.0342.

*2-(*N,N-*Diethylcarboxamido)phenanthren-9-yl trifluoromethanesulfonate (**18f**)*: To a solution of 2-(*N*,*N*-diethylcarboxamido)-9-phenanthrol (2.44 g, 8.3 mmol) and Et_3N (3.47 mL, 2.52 g, 24.9 mmol) in CH_2Cl_2 (250 mL) was added triflic anhydride (4.19 mL, 7.03 g, 24. mmol) slowly at 0°C. The resulting solution was stirred at rt overnight. Normal workup followed by flash chromatography (1:3) afforded 2.10 g (59%) of **18f**: mp 76–78°C (hexanes); IR (KBr) 1618, 1427, 1223, 1140 cm^{-1}; ^1H NMR δ 1.00–1.50 (br, 6 H), 3.20–3.80 (2 br, 4 H), 7.71–7.86 (m, 4 H), 7.94–7.95 (d, *J* = 1.7 Hz, 1 H), 8.16–8.20 (m, 1 H), 8.69–8.76 (m, 2 H); MS *m*/*e* (rel intensity) 425 (M^+, 14), 353 (30), 292 (66), 221 (31), 220 (36), 164 (36), 69 (100); HRMS calcd. for $C_{20}H_{l8}F_3NO_4S$: 425.0909; found: 425.0900.

*3-(*N,N-*diethylcarboxamido)phenanthren-9-yl trifluoromethanesulfonate (**18g**)*: To a suspension of 3-(*N*,*N*-diethylcarboxamido)-9-phenanthrol (1.47 g, 5.0 mmol) and Et_3N (2.09 mL, 1.52 g, 15.0 mmol) in CH_2Cl_2 (250 mL) at 0°C was added slowly triflic anhydride (2.52 mL, 4.23 g, 15.0 mmol). The resulting mixture was stirred and allowed to warm to rt. Normal workup followed by flash chromatography (1:1) afforded 1.46 g (69%) of **18g**: mp 89–90°C (hexanes); IR (KBr) 1629, 1413, 1215, 1137 cm^{-1}; ^1H NMR δ 1.05–1.48 (br, 6 H), 3.20–3.80 (2 br, 4 H), 7.63–7.68 (dd, *J* = 8.1, 1.5 Hz, 1 H), 7.73–7.86 (m, 3 H), 7.94–7.98 (d, *J* = 8.1 Hz, 1 H), 8.16–8.21 (m, 1 H), 8.71 (s, 1 H), 8.73–8.75 (m, 1 H); MS *m*/*e* (rel intensity) 425 (M^+, 75), 423 (41), 353 (82), 292 (69), 221 (24), 220 (100), 192 (51), 165 (32), 164 (90), 163 (48); HRMS calcd. for $C_{20}H_{l8}F_3NO_4S$: 425.0909; found: 425.0908.

General procedure for the synthesis of phenanthrenes (5) (method E):

*Phenanthrene (**5a**)*: A stirred mixture of phenanthren-9-yl trifluoromethane sulfonate (0.61 g, 2.0 mmol), $Pd(OAc)_2$ (0.018 g, 0.08 mmol), PPh_3 (0.042 g, 0.16 mmol), Et_3N (1.67 mL, 1.21 g, 12.0 mmol) and HCO_2H (0.31 mL of a 97% aqueous solution, 0.37 g, 8.00 mmol) in DMF (10 mL) was heated at 60–70°C overnight. After cooling to rt, the mixture was poured onto crushed ice (~20 mL) and the resulting solution was extracted with EtOAc (3 × 30 mL). The combined organic layer was dried (Na_2SO_4), filtered and concentrated to dryness in vacuo. Preparative TLC (hexane) afforded 0.239 g (67%) of **5a** which was shown to be identical to authentic material (Aldrich Chem. Co) by mp and spectroscopic comparison.

*1-Methoxyphenanthrene (**5b**)*: According to method E, treatment of 8-methoxy-phenanthren-9-yl trifluoromethanesulfonate (0.071 g, 0.20 mmol) with $Pd(OAc)_2$ (0.001 g, 0.004 mmol), PPh_3 (0.002 g, 0.008 mmol), Et_3N (0.084 mL, 0.06 g, 0.60 mmol) and HCO_2H (0.015 mL of a 97% aqueous solution, 0.018 g, 0.40 mmol) in DMF (1.5 mL) followed by flash chromatography (1:5) afforded 0.041 g (97%) of **5b**: mp 105–106°C (hexanes) (lit. (27) mp 105–106°C); ^1H NMR δ 4.03 (s, 3 H), 6.98–7.02 (d, *J* = 7.8 Hz, 1 H), 7.53–7.67 (m, 3 H), 7.72–7.76 (d, *J* = 9.1 Hz, 1 H), 7.87–7.91 (m, 1 H), 8.21–8.29 (m, 2 H), 8.64–8.68 (m, 1 H); MS *m*/*e* (rel intensity) 208 (M^+, 100), 193 (40), 165 (96).

*3-Methoxyphenanthrene (**5c**)*: According to method E, treatment of 6-methoxy-phenanthren-9-yl trifluoromethanesulfonate (0.178 g, 0.50 mmol) with $Pd(OAc)_2$ (0.002 g, 0.01 mmol), PPh_3 (0.005 g, 0.02 mmol), Et_3N (0.21 mL, 0.152 g, 1.50 mmol) and HCO_2H (0.04 mL of a 97% aqueous solution, 0.046 g, 1.0 mmol) in DMF (2 mL) followed by flash chromatography (hexanes) afforded 0.076 g (73%) of **5c**: mp 56–57°C (hexanes) (lit. (43) mp 57°C); ^1H NMR δ 4.03 (s, 3 H), 7.22–7.28 (dd, *J* = 8.7, 2.5 Hz, 1 H), 7.54–7.72 (m, 4 H), 7.79–7.83 (d, *J* = 8.7 Hz, 1 H), 7.85–7.90 (m, 1 H), 8.05–8.06 (d, *J* = 2.5 Hz, 1 H), 8.59–8.64 (m, 1 H); MS *m*/*e* (rel intensity) 208 (M^+, 76), 193 (19), 165 (100).

*2-Chlorophenanthrene (**5d**)*: According to method E, treatment of 2-chloro-phenanthren-9-yl trifluoromethanesulfonate (0.074 g, 0.21 mmol) with $Pd(OAc)_2$ (0.001 g, 0.004 mmol), PPh_3 (0.002 g, 0.008 mmol), Et_3N (0.09 mL, 0.062 g, 0.62 mmol) and HCO_2H (0.02 mL of a 97% aqueous solution, 0.019 g, 0.41 mmol) in DMF (2 mL) followed by preparative TLC (hexanes) afforded 0.030 g (68%) of **5d**: mp 82–83°C (lit. (44) mp 85.5–86°C); ^1H NMR δ 7.46–8.03 (m, 7 H), 8.46–8.87 (m, 2 H).

*4-Methoxyphenanthrene (**5e**)*: According to method E, treatment of 4-methoxy-phenanthren-9-yl trifluoromethanesulfonate (0.178 g, 0.50 mmol) with $Pd(OAc)_2$ (0.002 g, 0.01 mmol), PPh_3 (0.005 g, 0.02 mmol), Et_3N (0.21 mL, 0.152 g, 1.5 mmol) and HCO_2H (0.04 mL of a 97% aqueous solution, 0.046 g, 1.0 mmol) in DMF (2 mL) followed by flash chromatography (1:10) afforded 0.097 g (93%) of **5e**: mp 67–68°C (lit. (27) mp 69°C); ^1H NMR δ 4.14 (s, 3 H), 7.14–7.18 (m, 1 H), 7.50–7.76 (m, 6 H), 7.86–7.90 (dd, *J* = 7.5, 2.0 Hz, 1 H), 9.64- 9.68 (dd, *J* = 8.0, 1.4 Hz, 1 H); MS m/*e* (rel intensity) 208 (M^+, 100), 193 (35), 165 (66).

N,N-*Diethyl phenanthren-2-yl-carboxamide (**5f**)*: According to method E, treatment of 2-(*N*,*N*-diethylcarboxamido)phenanthren-9-yl trifluoromethanesulfonate (1.27 g, 3.0 mmol) with $Pd(OAc)_2$ (0.014 g, 0.06 mmol), PPh_3 (0.032 g, 0.12 mmol), Et_3N (1.25 mL, 0.911 g, 9.00 mmol) and HCO_2H (0.21 mL of a 97% aqueous solution, 0.258 g, 6.00 mmol) in DMF (15 mL) followed by flash chromatography (1:1) afforded 0.747 g (90%) of **5f**: mp 130–131°C (hexane–CH_2Cl_2); IR (KBr) 1613 cm^{-1}; ^1H NMR δ 1.23 (br, 6 H), 3.20–3.80 (2 br, 4 H), 7.58–7.82 (m, 5 H), 7.89–7.93 (m, 2 H), 8.66–8.73 (m, 2 H); MS *m*/*e* (rel intensity) 277 (M^+, 34), 276 (28), 205 (100), 177 (52), 176 (33). Anal. calcd. for $C_{19}H_{19}NO$: C 82.28, H 6.91, N, 5.05; found: C 82.13, H 6.89, N 5.04.

N,N-*Diethyl phenanthren-3-yl-carboxamide (**5g**)*: According to method E, treatment of 3-(*N*,*N*-diethylcarboxamido)phenanthren-9-yl trifluoromethane sulfonate (0.851 g, 2.00 mmol) with $Pd(OAc)_2$ (0.009 g, 0.04 mmol), PPh_3 (0.021 g, 0.08 mmol), Et_3N (0.84 mL, 0.607 g, 6.0 mmol) and HCO_2H (0.15 mL of a 97% aqueous solution, 0. 184 g, 4.00 mmol)

© 2000 NRC Canada

in DMF (10 mL) followed by flash chromatography (1:1) afforded 0.381 g (69%) of **5g**: mp 60–62°C (hexane–PhH); IR (KBr) 1604 cm^{-1}; ^1H NMR δ 1.00–1.50 (2 br, 6 H), 3.20–3.80 (2 br, 4 H), 7.58–7.81 (m, 5 H), 7.89–7.93 (m, 2 H), 8.65–8.70 (m, 2 H); MS *m*/*e* (rel intensity) 277 (M^+, 49), 276 (40), 206 (25), 205 (100), 177 (61), 176 (46), 170 (33), 152 (35); HRMS calcd. for $C_{19}H_{19}NO$: 277.1468; found: 277.1469.

N,N-*Diethyl phenanthren-9-yl*-O-*carbamate (**19**)*: A solution of 9-phenanthrol (1.94 g, 10.0 mmol) and *N*,*N*-diethylcarbamylchloride (1.77 mL, 1.90 g, 14.0 mmol) in pyridine (15 mL) was refluxed overnight, cooled, and poured onto crushed ice. The resulting solution was extracted with CH_2Cl_2 (3 x) and the organic layer was washed sequentially with saturated aqueous $NaHCO_3$ solution (2 x), aqueous HCl (2 x), brine and dried (Na_2SO_4) and filtered. The filtrate was concentrated *in vacuo* to dryness. Flash chromatography (1:2) afforded 2.50 g (85%) of **19**: mp 67–68°C (hexane–CH_2Cl_2); IR ($CHC1_3$) 1707 cm^{-1}; ^1H NMR δ 1.24–1.30 (t, *J* = 7.0 Hz, 3 H), 1.38–1.44 (t, *J* = 7.0 Hz, 3 H), 3.43–3.52 (q, *J* = 7.0 Hz, 2 H), 3.61–3.69 (q, *J* = 7.0 Hz, 2 H), 7.53–7.71 (m, 5 H), 7.82–7.85 (m, 1 H), 7.98–8.02 (m, 1 H), 8.63–8.72 (m, 2 H); MS *m*/*e* (rel intensity) 293 (M^+, 18), 165 (15), 100 (100). Anal. calcd. for $C_{19}H_{19}NO_2$: C 77.79, H 6.53, N 4.78; found: C 77.82, H 6.80, N 4.77.

N,N-*Diethyl 10-trimethylsilylphenanthren-9-yl*-O-*carbamate (**20a**)*: According to method A, to a solution of *t*-BuLi (0.75 mL of 1.60 M solution, 1.20 mmol) and *N*,*N*-diethyl phenanthren-9-yl-O-carbamate (0.29 g, 1.0 mmol) in THF (5 mL) was added TMSCl (0.51 mL, 0.44 g, 4.0 mmol). Normal workup followed by flash chromatography (1:3) afforded 0.32 g (88%) of **20a**: mp 136–137°C (hexane); IR ($CHC1_3$) 1695 cm^{-1}; ^1H NMR (CH_2Cl_2 was used as an internal standard) δ 1.25–1.30 (t, *J* = 7.1 Hz, 3 H), 1.43–1.49 (t, *J* = 7.1 Hz, 3 H), 3.35–4.00 (br, 4 H), 7.55–7.70 (m, 4 H), 7.81–7.85 (m, 1 H), 8.24–8.27 (m, 1 H), 8.67–8.74 (m, 2 H); MS *m*/*e* (rel intensity) 365 (M^+, 3), 350 (12), 250 (13), 165 (17), 100 (100). Anal. calcd. for $C_{22}H_{27}NO_2Si$: C 72.29, H 7.45, N 3.83; found: C 72.65, H 7.50, N 3.85.

N,N-*Diethyl 10-methylphenanthren-9-yl*-O-*carbamate (**20b**)*: According to method A, to a solution of *t*-BuLi **(**0.51 mL of a 1.64 M solution, 0.84 mmol) and *N*,*N*-diethyl phenanthren-9-yl-carbamate (0.21 g, 0.70 mmol) in THF (5 mL) was added iodomethane (0.18 mL, 0.40 g, 2.8 mmol). Normal workup followed by flash chromatography (1:1) afforded 0.198 g (92%) of **20b**: mp 82–84°C (hexane); IR ($CHC1_3$) 1711 cm^{-1}; ^1H NMR δ 1.25–1.30 (t, *J* = 7.1 Hz, 3 H), 1.42–1.48 (t, *J* = 7.1 Hz, 3 H), 2.58 (s, 3 H), 3.44–3.53 (q, *J* = 7.1 Hz, 2 H), 3.66–3.75 (q, *J* = 7.1 Hz, 2 H), 7.59–7.67 (m, 4 H), 7.85–7.89 (m, 1 H), 8.04–8.08 (m, 1 H), 8.65–8.71 (m, 2 H); MS *m*/*e* (rel intensity) 307 (M^+, 10), 178 (9), 100 (100); HRMS calcd. for $C_{20}H_{21}NO_2$: 307.1573; found: 307.1568.

*9-(*N,N-*Diethyl*-O-*carbamato)-phenanthren-10-yl-boronic acid (**20c**)*: To a solution of *N*,*N*-diethyl 10-trimethylsilylphenanthren-9-yl-*O*-carbamate (0.300 g, 0.82 mmol) in CH_2Cl_2 (5 mL) at –78°C was added BBr_3 (1.64 mL of 1.0 M solution in CH_2Cl_2, 1.64 mmol). The resulting mixture was stirred at rt overnight and MeOH (0.07 mL, 0.05 g, 1.64 mmol) was added. Normal workup afforded 0.273 g (99%) of **20c**, which was used without further purification in the cross coupling reaction described below.

*10-(*N,N-*Diethylcarboxamido)-9-phenanthrol (**21**)*: To a solution of *t*-BuLi (0.55 mL of a 1.70 M solution, 0.93 mmol) in THF (3 mL**)** at –78°C was added a solution of *N*,*N*-diethyl phenanthren-9-yl-O-carbamate (0.227 g, 0.77 mmol) in THF (2 mL). The reaction mixture was stirred at –78°C for 1 h and allowed to warm to rt overnight. Acidification (2 M HCl) to pH 5–6 followed by normal workup and flash chromatography (1:2) afforded 0.183 g (81%) **21**: mp 171–172°C (cyclohexane); IR ($CHC1_3$) 1598 cm^{-1}; ^1H NMR (DMSO-d_6) δ 0.82–1.34 (2 br, 6 H), 3.02–3.78 (br, 4 H), 7.48–7.62 (m, 3 H), 7.65–7.77 (m, 2 H), 8.31–8.35 (m, 1 H), 8.74–8.85 (m, 2 H), 9.78 (s, 1 H); MS *m*/*e* (rel intensity) 326 (M^+, 3), 293 (52), 221 (30), 165 (48), 164 (37), 149 (23). Anal. calcd. for $C_{19}H_{19}NO_2$: C 77.82, H 6.80, N 4.77; found: C 77.54, H 6.62, N 4.69.

N,N-*Diethyl 10-(4′-nitrophenyl)phenanthren-9-yl*-O-*carbamate (**23**)*: According to method B, 4-bromonitrobenzene (0.135 g, 0.67 mmol) was coupled with 9-(*N*,*N*-diethyl-*O*-carbamato)phenanthren-10-yl-boronic acid (0.273 g, 0.81 mmol) in the presence of $Pd(PPh_3)_4$ (0.039 g, 0.03 mmol). Normal workup followed by flash chromatography (1:5) afforded 0.219 g (80%) of **23**: mp 176–178°C (cyclohexane); IR ($CHC1_3$) 1713, 1518, 1348 cm^{-1}; ^1H NMR δ 0.95–1.07 (m, 6 H), 3.10–3.40 (br, 4 H), 7.37–7.79 (m, 7 H), 7.93–7.98 (m, 1 H), 8.34–8.39 (m, 2 H), 8.74–8.79 (d, *J* = 8.7 Hz, 2 H); MS *m*/*e* (rel intensity) 415 (25), 414 (M^+, 28), 315 (23), 268 (30), 239 (54), 100 (100); HRMS calcd. for $C_{25}H_{22}N_2O_4$: 414.1581; found: 414.1577.

N,N-*Diethyl phenanthren-4-yl*-O-*carbamate (**24**)*: To a solution of 4-methoxyphenanthrene (2.47 g, 11.8 mmol) in CH_2Cl_2 (60 mL) at –78°C was added BBr_3 (2.24 mL, 5.93 g, 23.7 mmol). The resulting mixture was stirred and allowed to warm to rt overnight. Normal workup followed by flash chromatography (1:6) afforded 2.08 g (91%) of 4-phenanthrol: mp 111–113°C (hexane) (lit. (45) mp 113–115°C); IR (KBr) 3514 cm^{-1}; ^1H NMR δ 5.71 (s, 1 H), 6.94–6.98 (dd, *J* = 7.5, 1.3 Hz, 1 H), 7.37–7.74 (m, 6 H), 7.85–7.89 (dd, *J* = 7.5, 1.9 Hz, 1 H), 9.61–9.65 (m, 1 H). A solution of the 4-phenanthrol (1.63 g, 8.4 mmol) in MeCN (50 mL) was treated with K_2CO_3 (1.62 g, 11.7 mmol) and *N*,*N*-diethylcarbamylchloride (1.49 mL, 1.59 g, 11.7 mmol) and the resulting mixture was refluxed overnight, cooled, and subjected to filtration. The filtrate was evaporated to dryness in vacuo. Normal workup followed by flash chromatography (1:5) afforded 2.39 g (97%) of **24**: mp 113–115°C (hexane); IR (KBr) 1705 cm^{-1}; ^1H NMR δ 1.23–1.29 (t, *J* = 7.1 Hz, 3 H), 1.41–1.47 (t, *J* = 7.1 Hz, 3 H), 3.43–3.52 (q, *J* = 7.1 Hz, 2 H), 3.71–3.80 (q, *J* = 7.1 Hz, 2 H), 7.31–7.34 (dd, *J* = 7.7, 1.3 Hz, 1 H), 7.53–7.61 (m, 3 H), 7.68–7.78 (m, 3 H), 7.84–7.91 (m, 1 H), 9.00–9.06 (m, 1 H); MS *m*/*e* (rel intensity) 293 (M^+, 12), 165 (13), 100 (100). Anal. calcd. for $C_{19}H_{19}NO_2$: C 77.79, H 6.53, N 4.78; found: C 77.77, H 6.53, N 4.69.

*3-(*N,N-*Diethylcarboxamido)-4-phenanthrol (**25**)*: To a yellow stirred solution of *s*-BuLi (4.01 mL of 1.15 M solution, 4.6 mmol) and TMEDA (0.70 mL, 0.54 g, 4.6 mmol) in THF (20 mL) at –78°C was added a solution of *N*,*N*-diethyl phenanthren-4-yl-*O*-carbamate (1.23 g, 4.2 mmol) in THF (5 mL). The resulting brown solution was allowed to warm to rt overnight. Normal workup followed by flash chromatography (1:1) afforded 1.22 g (99%) of **25**: oil; IR (neat) 3130 (br), 1589 cm^{-1}; ^1H NMR δ 1.30–1.36 (t, *J* = 7.1 Hz, 6 H), 3.55–3.64 (q, *J* = 7.1 Hz, 4 H), 7.33–7.37 (d, *J* = 8.3 Hz, 1 H), 7.44–7.48 (d, *J* = 8.3 Hz, 1 H), 7.56–7.72 (m, 3 H), 7.78–7.82 (d, *J* = 8.8 Hz, 1 H), 7.86–7.90 (dd, *J* = 7.7, 1.6 Hz, 1 H), 9.10 (br, 1 H), 9.81–9.84 (d, *J* = 8.7 Hz, 1 H); MS *m*/*e* (rel intensity) 293 (M^+, 59), 221 (26), 220 (100), 165 (20); HRMS calcd. for $C_{19}H_{19}NO_2$: 293.1417; found: 293.1433.

*1-Methoxy-9,10-phenanthraquinone (**26a**):* A solution of 8-methoxy-9-phenanthrol (0.173 g, 0.77 mmol) and salcomine (0.025 g, 0.077 mmol) in DMF (5 mL) at rt was subjected to a stream of O_2 via a bubbler for 4 h. The mixture was diluted with water (5 mL) and the resulting solution was extracted with EtOAc (3×). The organic layer was dried (Na_2SO_4), subjected to filtration and the filtrate was concentrated to dryness in vacuo. The resulting residue was recrystallized to afford 0.182 g (99%) of **26a**: mp 181–183°C (EtOAc); IR (KBr) 1688, 1670 cm^{-l}; ^1H NMR (DMSO-d_6) δ 3.90 (s, 3 H), 7.22–7.26 (d, *J* = 8.5 Hz, 1 H), 7.49–7.57 (ddd, *J* = 7.6, 7.5, 1.0 Hz, 1 H), 7.70–7.82 (m, 2 H), 7.86–7.90 (d, *J* = 7.9 Hz, 1 H), 7.94–7.99 (dd, *J* = 7.6, 1.5 Hz, 1 H), 8.26–8.30 (d, *J* = 8.2 Hz, 1 H); MS *m*/*e* (rel intensity) 238 (M^+, 42), 210 (46), 181 (100), 180 (30), 152 (54), 151 (25). Anal. calcd. for $C_{15}H_{10}O_3$: C 75.62, H 4.23; found: C 75.66, H 4.30.

*4-Methoxy-9,10-phenanthraquinone (**26b**)*: Following the above procedure, treatment of 5-methoxy-9-phenanthrol (0.276 g, 1.23 mmol) with O_2 in the presence of salcomine (0.04 g, 0.123 mmol) afforded 0.289 g (99%) of **26b**: mp 196–197°C (EtOAc); IR (KBr) 1689, 1661 cm^{-1}; ^1H NMR (DMSO-d_6) δ 4.01 (s, 3 H), 7.44–7.58 (m, 3 H), 7.67–7.78 (m, 2 H), 8.00–8.05 (dd, *J* = 7.7, 1.6 Hz, 1 H), 8.87–8.91 (d, *J* = 8.3 Hz, 1 H); MS *m*/*e* (rel intensity) 238 (M+, 25), 210 (79), 195 (23), 167 (28), 139 (100). Anal. calcd. for $C_{15}H_{10}O_3$: C 75.62, H 4.23; found: C 75.48, H 4.27.

*1-Methoxy-9-fluorenone (**28a**)*: A suspension of 1-methoxy-9,10-phenanthraquinone (0.165 g, 0.69 mmol) in aqueous KOH (2 M, 10 mL**)** was heated at 90°C for 1 h, cooled, and treated with conc. H_2SO_4 to pH 5–6. Normal workup gave a crude solid which was treated with $Pb(OAc)_4$ (0.841 g, 2.19 mmol) in benzene (10 mL) and the resulting mixture was stirred at rt overnight. The reaction mixture was diluted with water (10 mL), and subjected to filtration. Normal workup and flash chromatography (1:10) afforded 0.140 g (96%) of **28a**: mp 140–142°C (EtOAc) (lit. (46) mp 140–141°C); IR (nujol) 1699 cm^{-1}; ^1H NMR δ 3.98 (s, 3 H), 6.81–6.86 (d, *J* = 8.5 Hz, 1 H), 7.11–7.14 (d, *J* = 7.4 Hz, 1 H), 7.25–7.32 (ddd, *J* = 7.2, 7.2, 1.6 Hz, 1 H), 7.41–7.51 (m, 3 H), 7.63- 7.66 (dd, *J* = 7.2, 0.7 Hz); MS *m*/*e* (rel intensity) 210 (M^+, 86), 181 (100), 153 (20), 152 (44), 151 (24).

*4-Methoxy-9-fluorenone (**28b**)*: Following the above procedure, 4-methoxy-9,10-phenanthraquinone (0.098 g, 0.41 mmol) was sequentially treated with aqueous KOH (2 M, 10 mL) and $Pb(OAc)_4$ (0.549 g, 1.24 mmol) in benzene to furnish 0.086 g (99%) of **28b**: mp 114–115°C (EtOAc) (lit. (46) mp 114.5–115.5°C); IR (KBr) 1708 cm^{-1}; ^1H NMR δ 3.98 (s, 3 H), 7.03–7.06 (dd, *J* = 7.4, 1.7 Hz, 1 H), 7.19–7.31 (m, 3 H), 7.41–7.48 (ddd, *J* = 7.5, 7.5, 1.2 Hz, 1 H), 7.61–7.64 (d, *J* = 7.3 Hz, 1 H), 7.80–7.83 (d, *J* = 7.5 Hz, 1 H); MS *m*/*e* (rel intensity) 210 (M^+, 100), 195 (21),167 (20),139 (55).

Heck reaction using palladium complexed to dendrimers on silica

Howard Alper, Prabhat Arya, S. Christine Bourque, Gary. R. Jefferson, and Leo E. Manzer

Abstract: Polyamidoamine dendrimers, constructed on the surface of silica, were phosphonated using diphenylphosphinomethanol (prepared in situ) and complexed to form a palladium–dimethyl TMEDA complex. This catalyst was found to be effective in the Heck reaction of aryl bromides with both butyl acrylate and styrene, affording coupling products in moderate to good yields. The heterogeneous palladium catalyst can also be recycled and reused with only moderate reduction in activity.

Key words: dendrimer, Heck, palladium, silica.

Résumé : Utilisant du diphénylphosphinométhanol (préparé in situ), on a réalisé la phosphonation de dendrimères de polyamidoamines synthétisés sur une surface de silice et en a fait un complexe de palladium–« TMEDA » de diméthyle. On a trouvé que ce catalyseur est efficace dans la réaction de Heck des bromures d'aryles avec aussi bien l'acrylate de butyle que le styrène et que ces réactions fournissent des produits de couplage avec des rendements allant de modérés à bons. On peut aussi régénérer le catalyseur hétérogène et le réutiliser avec une perte mineure d'activité.

Mots clés : dendrimère, Heck, palladium, silce.

Introduction

The demand for cleaner, environmentally friendly chemistry is coming from many quarters. Legislative, public, and corporate pressure has led to the rapid development of new innovations in green technology. While the majority of new chemical processes developed in the last 50 years are catalytic, there are still problems associated with catalyst recovery, both in terms of reusing the catalyst or at least recovery of the precious metals often used, with the added advantage of easier purification of products.

Over the past 20 years the Heck reaction, used in the coupling of aryl halides with vinylic substrates, has been shown to be a versatile tool which allows easy access to often complex products from relatively simple substrates (1). Despite the practical ease of reaction and the reliably good yields, the Heck reaction has not developed past a laboratory method, bar a few examples (2).

The lack of transfer to an industrial scale is primarily due to the expense of the palladium catalyst, as high loadings of palladium (e.g., 10 mol%) (3) and, as with homogeneously catalyzed systems, costly removal of the catalyst residues are required. Only when the reaction products are of high commercial value (e.g., pharmaceutical products) can this catalytic system be used viably because the cost of the catalyst is appreciably a smaller percentage of the final product than in the bulk chemical case. Hence in the large scale synthesis of bulk chemicals, the Heck reaction has made little impact.

Over approximately the last 10 years, in an attempt to extend the Heck reaction to the bulk chemical sector, several groups have worked on developing heterogeneous catalytic systems (4). Such systems could, in principle, reduce the cost and technical problems associated with removal of the catalyst and also increase the lifetime of the palladium catalyst. The use of lower concentrations of palladium might also be a consequence of heterogenizing the catalyst. Many groups have attacked this problem and have made considerable headway in some cases. Of particular note is the work of Ying et al. (5), who have developed a palladium [0] complex on silica which shows very high turnover rates especially for activated bromoarene systems. However it should be noted that the catalyst preparation requires specialized techniques.

Most of the other examples in the literature utilize iodoarenes (6), the most reactive of the haloarene family in the Heck reaction, but unfortunately the most expensive and

also generally less readily available than its bromo and chloro counterparts. One of the main goals of the Heck reaction in both a heterogeneous and homogenous sense is to utilize the cheaper bromo- and chloroarenes.

Polymer supported metal complexes have attracted considerable interest over the last few years. Terasawa et al. (7) have studied the Heck reaction of styrene with iodobenzene comparing a variety of heterogeneous catalysts. A phosphinated polystyrene complex was compared to palladium with the analogous free palladium complex, palladium salts, Pd/C in terms of catalytic activity and selectivity, and it was found that the polymer supported palladium complex is highly active but noticeable deactivation was observed during repeated use. Zhang et al. reported a polymer supported phenanthroline palladium catalyzed arylation of acrylamide (8); however, when tributylamine was used the catalyst activity declined significantly on recycling, and preparation of the catalyst is complicated. Although there have been several advances in the Heck reaction in terms of increased turnovers and catalyst stability for both heterogeneous and homogenous systems, the catalyst lifetimes and turnovers still preclude industrial use.

We recently developed a dendritic silica supported bidentate phosphine ligand (9). It was postulated that this ligand could be utilized in the Heck reaction with a suitable palladium catalyst. The dendritic support is thought to work with many facets, one of which is to give the reaction a degree of homogenous character, as the dendritic support would be highly solvated in a suitable solvent system. It is also speculated that the ligand increases the stability of the catalytic system.

In recent years, major efforts have been directed toward the development of new catalytic systems that effectively combine the advantages of both heterogeneous and homogeneous catalysis (10). Such a catalyst would ideally be easily recoverable and potentially recyclable while maintaining high catalytic efficiency. Dendrimer–metal complexes are particularly attractive in this regard.

Dendrimers are highly branched macromolecules, which are capable of having multiple sites for metal coordination (11). In 1994, van Koten and coworkers demonstrated that soluble polycarbosilane dendrimer complexes of nickel (II) catalyze the addition of polyhaloalkenes to double bonds (12). Three years later, Reetz and coworkers synthesized a polyaminodiphosphine dendrimer to coordinate to rhodium and palladium catalysts (13). Our research has led to the development of heterogeneous polyaminoamidodiphosphonated dendrimers built on a silica gel core support (PPh_2–PAMAM–SiO_2). This article describes the use of these dendrimers, when complexed to palladium, as effective catalysts for the Heck reaction.

Results and discussion

(*a*) Preparation of PAMAM–SiO_2 dendrimers

Commercial aminopropyl silica gel was used to prepare generation 0–4 polyaminoamido (PAMAM) dendrimers (9). Propagation of the dendrimers was achieved by standard dendrimer building methods pioneered by Tomalia and coworkers (14). Amino propionate esters were obtained by Michael type addition of the preexisting amino group to methyl acrylate. Amidation of the ester units with ethylenediamine completes the generation, with repetition of the two steps affording the desired generation of the dendrimer.

Scheme 1.

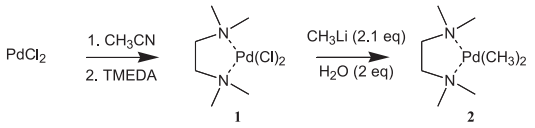

Table 1. Palladium content of the various PPh_2–PAMAM–SiO_2 dendrimers.

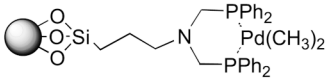
Generation	Percentage palladium (%)[a]	g Pd/g Si	mμ mol Pd/25 mg SiO_2
G-0	2.93	0.0293	6.91
G-1	1.34	0.0134	3.16
G-2	1.13	0.0113	2.66

[a]Determined by ICP analysis

Coordination of the dendrimers to palladium was effected first by phosphonation. Diphenylphosphinomethanol, prepared in situ from paraformaldehyde and diphenylphosphine, was excellent for the double phosphinomethylation of each terminal amine group.

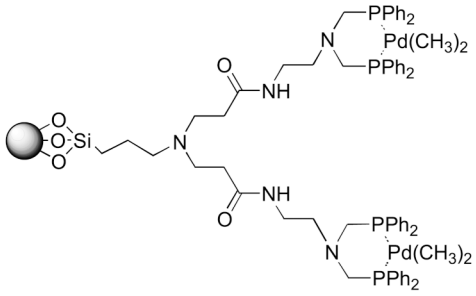
The complex **2** is easily synthesized starting from palladium chloride, in situ formation of the bis(acetonitrile)palladium dichloride (15), followed by displacement of the acetonitrile ligands with TMEDA forming complex **1**. Reaction of complex **1** with methyl lithium gives complex **2** in 65% overall yield (Scheme 1).

The palladium complex is coordinated to the dendrimer on silica by simply stirring the dendrimer in degassed benzene with one equivalent of palladium complex **2**, relative to the theoretical number of end phosphine groups for the respective dendrimer. The dendrimer complexes are easily isolated by microporous membrane filtration. The resulting complexed dendrimers (see Fig. 1) were characterized by ^{31}P solid state NMR (complexed δ = 6 ppm, uncomplexed δ = –27 ppm) (13*a*).



The palladium complexed PPh_2–PAMAM–SiO_2 dendrimers were digested with hydrofluoric acid or aqua regia (nitrohydrochloric acid) by microwave heating and analyzed for Pd content by ICP analysis. The palladium content of the various generations is summarized in Table 1. The degree of complexation decreases significantly with dendrimer generation from G-0 to G-2, and was so low for G-3 and G-4 as to preclude further studies with the latter generations of dendrimers. This is believed to be due to incomplete phosphonation reactions arising from steric crowding and ultimately resulting in the threshold of dendrimer growth being reached.

(*b*) Catalytic heck reaction of aryl bromides using palladium complexed silica supported dendrimers



As a model reaction for assessing the utility of these Heck catalysts, the reaction of bromobenzene with styrene in DMF at 120°C was investigated in the presence of sodium acetate as base, primarily because these were the conditions

employed by Reetz and co-workers for their dendritic Heck system. The catalytic activity of the palladium complexed PPh_2–PAMAM–SiO_2 dendrimers was investigated with re-

gards to the Heck reaction (Reaction [1]) and the results are summarized in Table 2. Treatment of styrene and bromobenzene in dimethylformamide, with Pd complexed PPh_2–PAMAM–SiO_2 dendrimer, and sodium acetate affords *trans* stilbene in good yield and regioselectivity for generations 0, 1, and 2. The yields of stilbene was significantly less when generation 3 and 4 dendrimer complexes are used as catalysts.

The best turnovers in terms of molecules of *trans*-stilbene formed per mol of palladium was achieved with the generation 2 catalyst, as may be expected as this catalyst would have the greatest homogenousity factor (Table 3).

The effect of temperature on the Heck reaction was studied with the generation 2 catalyst and it was found that the best yields were obtained when the temperature was in the 110 to 140°C range (Table 4). At lower temperatures the yields were low due to either poor conversion of the catalyst precursor to the catalyst via reductive elimination of the methyls, or just a factor of low turnovers at low temperatures. At temperatures above 140°C the yield was reduced by catalyst deactivation with noticeable palladium black formation.

The effect of the base on the reaction was studied in terms of yield and recoverability of the catalyst (Table 5). The inorganic bases; potassium carbonate and sodium acetate were used as well as the organic base, triethylamine. Potassium carbonate and sodium acetate gave the best yields, and low product yield was found using triethylamine (13*a*). This triethylamine effect was also observed by Reetz and coworkers using their dendritic Heck catalyst system.

As some loss in activity of the catalyst was noticed we examined the possibility of leaching of the catalyst into the reaction mixture. The reaction was carried out with styrene and bromobenzene using the G-2 catalyst, and after 16 h, the reaction was filtered under nitrogen. A further 2 mmol of

[b]Yields were determined by NMR analysis.

styrene and bromobenzene was added and sample was taken for GC analysis. The reaction was run for a further 48 h and no further reaction of the mixture took place.

The generality of the catalytic system was investigated for a variety of haloarenes, and the results are presented in Table 6. Initially the nature of the halogen used was studied. It was found that the reaction of bromo and iodobenzene gave similar yields with no detectable product using chlorobenzene. We then examined the effect of *para* substituents on the haloarenes. It was surprising to find that electron withdrawing substituents (nitro, ester) gave relatively low yields and conversions, while electron donating groups (methoxy, methyl) gave moderate to good yields of coupled products. This observation suggests that the oxidative addition step of the Heck reaction is relatively facile whereas the alkene insertion or reductive elimination is the rate determining step. This reactivity may be a function of the nitrogen in the ligand donating into the metal center leading to facile oxidative addition. The catalyst system was also found to be active for thiophenes with no catalyst poisoning resulting from the sulfur atom.

Summary

The dendrimer supported complexes, Pd–PPh_2–PAMAM–SiO_2, are new and highly active catalysts for the Heck reaction of a variety of bromoarenes with styrene and butyl acrylate, affording *para* substituted stilbenes and cinnamate esters in good yields. This dendritic system shows comparable activity to the Reetz dendrimer system (13) and can be easily recycled.

Experimental

General

Dimethylformamide (Aldrich) was used in anhydrous form. All the aryl bromides, iodobenzene and alkene substrates were purified before use. Aminopropyl silica gel was purchased from Fluka.

General procedure for the complexation of PPh_2–PAMAM–SiO_2 with palladium

The PPh_2–PAMAM–SiO_2 (1.0 mmol with respect to PPh_2) was added to a solution of Pd $(Me_2NCH_2CH_2NMe_2)(Me)_2$ (0.5 mmol) in freshly distilled benzene (20 mL). The mixture was stirred at room temperature overnight under nitrogen. The product was filtered through a 0.45 mm membrane filter under a stream of nitrogen and washed with ether (50 mL). Residual ether was removed in vacuo.

General procedure for the Heck reaction

The substrates, base, and solvent (dimethylformamide 20 mL) were placed in a 50 mL round bottom-flask equipped with a magnetic stirring bar and condenser connected to a vacuum line. The solution was flushed five times with nitrogen using a vacuum nitrogen cycle. The catalyst was then added. The autoclave was placed in an oil bath and the desired temperature was reached by stirring on a hot plate. After the appropriate reaction time, the reaction was allowed to cool to room temperature. The resulting solution was filtered to remove the catalyst. The filtrate was extracted with diethyl ether (4 × 40 mL), and the ether extracts were washed with brine and distilled water, followed by drying over magnesium sulfate. The product was analyzed by ^{1}H NMR spectroscopy and (or) gas chromatography, and identified by comparison of spectral results with literature data (6).

Synthesis of dimeric and tetrameric macrolactams with cytotoxic activity[1]

Gabriella Gentile, Daniela Fattori, Maurizio Botta, Federico Corelli, Domenico Fusar-Bassini, and Doriano Lamba

Abstract: Cyclization of amino acid **14**, in turn prepared from 4,4-dimethylcyclohex-2-en-1-one by standard chemistry, yielded the dimeric and tetrameric macrolactams **15** and **16**, respectively, representing the first examples of "taxoid-like" compounds with heterocyclic B rings. Compounds **15** and **16** exhibited moderate antiproliferative activity in an in vitro cytotoxicity assay. Consequently, an orthogonally diprotected, dimeric macrolactam **19** was synthesized and, after selective deprotection of the hydroxy group, was coupled with the docetaxel side chain to give the final compound **2**, showing three-dimensional shape similarity to paclitaxel. Contrary to our expectations, **2** proved to be as active as the parent compound **15**. The structure of **15** has been confirmed by X-ray crystallographic analysis and is also reported.

Key words: macrolactams, macrocyclic compounds, taxane analogs, cytotoxic activity.

Résumé: La cyclisation de l'acide aminé **14,** préparé à partir de la 4,4-diméthylcyclohex-2-én-1-one donne des macrolactames dimère **15** et tétramère **16** qui sont les premiers exemples de composés de type taxoïde avec un noyau B hétérocyclique. Les composés **15** et **16** exhibent une activité antiprolifère modérée lors d'un essai de cytotoxicité in vitro. En conséquence, on a synthétisé un macrolactame dimère **19**, ayant orthogonalement deux groupes protecteurs, et après une déprotection sélective du groupe hydroxyle, on l'a couplé avec la chaîne latérale du docétaxel pour obtenir le produit final **2,** dont la forme tridimensionnelle est semblable à celle du paclitaxel. Contrairement à nos attentes, le composé **2** s'est révélé aussi actif que le composé parent **15**. On rapporte la structure du composé **15** que l'on a confirmée par cristallographie de rayons X.

Mots clés: macrolactames, composés macrocycliques, analogues du taxane, activité cytotoxique.

[Traduit par la Rédaction]

Introduction

In the last years paclitaxel (1) (Fig. 1) has proven to be a major achievement in the field of cancer chemotherapy, particularly for the treatment of advanced ovarian and breast cancer (for several reviews on paclitaxel see ref. (1)). Due to the novelty of its mode of action (2) as well as to its unique structural complexity (3), it has been the objective of total synthetic (4) and structure–activity relationship studies (for selected recent contributions see ref. (5)). Intense efforts have been directed toward structural modifications of paclitaxel aimed at defining its pharmacophore (6) and developing analogues with better therapeutic profile and improved water-solubility (7*a*) (for a review see ref. (7*b*)). It has been recently reported in the literature that several macrocyclic compounds, such as taxuspines, sarcodictyins (and related eleutherobin and eleuthosides), epothilones, discodermolide, and rhazinilam (and related nine-membered macrolactams), though belonging to different chemical families, exert antitumor activity through a paclitaxel-like mechanism (for taxuspines see ref. (8*a*); sarcodictyins, eleutherobin, eleuthosides see ref. (8*b*); epothilones see ref. (8*c*); discodermolide see ref. (8*d*); rhazinilam and analogs thereof see ref. (8*e*)). In the course of our investigations on taxane systems (9) and on new analogues of paclitaxel and docetaxel (10), we conceived the possibility of preparing heterocyclic analogs which are expected to be more water-soluble (11).

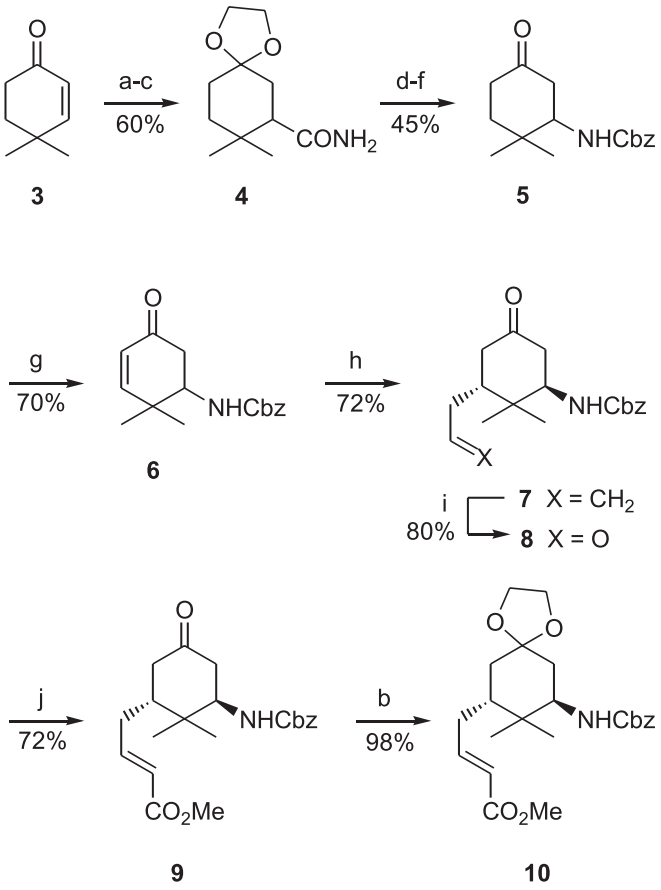
Fig. 1. Top: Structure of paclitaxel (1) and macrolactam **2**. Bottom: stereoview of the superimposition between lowest-energy conformations of **2** (thick) and paclitaxel (thin).

In particular, the superimposition between the lowest-energy conformation of the dimeric macrolactam **2** and the lowest-energy conformation of **1** (10) highlighted good shape similarity between the partners (Fig. 1) and led us to identify **2** as an interesting heterocyclic mimic of paclitaxel. We wish to describe herein our synthetic efforts in this direction.

Results and discussion

Enone **3** (12) (Scheme 1) was subjected to hydrocyanation (13) followed by ketalization and partial hydrolysis of the nitrile to give the primary amide **4** in 60% overall yield. Hofmann rearrangement of this amide was best accomplished by treatment with bromine and sodium hydroxide. The resulting amine was protected as the corresponding Cbz derivative and treated with HCl in THF to give **5**. The transformation of **5** into **6** could be efficiently[5] performed following the Saegusa procedure (14). Reaction of **5** with TMSCl in the presence of triethylamine afforded a silyl enol ether mixture, which was treated with palladium(II) acetate in refluxing acetonitrile in the presence of $CaCO_3$. Chromatographic purification on silica gel led to the enone **6** as the sole reaction product in an overall yield of 70% from **5**. Insertion of a side chain at C-5 was realized through $TiCl_4$-catalyzed reaction of allyltrimethylsilane with the enone system of **6** to give the allyl derivative **7** as the only isomer. The *trans* relative stereochemistry was assigned according to the usual stereochemical outcome of the Sakurai reaction (15*a*, *b*) (for a discussion of the stereochemistry of conjugate addition reactions to 5-substituted cyclohex-2-ene-1-one derivatives, see ref. (15*c*). Oxidative cleavage of the double bond afforded the aldehyde **8**, which was in turn subjected to Wadsworth–Emmons olefination with methyl (triphenylphosphoranylidene)acetate to give in 72% yield the unsaturated esters **9** as a 9:1 *E*:*Z* mixture.[6] Subsequent ketalization of **9** under standard conditions afforded compound **10**. This key intermediate (Scheme 2) was hydrogenated to give the saturated amine **11** and hydrolyzed to the free acid **12** in 92% and 93% yield, respectively. These two synthons were coupled to afford the amide **13**, which was in turn advanced to the amino acid **14**.



Having secured an access to **14**, several procedures based on the condensing reagents for peptide synthesis were investigated to accomplish its cyclization to the 16-membered lactam **15** (Scheme 3). DPPA-mediated cyclization of **14** provided the macrolactam **15** as a colorless solid in a most

[5] Attempts to convert **5** to **6** by regioselective bromination-dehydrobromination sequence afforded unsatisfactory results as a complex mixture of compounds was obtained. On the other hand, direct reaction of **5** with PhSeCl showed little regioselectivity providing, after selenoxide elimination, a mixture of the enone **6** and its regioisomer.

[6] For simplicity, only the predominant (*E*)-isomer of compounds **9**, **10**, **12**, **13**, **17**, and **18** are shown in the Schemes.

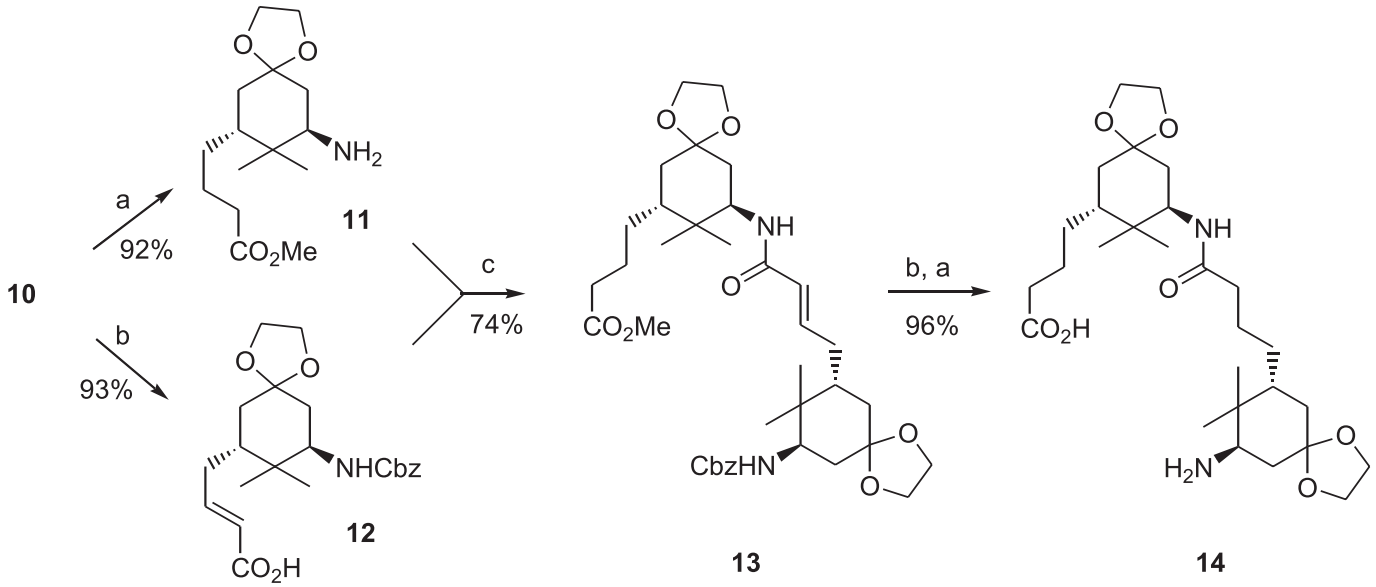
Scheme 1. Key: (a) KCN, EtOH, H_2O, AcOH, 40°C; (*b*) $HOCH_2CH_2OH$, CSA, toluene, reflux; (*c*) NaOH, 30% H_2O_2, EtOH, 50°C; (*d*) Br_2, NaOH, 0–80°C; (*e*) CbzCl, $NaHCO_3$, EtOH, H_2O; (*f*) Hcl, THF; (g) (*i*) LiHMDS, TMSCl, Et_3N, THF, –78°C; (*ii*) $Pd(OAc)_2$, CaCo3, CH_3CN, reflux; (h) allyltrimethylsilane, $TiCl_4$, CH_2Cl_2, –78 to –30°C; (*i*) OsO_4, $NaIO_4$, Et_2O, H_2O, rt; (j) methyl (triphenylphosphoranylidene)acetate, toluene, reflux.

satisfactory yield of 28%, along with the tetramer **16** (10%). 500 MHz ^{1}H NMR spectroscopy revealed that compound **15** was indeed a mixture of two isomers in the ratio 3:1, as evidenced by the presence of two doublets at 7.16 and 7.02 ppm relative to the NH groups and integrating for 1.5 and 0.5 protons, respectively.[7] Although attempts to separate these isomers by HPLC were unsuccessful, the major isomer was obtained in pure form by two successive recrystallizations from methanol–water.

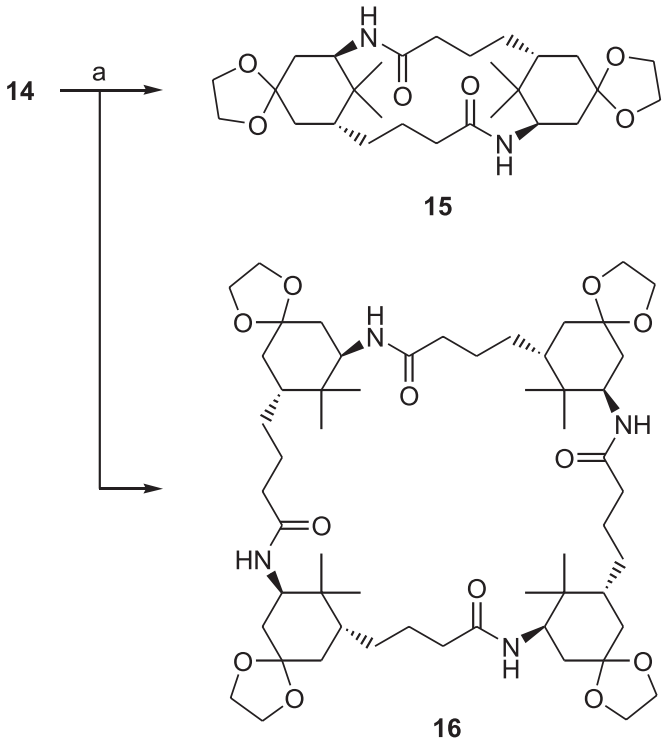
X-ray crystallographic analysis of this sample (Fig. 2) showed that the structure is centrosymmetric, with an *R*-relative configuration of both the chiral centers at C-2 and C-6 and a *trans* conformation of the N-1—C-9 amide bond. In terms of the conformational descriptors (16) (P = 56.5° and τ = 24.0°), an *envelope* conformation can be assigned to the dioxolane ring. The C-4, O-2, O-3, and C-10 atoms define a nearly perfect plane, with C-11, in the *flap* position, displaced out of the plane by 0.337 Å. The cyclohexane moiety exhibits a *chair* conformation, with C-3 and C-6 atoms displaced out of the plane defined by C-1, C-2, C-4, and C-5 by 0.647 Å and 0.643 Å, respectively, at opposite sites, the Cremer and Pople (17) puckering parameters being Q = 0.547 Å, θ = 3.4°, and ϕ = 42.4°.

Compounds **15** and **16** were evaluated in an in vitro cytotoxicity assay on a B16-F10 murine melanoma cell line and in a tubulin polymerization assay (18) performed spectrophotometrically. While no activity against tubulin assembly was observed, **15** and **16** displayed an IC_{50} value of 45 μM and 37 μM, respectively, in the cytotoxicity test. Although no attempt has been made to establish the mechanism of the antiproliferative activity of the tested compounds, the preliminary biological results indicated that **15**[8] might have been of interest as a lead compound in the search of new antitumor agents in spite of its modest cytotoxic activity (to the best of our knowledge, the tested compounds constitute the first example of "taxoid-like" compounds with heterocyclic B rings. For an example of analogs oxygenated in the C ring, see ref. (19)). In fact, it should be kept in mind that baccatin (i.e., paclitaxel without a C-13 side chain) itself shows a comparable cytotoxicity, which increases by four orders of magnitude after esterification at C-13 with the appropriate *N*-acylphenylisoserine side chain (20).



It now remained to elaborate the dimeric macrolactam **15** by introducing an *N*-acylphenylisoserine chain to enhance its cytotoxic activity. Since an attempt to selectively cleave only one ketal group in **15** proved to be unpractical because of the formation of mixtures, we turned our attention to ketone **9**. Reduction with $NaBH_4$ (Scheme 4) provided two isomers (in the ratio 7:1)[9] of the expected alcohol, whose structures were assigned on the basis of their ^{1}H NMR spectrum, which revealed an intramolecular hydrogen bonding between the OH and NH groups (which must be therefore *cis*) in the minor, less polar, isomer (δ_{NH} 6.23 vs. 4.88 ppm). Silylation of the hydroxy group of the major isomer followed by hydrolysis of methyl ester gave the acid **17** in 78% overall yield from **9**. Acylation of amine **11** with **17** under mixed anhydride conditions led to the amide **18**, which was advanced to the orthogonally protected macrolactam **19**. TBAF-mediated desilylation of **19** provided the hydroxy derivative **20**, which by reaction with (4*S*,5*R*)-*N*-(*tert*-butoxycarbonyl)-2-(2,4-dimethoxyphenyl)-4-phenyloxazolidine-5-carboxylic acid (**21**) as one (unspecified) stereoisomer (21) in the presence of *N*-cyclohexyl-*N*′-(2-morpholinoethyl)carbodiimide methyl *p*-toluenesulfonate (CMC) and 4-dimethylaminopyridine (DMAP), followed by selective cleavage of the aminoacetal group, was converted to the intended target **2** (an inseparable mixture of stereoisomers) in 32% overall yield from **19**.

In the cytotoxicity and tubulin polymerization assays **2** showed approximately the same biological profile as **15**. This result, though discouraging, is not completely surprising, since it is well known that neither an intact taxane



[7] No coalescence of these signals was observed by raising temperature until 80°C.
[8] Although **16** has proven to be the most active compound, it was not further considered as a possible lead owing to its molecular weight > 1000.
[9] Attempts to improve the stereoselectivity of the reduction by using bulkier reagents (L-selectride) or lower reaction temperature (–30 to –60°C) were unsuccessful.

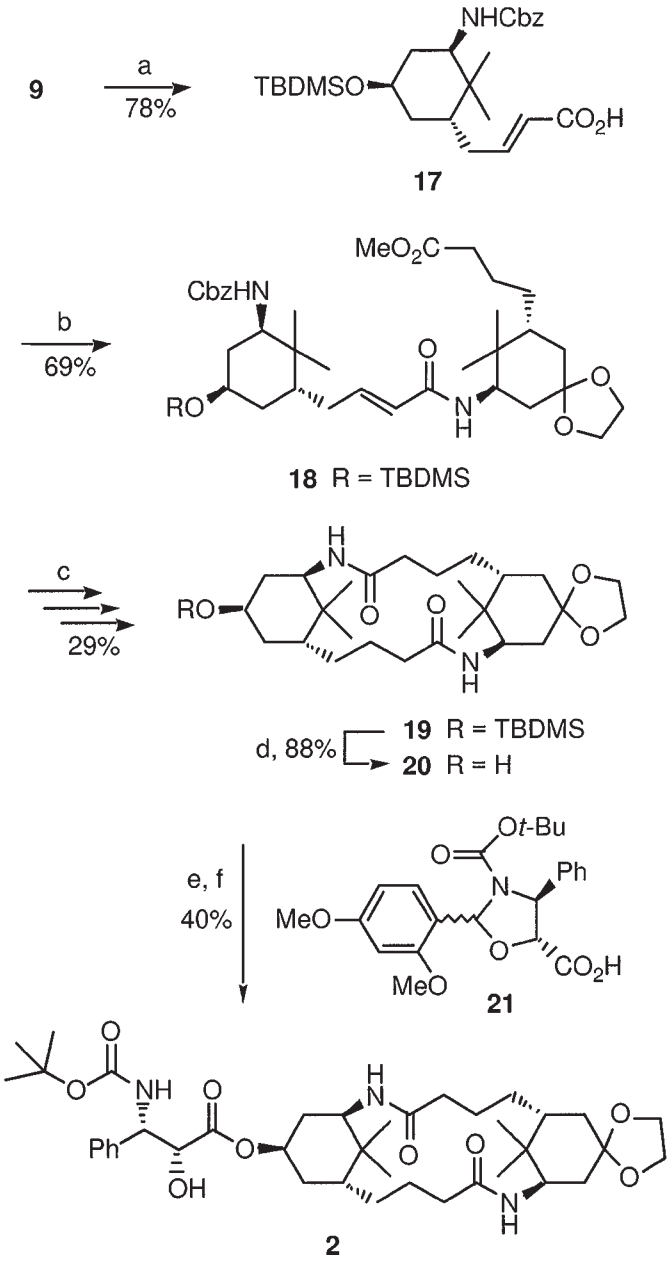
skeleton nor a phenylisoserine side chain are structural elements per se sufficient for cytotoxic and in vitro microtubule assembly activity. Thus, even if the inactive baccatin III becomes the fully active paclitaxel by esterification at C-13 with the appropriate chain, esterification of simpler cyclic alcohols with *N*-acylphenylisoserine does not lead to compounds with paclitaxel-like activities. Although the role of the paclitaxel side chain in affecting biological activity has not yet been fully determined, it is thought that the principal recognition partner is the taxane skeleton itself. The

Fig. 2. Perspective view and arbitrary atom labelling of compound **15**. Thermal ellipsoids are drawn at the 50% probability level; symmetry transformation used to generate equivalent atoms (′) is (–x + 1, –y + 1, –z + 1).

paclitaxel side chain may be preorganized through hydrogen bonding and may fit into a hydrophobic cleft on the taxane binding site, which stabilizes the drug–tubulin interaction (5*b*). Therefore, the moderate cytotoxicity of compounds **2** and **15** is likely to be due to mechanism(s) not involving microtubule stabilization.

Experimental

Materials



Reagents were from commercial suppliers and used without further purification. All solvents were dried over standard drying agents (22) and freshly distilled prior to use.

Instrumentation and techniques

Merck silica gel 60 was used for chromatography (70–230 mesh) and flash chromatography (230–400 mesh) columns. Analytical and preparative TLC were performed with Merck silica gel 60 F_{254} (0.2 mm and 2 mm thickness, respectively) precoated aluminum sheets with visualization by UV light,

charring with H_2SO_4 (10% in water), or charring with anisaldehyde in ethanolic sulfuric acid (23). Melting points are uncorrected. ^1H and ^{13}C NMR spectra were measured in $CDCl_3$ at 200 and 50 MHz, respectively, unless otherwise stated. Mass spectra were obtained at low and high resolution. Elemental analyses (C, H, N) were performed in house.

*2,2-Dimethyl-5-ethylenedioxycyclohexane-1-carboxamide (**4**)*

A solution of KCN (7.88 g, 121 mmol) in water (20 mL) was added slowly to a solution of **3** (7.51 g, 60 mmol) and AcOH (3.45 mL) in 95% EtOH (150 mL) warmed to 40°C. After stirring at 40°C for 4 h, the mixture was cooled to rt and filtered through a short plug of silica gel. The solution was evaporated and the residue was chromatographed on silica gel (toluene) to give 6.50 g (71%) of an oil, which crystallized on standing; mp 78–79°C. This compound was dissolved in a mixture of toluene (200 mL) and ethylene glycol (20 mL) containing camphorsulfonic acid (CSA, 400 mg). After stirring for 8 h under reflux with azeotropical removal of water, the mixture was cooled to rt and washed with 5% aqueous $NaHCO_3$ and brine, then evaporated under reduced pressure. The oily residue was dissolved in 95% EtOH (15 mL) and treated with 6 N NaOH (15 mL) and 30% H_2O_2 (15 mL). The mixture was heated at 50°C for 6 h, cooled to rt, and diluted with CH_2Cl_2 and 5% aqueous $Na_2S_2O_3$. The organic layer was extracted twice with CH_2Cl_2 and the combined organic solution was washed with brine, dried, and evaporated to afford **4** (6.42 g, 60% overall yield from **3**) as a white solid, which was purified by trituration with hexanes–Et_2O, mp 178–182°C. IR (KCl): 3628, 3395, 1662, 1546 cm^{-1}. ^1H NMR δ: 5.65 (d, 2H), 3.91 (s, 4H), 2.31 (dd, *J* = 3.5, 13.0 Hz, 1H), 2.00 (dd, *J* = 3.5, 13.0 Hz, 1H), 1.85–1.25 (m, 5H), 1.17 (s, 3H), 1.02 (s, 3H). ^{13}C NMR δ: 175.6, 108.7, 64.3, 64.1, 51.2, 38.8, 34.0, 32.1, 31.0, 30.3, 19.9. EIMS (*m*/*z*): 213 (M^+, 7), 169 (25), 99 (100), 86 (55). Anal. calcd. for $C_{11}H_{19}NO_3$: C 61.94, H 8.98, N 6.57; found: C 62.19, H 9.09, N 6.40.

*3-[(Benzyloxycarbonyl)amino]-4,4-dimethylcyclohexanone (**5**)*

Bromine (0.8 mL) was added to 2.5 N NaOH (30 mL) cooled in an ice bath, followed after 15 min by amide **4** (2.0 g, 9.75 mmol) in small portions. The mixture was stirred at 0–5°C for 45 min, then at rt for a further 30 min, and finally heated at 80°C for 1 h. After cooling, the reaction mixture was extracted with Et_2O (6 × 20 mL) and the combined organic solution was washed with brine and evaporated. The oily residue was dissolved in 95% EtOH (15 mL) and 5% aqueous Na_2CO_3 (10 mL) and benzyl chloroformate (1.08 mL, 7.55 mmol) was added dropwise. After stirring at rt for 3 h, the reaction mixture was diluted with water and extracted with Et_2O (4 × 50 mL). The organic layer was washed with brine, dried and evaporated to give an oil, which was purified by flash chromatography on silica gel (hexanes–EtOAc, 4:1). The yellow oil (1.58 g, 4.96 mmol) was dissolved in 30 mL of 1 N HCl–THF (1:1) and the solution was stirred at rt for two days. After removal of THF under reduced pressure, the aqueous phase was neutralized with solid $NaHCO_3$ and extracted with Et_2O (4 × 50 mL). The organic layer was washed with brine, dried, and evaporated. Flash chromatography of the residue on silica gel (hexanes–EtOAc, 4:1) gave **5** (1.26 g, 45% overall yield from **4**) as a white solid, which was recrystallized from hexanes–EtOAc (4:1), mp 106–107°C. IR (KCl): 3450, 3060, 2980, 1730, 1520 cm^{-1}. ^1H NMR δ: 7.35 (m, 5H), 5.11 (s, 2H), 4.88 (d, *J* = 10.0 Hz, 1H), 3.83 (ddd, *J* = 5.0, 10.0, 10.0 Hz, 1H), 2.61 (dd, *J* = 5.0, 15.0 Hz, 1H), 2.33 (m, 2H), 2.27 (dd, *J* = 10.0, 15.0 Hz, 1H), 1.67 (m, 2H), 1.09 (s, 3H), 1.00 (s, 3H). ^{13}C NMR δ: 208.59, 155.74, 136.27, 128.54, 127.55, 126.93, 66.95, 56.76, 44.64, 37.61, 36.17, 34.14, 27.25, 19.90. EIMS (*m*/*z*): 275 (M^+, 10), 219 (22), 184 (20), 91 (100). Anal. calcd. for $C_{16}H_{21}NO_3$: C 69.79, H 7.69, N 5.09; found: C 69.58, H 7.83, N 5.25.

*5-[(Benzyloxycarbony)lamino]-4,4-dimethylcyclohex-2-en-1-one (**6**)*

To a solution of LHMDS in THF (10.89 mL, 1 M, 10.89 mmol) was added a solution of **5** (1.0 g, 3.36 mmol) in THF (10 mL) dropwise at –78°C. The solution was stirred at this temperature for 1.5 h, and then freshly distilled Et_3N (2.50 mL, 18.15 mmol) and TMSCl (1.38 mL, 10.89 mmol) were added and the reaction was allowed to warm to rt. After filtration and evaporation of volatiles, the residual oil was dissolved in acetonitrile (30 mL) and $Pd(OAc)_2$ (896.4 mg, 3.99 mmol) and $CaCO_3$ (363.3 mg, 3.63 mmol, previously dried at 120°C overnight) were added. The mixture was refluxed for 2 h, then evaporated under reduced pressure. Flash chromatography of the crude residue on silica gel (hexanes–EtOAc, 3:1) provided **6** (694.9 mg, 70%) as a white solid, which was recrystallized from hexanes–EtOAc (4:1), mp 120°C. IR (KCl): 3437, 2969, 1721, 1679, 1512, 1466 cm^{-1}. ^1H NMR δ: 7.33 (m, 5H), 6.65 (d, *J* = 10.0 Hz, 1H), 5.89 (d, *J* = 10.0 Hz, 1H), 5.09 (s, 2H), 5.01 (br d *J* = 9 Hz, 1H), 4.11 (m, 1H), 2.65 (dd, *J* = 4.5, 16.5 Hz, 1H), 2.42 (dd, *J* = 10.0, 16.5 Hz, 1H), 1.20 (s, 3H), 1.08 (s, 3H). ^{13}C NMR δ: 208.43, 155.57, 136.09, 128.07, 66.08, 44.49, 37.47, 36.02, 33.99, 27.10, 19.73. EIMS (*m*/*z*): 273 (M^+, 5), 167 (19), 139 (10), 96 (100). Anal. calcd. for $C_{16}H_{19}NO_3$: C 70.31, H 7.01, N 5.13; found: C 70.51, H 6.96, N 5.03.

*3β-[(Benzyloxycarbonyl)amino]-4,4-dimethyl-5α-(2-propenyl)cyclohexanone (**7**)*

Titanium tetrachloride (1.2 mL, 10.97 mmol) was added dropwise to a solution of **6** (1.50 g, 5.49 mmol) in dry CH_2Cl_2 (112 mL) at –78°C. The solution was stirred at this temperature for 5 min, then a solution of freshly distilled allyltrimethylsilane (3.49 mL, 21.96 mmol) in dry CH_2Cl_2 (27 mL) was added slowly. The dark red mixture was kept at –78°C for 5 h, then warmed to –30°C. After 2 h the reaction was quenched with water (50 mL) and allowed to warm to rt. The organic layer was separated and the aqueous phase was extracted with Et_2O (4 × 100 mL). The combined organic solution was washed with brine, dried, and concentrated to a yellowish oil, which was purified by flash chromatography on silica gel (hexanes–EtOAc, 4:1) to give **7** (1.25 g, 72%) as white crystals, mp 79–80°C. IR (KCl): 3065, 1708, 1640, 1586, 1370 cm^{-1}. ^1H NMR δ: 7.33 (m, 5H), 5.61 (m, 1H), 5.07 (s, 2H), 5.00 (m, 2H), 4.70 (br d, *J* = 9.0 Hz, 1H), 4.01 (m, 1H), 2.73 (dd, *J* = 4.5, 16.5 Hz, 1H), 2.47–2.08 (m, 4H), 1.71 (m, 2H), 1.12 (s, 3H), 1.08 (s, 3H). ^{13}C NMR δ: 208.43, 155.62, 136.09, 128.05, 117.09, 66.83, 57.81, 44.46, 42.46, 42.09, 36.78, 36.35, 34.35, 23.69, 21.49. EIMS (*m*/*z*): 315 (M^+, 5), 272 (12), 224 (22), 180 (15), 114 (33), 91 (100). Anal. calcd. for $C_{19}H_{25}NO_3$: C 72.35, H 7.99, N 4.44; found: C 72.46, H 7.88, N 4.56.

*3β-[(Benzyloxycarbonyl)amino]-4,4-dimethyl-5α-(2-oxoethyl)cyclohexanone (**8**)*

OsO_4 (catalytic amount) was added as a single portion to a stirring solution of **7** (1.10 g, 3.50 mmol) in 70 mL of Et_2O–H_2O (1:1). After stirring for 5 min, the solution turned black and $NaIO_4$ (1.49 g, 7.0 mmol) was added in small portions. Stirring was continued for 8 h until TLC analysis indicated the absence of the starting material. The pale yellow organic layer was separated and the aqueous phase was extracted with Et_2O (4 × 100 mL). The combined organic solution was washed with brine, dried, and concentrated. Flash chromatography of the resulting oil on silica gel (hexanes–EtOAc, 7:3) gave the expected aldehyde **8** (0.89 g, 80%) as a colorless oil. IR ($CHCl_3$): 3064, 1711, 1585, 1468 cm^{-1}. ^1H NMR δ: 9.73 (s, 1H), 7.33 (m, 5H), 5.08 (s, 2H), 4.85 (br d, *J* = 9.0 Hz, 1H), 3.97 (m, 1H), 2.77–2.12 (m, 7H), 1.09 (s, 3H), 1.07 (s, 3H). ^{13}C NMR δ: 207.86, 200.16, 155.74, 136.05, 128.05, 66.83, 57.18, 44.48, 43.15, 36.21, 34.35, 36.21, 25.41, 23.35, 21.73. EIMS (*m*/*z*): 317 (M^+, 2), 182 (15), 108 (23), 91 (100). HRMS calcd. for $C_{18}H_{23}NO_4$: 317.16271; found 317.16180. Anal. calcd. for $C_{18}H_{23}NO_4$: C 68.12, H 7.30, N 4.41; found: C 68.36, H 7.26, N 4.29.

*4-[3β-[(Benzyloxycarbonyl)amino]-2,2-dimethyl-5-oxocyclohex-1α-yl]-2-butenoic acid methyl ester (**9**)*

To a solution of aldehyde **8** (102 mg, 0.32 mmol) in dry toluene (10 mL) at rt was added methyl (triphenylphosphoranylidene)acetate (131 mg, 0.32 mmol). The reaction mixture was stirred for 8 h at rt. Evaporation of the solvent followed by flash chromatography on silica gel (hexanes–EtOAc, 4:1) gave **9** (86 mg, 72%) as a 9:1 mixture of (*E*–*Z*)-isomers. A sample of the pure (*E*)-isomer was obtained by TLC, mp 104–105°C. IR ($CHCl_3$): 1658 cm^{-1}. ^1H NMR δ: 7.32 (m, 5H), 6.75 (ddd, *J* = 16.0, 9.0, 7.0 Hz, 1H), 5.80 (d, *J* = 16.0 Hz, 1H), 5.06 (s, 2H), 4.84 (br d, *J* = 9.0 Hz, 1H), 4.01 (m, 1H), 3.62 (s, 3H), 2.80–1.80 (m, 7H), 1.10 (s, 3H), 1.08 (s, 3H). EIMS (*m*/*z*): 355 (M^+–H_2O, 70), 281 (2), 223 (12), 95 (100), 81 (42), 67 (95). HRMS calcd. for $C_{21}H_{27}NO_5$: 373.18892; found: 373.18800. Anal. calcd. for $C_{21}H_{27}NO_5$: C 67.54, H 7.29, N 3.75; found: C 67.70, H 7.36, N 3.57.

*4-[3β-[(Benzyloxycarbonyl)amino]-5-ethylenedioxy-2,2-dimethylcyclohex-1α-yl]-2-butenoic acid methyl ester (**10**)*

A solution of **9** (267 mg, 0.72 mmol), camphorsulphonic acid (catalytic amount), and ethylene glycol (0.4 mL, 7.2 mmol) in toluene (30 mL) was stirred at 130°C for 4 h with azeotropical removal of water. The cooled solution was washed with 5% aqueous $NaHCO_3$ and brine, then evaporated under reduced pressure. The oily residue was flash chromatographed on silica gel (hexanes–EtOAc, 7:3) to give **10** (289 mg, 98%) as a colorless oil. ^1H NMR δ: 7.34 (m, 5H), 6.87 (ddd, *J* = 15.0, 8.0, 5.8 Hz, 1H), 6.05 (br d, *J* = 9.8 Hz, 1H), 5.70 (d, *J* = 15.0 Hz, 1H), 5.07 (s, 2H), 3.90 (m, 4H), 3.77 (m, 1H), 3.70 (s, 3H), 2.37–1.20 (m, 7H), 0.99 (s, 3H), 0.91 (s, 3H). HRMS calcd. for $C_{23}H_{31}NO_6$: 417.21514; found: 417.21610. Anal. calcd. for $C_{23}H_{31}NO_6$: C 66.16, H 7.49, N 3.36; found: C 65.80, H 7.59, N 3.11.

*4-(3β-Amino-5-ethylenedioxy-2,2-dimethylcyclohex-1α-yl)-butanoic acid methyl ester (**11**)*

A mixture of **10** (200 mg, 0.20 mmol) and Pd/C (20 mg, 10%) in EtOH (10 mL) was shaken in a Parr apparatus under 4 atm (1 atm = 101.325 kPa) of pressure of hydrogen for 8 h. Filtration of the mixture through Celite followed by solvent removal under reduced pressure gave **10** (137 mg, 92%) as a TLC-homogeneous colorless oil. IR ($CHCl_3$): 3155, 1731, 1580 cm^{-1}. ^1H NMR δ: 3.79 (m, 4H), 3.35 (m, 5H), 2.70 (br s, 2H), 2.16–1.02 (m, 10H), 0.80 (s, 3H), 0.70 (s, 3H). ^{13}C NMR δ: 173.78, 155.67, 108.53, 64.29, 64.18, 63.79, 63.72, 58.15, 56.00, 51.30, 37.05, 34.85, 34.02,

29.48, 28.78, 28.27, 25.28, 23.11, 19.82. FABMS (*m*/*z*): 286 (M^+ + H) (100), 269 (449), 215 (22). HRMS calcd. for $C_{15}H_{27}NO_4$: 285.19401; found: 285.19500. Anal. calcd. for $C_{15}H_{27}NO_4$: C 63.13, H 9.54, N 4.91; found: C 63.32, H 9.60, N 4.83.

*4-[3β-[(Benzyloxycarbonyl)amino]-5-ethylenedioxy-2,2-dimethylcyclohex-1α-yl]-2-butenoic acid (**12**)*

To a stirring solution of **10** (58.7 mg, 0.14 mmol) in MeOH–H_2O (3:2, 0.8 mL) was added LiOH (7.0 mg, 0.17 mmol) in one portion at rt. Stirring was continued for 1.5 h at 60°C, then the mixture was cooled to 0–5°C, acidified to pH ~ 4 by adding 6 N HCl, and repeatedly extracted with EtOAc. The combined organic phase was dried, and the solvent was removed under reduced pressure. The residue was purified by flash chromatography on silica gel (EtOAc) to afford **12** (52.8 mg, 93%) as a white foam. A sample of the pure (*E*)-isomer was obtained by TLC. IR ($CHCl_3$): 3500, 2946, 1698, 1287 cm^{-1}. ^1H NMR δ: 9.11 (br s, 1H), 7.34 (m, 5H), 6.97 (ddd, *J* = 15.0, 8.0, 5.8 Hz, 1H), 6.05 (br d, *J* = 9.8 Hz, 1H), 5.70 (d, *J* = 15.0 Hz, 1H), 5.07 (s, 2H), 3.90 (m, 4H), 3.77 (m, 1H), 3.70 (s, 3H), 2.47–1.20 (m, 5H), 1.00 (s, 3H), 0.91 (s, 3H). ^{13}C NMR δ: 156.21, 136.64, 128.31, 108.47, 66.38, 64.30, 63.90, 56.74, 38.07, 37.12, 36.05, 32.72, 24.61, 19.84. FABMS (*m*/*z*): 402 (M^+ – H), 294 (95), 255 (100), 149, (80). HRMS calcd. for $C_{22}H_{29}NO_6$: 403.19949; found: 403.20185. Anal. calcd. for $C_{22}H_{29}NO_6$: C 65.49, H 7.24, N 3.47; found: C 65.29, H 7.29, N 3.38.

*Synthesis of compound **13***

To a solution of **12** (282.1 mg, 0.70 mmol) in dry CH_2Cl_2 (14 mL) were added (at –15°C) *N*-methylmorpholine (85 μL, 0.78 mmol) and *i*-butyl chloroformate (90 μL, 0.70 mmol). After stirring at –15°C for 1 h, a solution of **11** (201 mg, 0.70 mmol) in dry CH_2Cl_2 (14 mL) was added slowly. The reaction was allowed to warm to rt, then was quenched with water and extracted with CH_2Cl_2 (4 × 15 mL). The combined organic phase was washed with brine, dried, and evaporated to give an oily residue, which after flash chromatography (SiO_2; hexanes–EtOAc, 4:1) afforded **13** (347.1 mg, 74%) as a colorless oil. A sample of the pure (*E*)-isomer was obtained by TLC. ^1H NMR δ: 7.33 (m, 5H), 6.78 (d, *J* = 9.0 Hz, 1H), 6.74 (m, *J* = 10.0, 7.0, 3.0 Hz, 1H), 6.05 (d, *J* = 8.5 Hz, 1H), 5.70 (d, *J* = 10.0 Hz, 1H), 5.08 (q, 2H), 4.01 (m, 1H), 3.93 (m, 10H), 3.87 (m, 1H), 3.63 (s, 3H), 2.35–1.19 (m, 16H), 0.98 (s, 3H), 0.9 (s, 9H). ^{13}C NMR δ: 186.22, 173.78, 164.66, 156.16, 136.73, 128.28, 127.81, 124.09, 108.56, 63.81, 56.92, 54.33, 37.19, 36.96, 35.82, 34.68, 32.38, 28.72, 24.37, 19.85, 14.02. FABMS (*m*/*z*): 671 (M^+ + H) (15), 269 (100), 225 (20), 165 (12), 147 (10). HRMS calcd. for $C_{37}H_{54}N_2O_9$: 670.38293; found: 670.38460. *Synthesis of amino acid **14***

Prepared in 96% overall yield from **13** by hydrolysis followed by hydrogenation according to the procedures described for the synthesis of **12** and **11**, respectively. Colorless foam. ^1H NMR δ: 7.24 (d, *J* = 9.0 Hz, 1H), 5.05 (br s, 1H), 3.88 (m, 8H), 3.20 (s, 2H), 2.35–1.19 (m, 24H), 0.85 (s, 3H), 0.83 (s, 9H). ^{13}C NMR δ: 171.72, 109.08, 107.96, 64.29, 63.77, 54.23, 53.22, 37.39, 35.82, 29.15, 28.56, 27.80, 25.09, 24.89, 23.56, 20.49, 19.71, 19.47. FABMS (*m*/*z*): 525 (M^+ + H). HRMS calcd. for $C_{28}H_{48}N_2O_7$: 524.34615; found: 524.34790. Anal. calcd. for $C_{28}H_{48}N_2O_7$: C 64.09, H 9.22, N 5.34; found: C 63.88, H 9.30, N 5.50.

*Preparation of macrolactams **15** and **16***

To a 5×10^{-4} M solution of **14** (58 mg, 0.11 mmol) in dry DMF (220 mL) was added $NaHCO_3$ (46 mg, 0.55 mmol) followed by DPPA (0.24 mL, 1.10 mmol). The reaction mixture was stirred at rt for five days, then the solvent was removed under reduced pressure and the residue was taken up in EtOAc (50 mL). The solution was washed with water and brine, dried, and evaporated. Flash chromatography of the residue on silica gel ($CHCl_3$–MeOH, 19:1) gave **15** (15.7 mg, 28%), followed by **16** (10.8 mg, 10%), as colorless foams.

15: IR ($CHCl_3$): 2421, 1652, 1593, 840 cm^{-1}. ^1H NMR (500 MHz) δ: 7.16 (d, 1.5H), 7.02 (d, 0.5H), 4.02 (m, 10H), 2.46 (m, 4H), 2.36 (m, 4H), 2.20 (m, 8H), 1.56 (m, 12H), 1.03 (m, 6H). ^{13}C NMR (75 MHz) δ: 172.66, 171.16, 109.99, 108.99, 64.42, 64.36, 64.20, 63.92, 55.06, 54.81, 37.83, 37.72, 37.23, 36.96, 34.94, 34.14, 33.63, 33.49, 30.50, 29.69, 25.69, 25.60, 22.98, 22.35, 20.48, 19.64, 19.56. HRMS calcd. for $C_{28}H_{46}N_2O_6$: 506.33559; found: 506.33390. Anal. calcd. for $C_{28}H_{46}N_2O_6$: C 66.37, H 9.15, N 5.53; found: C 66.52, H 9.06, N 5.38.

16: FD MS (*m*/*z*): 1014 (M^+ + H). Anal. calcd. for $C_{56}H_{92}N_4O_{12}$: C 66.37, H 9.15, N 5.53; found: C 66.57, H 9.21, N 5.33.

*4-[3β-[(Benzyloxycarbonyl)amino]-5β-[(tert-butyldimethylsilyl)oxy]-2,2-dimethylcyclohex-1α-yl]-2-butenoic acid (**17**)*

To a solution of **9** (100 mg, 0.27 mmol) in MeOH (10 mL) was added $NaBH_4$ (41 mg, 1.08 mmol) in one portion. After stirring at rt for 1 h, the solvent was removed under reduced pressure and the residue was taken up in EtOAc. Usual workup of the organic solution gave an oily mixture, which was separated by flash chromatography (SiO_2; hexanes–EtOAc, 3:2) to provide two isomers of the expected alcohol as colorless oils. Minor isomer (11 mg, 11%). R_f = 0.4. HRMS calcd. for $C_{21}H_{29}NO_5$: 375.20457; found: 375.20299. Major isomer (81 mg, 81%). R_f = 0.2. HRMS calcd. for $C_{21}H_{29}NO_5$: 375.20457; found: 375.20310.

TBDMSCl (165 mg, 1.10 mmol) was added to a solution of the above product (major isomer, 75 mg, 0.20 mmol) and imidazole (163 mg, 2.40 mmol) in dry DMF (1.5 mL). The reaction mixture was stirred at 70°C for 1 h, then cooled to rt, diluted with Et_2O (100 mL) and washed with water (5 × 2 mL). Solvent removal followed by flash chromatography (SiO_2; hexanes–EtOAc, 9:1) gave in quantitative yield the silylated compound, which was then hydrolyzed with LiOH using the same procedure described for the preparation of **12**. Flash chromatography of the crude product (SiO_2, EtOAc) afforded the expected acid **17** in 98% yield (94 mg, 78% overall yield from **9**) as a white foam. ^1H NMR δ: 7.35 (m, 5H), 6.93 (m, 1H), 5.85 (d, *J* = 10 Hz, 1H), 5.09 (overlapping m, 3H), 3.70 (m, 2H), 2.62–0.91 (m, 13H),

© 2000 NRC Canada

0.85 (s, 9H), 0.01 (s, 6H). ^{13}C NMR δ: 171.72, 109.08, 107.96, 64.29, 63.77, 54.23, 53.22, 37.39, 35.82, 29.15, 28.56, 27.80, 25.09, 24.89, 23.56, 20.49, 19.71, 19.47. FABMS (*m*/*z*): 498 (M^+ + Na). HRMS calcd. for $C_{26}H_{41}NO_5SiNa$: 498.26517; found: 498.26655. Anal. calcd. for $C_{26}H_{41}NO_5Si$: C 65.64, H 8.69, N 2.95; found: C 65.90, H 8.77, N 3.14.

*Synthesis of amide **18***

Starting from **17** and following the same procedure described for the preparation of **13**, the title compound was prepared in 69% yield after chromatographic purification (SiO_2; hexanes–EtOAc, 7:3). Separation by TLC gave a sample of the pure geometric isomers.

*(E)-**18***: R_f = 0.3. ^{1}H NMR δ: 7.32 (m, 5H), 6.75 (superimposed signals, 2H), 5.75 (d, *J* = 15 Hz, 1H), 5.20 (m, 2H), 4.83 (br d, 1H), 4.09 (m, 1H), 3.92 (m, 4H), 3.63 (overlapping signals, 5H), 2.32 (m, 2H), 2.04–1.05 (m, 16H), 0.94 (s, 6H), 0.90 (s, 6H), 0.88 (s, 9H), 0.01 (s, 6H). ES MS (*m*/*z*): 743 (M^+ + H). HRMS calcd. for $C_{41}H_{66}N_2O_8Si$: 742.45885; found: 742.46555. Anal. calcd. for $C_{41}H_{66}N_2O_8Si$: C 66.36, H 8.95, N 3.77; found: C 66.70, H 8.81, N 3.47.

*(Z)-**18***: R_f = 0.2. ^{1}H NMR δ: 7.32 (m, 5H), 6.75 (superimposed signals, 2H), 5.75 (d, *J* = 9.0 Hz, 1H), 5.26 (m, 2H), 4.83 (br d, 1H), 4.06 (m, 1H), 3.91 (m, 4H), 3.63 (overlapping signals, 5H), 2.28 (m, 2H), 2.03–1.05 (m, 16H), 0.93 (s, 6H), 0.90 (s, 6H), 0.88 (s, 9H), 0.01 (s, 6H). ES MS (*m*/*z*): 743 (M^+ + H). HRMS calcd. for $C_{41}H_{66}N_2O_8Si$: 742.45885; found: 742.45690. Anal. calcd. for $C_{41}H_{66}N_2O_8Si$: C 66.36, H 8.95, N 3.77; found: C 66.01, H 8.77, N 3.52.

*Synthesis of macrolactam **19***

Prepared in 29% overall yield (after chromatography on SiO_2; $CHCl_3$–MeOH, 19:1) from **18** through a sequence of hydrolysis-, hydrogenation-, DPPA-mediated macrolactamization as described for the conversion of **13** into **15**. ^{1}H NMR δ: 6.98 (br d, 2H), 3.98 (superimposed signals, 5H), 3.71 (m, 2H), 2.17–1.22 (m, 22H), 0.83 (s, 21H), 0.01 (s, 6H). HRMS calcd. for $C_{32}H_{58}N_2O_5Si$: 578.41150; found: 578.41312. Anal. calcd. for $C_{32}H_{58}N_2O_5Si$: C 66.39, H 10.10, N 4.84; found: C 66.58, H 10.22, N 4.56.

Preparation of 2

To a solution of **19** (17.3 mg, 0.03 mmol) in THF (1.0 mL) at 0°C was added a solution of *n*-Bu_4NF (0.12 mL, 1.0 M, 0.12 mmol) in THF, and the mixture was stirred for 3 h at rt, then quenched with saturated aqueous NH_4Cl, and diluted with Et_2O and the organic layer was washed with water and brine and dried. Filtration and evaporation of the solvent followed by column chromatography (SiO_2; $CHCl_3$–MeOH, 19:1) gave the expected alcohol **20** (12.2 mg, 88%) as a colorless oil. HRMS calcd. for $C_{26}H_{44}N_2O_5$: 464.32502; found: 464.32622.

To a solution of (4*S*,5*R*)-*N*-(*tert*-butoxycarbonyl)-2(2,4-dimethoxyphenyl)-4-phenyloxazolidine-5-carboxylic acid (**21**) (12.0 mg, 0.028 mmol), CMC (20.3 mg, 0.026 mmol) and DMAP (3.2 mg, 0.026 mmol) in dry toluene (2.0 mL) was added alcohol **20** (11.1 mg, 0.024 mmol) and the mixture was stirred at rt for 20 h. The filtered solution was concentrated to yield the crude product, which was redissolved in MeOH (3.0 mL) and 0.1 N HCl (1.5 mL). After stirring at rt for 2 h, the reaction was neutralized by adding 5% aqueous $NaHCO_3$ and concentrated to a small volume. Extraction with EtOAc followed by the usual workup of the organic solution afforded a residue, which was purified by column chromatography (SiO_2; $CHCl_3$–MeOH, 19:1) to give the final compound **2** (7.0 mg, 40% overall yield) as a colorless foam. ^{1}H NMR δ: 7.48 (m, 5H), 6.78 (br d, 2H), 5.59 (deformed d, *J* = 9.5 Hz, 1H), 5.40 (deformed d, *J* = 9.0 Hz, 1H), 5.03 (m, 1H), 3.98 (superimposed signals, 5H), 3.61 (m, 2H), 2.20–1.24 (m, 22H), 1.12 (s, 9H), 0.90 (s, 6H), 0.84 (s, 6H). HRMS calcd. for $C_{40}H_{61}N_3O_9$: 727.44078; found: 727.43811. Anal. calcd. for $C_{40}H_{61}N_3O_9$: C 66.00, H 8.45, N 5.77; found: C 59.73, H 8.58, N 5.95.

Single-crystal X-ray diffraction study of 15

Colourless prismatic crystals of **12** were grown from H_2O–MeOH at 277 K. Crystal data: $C_{28}H_{46}N_2O_6$; Mr = 506.67; space group, triclinic *P*1; *a* = 9.176(2) Å, *b* = 9.692(2) Å, γ = 8.530(2) Å, α = 107.47(2)°, β = 109.82(2)°, γ = 89.38(2)°; *V* = 677.3(3) Å^3; *Z* = 1; *F*(000) = 276; D_x = 1.242 g cm^{-3}; Cu K_α = 1.5418 Å; μ = 0.697 mm^{-1}. X-ray data were collected on a Rigaku AFC5R automated diffractometer (graphite-monochromated Cu K_α radiation). Intensity data were collected, the experimental conditions being $(\sin\theta/\lambda)_{max}$ = 0.57 Å^{-1}; 2θ – ω scan mode; scan range 1.0°, scan rate 1.0°–16.0° min^{-1} (depending on reflection intensity), background count time a quarter of the scan time. There was no significant intensity variation for 3 standard measured every 200 (1.3%). Lorentz, polarization, absorption (min and max transmission factors 0.91 and 1.00) but no extinction corrections were applied. Of the 2342 reflections measured, 2144 were unique (R_{int} = 0.067 based on F^2) and 1626 with $I > 2.0\sigma(I)$ were considered as observed. The structure was solved by direct methods and refined based on F^2, using the SHELXL-97 package (24). Difference Fourier syntheses, using only data with $(\sin\theta/\lambda)$ = 0.50 Å^{-1}, computed at the end of the anisotropic least-squares refinement, showed all H-atoms in configurationally feasible positions. The final refinements were carried out by full-matrix with the H-atoms allowed to ride on the corresponding C and N atoms (165 parameters). The final *R* values are 0.061 for 1626 $I > 2\sigma(I)$ and of 0.087 for all 2144 data; the *wR* are 0.156 and 0.173 respectively. The goodness of fit *S* is 1.072 for all 2144 data, based on F^2. Heights in final difference Fourier map ρ_{max} = 0.32 e Å^{-3} and ρ_{min} = –0.40 e Å^{-3}. A perspective view of the molecular structure of **15**[10] was prepared using ORTEP-3 (25).

Superimposition of macrolactam 2 with paclitaxel

Calculations and graphic manipulations were performed on a SiliconGraphics workstation Indigo R4000. The PCMODEL software package (26) equipped with the MMX force field

[10]Supplementary material has been deposited and may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Rsearch Council of Canada, Ottawa, Ontario, Canada, K1A 0S2. Tables of bond lengths and angles and hydrogen coordinates have also been deposited with the Cambridge Crystallographic Data Centre and can be obtained on request from: The Director, Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, U.K.

was used in this study to perform all the calculations. Solvent effects were not taken into account. All the graphic manipulations were accomplished using the program InsightII.[11] The lowest-energy conformation of paclitaxel, already determined in a previous study by some of us (10), was used here as the reference geometry. The lowest-energy conformation of **2** was secured by a conformational search performed following the protocol already applied to paclitaxel (10) to perform a reliable structural comparison.

Acknowledgments

Thanks are due to Dr. N. Mongelli, Pharmacia & Upjohn, Milano (Italy) for helpful discussions. Financial support from Pharmacia & Upjohn and the program P.O.P. Regione Calabria 1994–1998 — Misura 4.4 — "Ricerca Scientifica e Tecnologica" is gratefully acknowledged. M.B. wishes to thank the NATO International Scientific Exchange Programme "Bioactive Conformation and Design Mimics for the Anticancer Agent Taxol," 1996, for a collaborative research grant as well as the Merck Research Laboratories for the 1998 Academic Development Program (ADP) Chemistry Award.

Conformational effects in the diastereoselective protonation of chiral enolates derived from 2,4-dimethyl-1-tetralone using carbonyl chelating proton donors

Gregory S. Coumbarides, Jason Eames, and Neluka Weerasooriya

Abstract: The synthesis of *syn*-2,4-dimethyl-1-tetralone **6** via a reprotonation strategy using chelating proton donors is discussed. We comment on the comformational effects associated with these acids, and discuss the differences between direct protonation and deprotonation-reprotonation of chiral enolates in the presence of diisopropylamine and LiBr.

Key words: conformation, chelating proton donors, deprotonation-reprotonation strategy, diastereoselective protonation and solvent effects.

Résumé : On discute de la synthèse de la *syn*-2,4-diméthyl-1-tétralone **6** via une stratégie de reprotonation qui utilise des donneurs de protons chélateurs. Nous examinons les effets conformationnels associés à ces acides, et nous discutons des différences entre la protonation directe et la déprotonation-reprotonation des énolates chiraux en présence de la diisopropylamine et du LiBr.

Mots clés : conformation, donneurs de protons chélateurs, stratégie de déprotonation-reprotonation, protonation diastéréosélective, effets de solvant.

[Traduit par la Rédaction]

Diastereoselective protonation of chiral enolates is well documented (1). Of these reports, the majority deal with direct protonation of chiral enolates under either kinetic (2) or thermodynamic substrate control (3). There are fewer cases where the diastereoselective stereochemical determining protonation step is under reagent control (4), the most notable examples being the use of *chelating proton donors* (CPD's) (5) such as salicylic esters **1**, (5) and β-amino alcohols **2** (6). The behaviour of such acids are characterised by their ability to chelate to lithium of an enolate, and thus kinetically direct protonation, regioselectively on carbon of an enolate, like **3**, rather than the preferred kinetic O-protonation for non-coordinating acids to give enols (Scheme 1) (7).

We now wish to report our study into the use of carbonyl based chelating proton donors (like **4**) for regioselective and kinetic C-protonation of enolates by using a similar diastereoselective protonation approach. We also comment on factors (such as the acidity and conformation of the proton donor, solvent, and salt effects) which affect the outcome of the stereoselective protonation step, all of which help to elucidate the mechanism of protonation.

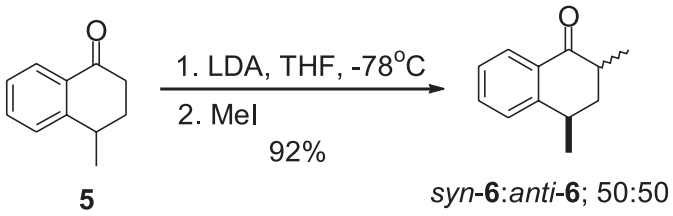
We chose the tetralone framework as our model system because there was no ambiguity with the formation and configuration of the *endo*-cyclic enolate geometry. The 2,4-dimethyl tetralone **6** required for this study was synthesised by deprotonation of the commercially available 4-methyl tetralone **5** with LDA in THF at –78°C, and subsequent alkylation with methyl iodide gave the *syn* and *anti*-2,4-dimethyl tetralone **6** as a partially separable mixture (50:50) of diastereoisomers in excellent yield (Scheme 2). Evidently, methylation of this intermediate chiral enolate occurs equally on both diastereotopic faces and shows that there was no substrate control from the resident stereocentre.

We first studied the diastereoselective protonation of the chiral enolate **8a** in the presence of the diisopropylamine (derived from the LDA), which has previously been documented to cause enolate deaggregation (4) and also act as a competitive base to cause internal proton return (8). Treatment of the diastereoisomeric mixture of 2,4-dimethyl tetralone **6** with LDA in THF at –78°C and re-protonation with a series of carbonyl-based acids gave the diastereoisomeric tetralones *syn*- and *anti*-**6** (Scheme 3).



The choice of proton donor (HA) used in this reprotonation step did give rather markedly different results. Conformationally restricted sp^2 nitrogen based amides, such as urea (Scheme 3, entry 1), thiourea (entry 2), and the 2-oxazolidinone (entry 3) gave poor diastereoisomeric control, slightly in favour of the *syn*-diastereoisomer. The ratio was substantially improved by using the more acidic (glacial) acetic acid (entry 4). But, greater diastereoselective control came from mildly acidic carbon-based acids like pentane-2,4-dione and ethyl acetoacetate (entry 5 and 6), whereas

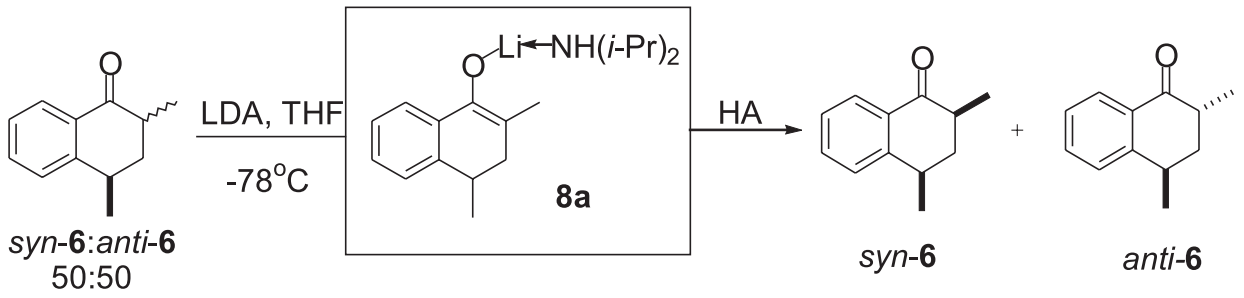
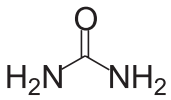
Scheme 2.

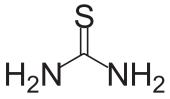
further addition of an ethyl ester linkage in the form of diethyl malonate (entry 7) caused the selectivity to be reduced dramatically. To attempt to assess whether this control was due to the difference in their coordination ability, conformation, or acidity; we chose to quench the enolate **8a** with conformationally restricted carbon-based acids like dimedone (entry 8) and Meldrum's acid (entry 9). The more acidic dimedone gave substantially lower diastereocontrol with respect to their parent acyclic acid (from 96:4 to 74:26), whereas Meldrum's acid gave an increase (from 52:48 to 79:21). The preferred conformer of such acids are clearly different than that of their near acyclic relatives. Both carbonyl groups are clearly in an fixed eclipsing conformation due to their cyclic framework, and since both gave very similar selectivity it does appear that their relative acidity plays a minor role. Protonation must occur via the conformation (e.g., **9**) leading to the *syn*-tetralone **6** as the major diastereoisomer (Scheme 4). For conformationally mobile acyclic 1,3-dicarbonyl-based acids, such as **10**, their preferred conformation (9) (where both carbonyl groups oppose each other to minimize the molecule's overall dipole moment) must be responsible for the higher diastereoselectivity. We would have imagined that the better the chelator, the tighter the transition state on protonation and therefore the better the selectivity. Because the chelating abilities of such acyclic proton donors are as: diethyl malonate > acetoacetate > pentane-2,4-dione, it does seem rather surprising that the better chelator, diethyl malonate, does not obey this trend. However, it does appear that there is a fine balance between these acids behaving as a coordinating acid like **11a** and as a chelating acid **11b**. When such acids do chelate to the lithium cation of the enolate in the form of **11b**, no stereocontrol was observed and this was presumably due to protonation occurring via the enol acid **11c** (9). The conformers that are responsible for the observed diastereocontrol is illustrated in Scheme 5.

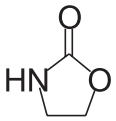
By comparison, direct protonation with MeOH gave a ratio of 60:40 in favour of the *syn*-tetralone **6** (93%). Whereas, under thermodynamic control by treatment of the *syn*-diastereoisomer **6** with *t*-BuOK in THF overnight favoured the equilibrium ratio (50:50). Clearly, the *syn*-diastereoisomer **6** is the kinetic product (relative stereochemistry determined by a 600 MHz NOESY) and thus protonation on the less hindered face of the enolate **8a** is preferred.

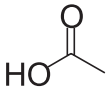


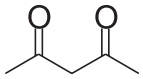
We next probed the effect of the residual diisopropylamine in **8a** on the stereochemistry determining protonation step. We chose to generate the enolate under "base free" conditions using Koga's silyl enol ether procedure (10). Treatment of the 2,4-dimethyl tetralone **6** with LDA at –78°C and quenching with Me_3SiCl gave the required silyl enol ether **12** in near quantitative yield (Scheme 6), and the addition of MeLi at 0°C generated the "base free" chiral enolate **8b**. Direct protonation of this lithium enolate at –78°C with a series of carbonyl chelating proton donors (as shown in Scheme 7) gave the diastereoisomeric tetralone **6** in good yield.

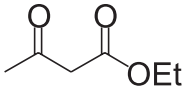


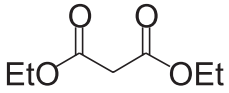


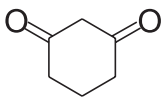


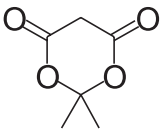












By comparison, in the absence of diisopropylamine, the diastereoselectivity of protonation was substantially reduced for the carbon-based acids, but a slight increase for acetic acid was observed; in all cases the *syn*-diastereoisomer was favoured (Scheme 7: entries 1–5). In the case of glacial acetic acid it appears that diisopropylammonium acetate (by in situ-reaction of acetic acid with diisopropylamine) does act as an additional acid (7) since the presence of the diisopropylamine (Scheme 7: entry 4) did have a detrimental effect on the diastereoselectivity. To determine the degree to which this diisopropylammonium salt behaved as an additional acid, we quenched the enolates **8a** (derived from **6**) and **8b** with diisopropylammonium chloride. A much lower diastereoselectivity was observed giving the *syn*- and *anti*-tetralone **6** in a ratio of 75:25 (85%) and 70:30 (80%) and clearly in these cases the diastereoselectivity was being compromised by competitive protonation from the ammonium salt.

However, in the case of the carbon-based acids, such as the more acidic pentane-2,4-dione, full deprotonation by diisopropylamine is not favoured and proton transfer is known to be much slower, by at least four orders of magnitude (9). Even more surprising, the presence of this amine in the enolate **8a** and not **8b**, clearly makes the enolates different; since the diastereoselectivity of protonation with a better chelator, such as ethyl acetoacetate falls substantially (95:5 to 70:30) in the absence of amine. The enolate **8b** can be converted into **8a** (by the simple addition of diisopropylamine) and quenching with ethyl acetoacetate gives identical diastereoselectivity (95:5) in 83% yield. An attempt to increase the diastereoselectivity by protonation in a non polar solvent like toluene, to promote chelation, only lowered the diastereoselectivity (62:38; 82%) in favour of *syn*-**6**. This results in a much lower diastereoselectivity, and thus a reversal of coordination ability dominants – the poorer the donor, the better the control. As expected, for the conformationally restricted cyclic carbon-based acids no real change occurred.

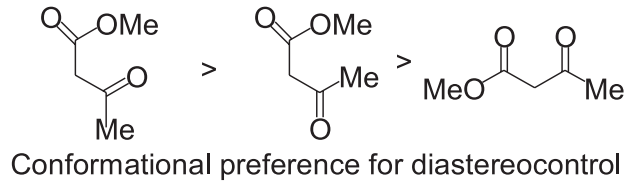
8		74:29	80
9		79:21	74



By the simple addition of LiBr to the enolate (by treatment of **7** with a MeLi·LiBr complex) the diastereoselectivity of protonation improved even further (Scheme 7: entries 6–10), giving exclusively the *syn*-tetralone **6** (>98:2 by ^{1}H NMR) by using ethyl acetoacetate as the proton source. The effect of diisopropylamine and LiBr on the behaviour of the lithium enolate is dramatic and appears to create the optimum environment for simple donation from these carbonyl chelating proton donors. This is presumably due to a fine balance between the electronic properties of the lithium enolate aggregate and the ability for direct coordination. Under these conditions, is it surprisingly advantageous to use weakly coordinating 1,3-dicarbonyl acids. It has previously been reported that such proton donors like acetoacetate act as genuine carbon-based acids like **13**, rather than the kinetically preferred oxygen-based enol acids such as **14**. We are currently investigating the degree to which this is true under our reaction conditions.

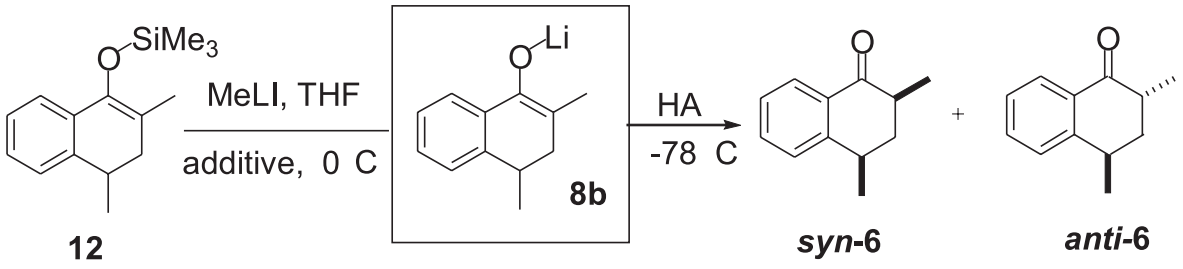
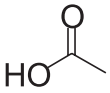
Scheme 6.

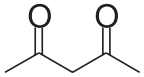
In conclusion, we have shown that carbonyl based acids (like acetic acid, pentane-2,4-dione and acetoactetate) can act as potential *chelating proton donors* for kinetic C-protonation of enolates. Subtle changes in the enolate substructure, conformation of the acid, change in the solvent, and the presence of amine and LiBr, does have a dramatic effect on the observed diastereoselectivity of protonation of these chiral enolates. High diastereoselectivity (up to >98:2) is generally observed in the presence of diisopropylamine and LiBr when using acyclic 1,3-dicarbonyl acids under reagent control.

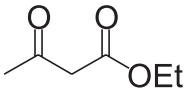
Experimental

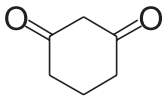


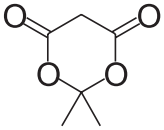
All solvents were distilled before use. Tetrahydrofuran (THF) and ether were freshly distilled from $LiAlH_4$. Triphenylmethane was used as the indicator for THF. All reactions were carried out under nitrogen using oven-dried glassware. Flash column chromatography was carried out using Merck Kieselgel 60 (230–400 mesh). Thin layer chromatography (TLC) was carried out on commercially available pre-coated plates (Merck Kieselgel $60F_{254}$ silica). Proton and carbon NMR spectra were recorded on a Bruker AM 250 Fourier transform spectrometers using an internal deuterium lock. Chemical shifts are quoted in parts per million downfield from tetramethylsilane. Carbon NMR spectra were recorded with broad proton decoupling. Infrared spectra were recorded on a Shimadzu 8300 FTIR machine and mass spectra were recorded on a Kratos 50MSTC machine using a DS503 data system for high resolution analysis.

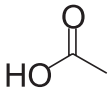


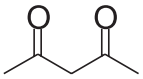


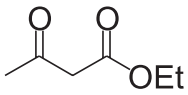


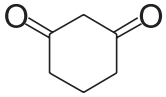


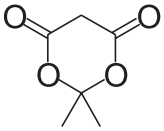












***syn*-(2*RS*,4*SR*)-Dimethyl tetralone 6 and *anti*-(2*RS*,4*RS*)-dimethyl tetralone 6**

4-Methyl tetralone **5** (1.86 g, 1.7 mL, 11.6 mmol) was slowly added dropwise to a stirred solution of LDA (6.38 mL, 2 M in THF, 11.6 mmol) in THF (100 mL) at –78°C and stirred for 20 min. MeI (1.64 g, 0.72 mL, 11.6 mmol) was added and this solution was stirred for 12 h. A solution of NH_4Cl (50 mL) was added and the mixture was extracted with ether (3 × 50 mL). The combined organic layers were dried ($MgSO_4$) and evaporated under reduced pressure. The residue was purified by flash column chromatography on silica gel eluting with light petroleum (bp 40–60°C) – ether (19:1) to give the *syn*- and *anti*-2,4-dimethyl tetralone **6** (1.86 g, 92%) as a colourless oil; R_f (light petroleum (bp 40–60°C):ether (9:1)) 0.5; $\nu_{max}(CHCl_3)$ (cm^{-1}): 2962, 2927 and 2807 (CH), 1685 (CO) and 1600 (br, Ar); δ_H (250 MHz; $CDCl_3$) 8.04 (1H, d, J = 7.0, CH; Ar), 7.51 (3H, t, J = 7.0, CH; Ar), 7.35 (1H. d, J = 7.0, CH; Ar), 7.30 (1H, t, J = 7.0, CH; Ar), 3.20 (1H, m, *CH*Me[a]) 3.06 (1H, septet, J = 7.1, C*H*Me), 2.62 (2H, m, $CH_AH_B{}^s$ and $CH_AH_B{}^a$), 2.20 (2H, m, J = 13.9 and 7.1, $CH_AH_B{}^s$ and $CH_AH_B{}^a$), 1.59 (1H, q, J = 13.9, $CH_AH_B{}^s$), 1.50 (1H, m, $CH_AH_B{}^a$), 1.41 (3H, d, J = 7.1, *Me*CH[s]), 1.40 (3H, d, J = 7.2, *Me*CH[a]), 1.25 (3H, d, J = 7.2, *Me*CH[s]), and 1.23 (3H, d, J = 7.2, *Me*CH[a]); δ_C (67.5 MHz; $CDCl_3$) 200.9[a], 200.8[s], 148.9[a], 148.2[s], 133.3[a], 133.2[s], 132.2[s], 128.3[a], 127.5[a], 127.3[s], 126.5[a], 126.3[s], 126.4[a], 43.0[a], 42.9[s], 41.0[s], 37.94[a], 37.3[a], 31.1[s], 31.7[a], 21.7[a], 20.3[s], 15.7[a], 15.4[s] (Found M^+, 174.1054. $C_{12}H_{14}O$ requires M^+, 174.1044); *m*/*z* 174.1 (5%, M), 173.9 (30, M – CH_2), 130.9 (100, M – COMe), and 117.9 (20, M – COCHMe).

($MgSO_4$) and evaporated under reduced pressure. The residue was purified by flash column chromatography on silica gel eluting with light petroleum (bp 40–60°C) – ether (19:1) to give the 2-trimethylsiloxy-4-methyltetral-2-ene **12** (3.05 g, 97%) as a colourless oil; R_f (light petroleum (bp 40–60°C):ether (9:1)) 0.9; $\nu_{max}(CHCl_3)$ (cm^{-1}): 2958, 2908 and 2827 (CH), 1654 (br, Ar); δ_H (250 MHz; $CDCl_3$) 7.30–7.1 (4H, m, Ar), 2.89 (1H, sextet, J = 6.9, C*H*Me), 2.45 (1H, dd, J = 15.0 and 6.9, CH_AH_B), 2.10 (1H, dd, J = 15.0 and 6.9, CH_AH_B), 1.80 (3H, s, Me), 1.25 (3H, d, J = 6.9, Me), and 0.2 (9H, s, $SiMe_3$); δ_C (67.5 MHz; $CDCl_3$) 141.8, 140.8, 133.5, 126.5, 125.9, 125.4, 121.75, 114.9, 37.0, 32.2, 20.0, 17.6, 0.6 (Found M^+, 246.0634. $C_{12}H_{22}OSi$ requires M^+, 246.1439); *m*/*z* 246.1 (100%, M) and 74.6 (45, $SiMe_3$).

Typical deprotonation–reprotonation procedure using LDA: 2,4-Methyl tetralone **6** (0.29 g, 1.67 mmol) was slowly added dropwise to a stirred solution of LDA (1 mL, 2 M in THF, 2 mmol) in THF (5 mL) at –78°C and stirred for 20 min. The chosen proton source (2 mmol) was added and this solution was stirred for 30 min. A solution of NH_4Cl (10 mL) was added and the mixture was extracted with ether (3 × 20 mL). The combined organic layers were dried ($MgSO_4$) and evaporated under reduced pressure. The residue was purified by flash column chromatography on silica gel eluting with light petroleum (bp 40–60°C) – ether (19:1) gave the 2,4-dimethyl tetralone **6** as a mixture of diastereoisomers. The *syn*:*anti* ratio of 2,4-dimethyl tetralone **6** was measured by ^1H NMR spectroscopy.

*Typical deprotonation–reprotonation procedure using a "base" free enolate **8b***: A solution of MeLi (0.8 mL, 1 M in ether, 0.8 mmol) was added dropwise to the silyl enol ether **12** (0.2 g, 0.81 mmol) at room temperature. The resulting solution was stirred for 1 h. THF (3 mL) was then added and the solution cooled to –78°C. The chosen proton source (1 mmol) was then added and the solution stirred for 30 min. A solution of NH_4Cl (10 mL) was added and the mixture was extracted with ether (3 × 20 mL). The combined organic layers were dried ($MgSO_4$) and evaporated under reduced pressure. The residue was purified by flash column chromatography on silica gel eluting with light petroleum (bp 40–60°C) – ether (19:1) gave the 2,4-dimethyl tetralone **6** as a mixture of diastereoisomers.

*Typical deprotonation–reprotonation procedure using a "base" free enolate **8b** in the presence of LiBr*: A solution of MeLi–LiBr (0.65 mL, 1.54 M in ether, 1 mmol) was added dropwise to the silyl enol ether **12** (0.25 g, 1 mmol) at room temperature. The resulting solution was stirred for 1 h. THF (3 mL) was then added and the solution cooled to –78°C. The chosen proton source (1 mmol) was then added and the solution stirred for 30 min. A solution of NH_4Cl (10 mL) was added and the mixture was extracted with ether (3 × 20 mL). The combined organic layers were dried ($MgSO_4$) and evaporated under reduced pressure. The residue was purified by flash column chromatography on silica gel eluting with light petroleum (bp 40–60°C) – ether (19:1) gave the 2,4-dimethyl tetralone **6** as a mixture of diastereoisomers.

Benzyloxy(4-substituted benzyloxy)carbenes. Generation from oxadiazolines and fragmentation to radical pairs in solution

Nadine Merkley and John Warkentin

Abstract: Thermolysis of 2,2-dibenzyloxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline in benzene at 110°C leads to dibenzyloxycarbene. The carbene was trapped with *tert*-butyl alcohol to afford dibenzyl-*tert*-butyl orthoformate. In the absence of a trapping agent for the carbene, it fragmented to benzyloxycarbonyl and benzyl radicals, as shown by trapping the latter with TEMPO. In the absence of both TEMPO and *tert*-butyl alcohol, the radicals were partitioned between coupling to benzyl phenylacetate and decarboxylation, with subsequent formation of bibenzyl. The preferred sense of fragmentation of the analogous carbenes from benzyloxy-(*p*-substituted-benzyloxy)carbenes was determined by comparing the yields of the two possible esters, $ArCH_2O(CO)CH_2Ph$ and $PhCH_2O(CO)CH_2Ar$. It was found that an electron-withdrawing group in the *para* position favoured fragmentation to the benzylic radical containing that group. A Hammett plot of the data gave a best fit with σ^- substituent constants (r = 0.994, $\rho_{(PhH,\ 110°C)}$ = 0.7) suggesting that the fragmentation involves charge separation in the sense that increases electron density on the group that is becoming a benzylic radical and decreases electron density on the carbonyl group that is becoming the benzyloxycarbonyl radical.

Key words: carbene, dibenzyloxycarbene, fragmentation, substituent effect, radical pair, TEMPO.

Résumé : La thermolyse du 2,2-dibenzyloxy-5,5-diméthyl-Δ^3-1,3,4-oxadiazoline, dans le benzène à 100°C, conduit à la formation de dibenzyloxycarbène. On a piégé le carbène à l'aide d'alcool *tert*-butylique, avec formation d'orthoformiate de dibenzyle et de *tert*-butyle. En absence d'agent pour piéger le carbène, il se fragmente pour conduire à la formation de radicaux benzyloxycarbonyle et benzyle dont l'existence à été démontrée en piégeant le dernier à l'aide de « TEMPO ». En absence d'alcool *tert*-butylique ainsi que de « TEMPO », les radicaux se répartissent entre un couplage conduisant au phénylacétate de benzyle et une décarboxylation avec formation subséquente de dibenzyle. En se basant sur une comparaison des rendements des deux esters possibles, $ArCH_2O(CO)CH_2Ph$ et $PhCH_2O(CO)CH_2Ar$, on a déterminé la voie préférée de fragmentation de carbènes analogues provenant de carbènes portant des groupes benzyloxyles différents, l'un substitué en para et l'autre non substitué. On a trouvé qu'un groupe électroaffinitaire en position para favorise la fragmentation conduisant aux radical benzylique contenant ce groupe. Le meilleur ajustement de la courbe d'Hammett des données est obtenu avec des constantes de substituants σ^- (r = 0,994, $\rho_{(PhH,\ 110°C)}$ = 0,7), ce qui suggère que l'état de transition pour la fragmentation implique une séparation de charge dans le sens qui augmente la densité électronique sur le groupe qui devient un radical benzylique et qui diminue la densité électronique sur le groupe carbonyle qui devient le radical benzyloxycarbonyle.

Mots clés : carbène, dibenzyloxycarbène, fragmentation, effet de substituant, paire de radicaux, « TEMPO ».

[Traduit par la Rédaction]

Introduction

Most reactions of carbenes increase the co-ordination number of the carbene carbon from two to four, as expected for a species having a pair of electrons in a σ–orbital and a virtual *p*-orbital (singlet) or an unpaired electron in each of two singly occupied orbitals (triplet). It may be surprising that stabilized carbenes can break a bond to the carbene carbon, instead of forming new ones, but such a fragmentation has been observed with oxycarbenes and dioxycarbenes. Presumably it is the formation of the strong carbonyl double bond that drives those fragmentations, which can be heterolytic or homolytic. Heterolytic fragmentations, to ion pairs, have been reported when alkoxy(halo)carbenes are generated in a polar solvent such as acetonitrile, Scheme 1 (1–5). Homolytic fragmentations of dioxycarbenes can occur in the gas phase or in non-polar solvents, particularly if one of the oxy groups is allylic or benzylic, Scheme 1 (6–10).

Recently it was reported that methoxy(cinnamyloxy)carbene and its isomer, generated by thermolysis of oxadiazolines **1a** and **1b** in benzene at 110°C (10) fragment to radical pairs. The carbene from **1a** could be trapped with *tert*-butyl alcohol and the radicals could be trapped with TEMPO. Moreover, the sequence oxadiazoline → carbene → radical pair was supported, Scheme 2, by showing that the yield of orthoformate increased, at the expense of esters, with

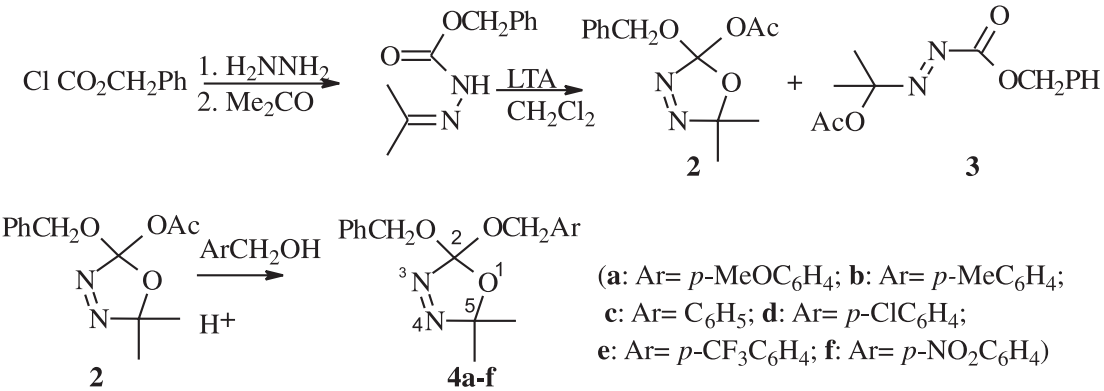
increasing concentration of carbene trap. More recently benzyloxymethoxycarbene was shown to fragment similarly, to methoxycarbonyl and benzyl radicals, and again both the carbene and the radicals were trapped (11). Although *p*-substituted benzyloxy oxadiazolines were studied also, it was not possible to make strong inferences about the effects of *p*-substituents on the ease of carbene fragmentation from the yields of esters, which were below 50%. In those circumstances a dependence of yields on substituents could possibly be attributed to a substituent effect on a competing reaction, such as the observed alternative fragmentation of the oxadiazolines to carbonates and diazopropane (11). For that reason we prepared unsymmetric bis-benzyloxy oxadiazolines in order to have internal competition in a carbene that could fragment to either the benzyl radical and a *p*-substituted benzyloxycarbonyl radical or to a *p*-substituted benzyl radical and the benzyloxycarbonyl radical. We now report the results of that study.



Methods results and discussion

The oxadiazoline substrates (**4a**–**f**) were prepared from a common precursor, namely 2-acetoxy-2-benzyloxy oxadiazoline (**2**), by means of the substitution reaction in Scheme 3. Precursor **2** was obtained by oxidative cyclization of the benzyloxycarbonyl hydrazone of acetone with lead tetraacetate in dichloromethane, which afforded **2** and **3** in the ratio 60:40. Although that mixture could be used directly for the substitution, substantial purification was achieved by washing with base and subsequent chromatography on silica. The oxadiazoline produced in this way did contain a small amount (ca. 5%) of dibenzyl carbonate and the final yield of that product from the thermolysis was corrected for the

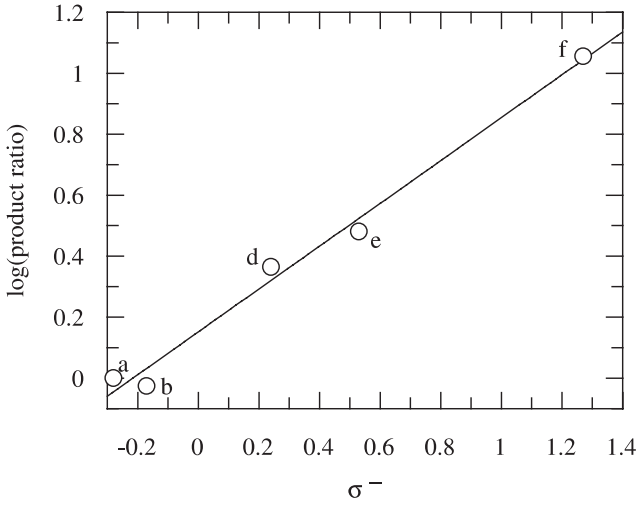
quantity initially present. Thermolyses were done in evacuated, sealed glass tubes that were heated for 24 h at 110.0 ± 0.1°C with an oil bath.

The mechanism of thermolysis of oxadiazolines analogous to **4** generally involves 1,3-dipolar cycloreversion in the first step, to afford a carbonyl ylide intermediate (12–14). The latter then fragments to acetone and a dialkoxycarbene, Scheme 4. An alternative mechanism, proposed by Smith (15) on the basis of computation, involving concerted fragmentation to N_2, acetone, and dialkoxycarbenes, cannot be ruled out for an oxadiazoline with new substituents. In the present case, knowledge of the mechanism by which the carbene intermediate is generated is not critical, nor does the carbene have to be formed in essentially quantitative yield. In Scheme 4, stepwise fragmentation is illustrated with the important feature being the intramolecular competition in the fragmentation of carbene **6**. Formation of a carbene intermediate was established by trapping **6c** with *tert*-butyl alcohol (Fig. 1). It was assumed that the other oxadiazolines formed analogous carbenes, albeit not necessarily with the same efficiency. Products from thermolysis of **4c** in the absence of a trap included acetone (88%),[2] bibenzyl (14%), benzyl phenylacetate (29%), dibenzyl carbonate (6%), a trace of benzyl alcohol, benzyl formate (22%), and tribenzyl orthoformate (19%). The latter two are presumably derived from adventitious water, which traps the carbene intermediate to form benzyl formate and benzyl alcohol via the hemi orthoformate. Benzyl alcohol then traps the carbene to generate the orthoformate. Products from **4a**, **b**, and **d**–**f** were more complex, containing three bibenzyls (primarily $ArCH_2CH_2Ph$, with smaller amounts of $PhCH_2CH_2Ph$ and $ArCH_2CH_2Ar$), two orthoformates, ($HC(OPh)_2OAr$ and

Fig. 1. GC integrals, on an arbitrary scale, vs. concentration of *tert*-BuOH. The scatter is believed to be caused by the various concentrations of adventitious water.

Scheme 5.



$HCOPh(OAr)_2$), an unsymmetric carbonate ($ArOCO_2Ph$) (all indicated by GC/MS), and two esters. The product composition was not determined in detail but it was possible to determine the relative yields of esters **7** and **8** in each case, although the C_6D_6 had to be evaporated and replaced with CCl_4 in the case of products from **4a** because the ^1H NMR signals of interest were not resolved in benzene solution. Identities of the isomers **7** and **8** in each of the reaction mixtures were secured through comparison with the ^1H NMR spectra of authentic compounds.

The bibenzyls are strong indicators of radical chemistry and radical intermediates were confirmed by capturing benzyl radicals from **4c** with TEMPO, Scheme 5. Trapping of benzyloxycarbonyl radicals with TEMPO was not to be expected because the rate constant for decarboxylation of benzyloxycarbonyl radicals has the value $k_{110°C} \approx 10^9\ s^{-1}$ (extrapolated from published data) (16). In the case of benzyloxymethoxycarbene, both the methoxycarbonyl and benzyl radicals were trapped with TEMPO (**9**) (11).

[2] We have not always used an adequate pulse delay when examining oxygen-free solutions by ^1H NMR spectroscopy. The yield of acetone, in particular, comes out too low if an inadequate pulse delay is used.

Fig. 2. Logarithms of the ratios of esters (**8**/**7**) versus σ^- substituent constants.

The sense and magnitude of the selectivity in the carbene fragmentation step should be reflected in the relative yields of esters **7a**, **b**, **d**–**f** and **8a**, **b**, **d**–**f** from the corresponding precursors (**4a**, **b**, **d**–**f**). The results show clearly that there is selectivity in the sense favouring fragmentation to afford the benzylic radical with an electron-withdrawing group in the *para* position. The ratios (**8**:**7**) were: **a**, 1.0; **b**, 0.94; **d**, 2.3; **e**, 3.0; **f**, 11.4. A good correlation of logarithms of product ratios (assumed to reflect the ratios of fragmentation rate constants well) with σ^- substituent constants was found, with $\rho_{(PhH,\ 110°C)} = 0.7$, (Fig. 2), indicating that the fragmentation of the carbenes is lower in energy if electron density is allowed to increase at the carbon atom that is becoming the benzylic radical fragment. A corollary is that the electron density at the other developing fragment must decrease correspondingly. The correlation with σ^- suggests that the fragmentation has more polar character (benzyl anion-like and benzyloxycarbonyl cation-like) than radical character. Whether or not there is a transition state for the homolysis is not known. For homolysis of a model system there is a transition state only for the conformation with the departing group *syn* to the carben's lone pair (9).

The benzyloxycarbonyl–benzyl radical pair is formed in the singlet state (9, 10, 17) in a solvent cage. Coupling in the cage must be very fast, given that it can compete with both decarboxylation of the benzyloxycarbonyl radical and diffusive separation of that pair. Very fast coupling of such pairs is reasonable, given that the rate constant for cage coupling is not limited by diffusion but only by a very small kinetic barrier, if any. An alternative explanation would have the esters originating from 1,2-rearrangement of the carbenes rather than from radical coupling. Carbene rearrangement is very unlikely, given that computation shows the barrier to fragmentation to be much lower than that for 1,2-rearrangement in allyloxyhydroxycarbene, a model for **6** (17).

Experimental

General

Although some of the compounds encountered in this work have been reported previously, NMR and spectra were generally not included. We report NMR spectra for both $CDCl_3$ and C_6D_6; the latter because reactions were run in C_6D_6. Chemical shifts (ppm) for $CDCl_3$ are referenced to TMS, while those for C_6D_6 are referenced to *p*-xylene (2.10 ppm) or 1,4-dimethoxybenzene (6.80 ppm). The numbers in brackets in the MS data are relative signal intensities.

Synthesis of oxadiazolines (4)

A solution of benzyl chloroformate (10.0 mL, 0.071 mol) in ether (72 mL) was added slowly (ca. 1 h) to a cooled solution (–5°C) of hydrazine monohydrate (16.8 mL, 0.33 mol) in ether (10.0 mL) (18). After addition, the ice bath was removed and stirring was continued for 1 h. The white precipitate formed during the reaction dissolved upon the addition of water. The ether layer was separated and washed three times with water (25 mL) before it was dried with magnesium sulphate. After filtering, the ether was removed with a rotary evaporator to leave benzyl hydrazinocarboxylate as a white solid (7.55 g, 0.045 mol), 82% yield, mp 65–66°C; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 3.74 (s, 2H, NH_2), 5.12 (s, 2H, CH_2O), 6.12 (s, 1H, NH), 7.3 (m, 5H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 67.34 (CH_2), 128.21, 128.34, 128.57, 136.03, 155.55 (C=O); MS (EI) *m*/*z*: 122 (9), 91 (100), 65 (9); MS (CI, NH_3) *m*/*z*: 184 ($(M + NH_4)^+$, 33), 167 ($(M + H)^+$, 100), 123 (12), 108 (21), 91 (62).

Magnesium sulphate (5g) was added to a solution of benzyl hydrazinocarboxylate (7.55 g, 0.045 mol) in 40 mL of acetone and the reaction mixture was stirred overnight. The magnesium sulphate was removed by vacuum filtration and the solvent was removed with a rotary evaporator. The resultant white solid (**1**) (7.15 g, 82%) melted at 75–77°C, lit (19) mp 85°C; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.76 (s, 3H), 2.00 (s, 3H), 5.21 (s, 2H), 7.34 (m, 5H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 16.08 (CH_3), 25.28 (CH_3), 67.33 (CH_2), 128.31, 128.41, 128.52, 135.98, 151.14 (C=N), 154.80 (C=O); MS (EI) *m*/*z*: 206 (M^+, 1), 91 (100), 65 (10), 49 (22); MS (CI, NH_3) *m*/*z*: 207 ($(M + H)^+$, 100), 91 (32).

Acetone benzyloxycarbonyl hydrazone (7.15 g, 0.037 mol) in dichloromethane (70 mL) was added dropwise to a solution of lead (IV) acetate (28.0 g, 0.106 mol) in ice-cold dichloromethane (60 mL) under nitrogen. After the addition the ice bath was removed and the solution was stirred for two hours. The mixture was filtered through Celite and washed once with water and twice with 5% sodium bicarbonate. After filtration through a layer of Celite to remove additional lead salts, the dichloromethane layer was dried over magnesium sulphate. Fitration and evaporation of the solvent left a yellow oil (5.43 g, 58%) which was a mixture of the oxadiazoline **2** (60 parts) and the acyclic by-product **3** (40 parts). ^{1}H NMR of **2** (200 MHz, $CDCl_3$) δ: 1.52 (s, 3H, CCH_3), 1.67 (s, 3H, CCH_3, 2.10 (s, OAc, overlapping with OAc signal from **3**), 4.91 (d, ^2J = 8.6 Hz, 1H), 4.99 (d, ^2J = 8.6 Hz, 1H), 7.2–7.5 (m, overlapping with m from **3**, the overlapping signals integrated satisfactorily; ^{1}H NMR of **3** (200 MHz, $CDCl_3$) δ: 1.63 (s, 6H, $C(CH_3)_2$, 2.10 (s, OAc, overlapping with OAc signal from **2**), 5.40 (s, 2H, CH_2), 7.2–7.5 (m, overlapping with m from **2**), the overlapping signals integrated satisfactorily; ^{13}C NMR (composite spectrum, 50 MHz, $CDCl_3$) δ: 20.51 (H_3CC=O), 21.39 (H_3C-C=O), 22.45 (CH_3), 24.12 (CH_3), 24.47 (CH_3), 25.27 (CH_3), 67.51 (CH_2), 69.96 (CH_2), 122.47 (C5), 127.89, 128.10,

128.45, 128.66, 128.71, 128.79, 133.18, 134.14, 136.08 (C2), 166.45 (O(C=O) 169.17 (N-C=O-O).

Benzyl alcohol (0.48 g, 4.4 mmol) and a mixture of **2** and **3** (above, 0.10 g, 3.7 mmol) were dissolved in dichloromethane (30 mL) before trifluoroacetic acid (0.096 mL, 1.25 mmol) was added to the reaction mixture. After stirring for approximately 1 h, progress was monitored by ^{1}H NMR spectroscopy, revealing that the pair of doublets at 4.93 ppm had been replaced with a new pair of doublets at 4.85 ppm (200 MHz, $CDCl_3$). Aqueous NaOH (35 mL) was added and the mixture was stirred for another hour. The dichloromethane layer was separated, washed twice with water (15 mL), and dried over magnesium sulphate. After filtration and removal of the dichloromethane the components of the reaction mixture were separated by means of centrifugal chromatography (Chromatotron, 100% hexanes). The pale yellow oil obtained (0.29 g, 41%) was **4c** containing about 4.5% of dibenzylcarbonate. ^{1}H NMR (300 MHz, C_6D_6) δ: 1.30 (s, 6H), 4.80 (d, ^2J = –11.6 Hz, 2H, CH_2Ph), 4.91 (d, ^2J = –11.6 Hz, 2H, CH_2Ph), 7.06–7.41 (m, 10H); ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.50 (s, 6H), 4.76 (d, ^2J = –11.4 Hz, 2H, CH_2Ph), 4.86 (d, ^2J = –11.4 Hz, 2H, CH_2Ph), 7.30–7.35 (m, 10H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 24.1 (CH_3), 66.9 (CH_2), 119.6 (C5), 127.8, 127.9, 128.4, 136.2 (C2), 136.7.

Oxadiazolines **4a**, **b**, and **d**–**f** were prepared by the above procedure for **4c**, with substituted benzyl alcohols instead of benzyl alcohol

4a: Yellow oil, yield 53%; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.59 (s, 6H), 3.79 (s, 3H), 4.72 (d, ^2J = –11.2 Hz, 1H), 4.78 (d, ^2J = –11.5 Hz, 1H), 4.83 (d, ^2J = –11.2 Hz, 1H), 4.88 (d, ^2J = –11.5 Hz, 1H), 6.86 (d, ^3J = 8.62 Hz, 2H) 7.29–7.33 (m, 7H); ^{1}H NMR (200 MHz, C_6D_6) δ: 1.23 (s, 3H), 1.25 (s, 3H), 3.27 (s, 3H), 4.72–4.92 (m, 4H), 6.69 (d, ^3J = 6.6 Hz, 2H), 6.71–7.25 (m, 7H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 24.01, 55.14, 66.56, 66.69, 113.71, 119.32 (C5), 127.67, 128.27, 128.67, 129.45, 136.66 (C2, PhC1), 159.31(ArC4) MS (EI) *m*/*z*: 191 (3), 163 (51), 121 (100), 91 (87), 84 (24), 43 (24); MS (CI, NH_3) *m*/*z*: 260 (4), 163 (20), 121 (100), 108 (23), 65 (8), 43 (12).

4f: Yellow oil, yield 56%; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.57 (s, 3H), 1.59 (s, 3H), 4.71 (d, ^2J = –11.4 Hz, 1H), 4.79 (d, ^2J = –11.4 Hz, 1H), 4.88 (d, ^2J = –13.1 Hz, 1H), 4.97 (d, ^2J = –13.1 Hz, 1H), 7.24–7.32 (m, 5H), 7.47 (d, ^3J = 8.6 Hz, 2H), 8.16 (d, ^3J = 8.6 Hz, 2H); ^{1}H NMR (300 MHz, C_6D_6) δ: 1.23 (s, 6H), 4.53–4.72 (m, 4H), 6.82 (d, ^3J = 8.8 Hz, 2H), 7.00–7.21 (m, 5H), 7.74 (d, ^3J = 8.8 Hz, 2H); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 23.89, 24.11, 65.46, 66.85, 119.96 (C5), 123.48, 127.64, 127.73, 127.96, 128.36, 136.24, 136.48 (C2), 144.19, 147.36; MS (EI) *m*/*z*: 137 (13), 136 (95), 91 (100), 49 (24), 43 (16); MS (CI, NH_3) *m*/*z*: 254 (2), 153 (13), 136 (24), 107 (60), 91 (100), 60 (16).

Typical thermolysis of an oxadiazoline

The following procedure for **4c** was also followed for the others except that *p*-xylene was the reference. Signals from 1,4-dimethoxybenxene interfered in those cases. Neither internal standard reacted to afford any products detectable by GC/MS.

A solution of dibenzyloxy oxadiazoline (**4c**, 15.9 mg, 0.05mmol) containing 4.6% of dibenzyl carbonate and 1,4-dimethoxybenzene (1.0 mg, 0.0072 mmol) as internal standard, in 0.52 mL of benzene-d_6 in an NMR tube was degassed three times (freeze-pump-thaw sequence) before sealing. The NMR tube was then kept for 24 h in an oil bath at 110 ± 0.1°C. Product yields were determined by ^{1}H NMR spectroscopy, with a pulse delay time of 3 min for products from **4c** and 5 min for the other mixtures, to ensure reliable integral ratios for **7** and **8** (average of 5 intergrations). Chemical shifts (CH_2CO) in C_6D_6 (those of **7a** and **8a** in CCl_4) used for measurement of those relative yields were: *p*-xylene, 2.10; 1,4-dimethoxybenzene, 6.80; **7a**, 3.52; **8a**, 3.48; **7b**, 3.32; **8b**, 3.34; **7d**, 3.29; **8d**, 3.12; **7e**, 3.31; **8e**, 3.14; **7f**, 3.31; **8f**, 3.06.

Products from **4c** were: acetone, 88%, ^{1}H NMR (200 MHz, C_6D_6) δ: 1.606 (s). Bibenzyl, 14%, ^{1}H NMR (200 MHz, C_6D_6) δ: 2.78 (s, 4H), 7.02–7.20 (m, overlap with other signals); GC/MS (EI) *m*/*z*: 182 (M^+, 26), 91 (100), 65 (13). Benzyl phenylacetate, 29%, ^{1}H NMR (200 MHz, C_6D_6) δ: 3.38 (s, 2H), 4.96 (s, 2H), 7.02–7.20 (m, overlap with other signals); GC/MS (EI) *m*/*z*: 226 (M^+, 1), 91 (100), 65 (10). Dibenzyl carbonate, 6%, ^{1}H NMR (200 MHz, C_6D_6) δ: 4.98 (s, 4H), 7.02–7.20 (m, overlap with other signals), GC/MS (EI) *m*/*z*: 180 (33), 151 (26), 107 (60), 91 (100), 79 (48), 65 (29). Tribenzyl orthoformate,

19%, ^{1}H NMR (200 MHz, C_6D_6) δ: 4.66 (6H), 5.46 (s, 1H), 7.02–7.20 (overlap with other signals); GC/MS (EI), *m/z*: 197 (9), 181 (10), 107 (10), 91 (100). Benzyl formate, 22%, ^{1}H NMR (200 MHz, C_6D_6) δ: 4.91 (2H), 7.02–7.20 (m, overlap with other signals), 7.60 (1H).

Synthesis of benzyl arylacetate reference compounds

The required arylacetyl chloride **8a**, **b**, **d–f** (0.061 g, 6.4 mmol) was dissolved in benzene (5 mL) and added slowly to a solution of benzyl alcohol (0.16 g, 0.8 mmol) in pyridine (0.2 mL, 2.3 mmol) which was cooled in an ice bath. After addition the stirring was continued for one hour. The benzene layer was washed twice with water (5 mL), and dried with magnesium sulphate. After filtration and evaporation of the benzene, the ^{1}H NMR spectrum in C_6D_6, referenced to *p*-xylene at 2.10 ppm, was recorded.

8c: (20) pale yellow oil; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 3.60 (s, 2H), 5.03 (s, 2H), 7.08–7.29 (m, 10H); ^{1}H NMR (300 MHz, C_6D_6) δ: 3.40 (s, 2H), 4.97 (s, 2H), 7.09–7.22 (m, 10H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 41.33, 66.61, 128.18, 128.54, 129.27, 135.83, 171.39 (C=O); ^{13}C NMR (75 MHz, C_6D_6) δ: 41.35, 66.42, 128.2, 128.3, 128.7, 129.6, 134.5, 170.92 (C=O). GC/MS (EI) *m/z*: 226 (M^+, 1), 91 (100), 65 (10).

8a: (21–23) Oil; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 3.59 (s, 2H), 3.78 (s, 3H), 5.10 (s, 2H), 6.84 (d, ^3J = 8.6 Hz, 2H), 7.16–7.30 (m, 7H); ^{1}H NMR (300 MHz, C_6D_6) δ: 3.23 (s, 3H), 3.32 (s, 2H), 4.92 (s, 2H), 6.68 (d, ^3J = 8.7 Hz, 2H), 7.00–7.08 (m, 7H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 40.43, 55.26, 66.55, 114.00, 128.10, 128.51, 130.30, 132.29, 172.93 (C=O).

8b: (24) Oil; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.33 (s, 3H), 3.63 (s, 2H), 5.13 (s, 2H), 7.10–1.33 (m, 9H); ^{1}H NMR (300 MHz, C_6D_6) δ: 2.02 (s, 3H), 3.34 (s, 2H), 4.90 (s, 2H), 6.87–7.12 (m, 9H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 21.03, 40.91, 66.53, 128.09, 128.49, 129.24, 130.83, 135.92, 136.70, 171.57 (C=O); MS (EI) *m/z*: 240 (M^+, 25), 193 (13), 181 (16), 105 (100), 91 (76); MS (CI, NH_3) *m/z*: 258 (($M + NH_4$)$^+$, 13), 241 (($M + H$)$^+$, 5), 216 (79), 108 (51), 91 (100).

8d: (23) oil; ^{1}H NMR (300 MHz, $CDCl_3$) δ: 3.60 (s, 2H), 5.10 (s, 2H), 7.16–7.32 (m, 9H); ^{1}H NMR (300 MHz, C_6D_6) δ: 3.13 (s, 2H), 4.88 (s, 2H), 6.76 (d, ^3J = 8.4 Hz, 2H), 6.79–7.15 (m, 7H); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 40.52, 66.69, 128.09, 128.24, 128.49, 130.60, 132.25, 133.04, 170.91 (C=O); MS (EI) *m/z*: 260 (M^+, 10), 181 (10), 127 (24), 125 (60), 91 (100), 65 (16), 63 (10); MS (CI, NH_3) *m/z*: 278 (($M + NH_4$)$^+$, 55), 125 (44), 108 (49), 91 (100), 80 (42); HRMS calculated for $C_{15}H_{13}O_2Cl$: 260.0604, found: 260.0603.

8e: Oil; ^{1}H NMR (300 MHz, $CDCl_3$) δ: 3.71 (s, 2H), 5.13 (s, 2H), 7.28–7.35 (m, 5H) 7.38 (d, ^3J = 8.1 Hz, 2H), 7.56 (d, ^3J = 8.1 Hz, 2H); ^{1}H NMR (300 MHz, C_6D_6) δ: 3.13 (s, 2H), 4.88 (s, 2H), 6.76 (d, ^3J = 8.0 Hz, 2H), 6.79–7.15 (m, 7H); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 29.69, 66.95, 125.48, 125.55, 128.24, 128.38, 128.54, 128.61, 129.37, 129.71, 135.61, 137.84, 170.55 (C=O); ^{19}F NMR (282 MHz, $CDCl_3$, ref. CCl_3F) δ: –62.82 (s); MS (EI) *m/z*: 294 (M^+, 3), 181 (8), 159 (5), 108 (21), 91 (100), 65 (10); MS (CI, NH_3) *m/z*: (($M + NH_4$)$^+$, 5), 159 (5), 108 (21), 91 (100); HRMS calculated for $C_{16}H_{13}O_2F_3$: 294.0867, found: 294.0872.

8f: pale yellow solid, mp 80–84°C, lit. (25) mp 90–92°C; ^{1}H NMR (300 MHz, $CDCl_3$) δ: 3.76 (s, 2H), 5.14 (s, 2H), 7.29–7.35 (m, 5H), 7.43 (d, ^3J = 8.7 Hz, 2H), 8.16 (d, ^3J = 6.6 Hz, 2H); ^{1}H NMR (300 MHz, C_6D_6) δ: 3.03 (s, 2H), 4.27 (s, 2H), 4.86 (s, 2H), 6.66 (d, ^3J = 8.7 Hz, 2H), 6.93–7.07 (m, 5H), 7.69 (d, ^3J = 8.7 Hz, 2H); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 40.96, 67.14, 123.73, 126.97, 128.61, 130.29, 135.35, 141.12, 169.98; MS (EI) *m/z*: 271 (M^+, 8), 136 (8), 91 (100), 65 (9); MS (CI, NH_3) *m/z*: 289 (($M + NH_4$)$^+$, 6), 271 (M^+, 3), 135 (10), 108 (9), 91 (100); HRMS calculated for $C_{15}H_{13}NO_4$: 271.0845; found: 271.0827.

Synthesis of 4-substituted-benzyl phenylacetates (7a–f)

A solution of phenylacetyl chloride (0.51 g, 3.0 mmol) in benzene (5 mL) was added slowly to a cooled solution of the appropriate arylmethanol (0.4 g, 3.0 mmol) in pyridine (0.5 mL, 9.0 mmol). After one hour the benzene solution was washed twice with water and dried with magnesium sulphate. Benzene was removed with a rotary evaporator. Some of the esters were purified by radial chromatography (Chromatotron, 10% EtOAc in hexanes).

7a: (21,22) Oil; ^{1}H NMR (300 MHz, $CDCl_3$) δ: 3.61 (s, 2H), 3.77 (s, 2H), 5.04 (s, 2H), 6.83–6.87 (m, 2H), 7.20–7.28 (m, 7H); ^{1}H NMR (300 MHz, C_6D_6) δ: 3.20 (s, 3H), 3.32 (s, 2H), 4.89 (s, 2H), 6.65 (d, ^3J = 8.7 Hz, 2H), 7.00–7.10 (m, 7H); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 41.28, 55.17, 66.37, 113.56 (C2), 126.97, 127.93, 128.46, 129.19, 129.89, 133.90, 159.55, 171.39 (C=O); MS (EI) *m/z*: 256 (M^+, 21), 121 (100), 91 (37); MS (CI, NH_3) *m/z*: 256 (M^+, 8), 138 (8), 121 (100).

7b: (24) Oil; ^{1}H NMR (300 MHz, $CDCl_3$) δ: 2.34 (s, 3H), 6.65 (s, 2H), 5.08 (s, 2H), 7.13–7.31 (m, 9H); ^{1}H NMR (300 MHz, C_6D_6) δ: 2.00 (s, 3H), 3.32 (s, 2H), 4.91 (s, 2H) 6.85–7.12 (m, 9H); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 21.16, 41.36, 66.57, 127.06, 128.27, 128.55, 129.21, 129.27, 132.89, 133.95, 138.03, 171.41(C=O); MS (EI) *m/z*: 240 (M^+, 16), 209 (5), 105 (100), 91 (46), 65 (12); MS (CI, NH_3) *m/z*: (($M + NH_4$)$^+$, 26), 154 (16), 105 (100), 91 (34), 65 (5).

7d: Oil; ^{1}H NMR (300 MHz, $CDCl_3$) δ: 3.63(s, 2H), 5.05 (s, 2H), 7.17–7.29 (m, 9H); ^{1}H NMR (300 MHz, C_6D_6) δ: 3.29 (s, 2H), 4.69 (s, 2H), 6.73 (d, ^3J = 8.4 Hz, 2H), 6.93–7.12 (m, 7H); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 41.23, 65.64, 127.10, 128.52, 128.62, 129.17, 133.67, 134.29 (C2), 171.19 (C=O); MS (EI) *m/z*: 260 (M^+, 8), 125 (87), 91 (100), 65 (18), 51 (5); MS (CI, NH_3) *m/z*: 278 (($M + NH_4$)$^+$, 55), 260 (M^+, 5), 184 (42), 125 (100), 108 (19), 91 (39); HRMS calculated for $C_{15}H_{13}O_2Cl$: 260.0604 found: 260.0603.

HRMS calculated for $C_{15}H_{13}NO_4$: 271.0845, found: 271.0861.

Dibenzylcarbonate

To benzyl alcohol (1.5 g, 13 mmol) and pyridine (0.98 g, 12.3 mmol) in 60 mL of dichloromethane under nitrogen, 1,1-carbonyldiimidazole (1 g, 6.1 mmol) in 20 mL of dichloromethane was added during 1 h. The solution was stirred overnight, washed once with water, twice with 5% HCl, once with water, and then with brine. Drying with magnesium sulphate, filtration, and removal of the solvent left crude dibenzyl carbonate that was purified by centrifugal chromatography, mp 28–29°C (lit. (26) mp 27.3–29.1°C); ^1H NMR (200 MHz $CDCl_3$) δ: 5.09 (s, 4H), 7.13–7.37 (m, 10H); ^1H NMR (200 MHz, C_6D_6) δ: 4.94 (s, 4H), 7.04–7.17 (m, 10H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 69.58 (CH_2), 128.21, 128.47, 135.13, 154.99 (C=O); MS (EI) *m/z*: 180 (4), 151 (5), 107 (32), 91 (100), 79 (32), 65 (14), 51 (11); MS (CI) *m/z*: 260 ($(M + NH_4)^+$, 100), 243 $(M + H)^+$, 10), 198 (26), 181 (32), 108 (73), 91 (72).

Tribenzylorthoformate

To **4c** (30.3 mg, 0.106 mmol, containing 9% carbonate) in benzene (1 mL) was added dimethoxybenzene (3.6 mg, 0.026 mmol, internal standard) and benzyl alcohol (60.6 mg, 0.56 mmol). The solution was flame sealed into an NMR tube after three freeze-pump-thaw cycles and heated at 110°C for 24 h. Column chromatography with 10% EtOAc in hexanes yielded tribenzylorthoformate (27). ^1H NMR (200 MHz, $CDCl_3$) δ: 4.66 (s, 6H), 5.43 (s, 1H), 7.24–7.35 (m, 15H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 66.33, 111.51 (orthoformyl), 127.71, 127.88, 128.41, 128.58, 137.46.

Benzyl formate

Benzyl alcohol (2.16 g, 0.02 mol), ethyl formate (1 g, 0.013 mol) and a catalytic amount of H_2SO_4 were dissolved in 10 mL of benzene and heated at 50°C for 24 h. After cooling the solution was washed with 10 mL of 10% NaOH and then with 10 mL of saturated NaCl. Evaporation of the solvent and unreacted ethyl formate left benzyl formate (28) that was purified by means of centrifugal chromatography (Chromatotron, 10% EtOAc in hexanes). ^1H NMR (200 MHz, $CDCl_3$) δ: 4.60 (s, 2H), 7.23–7.43 (m, 5H), 8.13 (s, 1H); ^1H NMR (200 MHz, C_6D_6) δ: 4.91 (s, 2H), 7.12–7.15 (m. 5H), 7.63 (s, 1H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 65.64, 128.32, 128.48, 128.62, 135.19, 160.71 (C=O).

Ratios of non-ester products

The thermolysis mixtures from the substituted dibenzyloxy oxadiazolines **4a**, **b**, **d**, and **e** were analyzed by means of GC/MS (DB-5 capillary column, i.d. 0.25 mm) and GC/FID (DB-1 megabore column, 0.53 mm i.d., flow rate 15 mL/min) equipped with an integrator. Both separated all of the products except the isomeric esters. Correction factors were used to correct the responses from the FID (29). Thermolysis of each of the substrates **4a**, **b**, and **d**–**f** gave 2 benzyl formates and 3 bibenzyls, which were identified from their mass spectra, as well as two orthoformates. Ratios were estimated from GC/FID data. Identification of benzyl formate, bibenzyl and tribenzyl orthoformate was confirmed by comparison with the GC trace of authentic samples.

The following are some product ratios. Benzyl formates, HCO_2CH_2Ph:HCO_2CH_2Ar from **4a**, 1.0:0.79; **4b**, 1.0:0.42; **4d**, 1.0:1.5; **4e**, 1.0:1.6. Bibenzyls, $PhCH_2CH_2Ph$:$PhCH_2CH_2Ar$:$ArCH_2CH_2Ar$ from **4a**, 1.0:1.7:0.40; **4b**, 1.0:1.8:0.85; **4d**, 1.0:1.7:0.70; **4e**, 1.0:1.9:0.74. Orthoformates, $HC(OCH_2Ph)_2OCH_2Ar$:$HCOCH_2Ph(OCH_2Ar)_2$ from **4a**, 0.39:1.0; **4b**, 1.15:1.0; **4d**, 1.06:1.0

Thermolysis of 4c in the presence of *tert*-butyl alcohol

A solution of **4c** (224 mg, 0.72 mmol), containing 4.6% dibenzyl carbonate, *tert*-butyl alcohol (1.69 g, 22.9 mmol) and 1,4 dimethoxybenzene (10.1 mg, internal standard) in dry benzene (28 mL) was sealed into a resealable thermolysis tube after three cycles of freeze-pump-thaw degassing. The sealed tube was kept at 110 ± 0.1°C in an oil bath for 24 h. Removal of the solvent and unreacted *tert*-butyl alcohol with a rotary evaporator left dibenzyl *tert*-butyl orthoformate in 43% yield. ^1H NMR (200 MHz, C_6D_6) δ: 1.19 (s, 9H), 4.74 (s, 4H), 5.62 (s, 1H), 7.13–7.43 (m, 10H); ^{13}C NMR (50 MHz, C_6D_6) δ: 28.8 (CH_3), 65.1 (CH_2), 74.2 (CMe_3), 108.8 (orthoformyl), 127.5, 127.9, 128.5, 138.9. Dibenzyl carbonate (3%) was also formed; spectra above.

Thermolysis of 4c in the presence of TEMPO (9)

A solution of **4c** (30.6 mg, 0.098 mmol), **9** (131.4 mg, 0.84 mmol), and 1,4-dimethoxy benzene (2.3 mg, internal standard) in 0.8 mL of dry benzene was degassed as described above before it was sealed into a thermolysis tube for 24 h of heating at 110°C. The products from the thermolysis, listed below, were identified by means of GC/FID (DB-1 column, 30m × 0.53 mm, flow rate 15 mL min^{-1}), by coinjection of authentic samples. A correction factor was applied to the GC integrals for the yield calculations (29).

Benzyl formate, 18%, retention time 10.0 min; **10**, 18%, retention time 26.6 min; benzyl phenylacetate, 13%, retention time 28.1 min; dibenzyl carbonate, 18%, retention time 30.4 min; tribenzylorthoformate, 42%, retention time 41.2 min.

Synthesis of authentic 10

Adduct **10** was prepared from TEMPO, toluene, and di-*tert*-butylperoxide as described previously (11).

Thermolysis rate constant for 4c

The rate of fragmentation of **4c** was monitored by ^1H NMR spectroscopy (200 MHz). A solution of **4c** (16.9 mg, 0.05 mmol) and *p*-xylene (1 μL, 0.008 mmol) in benzene-d_6 (0.54 mL) was sealed into an NMR tube after three sequences

of freeze-pump-thaw degassing. The tube was removed at intervals from an oil bath at 110°C and cooled to room temperature before the ^{1}H NMR spectrum was obtained. Corrections to the time scale were not made for cooling and reheating of the contents of the tube.

A plot of ln (I_t/I_0) vs. time, where I_t and I_0 are the normalized integrals for the oxadiazoline CH_3 hydrogens at time t and time zero, was linear (12 data points, r = 0.9963). The first order decomposition rate constant ($k_{110°C} = 8.7 \times 10^{-5}$ s^{-1}) was obtained from the slope of the least squares line through the origin. The fragmentation of **4f**, followed by the above procedure, gave $k_{110°C} = 7.9 \times 10^{-5}$ s^{-1} (r = 0.9985).

Dependence of product yields on concentration of *tert*-BuOH

Solutions of dibenzyloxy oxadiazoline (**4c**, 0.023 M), 1,4-dimethoxybenzene (0.009 M) and *tert*-BuOH (0.01, 0.04, 0.08, 0.12, 0.16, 0.24, 0.32, 0.18, and 0.70 M) in one mL of benzene were heated at 110°C for 24 h after being flame sealed into an NMR tube following degassing by means of the freeze-pump-thaw cycle. Plots of the normalized GC integrals, for the ester and for dibenzyl *tert*-butyl orthoformate, against the *tert*-BuOH concentration, are in Fig. 1.

Methylamination of some 3,6-dinitro-1,8-naphthyridines with liquid methylamine – potassium permanganate

Marian Woźniak, Maria Grzegożek, and Piotr Suryło

Abstract: 3,6-Dinitro-1,8-naphthyridine and its 2-substituted derivatives are dehydro-methylaminated with the solution of potassium permanganate in liquid methylamine (LMA–PP) to the corresponding mono- or mono- and bis(methylamino)-3,6-dinitro-1,8-naphthyridines. In the case of 2-chloro- and 2-methoxy-3,6-dinitro-1,8-naphthyridine the replacement of chloro and methoxy substituents by the $NHCH_3$ group occurs as well. Quantum-chemical calculations indicate the reactions to be controlled by the interaction of the frontal molecular orbitals (FMO) of the reagents. Moreover the heats of formation of intermediary methylamino-σ-adducts and transition states are calculated for the reaction studied. The calculations show satisfactory agreement between calculated and observed results. A convenient synthesis of some 2-substituted-3,6-dinitro-1,8-naphthyridines is reported.

Key words: methylaminations, calculations PM3, nitro-1,8-naphthyridines, oxidation.

Résumé : Sous l'influence d'une solution de permanganate de potassium en solution dans de la méthylamine liquide (PP–MAL), la 3,6-dinitro-1,8-naphtyridine et ses dérivés substitués en position 2 subissent une réaction de déhydro-méthylamination pour conduire aux mono- ou mono- et bis(méthylamino)-3,6-dinitro-1,8-naphtyridines. Dans les cas des 2-chloro- et 2-méthoxy-3,6-dinitro-1,8-naphtyridines, on observe aussi un remplacement des substituants chloro ou méthoxy par le groupe $NHCH_3$. Des calculs de chimie quantique indiquent que les réactions sont contrôlées par l'interaction entre les orbitales moléculaires frontales des réactifs. On a calculé de plus les chaleurs de formation des adduits-σ-méthylamino intermédiaires et des états de transition de la réaction étudiée. Les calculs conduisent à un accord satisfaisant entre les résultats observés et calculés. On a mis au point une méthode pratique de synthèse pour quelques 3,6-dinitro-1,8-naphtyridines substituées en position 2.

Mots clés : méthylaminations, calculs PM3, nitro-1,8-naphtyridines, oxydation.

In a previous paper we reported that 3-nitro-1,8-naphthyridine and some of its 2-substituted derivatives are dehydro-methylaminated in the solution of potassium permanganate in liquid methylamine (LMA–PP) to the corresponding 4-(methylamino)-3-nitro-1,8-naphthyridines (1). The reactions proceed through intermediates 4-methylamino-σ-adducts which in the next stage are oxidized by $KMnO_4$ to the 4-methylamino products.

The methylamination reactions of the 3-nitro-1,8-naphthyridines occur selectively in a good yield. Extending our investigations on the dehydro-methylamination of nitronaphthyridines we studied recently, analogous methylamination with LMA–PP of some 3,6-dinitro-1,8-naphthyridines. The presence of the second nitro group at the 1,8-naphthyridine ring with its strongly π-electron withdrawing properties causes considerable increase of π-electron deficiency of 1,8-naphthyridine ring. Therefore, it was interesting to compare the results of both methylaminations i.e., of 3-nitro- and of 3,6-dinitro-1,8-naphthyridines. Moreover, new methylamino derivatives of 3,6-dinitro-1,8-naphthyridine synthesized in this manner can show interesting biological and useful properties (on the application of methylamino nitroaromatics see ref. (2)).[2 3 4]

The methylamination of the 3,6-dinitro-1,8-naphthyridines was carried out under the same conditions as previously i.e., at the boiling point (ca. –7°C) of liquid methylamine. The results obtained are compiled in Scheme 1. The structure of the obtained methylamino products has been established on the basis of spectroscopic data, in particular ^{1}H NMR data, and in a few cases also by a comparison of their properties with those of authentic compounds, synthesized independently (see Experimental part).

Amination of unsubstituted 3,6-dinitro-1,8-naphthyridine, **1a**, with LMA–PP affords three products of dehydro-methylamination: 2,4-bis(methylamino)-3,6-dinitro-1,8-naphthyridine, **2a**, 3,5-bis(methylamino)-3,6-dinitro-1.8-naphthyridine,

2b, and 2-(methylamino)-3,6-dinitro-1,8-naphthyridine, **2c**. The bis(methylamino) product **2b** showed in the aromatic region of its ^{1}H NMR only one singlet, δ (DMSO) = 9.20. This ^{1}H NMR pattern can be assigned to the structure of 2,7- or 4,5-bis(methylamino)-1,8-naphthyridine. On the basis of our quantum-chemical calculations (see further) the structure of **2b** was determined tentatively as 4,5-bis(methylamino)-3,6-dinitro-1,8-naphthyridine. Additional suggestion for this structure is the fact that in analogous amination of 3,6-dinitro- (3) and of 2-substituted 3,6-dinitro-1,8-naphthyridines (4) with liquid ammonia – potassium permanganate no amino substitution in position 7 was observed.

2-(Methylamino)-3,6-dinitro-1,8-naphthyridine, **1b**, is aminated with LMA–PP to 2,4-bis(methylamino)-3,6-dinitro-1,8-naphthyridine, **2a**, with fair yield. Similarly from 2-amino-3,6-dinitro-1,8-naphthyridine, **1c**, and from 2-(phenylamino)-3,6-dinitro-1,8-naphthyridine, **1d**, only mono 4-methylamino derivatives **2d** and **2e**, respectively, were obtained.

2-Chloro-3,6-dinitro-1,8-naphthyridine, **1e**, undergoes with LMA–PP simultaneously dehydro-methylamination in position 4 and dechloro-methylamination to give 2,4-bis(methylamino)-3,6-dinitro-1,8-naphthyridine, **2a**. No indications for the presence of 2-chloro-4-(methylamino)-3,6-dinitro-1,8-naphthyridine was found.

Treatment of 2-methoxy-3,6-dinitro-1,8-naphthyridine, **1f,** with LMA–PP gives 2-methoxy-4,5-bis(methylamino)-3,6-dinitro-1,8-naphthyridine, **2f**, and 2,4-bis(methylamino)-3,6-dinitro-1,8-naphthyridine, **2a**. In this reaction **1f** undergoes partly demethoxy-methylamination to form **2a**. The amination of 2-chloro-3,6-dinitro-, **1e**, and 2-methoxy-3,6-dinitro-1,8-naphthyridine, **1f**, probably does not proceed via rate-limiting formation of the σ-adduct, i.e., once formed the adduct loses chloride or methoxide anion. In the case of addition at the position where oxidation by permanganate is required to give the substituted product, is it not possible that the addition is highly reversible. Therefore it seems that at first replacement of 2-chloro or 2-methoxy substituent in **1e** or **1f** occurs and then oxidative amination in position 4.

Amination of 2-hydroxy-3,6-dinitro-1,8-naphthyridine [3,6-dinitro-1,8-naphthyridin-2(1*H*)-one], **1g**, with LMA–PP gives a nonseparable mixture of two isomeric products of dehydro-methylamination: 2-hydroxy-4-(methylamino)-3,6-dinitro-1,8-naphthyridine [4-(methylamino)-3,6-dinitro-1,8-naphthyridin-2(1H)-one], **2g**, and 2-hydroxy-5-(methylamino)-3,6-dinitro-1,8-naphthyridine [5-(methylamino)-3,6-dinitro-1,8-naphthyridin-2(1H)-one, **2h**. Both **2g** and **2h** have very similar R_f values in various eluent systems. They were identified by mass spectrometry and ^{1}H NMR spectroscopy. Based on the peak areas of the ^{1}H NMR resonance signals for 7H in **2g** and **2h** the ratio of **2g**:**2h** could be established as ca. 2:1.

In comparison with the methylamination of the 3-nitro-1,8-naphthyridines by LMA–PP the reactions of the 3,6-dinitro-1,8-naphthyridines with LMA–PP occur less selectively and with lower yield. In the reactions form many tarry substances and small amounts of unidentified products. In all cases the reaction products had to be purified or separated by column chromatography. It is reasonable to suppose that intermediary methylamino-σ-adducts of the 3,6-dinitro-1,8-naphthyridines possessing nonaromatic structure are not stable and give with potassium permanganate, besides methylamino products, also products of decomposition. During the reactions manganese dioxide is formed as a result of the reduction of potassium permanganate. On the other hand, liquid methylamine at low reaction temperature (–7°C) is stable and we do not observe detectable amounts of its oxidation products.

We tried to determine, as previously (1), the structure of intermediate methylamino-σ-adducts of some of the 3,6-dinitro-1,8-naphthyridines by ^{1}H NMR technique. However due to the very low solubility of these intermediates in liquid methylamine, it was not possible to assign the proton signals

[a]The quantum-chemical calculations were done by the PM3 method.

for σ-adducts. It should be noted that 3,6-dinitro-1,8-naphthyridines containing amino substituents in position 2 (the compounds **1b**, **1c**, and **1d**), in contrary to other studied 3,6-dinitro-1,8-naphthyridines, react with LMA–PP exclusively to the mono 4-methylamino products. It is probably due to the strongly electron-donating properties of the amino groups' deactivating naphthyridine ring for the further nucleophilic attack. Contrary to 2-methoxy-3-nitro-1,8-naphthyridine, 2-methoxy-3,6-dinitro-1,8-naphthyridine, **1f,** partly undergoes demethoxy-methylaminaton with LMA–PP.

2,4-Bis(methylamino)-3,6-dinitro-1,8-naphthyridine, **2a**, obtained in the reactions of **1a**, **1b**, and **1c** with LMA–PP undergoes acid hydrolysis only in position 4 to give with high yield, isomeric to **2g** and **2h**, 4-hydroxy-2-(methylamino)-3,6-dinitro-1,8-naphthyridine [2-(methylamino)-3,6-dinitro-1,8-naphthyridin-4(1H)-one], **2i** (R^1 = $NHCH_3$, R^2 = OH, R^3 = H). That is a convenient manner to prepare **2i**.

To understand better the nature of regioselectivity of the methylamination reactions studied, we applied the perturbation theory of molecular orbitals (PMO). The calculations of the π-electron energy (ΔE_π) for all positions in the studied dinitronaphthyridines were carried out according to a simplified second-order perturbation (eq. [1]), as in a previous work (5) by the PM3 method.

$$[1] \qquad \Delta E_\pi \approx 2\left[\frac{C_S^2(\mathrm{LUMO})}{\left|E^{\mathrm{N}}_{\mathrm{HOMO}} - E^{\mathrm{A}}_{\mathrm{LUMO}}\right|} + \frac{C_S^2(\mathrm{LUMO}+1)}{\left|E^{\mathrm{N}}_{\mathrm{HOMO}} - E^{\mathrm{A}}_{\mathrm{LUMO+1}}\right|}\right]$$

The value of the LUMO and LUMO +1 energy levels (E^A) and respective coefficient C_A for the starting dinitronaphthyridines were calculated by PM3 method. They are available upon request. For the methylamine the value $E^{\mathrm{N}}_{\mathrm{HOMO}}$ = –9.40 eV was found.

The results of these calculations are given in Table 1 and they indicate that the methylamination of 3,6-dinitronaphthyridines (**1a**–**g)** ought to occur mainly in the C-4 position for which, in fact, the highest values of ΔE_π have been found. Thus it seems that the methylamination of **1b**–**d** and **1g** is controlled by the interaction of the frontal molecular orbital (FMO) of the reagents because these data correlate well with experimentally observed substitution products (Scheme 1). In **1a** the calculations predict the methylamination at C-4 but it has not been confirmed experimentally. In this case, the formation of the 2,4-(**3a**) and 4,5-(**3b**)-bis(methylamino) and 2-(**3c**)-(methylamino) products were observed. The same conclusion can be reached for reactions of methylamination of 2-chloro-(**1e**) and 2-methoxy-(**1f**)-3,6-dinitro-(**1a**)1,8-naphthyridines where first of all the nucleophilic displacement of chloro and methoxy group and then the methylamination in position C-4 respectively was observed.

In addition, we wished to explain regioselectivity of the attack of methylamine on the 3,6-dinitro-1,8-naphthyridine ring system. First, we calculated heats of formation (ΔH) of the ground state of the reaction system and of the intermediate σ-adducts **2a**–**g** and transition structures (TS) for all the unsubstituted positions in **1a**–**g** and additionally for position C-2 substituted by chloro and methoxy group in **1e**–**f**, using the PM3 method (see Table 2).[5]

The results of calculations indicate that the heats of formation of intermediary σ-adducts **2a**–**g** at the position C-4 have, in comparison with other positions in dinitronaphthyridines, the lowest energy values just as the values for the energy of activation ($\Delta E^{\#}$) at the same C-4 position in **1a**–**g.** It indicates that the C-4 positions in studied dinitronaphthyridines are favored for nucleophilic attack. Fig. 1 shows the reaction profile obtained by calculations with the PM3 method and the structures of the ground state, transition states, and intermediates for the reactions studied.

In conclusion, FMO perturbation theory correctly predicts the observed course of the most of the reactions studied. Additionally, the results of calculations of reaction pathways for the nucleophilic attack of methylamine confirm the regioselectivity of methylamination **1b**–**d** and **1g**. For compounds **1e**–**f** the substitution of chloro and methoxy groups occurs faster than dehydro-methylamination and this effect suggests the multistep addition–elimination process. However, the calculations of the reaction pathways do not con-

[5]The PM3 method was used for the semiempirical MO calculations using the MOPAC (version 6) molecular orbital package. The starting geometries and intermediary structures were obtained from the corresponding molecular models, fully optimized using keywords PRECISE. Transitions states (TS) were calculated using a SADDLE subroutine. An NLLSQ procedure was used for gradient optimization (<0.1 kcal/mol/Å). Calculations were performed until at least one negative Hessian was obtained. The THERMO procedure was used to correct the results of calculations for temperature 266 K.

[b] The results of calculations were corrected for temperature 266 K.

firm this process. In the case of **1a** the calculations predict C-4 as the favorable site for nucleophilic attack but on the base of results of study reaction it is difficult to predict which positions (C-2 or C-4) are attacked by nucleophilic reagents at first.

Experimental

Melting points (uncorrected) were determined on a Kofler plate. The ^{1}H NMR spectra were recorded on Tesla BS-587A (80 MHz) spectrometer. The infrared spectra were recorded on UR-20 or Bio-Rad FTS-175C spectrometer (in potassium bromide pellets). The mass spectra were recorded on LKB GC–MS 9000 spectrometer. Silica gel (Merck, 230–400 mesh) was used for column chromatography. Quantum-chemical calculations were carried out with PM3 method using MOPAC program (version 6.0) available from Research Laboratory, US Air Force Academy, Colorado Springs, U.S.A.

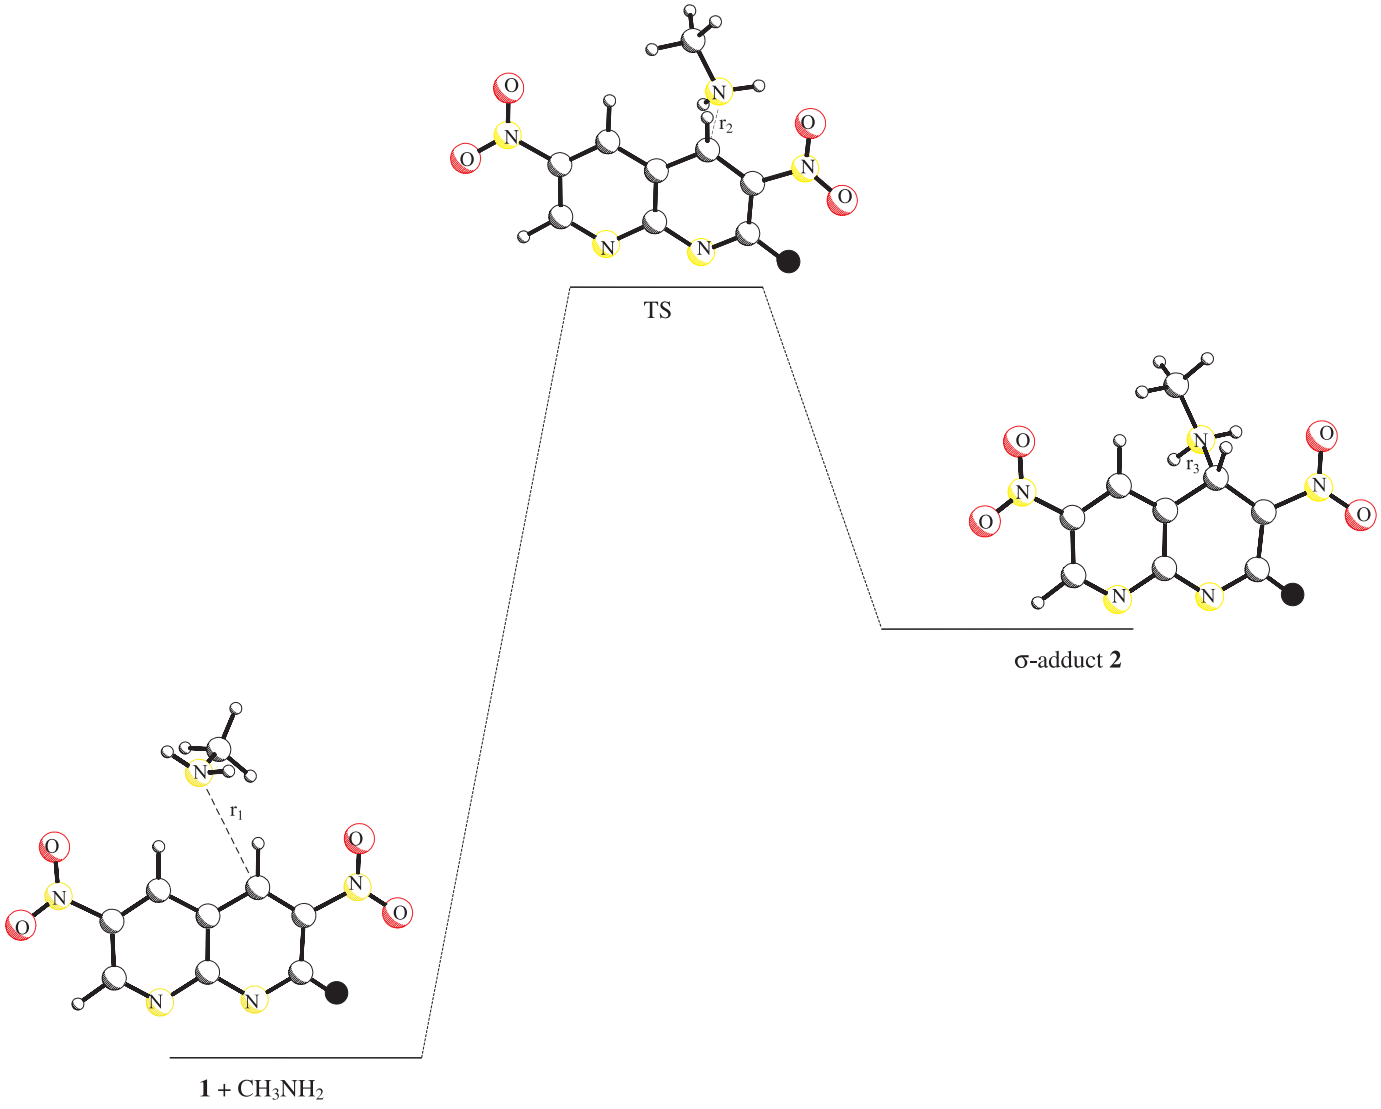
1. Synthesis of starting and references compounds

3,6-Dinitro-, **1a** (3), 2-chloro-3,6-dinitro-, **1e** (6), and 2-amino-1,8-naphthyridine (7) were prepared according to the literature procedures. 2-Hydroxy-3,6-dinitro-1,8-naphthyridine, **1g**, was prepared by the procedure described earlier (6), however by using 65% oleum the reaction time could be shortened from 30 h to 3 h. Attempts to obtain 2-amino-3,6-dinitro-1,8-naphthyridine, **1c**, by nitration of 2-amino-1,8-naphthyridine under various conditions gave 2-hydroxy-3,6-dinitro-, **2g** or 2-hydroxy-3-nitro-1,8-naphthyridine. Nitration of 2-amino-1,8-naphthyridine at 0°C yielded 2-nitramino-1,8-naphthyridine which, however, could not be rearranged to an amino nitro-1,8-naphthyridine.

*2-(Methylamino)-3,6-dinitro-1,8-naphthyridine (**1b**)*

2-Chloro-3,6-dinitro-1,8-naphthyridine (0.2 g, 0.8 mmol) in 20 mL of saturated methanol solution of methylamine was stirred at r t for 10 min. Precipitated yellow crystals were filtered off and washed with methanol to yield 0.12 g (60%) of **1b**, mp 234–236°C. MS (70 eV), *m*/*z* (%): 249 (18) [M^+], 165 (100). IR ν_{max}: 3424 (NH), 1557 (NO_2, as), 1339 (NO_2, s) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 9.74 (7H, d), 9.09 (4H. s), 8.95 (5H, d), 8.38 (NH, br.s), 3.38 (CH_3, d), $J_{5,7}$ = 2.9 Hz, $J_{NH,CH}$ = 4.9 Hz. Anal. calcd. for $C_9H_7N_5O_4$: C 43.38, H 2.38, N 28.11; found: C 43.61, H 2.71, N 28.01.

*2-Amino-3,6-dinitro-1,8-naphthyridine (**1c**)*



2-Chloro-3,6-dinitro-1,8-naphthyridine (0.1 g, 0.4 mmol) in 25 mL of saturated methanol solution of ammonia was stirred at r t for 15 h. Methanol and ammonia were removed under vacuum and the residue obtained was crystallized from nitromethane to yield 75 mg (75%) of **1c**; yellow needles with mp >350°C. [Lit. (6) mp >350°C]. MS (70 eV), *m*/*z* (%): 235 (100) [M^+]. IR ν_{max}: 3459 (NH), 1538 (NO_2, as), 1325 (NO_2, s) cm^{-1}. ^{1}H NMR (DMSO) δ: 9.57 (7H, d), 9.46 (4H, s), 9.35 (5H, d), 8.44 (NH, br. s), $J_{5,7}$ = 2.9 Hz. Anal. calcd. for $C_8H_5N_5O_4$: C 40.86, H 2.14, N 29.78; found: C 40.82, H 2.09, N 26.69.

*2-(Phenylamino)-3,6-dinitro-1,8-naphthyridine (**1d**)*

2-Chloro-3,6-dinitro-1,8-naphthyridine (0.15 g, 0.6 mmol) and 0.1 mL (1.1 mmol) of fresh distilled aniline in 25 mL of

Fig. 1. PM3 results for the pathway from **1** →**2**; details are given in Table 2 ; ● = R (R = H, $NHCH_3$, NH_2, NHPh, Cl, OCH_3, OH).

methanol was heated on a water bath for 10 h. Methanol and the excess of aniline were removed and to the residue 15 mL of 15% water solution of sodium hydroxide was added. The solid was filtered off and crystallized from a mixture of water and dioxane to afford 0.13 g (70%) of **1f**; red prisms with mp 300–303°C. MS (70 eV), *m*/*z* (%): 311 (54) [M^+], 310 (100) [M^+– H]$^+$. IR ν_{max}: 3330 (NH), 1571 (NO_2, as), 1341 (NO_2, s) cm^{-1}. ^1H NMR (CF_3COOD) δ: 9.77 (7H, d), 9.69 (5H, d), 9.60 (4H, s), 7.71–7.61 (phenyl, m), $J_{5,7}$ = 2.7 Hz. Anal. calcd. for $C_{14}H_9N_5O_4$: C 54.02, H 2.91, N 22.50; found: C 53.91, H 2.89, N 22.11.

*2-Methoxy-3,6-dinitro-1,8-naphthyridine (**1f**)*

To a solution of 0.1 g (0.4 mmol) of 2-chloro-3,6-dinitro-1,8-naphthyridine ca. 5 mg of sodium hydroxide was added and then heated on a water bath for 7.5 h. The excess of methanol was distilled off and the residue was twice crystallized from *n*-octane (charcoal) to give 40 mg (40%) of **1f**; white needles with mp 172–173°C. MS (70 eV), *m*/*z* (%): 250 (35) [M^+], 230 (100) [M^+– NO]$^+$. IR ν_{max}: 1549 (NO_2, as), 1336 (NO_2, s) cm^{-1}. ^1H NMR ($CDCl_3$) δ: 9.86 (7H, d), 9.11 (5H, d), 8.83 (4H, s), 4.38 (CH_3, s), $J_{5,7}$ = 2.7 Hz. Anal. calcd. for $C_9H_6N_4O_5$: C 43.21, H 2.42, N 22.11; found: C 43.24, H 2.38, N 22.11.

*2-Hydroxy-3,6-dinitro-1,8-naphthyridine (**1g**)*

A solution of 2.0 g (13.7 mmol) of 2-hydroxy-1,8-naphthyridine in 20 mL of fuming nitric acid (*d* = 1.51) and 20 mL of fuming sulfuric acid containing 65% sulfur trioxide, was heated at 100–110°C on an oil bath for 3 h. The solution was cooled and poured on 150 g of crushed ice and the mixture was neutralized to pH ~ 6 with water solution of ammonia. The precipitate obtained was filtered off, washed with water, and crystallized from water to give 1.8 g (56%) of **1g**; yellow crystals with mp 302–310°C (decomp.) The compound was identical to the reference sample.

Nitration of 2-amino-1,8-naphthyridine

(*a*) A mixture of 2-amino-1,8-naphthyridine (0.1 g, 0.7 mmol), 2 mL of sulfuric acid, and 0.4 mL of nitric acid

© 2000 NRC Canada

(d = 1.42) was heated on a water bath for 3 h. The solution was poured on ca. 50 mL of cold water. The precipitate was filtered off, washed with water, and dried to yield 50 mg (39%) of 2-hydroxy-3-nitro-1,8-naphthyridine; light-yellow crystals with mp 265–320°C (subl.), (Lit (7) 265–320°C (subl.)). The compound was identical (IR and ^{1}H NMR) to the reference sample (7). The water filtrate was neutralized with water ammonia, acidified with acetic acid to pH 5, and extracted continuously with chloroform for 5 h. Chloroform was removed from the extract, the solid was dried under vacuum, washed with hexane to give 55 mg of 2-hydroxy-1,8-naphthyridine with mp 197–203°C, (Lit. (7) 198–199°C). ^{1}H NMR spectroscopy showed that the product contained ca. 5% of 2-hydroxy-3-nitro-1,8-naphthyridine and no amount of starting material.

(*b*) 2-Amino-1,8-naphthyridine (0.2 g, 0.14 mmol) was nitrated with 2 mL of fuming nitric acid and 2 mL of 65% oleum in the same manner as that described for nitration of 2-hydroxy-1,8-naphthyridine. After crystallization from water 0.15 g (50%) of 2-hydroxy-3,6-dinitro-1,8-naphthyridine, **1g**, was obtained. The compound was identified by comparison properties (mp, IR, and ^{1}H NMR) with those of the reference sample.

(*c*) To the stirred solution of 2-amino-1,8-naphthyridine (50 mg, 0.035 mmol) in 1 mL of sulfuric acid, 0.2 mL of nitric acid (d = 1.42) was added at 0°C. The solution was kept at 0°C for 0.5 h and then at r t for 20 h. The solution was neutralized with water ammonia, acidified to pH ~ 5 with acetic acid, and extracted continuously with chloroform for 5 h. Chloroform was stripped off and the residue was purified by column chromatography (2.5 × 50 cm) using 500 mL of chloroform–methanol (10 : 1) as the eluent. The eluent was removed and the residue was crystallized from methanol to yield 40 mg (61%) of 2-nitramino-1,8-naphthyridine; light-yellow needles which above 140°C are transformed into plates with mp 210–211°C. MS (70 eV), *m*/*z* (%): 190 (12) [M^+], 144 (100) [M^+–NO_2]$^+$. IR ν_{max}: 3450 (NH), 1545 (NO_2), 1370 (NO_2, s) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 8.74 (7H, dd), 8.16 (5H, dd), 8.12 (4H, d), 7.56 (6, dd), 7.12 (3H, d), $J_{3,4}$ = 9.0 Hz, $J_{5,6}$ = 8.5 Hz, $J_{5,7}$ = 2.0 Hz, $J_{6,7}$ = 5.0 Hz. Anal. calcd. for $C_8H_6N_4O_2$: C 50.53, H 3.18, N 29.46; found: C 50.44, H 3.16, N 29.30.

2. General procedure: amination of 3,6-dinitro-1,8-naphthyridines with methylamine – potassium permanganate

0.2–0.3 g of potassium permanganate was added to 25–30 mL of liquid methylamine and 0.1–0.2 g of dinitronaphthyridine and the resulting mixture stirred at –7°C for 0.5 h. After evaporation of methylamine ca. 30 mL of water was added to the residue and the mixture was extracted continuously with chloroform for 15 h. The residue obtained after evaporation of the solvent from the extract was worked up in the manner described below.

*Methylamination of 3,6-dinitro-1,8-naphthyridine (**1a**)*

0.1 g (0.45 mmol) of **1a** was treated according to the general procedure. The residue was separated by column chromatography (2.5 × 70 cm). The first fraction was eluted with 2 L of dichloromethane and after stripping off the eluent was washed with methanol to give 10 mg (9%) of 2-methylamino-3,6-dinitro-1,8-naphthyridine, **2c** (**1b**). The compound had the same properties as **1b** synthesized from **1e** (see section 1). The second fraction was eluted with 500 mL of chloroform–methanol (10 : 1) and crystallized from toluene to yield 55 mg (44%) of 2,4-bis(methylamino)-3,6-dinitro-1,8-naphthyridine, **2a**; yellow needles with mp 268–270°C (decomp.). MS (70 eV), *m*/*z* (%): 278 (53) [M^+], 261 (100). IR ν_{max}: 2365 (NH), 1560 (NO_2, as), 1295 (NO_2, s) cm^{-1}. ^{1}H NMR (DMSO) δ: 9.48 (7H, d), 9.37 (5H, d), 8.19 (NH, br.s), 2.99 (CH_3, d), 2.87 (CH_3, s), $J_{5,7}$ = 2.5 Hz, $J_{CH,NH}$ = 4.0 Hz. Anal. calcd. for $C_{10}H_{10}N_6O_4$: C 43.17, H 3.62, N 30.21; found: C 43.15, H 3.62, N 30.03.

The third fraction (500 mL, chloroform–methanol (10:1)) was crystallized from methanol to give 15 mg (12%) of 4,5-bis(methylamino)-3,6-dinitro-1,8-naphthyridine; dark yellow needles with mp 261–263°C (decomp). MS (70 eV), *m*/*z* (%): 278 (10) [M^+], 261 (100) [M^+–OH]$^+$. IR ν_{max}: 3288 (NH), 1569 (NO_2, as), 1385 (NO_2,s) cm^{-1}. ^{1}H NMR (DMSO) δ: 9.20 (2H, 7H, s), 8.69 (NH, br.s), 2.72 (CH_3, s). Anal. calcd. for $C_{10}H_{10}N_6O$: C 43.17, H 3.62, N 30.21; found: C 43.09, H 3.52, N 30.35.

*Methylamination of 2-(methylamino)-3,6-dinitro-1,8-naphthyridine (**1b**)*

0.1 g (0.4 mmol) of **1b** was treated according to the general procedure. The residue was dissolved in the mixture of chloroform–methanol (10 : 1) and purified by column chromatography using 150 mL of the same solvent as eluent. The eluent was removed and the residue was crystallized from toluene to yield 70 mg (62%) of 2,4-bis(methylamino)-3,6-dinitro-1,8-naphthyridine, **2a**. The compound showed identical properties (mp, ^{1}H NMR, IR) with those of **2a** obtained from **1a**.

*Methylamination of 2-amino-3,6-dinitro-1,8-naphthyridine (**1c**)*

0.1 g (0.43 mmol) of **1c** was treated according to the general procedure. The residue was purified by column chromatography (2.5 × 50 cm), using 1 L of chloroform–methanol (5:0.25) as eluent, and crystallized from methanol to afford 55 mg (50%) of 2-amino-4-(methylamino)-3,6-dinitro-1,8-naphthyridine, **2d**; yellow needles with mp >280^o C (decomp.). MS (70 eV), *m*/*z* (%): 264 (100) [M^+], 247 (30) [M^+– OH]$^+$. IR ν_{max}: 3425, 3250, 3105 (NH), 1535 (NO_2, as), 1345 (NO_2, s) cm^{-1}. ^{1}H NMR (DMSO) δ: 9.46 (7H, d), 9.36 (5H, d), 2.87 (CH_3, s), $J_{5,7}$ = 2.5 Hz. Anal. calcd. for $C_9H_8N_6O_4$: C 40.91, H 3.08, N 31.81; found: C 40.75, H 3.12, N 31.62.

*Methylamination of 2-(phenylamino)-3,6-dinitro-1,8-naphthyridine (**1d**)*

0.16 g (0.52 mmol) of **1d** was treated according to the general procedure. The residue was purified by column chromatography (2.5 × 50 cm) using 500 mL of chloroform–methanol (5:0.25) as the eluent. The eluent was removed and the residue was crystallized from methanol to give 80 mg (46%) of 4-(methylamino)-2-(phenylamino)-3,6-dinitro-1,8-naphthyridine, **2e**; orange plates with mp 254–256°C (decomp.). MS (70 eV), *m*/*z* (%): 340 (35) [M]$^+$, 339 (100) [M^+–1]. IR ν_{max}: 3440, 3330 (NH), 1540 (NO_2, as), 1320 (NO_2, s) cm^{-1}. ^{1}H NMR (DMSO) δ: 9.54 (7H, d), 9.41 (5H,

d), 7.87–7.16 (phenyl, m), 2.91 (CH_3, s), $J_{5,7}$ = 2.5 Hz. Anal. calcd. for $C_{15}H_{12}N_6O_4$: C 52.94, H 3.55, N 24.70; found: C 52.80, H 3.68, N 24.51.

*Methylamination of 2-chloro-3,6-dinitro-1,8-naphthyridine (**1e**)*

0.2 g (0.78 mmol) of **1e** was treated according to the general procedure. The residue was purified by column chromatography (2.5 × 50 cm) using 500 mL of chloroform–methanol (5:0.2) as the eluent and crystallized from toluene to yield 0.14 g (65%) of 2,4-bis(methylamino)-3,6-dinitro-1,8-naphthyridine, **1a**. The compound was identical (mp, IR, ^{1}H NMR) with **2a** obtained by methylamination of **1a**.

*Methylamination of 2-methoxy-3,6-dinitro-1,8-naphthyridine (**1f**)*

0.1 g (0.4 mmol) of **1f** was treated according to the general procedure. The residue was separated by column chromatography (2.5 × 70 cm) using chloroform as the eluent. The first fraction (500 mL) was crystallized from methanol to give 30 mg (22%) of 2-methoxy-4,5-bis(methylamino)-3,6-dinitro-1,8-naphthyridine, **2f**; orange needles with mp 245–247°C. MS (70 eV), *m*/*z* (%): 308 (35) [M^+], 290 (100). IR ν_{max}: 3425, 3366 (NH), 1545 (NO_2, as), 1330 (NO_2,s) cm^{-1}. ^{1}H NMR (DMSO) δ: 9.33 (7H, s), 8.45 (NH, br.s), 4.09 (OCH_3, s), 3.05 (NCH_3, d), 2.98 (NCH_3, s), $J_{CH,NH}$ = 4.0 Hz. Anal. calcd. for $C_{11}H_{12}N_6O_5$: C 42.86, H 3.92, N 27.26; found C 43.07, H 3.91, N 27.00.

The second fraction (700 mL) was crystallized from toluene to yield 45 mg (44%) of 2,4-bis(methylamino)-3,6-dinitro-1,8-naphthyridine, **2a**. The compound showed identical properties (mp, IR, ^{1}H NMR) with those of **2a** obtained from **1a** (or **1b**).

*Methylamination of 2-hydroxy-3,6-dinitro-1,8-naphthyridine (**1g**)*

0.13 g (0.55 mmol) of **1g** was treated according to the general procedure. The residue was purified by column chromatography (2.4 × 30 cm) using chloroform–methanol (10:1) as the eluent.

The eluent was removed and the remaining solid was washed with methanol to give 60 mg (41%) of the mixture of 2-hydroxy-4-(methylamino)-3,6-dinitro-1,8-naphthyridine, **2g** and of 2-hydroxy-5-(methylamino)-3,6-dinitro-1,8-naphthyridine, **2h**; yellow plates with mp >290°C. MS (70 eV), *m*/*z* (%): 265 (100) [M^+], 247 (74). IR ν_{max} : 3371 (NH), 1674 (CO), 1566 (NO_2, as), 1332 (NO_2, s) cm^{-1}. ^{1}H NMR (DMSO) δ of **2g**: 9.53 (7H, d), 9.39 (5H, d), 3.02 (CH_3, s), $J_{5,7}$ = 2.5 Hz. ^{1}H NMR (DMSO) δ of **2h**: 8.87 (7H, s), 4.83 (4H, s), 2.84 (CH_3, s). Anal. calcd. for $C_9H_7N_5O_5$: C 40.76, H 2.66, N 26.41; found: 40.85, H 2.71, N 26.53.

3. Hydrolysis of 2,4-bis(methylamino)-3,6-dnitro-1,8-naphthyridine (2a)

60 mg (0.22 mmol) of **2a**, 4 mL of hydrochloric acid (*d* = 1.18), and 4 mL of water were heated at boiling point for 8 h. The solution was neutralized with water ammonia. The solid was filtered off, washed with water and then with methanol, and dried to give 55 mg (95%) of 2-(methylamino)-4-hydroxy-3,6-dinitro-1,8-naphthyridine [2-(methylamino)-3,6-dinitro-1,8-naphthyridin-4-(1H)-one], **2j**; yellow needles with mp >280°C (decomp.). MS (70 eV), *m*/*z* (%): 265 (33) [M^+], 247 (100). IR ν_{max}: 3355 (NH), 1630 (CO), 1530 (NO_2, as), 1335 (NO_2,s) cm^{-1}. ^{1}H NMR (DMSO) δ: 9.22 (7H, d), 8.81 (5H, d), 7.22 (NH, br.s), 3.06 (CH_3, s), $J_{5,7}$ = 2.5 Hz. Anal. calcd. for $C_9H_7N_5O_5$: C 40.76, H 2.66, N 26.41; found: C 40.98, H 2.80, N 26.25.

Acknowledgments

The authors wish to thank Dr. P. Kowalski for his help with the quantum-chemical calculations and Dr. E. Cholewka for measuring the ^{1}H NMR and IR spectra.

The Suzuki, the Heck, and the Stille reaction — three versatile methods for the introduction of new C—C bonds on solid support

Robert Franzén

Abstract: Metal-catalyzed coupling reactions are very efficient and reliable methods for the introduction of new carbon–carbon bonds onto molecules attached to a solid support. This review summarizes recent advances in utilizing the three most used methods, the Suzuki reaction, the Heck reaction, and the Stille reaction, in the field of solid phase organic synthesis resulting in small organic molecule libraries.

Key words: metal-catalyzed coupling reactions, carbon—carbon bonds, solid phase synthesis, combinatorial chemistry, drug discovery.

Résumé : Les réactions de couplage catalysées par les métaux sont des méthodes efficaces et fiables pour l'introduction de nouvelles liaisons carbone-carbone dans des molécules attachées à un support solide. Cette revue résume les développements récents dans l'utilisation des trois méthodes les plus courantes, la réaction de Suzuki, la réaction de Heck et la réaction de Stille, dans le domaine de la synthèse organique en phase solide conduisant à l'élaboration de librairies de petites molécules organiques.

Mots clés : réactions de couplage à catalyse métallique, liasons carbone—carbone, synthèse en phase solide, chimie combinatoire, découverte de médicaments.

[Traduit par la Rédaction]

Introduction

Over the past 10 years, small molecule solid phase synthesis has become an important part in the discovery of new drugs (1, 2). In fact, most of the organic chemical libraries synthesized to date have been constructed using solid-phase methods. In the development of organic chemistry, the carbon–carbon bond formation has always been one of the most useful and fundamental reactions, (3–5) and numerous papers and reviews have detailed the progress of several reactions in solution phase since the end of the 19th century. The literature for new synthetic methods of carbon–carbon bond formation on solid-support has not been extensively reviewed. Recently, a short review by Andres et al. (6) on the utilization of some metal-catalyzed coupling reactions on solid phase was published. The current paper summarizes recent developments in metal-catalyzed coupling reactions performed on a polymeric material. The three following methods are investigated in detail: (*i*) the cross-coupling of aryl halides with aryl boronic acids (*the Suzuki coupling*); (*ii*) the palladium-catalyzed reaction between an aryl and (or)alkyl halide and a vinyl functionality (*the Heck reaction*); and (*iii*) the palladium-catalyzed cross-coupling reaction of organotin reagents with a variety of organic electrophiles (*the Stille reaction*) on solid support. Only one remarkable preparation of compound libraries on solid phase utilizing the Stille reaction in the synthesis of hundreds of 1,4-benzodiazepine derivatives was reported by Plunkett and Ellman (7). The Suzuki reaction and the Heck reaction have not been applied for the preparation of compound libraries consisting of more than 20 compounds.

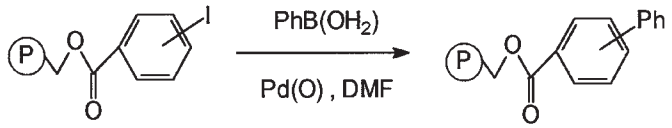
The Suzuki coupling

Palladium-catalyzed coupling via Suzuki reactions are powerful methods for C—C bond formation (8–10). The reaction generally results in an excellent yield when performed at temperatures of 60–80°C. Therefore, it is of high interest to adapt this reaction to a resin mounted procedure.



Solid-phase Suzuki coupling was first utilized in the preparation of biaryls. In the work by Frenette and Friesen (11) the cross-coupling reaction between aryl boronic acids and aryl bromides and iodides catalyzed by palladium on Merrifield resin was studied (Scheme 1). The biaryl products were released from the solid support by simple transesterification. A similar reaction was demonstrated by Guiles et al. (Scheme 2) (12). Han et al. (13) reacted several polymer bound arylhalides with a wide range of functionalized boronic acids under the Suzuki cross-coupling reaction conditions (Scheme 3) and produced several *ipso*-substitution products in good yields. Finally the Suzuki coupling for the production of biaryls has also been assisted by microwave irradiation as demonstrated by Larhed et al. (14) (Scheme 4).

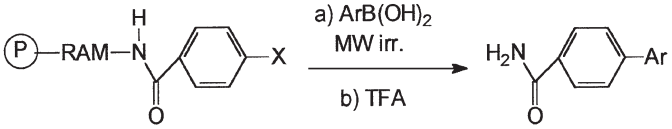
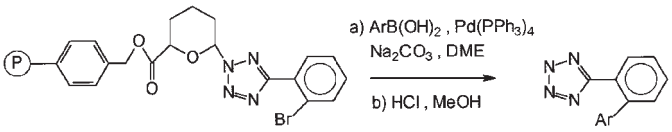
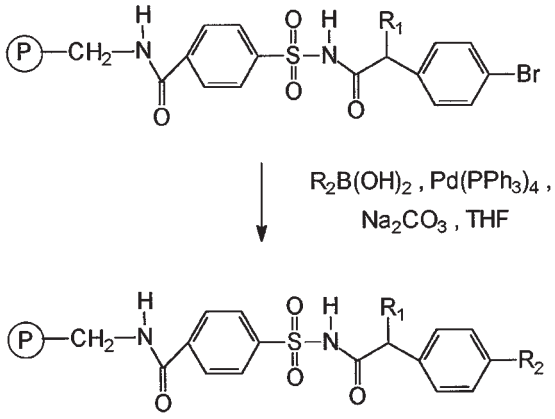


Scheme 2.

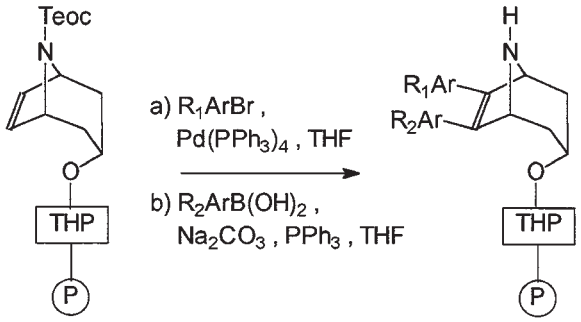


Scheme 3.

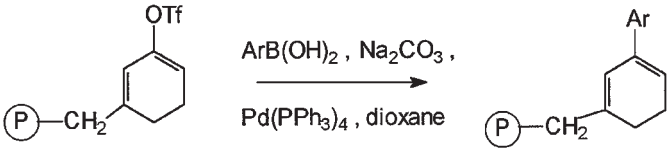
Scheme 4.



Scheme 5.



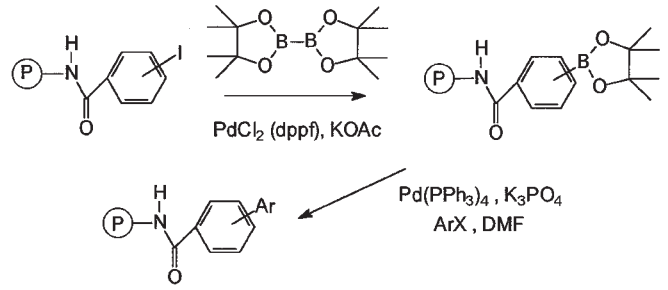
A Suzuki type solid-phase aryl–aryl coupling reaction for the preparation of various biphenyltetrazole derivatives was demonstrated by Yoo et al. (15) (Scheme 5). Marquis and Arlt (16) and Rottlander and Knochel (17) have also demonstrated that several biphenyls can be prepared from palladium-catalyzed reactions of aryl zinc bromides instead of phenyl boronic acids. Backes and Ellman (18) used the Suzuki reaction on solid support starting from a polymer supported acyl sulfonamide (Scheme 6) and in another paper Koh and Ellman (19) reported a palladium-mediated three component coupling (Scheme 7). In the work, several aryl boronic acids were used as coupling partners according to standard Suzuki coupling conditions. Ellman and co-workers (20) has also demonstrated that a Suzuki cross-coupling can



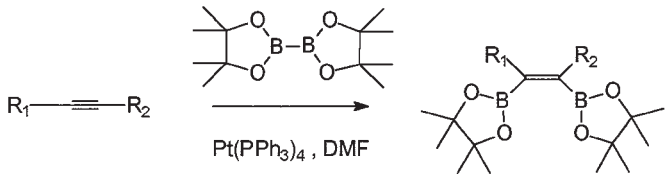
Scheme 6.

Scheme 7.

Scheme 8.



be performed in the synthesis of a 1,4-benzodiazepine-2,5-dione on solid support. Fraley and Rubino (21) utilized a Suzuki cross-coupling reaction between a vinyl triflate resin and boronic acid catalyzed by $Pd(PPh_3)_4$ (Scheme 8). Also a variety of other boronic coupling agents (heteroaryl, alkyl, alkenyl, and alkynyl) have been optimized under conditions similar to those used for the phenyl boronic acid coupling (12). Commonly, it has been concluded that the optimal Pd catalyst varies strongly depending upon the boronic coupling partner (22). In this paper, the importance of resin type and solvent composition for Suzuki reactions wherein the boronic acid moiety is either in solution or attached to the resin, was noticed.



Piettre and Baltzer (23) modified the solid-phase reaction and treated polymer-bound aryl halides with pinacol ester of diboron under palladium (0) catalysis and produced polymer-bound boronates that could be used for Suzuki coupling reaction with a variety of aryl halides (Scheme 9). A coupling of a resin bound aryl iodide with phenyl boronic acid produced the biaryl compound in different yield depending on the catalysis system used in the reaction. When using the $PdCl_2$(dccf) as catalyst in the presence of triethylamine in DMF the best yield could be obtained. Ishiyama et al. (24)

described the platinum-catalyzed diboration of alkynes to give bis(boryl)alkenes with very high *cis* selectivity (Scheme 10). Brown and Armstrong (25, 26) have utilized this approach in the preparation of tetra-substituted ethylenes (Scheme 11) and Tamoxifen derivatives (Scheme 12) on solid support via resin capture. The Suzuki coupling reaction has also been utilized in the preparation of new linkers and resins to be used in combinatorial chemistry (27–29). Due to the high yield in the cross-coupling on solid-support, the reaction has been used for reaction monitoring in Spin Echo Magic Angle Spinning ^{1}H NMR experiments (30).

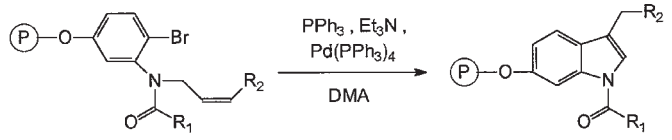
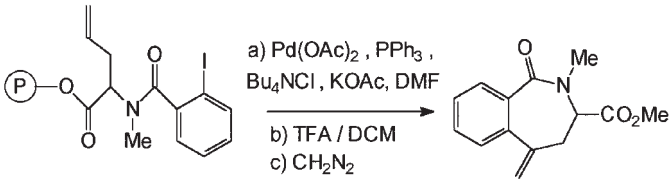
Scheme 15.



The Heck reaction

The Heck reaction (31, 32) has shown to be very useful for the preparation of especially disubstituted olefins. In the palladium catalyzed reaction the carbon–carbon bond is formed from a vinyl functionality and an aryl and (or) alkyl halide. The reaction is well adapted for automation due to the fact that it does not require inert atmosphere conditions. The intramolecular Heck reaction has been well-established as a powerful tool for the construction of complex polycyclic ring systems in the context of natural product synthesis. This process has been adapted in the solid-phase synthesis of several different types of molecules.



Yu et al. (33) used the reaction of polymer bound aryl iodide or styrene with olefins or arylhalides in the generation of 1,2-disubstituted olefin libraries (Scheme 13). Hiroshige et al. (34) studied the formation of a C—C bond in the palladium-promoted vinylation of aryl iodide bound to a solid support (Scheme 14). The solvent effect of Pd-catalyzed vinylation using different vinylic reagents was examined. The same group demonstrated also later that a macrocyclic molecule could efficiently be generated on solid support using a modified Heck reaction (35). This palladium-catalyzed intramolecular Heck reaction was also used by Goff and Zuckermann (36) (Scheme 15) for the solid-phase synthesis of substituted peptoid 1(2*H*)-isoquinolinones and by Yun

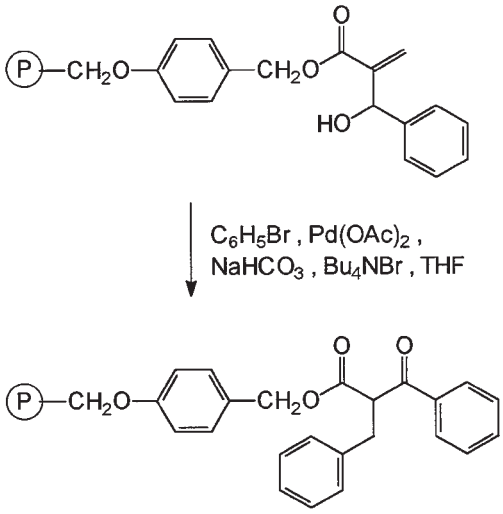
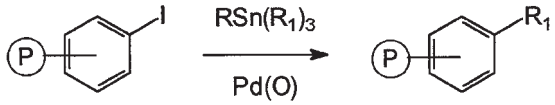
Scheme 20.



Scheme 21.

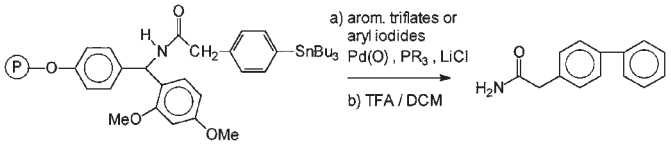


and Mohan (37) (Scheme 16) for the synthesis of indole analogues. A macrocyclization on solid-support using the Heck reaction has also been utilized by Akaji and Kiso (38) when a cyclic tetrapeptide derivative was synthesized. Lately, Bolton and Hodges (39) (Scheme 17) have prepared substituted benzazepines via intramolecular Heck cyclization on solid-phase.

Scheme 22.

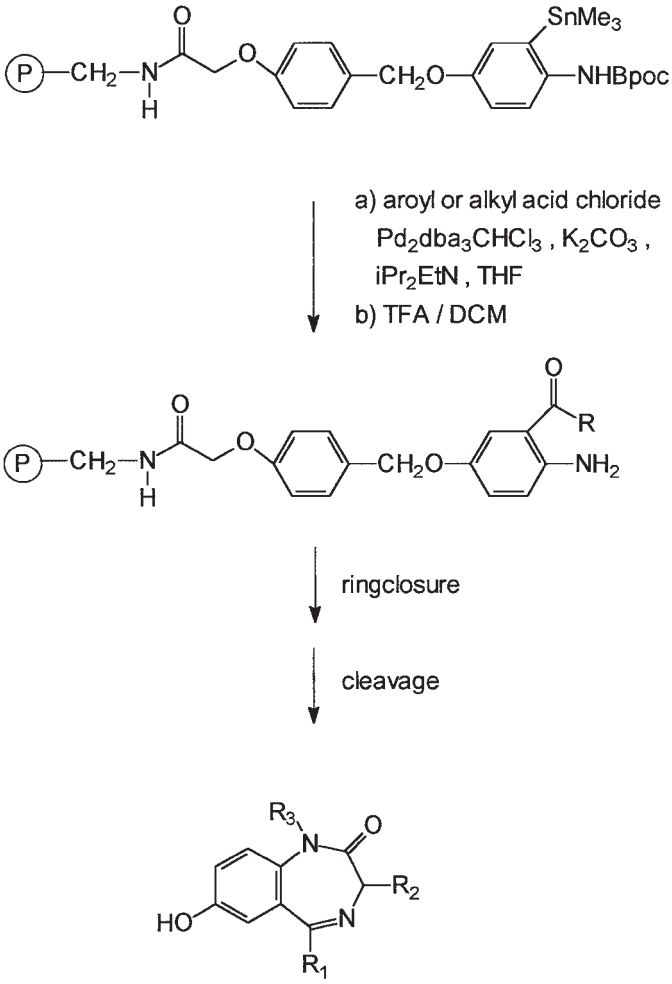
Scheme 23.

Fancelli et al. (40) utilized the solid-phase Heck-coupling in the preparation of 2-substituted benzofuran carboxylic acids (Scheme 18). The reaction between the resin-bound hydroxy iodide and several acetylenes was examined. In the synthesis of phenyl acetylene oligomers, the Heck reaction was employed between a resin-bound aryl iodide and a terminal acetylene (41) (Scheme 19).



Beaver et al. (42) (Scheme 20) have performed Heck reactions with sulfonamide resins. The resin bound aryliodide reacted with methyl acrylate in the presence of $Pd(OAc)_2$. Following cleavage the α,β-unsaturated methyl ester phenyl sulfonide was obtained in high yield. The Heck reaction has also been used in the solid-phase synthesis of fused bicyclic amino acid derivatives (Scheme 21) (43) and in the monitoring of a solid-phase reaction by MAS NMR spectroscopy. Recently, β-keto esters have been prepared on solid support via a sequential Baylis–Hillman and Heck reaction (Scheme 22) (44).

The Stille reaction



Palladium-catalyzed substitution and addition involving organotin compounds (45–47) have been used by many research groups throughout the world for synthetic purposes. Several applications of the Stille reaction for efficient carbon–carbon bond formation on solid-support have been reported: (*i*) Desphande (48) used the Stille coupling reaction on solid support for the preparation of biaryls. In his report, he coupled vinyl and (or) aryl stannanes with polymer bound aryl iodides (Scheme 23). The cross-coupled products were obtained following cleavage from the support in high yield. A year later, Forman and Sucholeiki (49) used the reaction for the preparation of biaryl derivatives and studied the reaction of polymer-bound aryl stannanes with aryl iodides

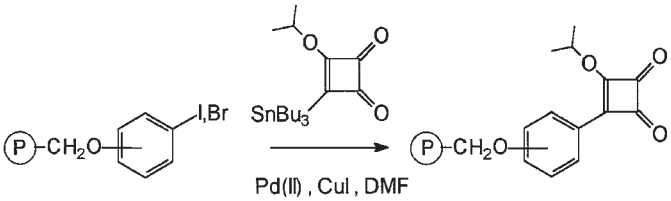
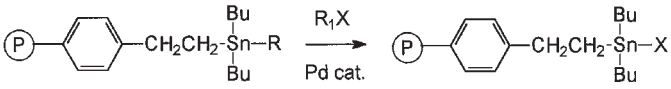
Scheme 24.

Scheme 25.



or triflates (Scheme 24). Tributylphenyltin was attached by an amide bond to the Rink amide resin and a palladium-mediated coupling with aryl triflates and aryl iodides was investigated.



Ellman and co-workers (7, 50, 51) have demonstrated in several papers how the Stille coupling can be utilized in the preparation of small molecule libraries. His group discovered an excellent method (52) for the preparation of 1,4-benzodiazepine derivatives on solid-support and using the Stille coupling he could produce structurally diverse derivatives a few years later (7, 50, 51) (Scheme 25). Recently (53), the group has utilized the Stille coupling in the preparation of new traceless linkers to be used in solid-phase synthesis.

In the preparation of cyclobutenedione derivatives on solid-support, Tempest and Armstrong (54) used a Mitsonobu reaction (55) coupled with a tributyltin isopropyl squarate under Stille conditions (Scheme 26). The reaction

Scheme 26.

Scheme 27.

proceeded well and after TFA cleavage only the expected product was obtained in high yield. Finally, Kuhn and Neumann (56) (Scheme 27) investigated the Stille reaction carried out with polymer-supported organotin reagents. This work showed that organitin by-products could easily be separated by filtration and that the target molecule was free of toxic organotin materials.

Concluding remarks

Carbon–carbon bond formation reactions on solid-support are highly useful and versatile methods needed for the development of modern drug discovery. This review encompasses most of the metal-catalyzed coupling reactions performed on solid-support starting from 1980. The review focuses on the investigation of the solid-phase adaption of the Suzuki, the Heck, and the Stille coupling reactions due to the fact that these have proven to be both reliable and efficient methods.

Synthesis and photophysical properties of fluorophore-labeled abscisic acid

X. Hou, S.R. Abrams, J.J. Balsevich, N. Irvine, T. Norstrom, M. Sikorski, H.K. Sinha, and R.P. Steer

Abstract: The 8′-benzophenone, 8′-dansylhydrazone, 3′-*S*-(2-ethyldansylamide), and 3′-*S*-acetamidofluorescein derivatives of the plant hormone abscisic acid (ABA) have been synthesized for use in photoaffinity labeling (the benzophenone derivative) or fluorescence probe experiments and have been spectroscopically characterized. One of the three fluorescent compounds, the 3′-tethered fluorescein derivative, exhibits spectroscopic and photophysical properties which indicate that it could be an excellent fluorescent probe of ABA interactions in vivo. The 3′-tethered fluorescein and ABA moieties do not interact strongly, so that the fluorescence properties of the fluorescein-labelled hormone are very similar to those of fluorescein itself. Measurements of the absorption, emission, and fluorescence excitation spectra, fluorescence quantum yields, and fluorescence decay parameters of this derivative as a function of pH indicate that the photophysics is dominated by ground and excited state prototropic equilibria involving only the fluorescein moiety. The fluorescein dianion is the only significant absorber and emitter at pH > 6.7, whereas only the cation absorbs and emits at pH < 0. In the intervening pH range, strong emission from the monoanion and weak emission from two neutral species, tentatively assigned to the zwitterion and the lactone of the fluorescein moiety, is observed.

Key words: abscisic acid, fluorescein, synthesis, photophysics.

Résumé : On a effectué la synthèse de dérivés 8′-benzophénone, 8′-dansylhydrazone, 3′-*S*-(2-éthyldanzylamide) et 3′-*S*-acétamidofluorescéine de l'acide abscisique (« ABA »), une hormone végétale. Ces dérivés, préparés pour utilisation comme sonde de fluorescence ou dans des expériences de marquage par photoaffinité (le dérivé benzophénone), ont été caractérisés par spectroscopie. L'un des trois composés fluorescents, le dérivé de la fluorescéine attaché en position 3′, possède des propriétés spectroscopiques et photophysiques qui suggèrent qu'il pourrait très bien agir comme sonde fluorescente des interactions « ABA » in vivo. Les portions « ABA » et fluorescéine attachée en position 3′ n'interagissent pas très fortement ce qui fait que les propriétés de fluorescence de l'hormone marquée à la fluorescéine sont très semblables à celles de la fluorescéine seule. Des mesures des spectres d'absorption, d'émission et d'excitation de fluorescence, des rendements quantiques de fluorescence et des paramètres de décroissance de la fluorescence en fonction du pH indiquent que la photophysique est dominée par les équilibres protoniques des états excité et fondamental n'impliquant que la portion fluorescéine. Le dianion de la fluorescéine est la seule entité absorbante et émettrice significative à des pH > 6,7 alors que seul de cation absorbe et émet à des pH < 0. Dans la zone des pH intermédiaires, on observe une émission forte de la part du monoanion et une faible émission provenant de deux entités neutres que l'on attribue provisoirement au zwitterion et à la lactone de la portion fluorescéine.

Mots clés : acide abscisique, fluorescéine, synthèse, photophysique.

[Traduit par la Rédaction]

Introduction

The plant hormone abscisic acid (**1**, ABA) is a signaling compound found in all higher plants (1). ABA is involved in mediating numerous aspects of plant growth and development including plants' responses to environmental stress and processes in seed development such as deposition of storage reserves, induction of desiccation tolerance, and control of germination (2). The plant biomolecules that interact with ABA as receptors and carriers and the enzymes that act on the hormone are targets of biotechnology research for improving environmental stress tolerance and plant productivity. The present study is directed towards developing photochemical and photophysical tools for probing the interactions of ABA with plant biomolecules that bind the hormone.

The ABA signal transduction pathway is a subject of intense investigation but, although progress has been made, a clear understanding of how the hormone is initially perceived has not emerged (3). In particular, the location of receptors in plant tissues or cells has not been clearly

1

determined (4). In addition, the nature and multiplicity of ABA receptors are unknown, although evidence from experiments with chiral analogs indicate that there may be more than one receptor for ABA in a given plant (5). Attempts to identify ABA receptors by photoaffinity labeling have met with little success (6). There are several reports of the isolation of ABA binding proteins using affinity chromatography techniques, but the function of the isolated proteins is unclear. Carrier proteins that transport ABA across membranes have been partially characterized, and structural variants of ABA have been useful for probing the structural requirements of the active sites (see for example ref. (7)). Nevertheless, the nature and locations of the receptors remain unclear, and this has motivated us to consider developing fluorescent probes and photoaffinity labels for elucidating these aspects of ABA's function.

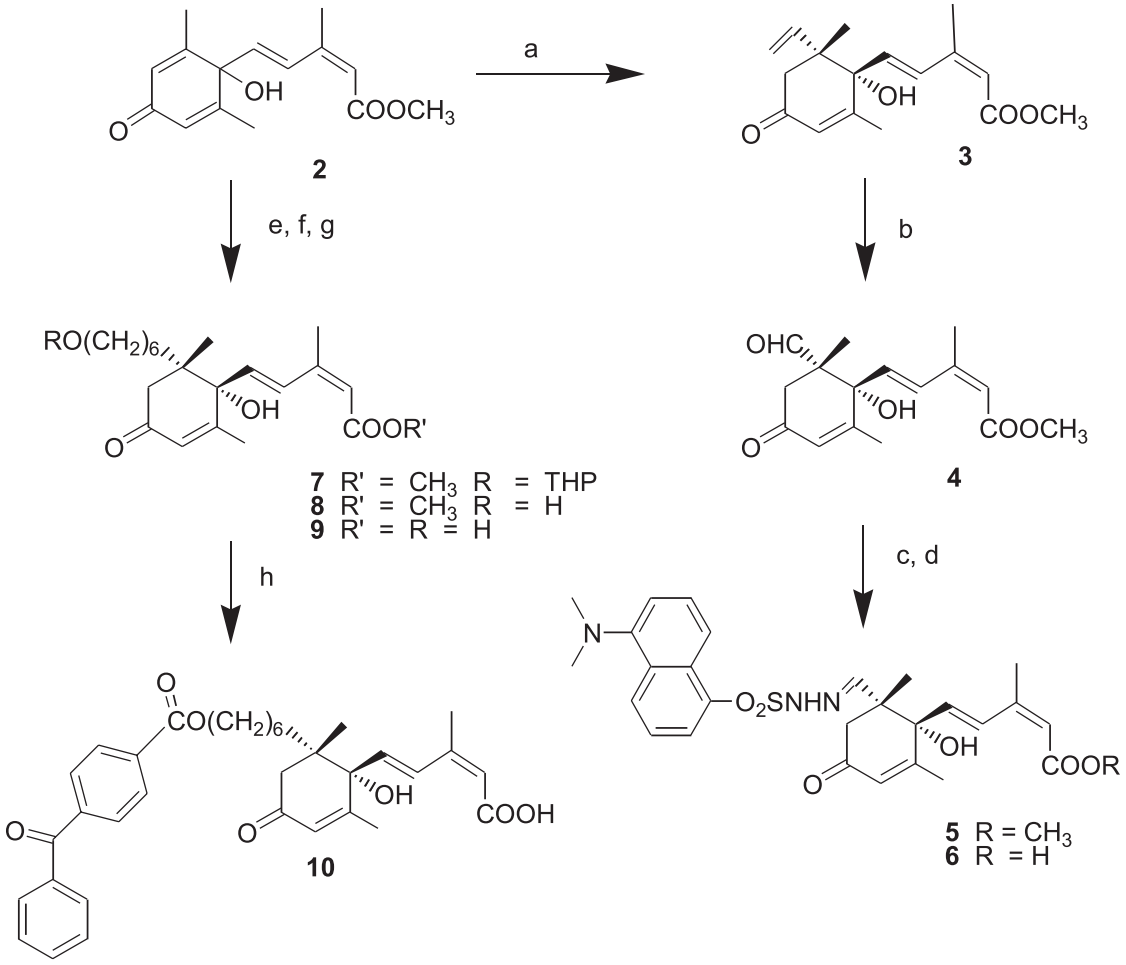
Photochemical or photophysical probes for studying the binding of ABA in a biological matrix must incorporate an ABA-like molecular structure that can bind in the active site(s). The ABA moiety needs to be linked through a tether to a molecular fragment that has the desired photochemical or photophysical properties (reactivity or fluorescence, respectively) while maintaining its biological activity. Changes to the structure of ABA generally reduce its biological activity and also are likely to affect its binding to receptors. In particular, the activity of ABA is generally reduced when the carbonyl group of the ring or the carboxyl group of the sidechain is modified (8). Thus, other sites on the ABA molecule are required for attaching a photochemically reactive fragment or fluorophore. In the present studies, two different points of connection were considered. Modification of the molecule by substitution at the 3′-carbon (for the conventional numbering system see the ABA structure, Fig. 1) had previously been shown to afford molecules with biological activity; the 3′-modified ABA had been used for affinity chromatography in purifying anti-ABA monoclonal antibodies (9). Alteration of the ABA molecule by substitution at the 8′-carbon atom has also afforded analogs with high biological activity, due in part, to their reduced metabolism by enzymes that degrade the hormone (10). To increase the probability that the ABA derivatives would have biological activity, tethers of different length and structure were incorporated at the 3′- or 8′-carbon atom.

In an effort to expand our knowledge of ABA's in vivo molecular function, we have synthesized several derivatives, one for photoaffinity labeling and three fluorescence probes, and have characterized them using spectroscopic and photophysical measurements. For the present work on the initial development of a method for synthesis and material for photophysical characterization, racemic compounds have been employed. For studies with ABA-binding proteins, probes having the ABA portion in optically pure form will be required. One derivative substituted at the 3′ position by a tethered fluorescein moiety has been found to exhibit promise as a fluorescence probe.

Results

Four ABA derivatives were synthesized: (*i*) an 8′-tethered benzophenone derivative **10** for possible photoaffinity labelling experiments; and (*ii*) an 8′-tethered dansyl derivative **6**; (*iii*) a similar 3′-tethered dansyl derivative **14**; (*iv*) and a 3′-tethered fluorescein derivative **12** for possible fluorescence labeling studies.

The 8′-tethered ABA derivatives were synthesized as shown in Scheme 1, starting with cyclohexadienone **2** (11). Conjugate addition of vinyl magnesium bromide gave the known 8′-methylene ABA methyl ester **3** (10). Ozonolysis afforded the aldehyde **4**, which on reaction with dansyl chloride led to the dansyl derivative **5** which was converted to the abscisic acid derivative **6** by alkaline hydrolysis. The benzophenone derivative **10** was synthesized in four steps from **2**, by conjugate addition of the Grignard reagent derived from the THP ether of 6-bromohexanol, deprotection of the primary alcohol and the carboxylic acid, and coupling of the benzophenone with the activated derivative affording the tethered 8′-benzophenone ABA analog.



The fluorescent derivatives of ABA altered at the 3′-carbon were prepared as shown in Scheme 2, starting with the known 2′,3′-epoxide of ABA (**11**) (12). The fluorescein group was added to the 3′-carbon by first making the thiol derivative (**12**) which was further reacted with the iodoacetamide derivative of fluorescein affording the tethered ABA analog **13**. The 3′-dansyl derivative of ABA **14** was synthesized from the ABA epoxide **11** and the thioacetate dansyl derivative.

The benzophenone derivative of ABA behaves like many such compounds prepared for photoaffinity labeling (13). It exhibits a weak $n \rightarrow \pi^*$ transition in the near UV and a strong $\pi \rightarrow \pi^*$ transition further to the blue with λ_{max} = 256 nm and $\varepsilon_{max} = 3.0 \times 10^4$ M^{-1} cm^{-1} in 50% v/v water–methanol. It is almost nonfluorescent in solution. It is therefore suitable from a spectroscopic perspective for photoaffinity labelling since it can be excited in the $\lambda >$ 320 nm range where damage to proteins is minimized, and in the free form it will not contribute significant intensity to a fluorescent signal developed by photoreaction of the benzophenone moiety in the active site. The only drawback is the poor solubility of this ABA derivative in pure water.

The dansyl-ABA derivatives exhibit a moderately strong absorption band (shoulder) in the near UV with a maximum near 327 nm and a strongly Stokes-shifted fluorescence emission band with a maximum near 575 nm in neutral aqueous solution. As is typical of dansyl derivatives in polar solvents (14, 15), the quantum yields of emission, ϕ_f, are low in aqueous solution. For the 3′-derivative for example, ϕ_f increases from 3.9×10^{-3} to 6.9×10^{-3} as the pH decreases from 10.6 to 8.3, and then falls monotonically with further decreases in pH to $<10^{-5}$ at pH = 2. These quantum yields of fluorescence are independent of the concentration

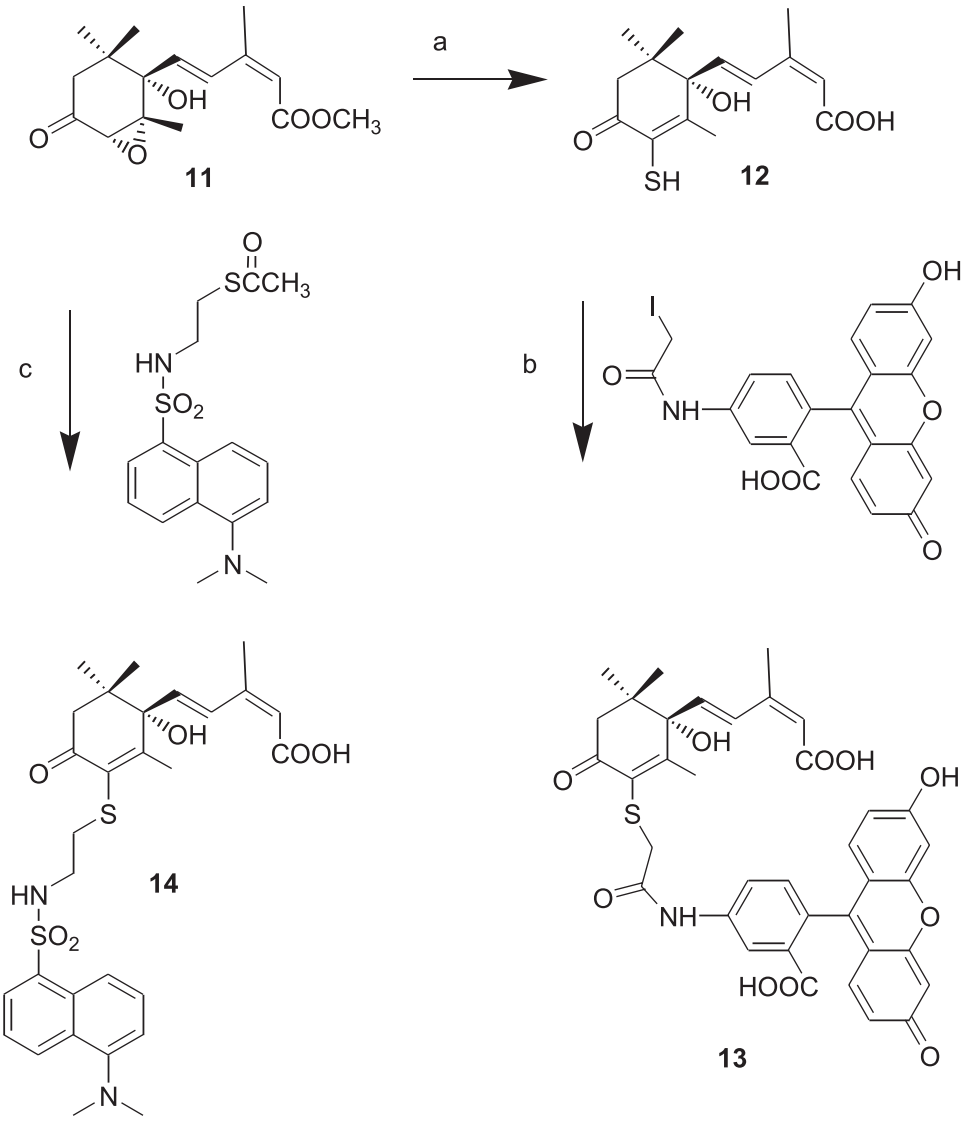
Scheme 1. a, vinyl magnesium bromide; **b**, ozone; **c,** dansyl hydrazine and trichloroacetic acid; **d**, 10% potassium hydroxide in methanol; **e**, magnesium and 2-(6-bromohexoxy)-tetrahydro-2*H*-pyran; **f**, pyridinium *p*-toluenesulfonate; **g**, 10% potassium hydroxide in methanol; **h**, 3′-*O*-(4-benzoyl)-benzoyl imidazolide.

of the 3′-dansyl-ABA compound in the 10^{-6} – 2×10^{-6} M range. Although the dependence of the spectra and emission quantum yields on the polarity of the surrounding medium might be exploited to educe some information about the nature of the ABA binding site, the temporal fluorescence behaviour of both the 3′- and the 8′-derivatives proved to be complex, with the excited state fluorescence decays exhibiting multiple-exponential character. This behaviour is unlike those of other dansyl derivatives which are known to exhibit single-exponential fluorescence decay functions. The reasons for this behaviour were not explored, but it was concluded that these derivatives were not altogether suitable for use as fluorescent probes and they were not further investigated.

Preliminary experiments showed that the 3′-substituted fluorescein derivative suffered from none of the shortcomings of the dansyl derivatives, and this compound was therefore subjected to a detailed photophysical examination. The emission and fluorescence excitation spectra of the 3′-substituted fluorescein derivative as a function of pH are shown in Fig. 2. These spectra suggest that this compound behaves much like fluorescein itself which is known to exhibit multiple prototropic equilibria in aqueous solution. To aid in the analysis, the spectroscopy and photophysics of the fluorescein-ABA derivative were examined in several different pH ranges.



(*i*) 11.7 = pH = 6.7

In this pH range, the absorption, corrected fluorescence excitation, and emission spectra of the fluorescein-labelled compound (Fig. 2A) are all independent of pH. In addition, the corrected fluorescence excitation spectra are identical with the absorption spectra (λ_{max} = 492 nm) throughout the near UV-vis range, the emission spectra (λ_{max} = 517 nm) are independent of excitation wavelength, and the excitation spectra are independent of emission wavelength. The temporal fluorescence decay profiles (Fig. 3A) are well-represented by a single exponential decay function with an average lifetime of $\tau = 4.30 \pm 0.04$ ns, independent of pH in this range. The quantum yield of fluorescence is $\phi_f = 0.89 \pm 0.04$, also independent of pH in this range. The compound is stable in aqueous base up to at least pH 12.

These observations all lead to the conclusion that, in this pH range, a single chemical species is responsible for the absorption and that its excitation yields a single emitting species. By analogy with the spectra, lifetimes and quantum yields (Tables 1 and 2) of fluorescein itself (16, 17), the

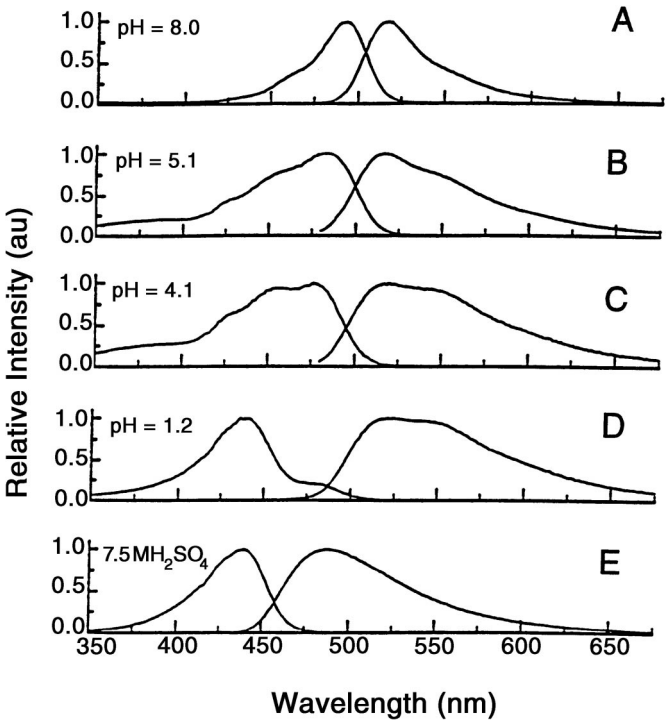
Scheme 2. a, sodium hydride, thiol acetic acid; **b**, iodoacetamidofluorescein; **c**, 1 M sodium hydroxide.

absorber and emitter in this pH range are assigned to the ground (S_0) and lowest excited singlet (S_1) states of the dianion of the fluorophore. Fluorescein itself has ground state pK_a values (16) of 2.08, 4.31, and 6.43, corresponding to the equilibria shown in Scheme 3, and therefore exists as the dianion in this pH range. ABA itself, with pK_a = 4.8 (carboxyl dissociation (1)), exists as the monoanion in this pH range, but the state of ionization of the ABA moiety has no significant effect on the spectra and photophysical properties of the fluorophor. These observations suggest that there is little interaction between the ABA and fluorescein moieties in the 3′-tethered compound.

The above photophysical data may be used to calculate the radiative rate constant, k_r, and the sum of the rate constants, Σk_{nr}, of all nonradiative processes by which the fluorescent S_1 state of the dianion of the fluorophore relaxes to the ground state. Using the well-known (18) relationships $k_r = \phi_f/\tau$ and $\Sigma k_{nr} = (1 - \phi_f)/\tau$, values of $k_r = (2.1 \pm 0.1) \times 10^8$ s^{-1} and $\Sigma k_{nr} = (2.6 \pm 0.1) \times 10^7$ s^{-1} are calculated when the average values of ϕ_f and τ in the range $11.7 \geq pH \geq 6.7$ are employed. These values are very similar to $k_r = 2.3 \times 10^8$ s^{-1} and $\Sigma k_{nr} = 1.7 \times 10^7$ s^{-1} which may be calculated for the S_1 state of the dianion of fluorescein itself using the reported values (14) of $\phi_f = 0.93$ and $\tau = 4.1$ ns.



(*ii*) 6 ≥ pH ≥ 5

In fluorescein itself, pK_3 = 6.43 for the ground state prototropic equilibrium between the monoanion and the dianion in aqueous solution at room temperature, and the monoanion reaches its maximum concentration at pH ≈ 5 (16). For the 3′-tethered fluorescein derivative of ABA, evidence of significant amounts of fluorescent monoanion is found at pH < 6, and changes in both the spectra and excited state decay parameters are readily observed in the 6 ≥ pH ≥ 5 range (cf. Fig. 1). The absorption and corrected fluorescence excitation spectra decrease in intensity with decreasing pH at constant solute concentration and their λ_{max} shift to lower wavelengths, whereas the emission spectra broaden and a shoulder at ca. 560 nm becomes more prominent. The overall quantum yield of fluorescence drops from 0.89 at higher pH to ca. 0.3 in this range.

In this pH range, the temporal fluorescence profiles are best described by double exponential decay functions

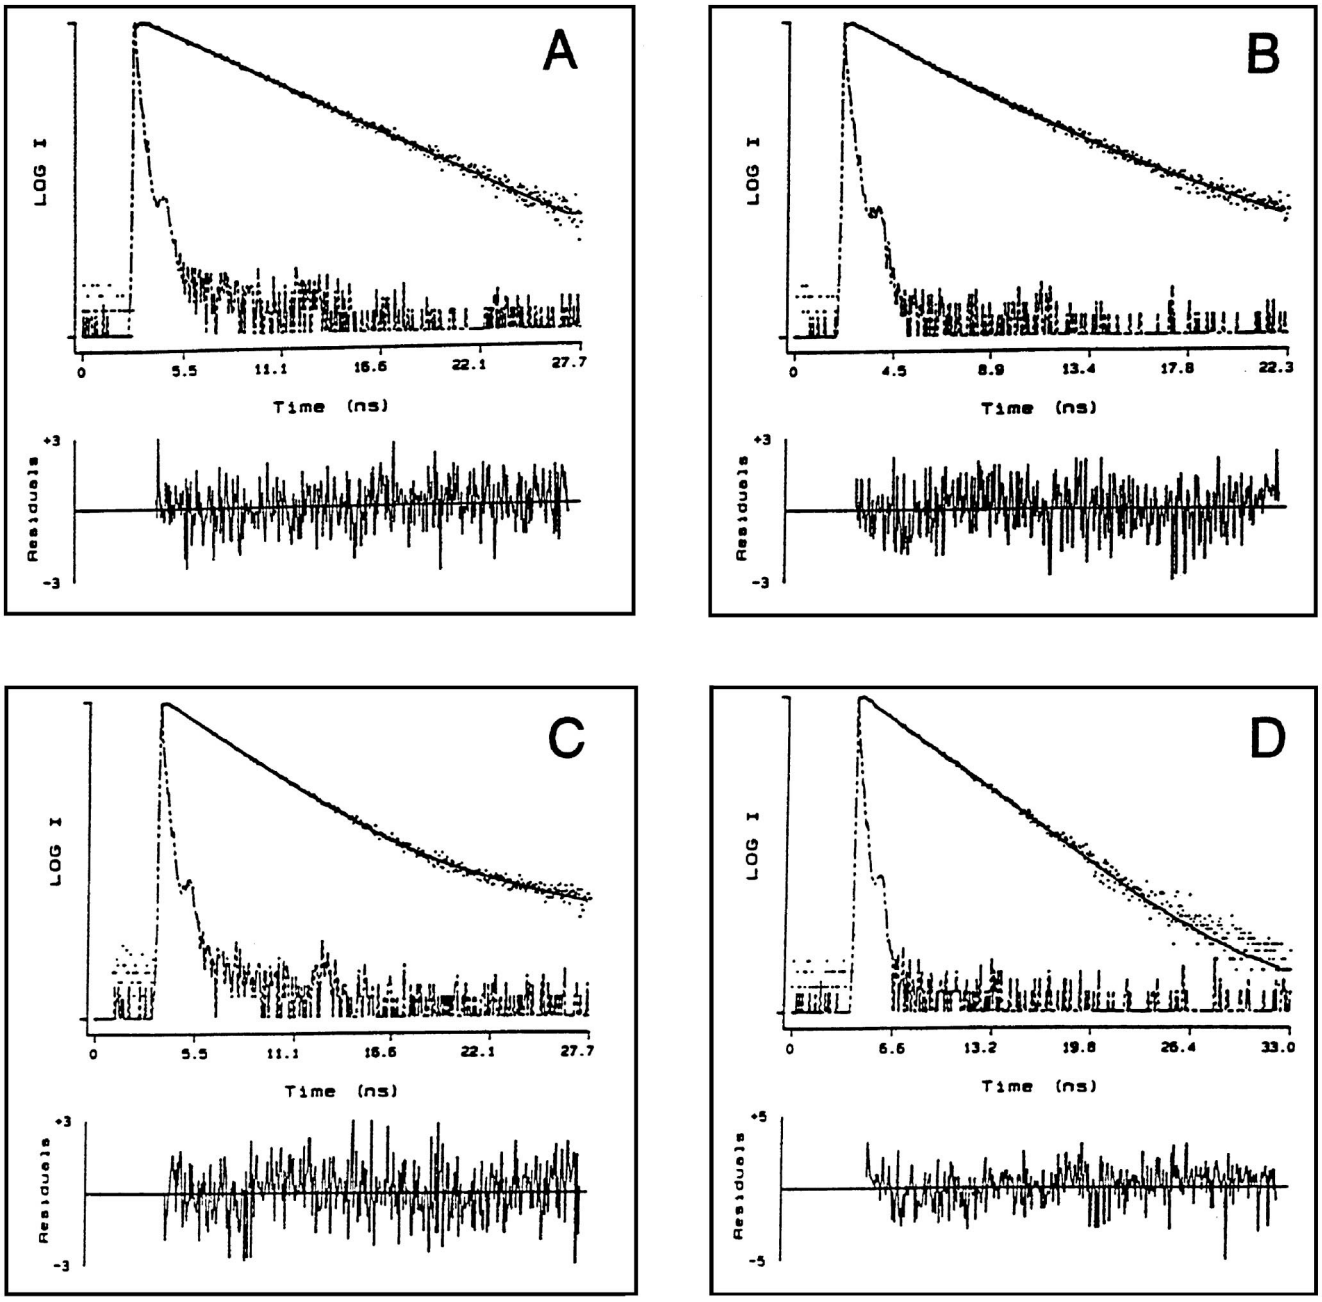
Fig. 2. Corrected emission and emission–excitation spectra of the 3′-tethered fluorescein derivative of ABA as a function of pH. A, region (*i*) pH = 8.0; B, region (*ii*) pH = 5.1; C, region (*iii*) pH = 4.2; D, region (*iv*), pH = 1.2; E, region (*v*), 7.5 M H_2SO_4.

(Fig. 3B), $I(t) = a_1 \exp(-t/\tau_1) + a_2 \exp(-t/\tau_2)$, in which the two emitters have average lifetimes of 4.32 ± 0.04 ns and 2.19 ± 0.02 ns. The fraction of the emission due to the jth emitter can be obtained from the relationship $F_j = a_j\tau_j/\Sigma a_i\tau_i$. Analysis of the temporal fluorescence data shows that the fraction of the emission due to the longer-lived emitter decreases and the fraction due to the shorter-lived emitter increases with decreasing pH, Table 2. The fraction of the emission from the shorter-lived species also increases slightly with increasing emission wavelength at fixed pH (Table 2), consistent with the shorter-lived species having a red-shifted emission spectrum compared with that of the longer-lived species.

It is reasonable to assign the longer-lived species which has an emission spectrum shaded more to the blue to the dianion of the fluorescein moiety in its S_1 state, and to assign the shorter-lived species to the monoanion of the fluorophore, consistent with its more red-shaded emission spectrum. The lifetime of the longer-lived species is identical to that measured for the excited dianion in the higher pH region. A lifetime of approximately 3 ns has been measured for the monoanion of fluorescein itself using a modulated fluorescence excitation technique (16). The lifetime of the monoanion of the fluorescein–ABA compound obtained in the 6 ≥ pH ≥ 5 range is 2.19 ns, which is similar to the lifetime of the monoanion of fluorescein itself at similar pH.

(*iii*) 4.1 ≥ pH ≥ 2.7



In this region the absorption and corrected emission–excitation spectra are pH sensitive but the emission spectra are not (Fig. 2C). Two features, one at ca. 475 nm and another, some 25–35 nm further to the blue, are prominent in the visible portion of the absorption and emission–excitation spectra. The feature at ca. 475 nm does not change position with decreasing pH, but the feature immediately to the blue increases in relative intensity and shifts to shorter wavelengths in this pH range. The emission spectrum exhibits two features, a maximum at 519 nm and a shoulder at ca. 550 nm whose relative intensities are independent of pH and excitation wavelength at pH = 3.4 (vide infra). The temporal fluorescence decay profile is complex, but is adequately modeled by a triple exponential function, as exemplified by Fig. 3C. The component of intermediate lifetime dominates the distribution of emitting species ($F \geq 0.85$, independent of pH), as shown in Table 2.

Fluorescein itself exhibits $pK_2 = 4.31$ and $pK_1 = 2.08$, and neutral species dominate the ground state equilibria in the 4 ≥ pH ≥ 3 region (16). The neutral species can exist in *p*-quinoid, lactone, and zwitterionic forms, with their total reaching a maximum mol fraction at ca. pH = 3.5. A similar distribution of species is expected in the 3′-tethered fluorescein derivative of ABA, so that in the ground state at pH = 3.4 the total mol fraction of the neutral species is expected to be at least 0.7 (16). The change in the ground state distribution with pH thus accounts for the changes in the absorption and fluorescence excitation spectra of the 3′-tethered derivative in this region. In contrast, the emission spectrum is not pH sensitive for excitation at a fixed wavelength and is similar to the emission spectrum of the monoanion. This observation suggests that the dominant emitting species, the monoanion, is obtained by fast protolytic dissociation of one or more of the excited neutral species, as is found in fluorescein itself (16). This interpretation is consistent with the fluorescence lifetime data, in which the dominant emitting species ($F = 0.89$, independent of pH) has a lifetime of ca. 2.6 ns, a value which is not significantly different from the lifetime of the anion measured at higher pH where the decay is less complex.

Fluorescence decay measurements using excitation modulation and phase sensitive detection revealed only a single emitter with a lifetime of ca. 3 ns in aqueous fluorescein itself in this pH range (16). Thus, earlier work on fluorescein provides no clue to the assignment of the minor components in the three-component decay of the emission from the 3′-tethered fluorescein derivative of ABA. Nevertheless, it is reasonable to assign these minor components to emission from the excited states of two of the three forms of the neutral species which dominate the ground state equilibria in this pH range. Note that the minor components contribute no more than 15% of the total emission, according to the analysis of the lifetime data. Provided that the neutral species do not exhibit large quantum yields of fluorescence, and their emission spectra are not completely different from that of the dominant monoanionic emitter, emission from the minor species would be difficult to detect by spectroscopic means alone. Detailed studies of the photophysics of several rhodamine dyes in polar solvents (19, 20) suggest that the electrically neutral lactone and zwitterionic forms of those compounds, which are structurally similar to fluorescein, are both either weakly fluorescent or nonfluorescent. For example, in butyronitrile the excited state lifetimes of the zwitterion of rhodamine B are typically

Fig. 3. Temporal fluorescence decay profiles of the 3′-tethered fluorescein derivative of ABA as a function of pH. λ_{ex} = 310 nm. In each case the $\log_{10}$ of the total number of counts in each channel minus background (log *I*) is plotted against time in ns. The maximum number of counts in the peak channel is ca. 10^4 for the monoexponential decays and ca. 2×10^4 for the multiexponential decays. The dashed line is the instrument response function; the dots are the TCSPC data points; the solid line is the best fit of the trial decay function convoluted with the instrument response function. The bottom panel gives the distribution of weighted residuals between the data and the computed fit. A, region (*i*) pH = 11.7, τ = 4.26 ns, χ^2 = 1.00. B, region (*ii*), pH = 5.1, a_1 = 0.31, τ_1 = 4.49 ns, a_2 = 0.69, τ_2 = 2.30 ns, F_1 = 0.46, F_2 = 0.54, χ^2 = 1.05. C, region (*iii*), pH = 4.1, a_1 = 0.85, τ_1 = 2.58 ns, a_2 = 0.12, τ_2 = 0.74 ns, a_3 = 0.03, τ_3 = 8.00 ns, F_1 = 0.89, F_2 = 0.0.04, F_3 = 0.0.08, χ^2 = 1.16. D, region (*v*), 7.5 M H_2SO_4, τ = 3.35 ns, χ^2 = 1.08.

in the range of 0.1–0.7 ns, and are 5–10 ns for the lactone (19). If the neutral forms of fluorescein and rhodamine are similar, one might reasonably assign the shortest-lived ($\tau \approx$ 0.7 ns), least abundant (F = 0.04) component in the triple-exponential decay of the fluorescein–ABA compound at pH = 3.4 to the excited state of the zwitterion, and the longest-lived ($\tau \approx$ 8–10 ns) component (with F = 0.08) to the excited lactone.

(*iv*) 2.2 ≥ pH ≥ ca. 0

The absorption and emission–excitation spectra are pH sensitive in this region with the feature at ca. 475 nm

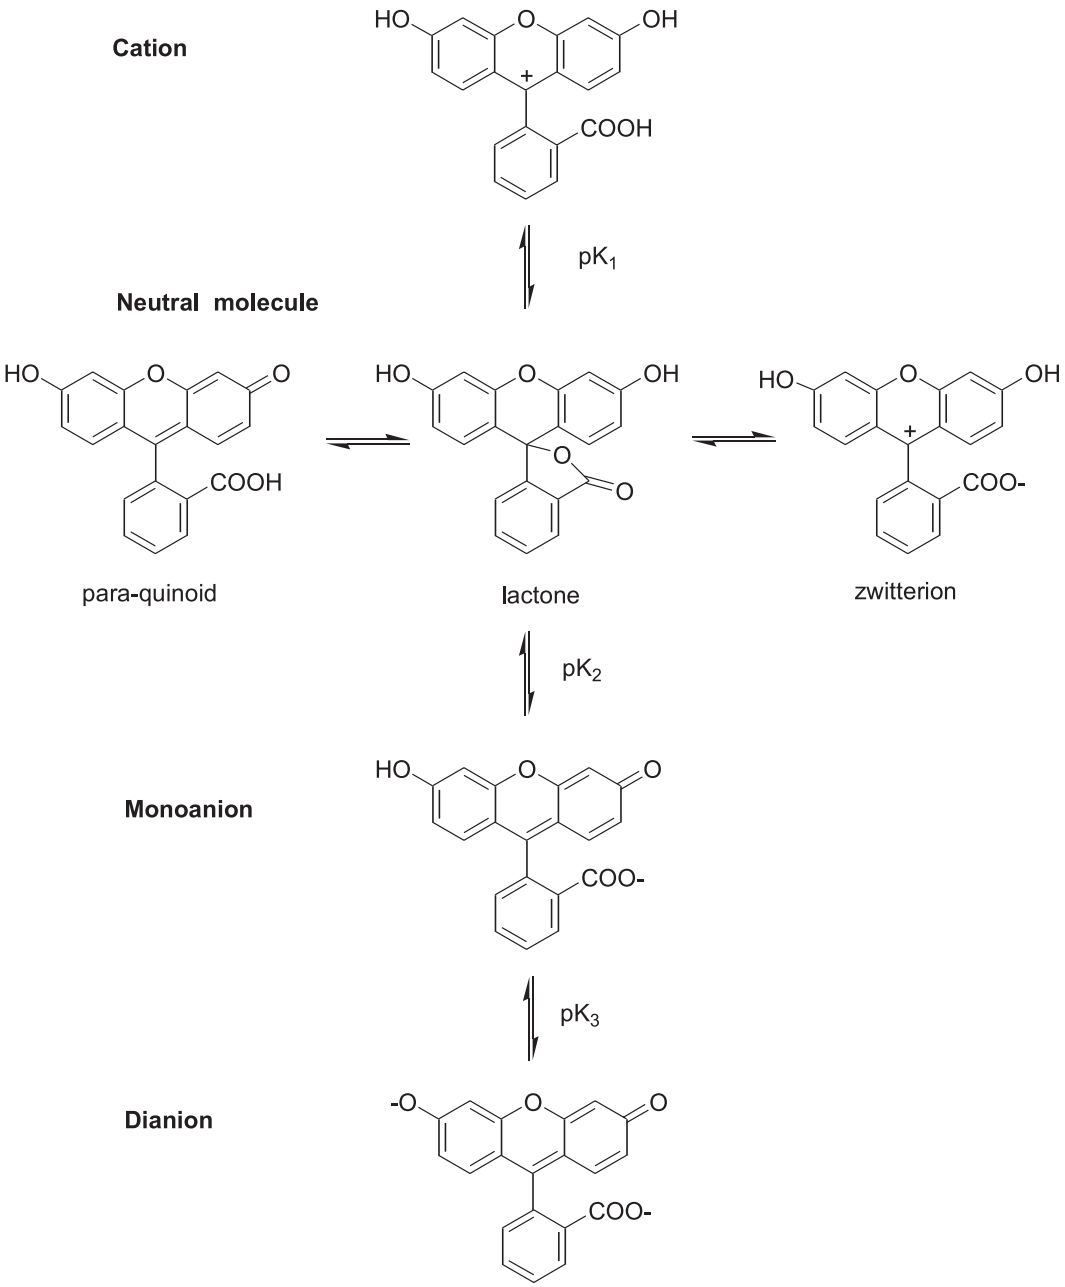
disappearing at pH ≤ 1.2 (Fig. 2), but the emission spectrum remains approximately independent of pH and similar to those seen in the intermediate pH ranges and attributed to the excited monoanion. The temporal fluorescence profiles are very complex in this region and can only be modeled if four or more components are summed in the fitting function. We did not attempt to extract information from the spectra and decay curves obtained in this pH range, and can only state that multiple ground and excited state prototropic equilibria are the sources of the complexity.

(*v*) 7.5 M aqueous H_2SO_4

The spectra and temporal decays of the 3′-tethered fluorescein ABA derivative are very simple in strongly acid media. The absorption and corrected fluorescence excitation spectra are identical in the visible region of the spectrum and consist of a single, unstructured feature with a maximum at 439 nm. The emission spectrum is a good mirror image of the absorption spectrum and exhibits a maximum at 488 nm (Fig. 2E). The fluorescence decay profile is well-described by a single-exponential decay function with τ = 3.36 ± 0.03 ns, independent of emission wavelength (Fig. 3D and Table 2). The fluorescence quantum yield is 0.18 ± 0.09, a value which is identical with that obtained for fluorescein itself in 10 M HCl (17).

The simplest interpretation of these data is that the absorption in the visible is due exclusively to the ground state of the cation of the fluorophore, and that the emission is exclusively from the corresponding excited cation. The most likely structure of such a cation is one in which the keto group of the fluorescein moiety is protonated and the molecule exists primarily in a resonance form in which the positive charge is centered on C-9 (cf. Scheme 3). Using the measured quantum yield and lifetime data allows the calculation of values of $k_r = (5.4 \pm 0.3) \times 10^7$ s^{-1} and $\Sigma k_{nr} = (2.4 \pm 0.1) \times 10^8$ s^{-1}, the decay constants of the excited cation.



To ensure that the emitting species was the tethered fluorescein–ABA compound and not protonated fluorescein resulting from its hydrolysis, the spectra of fluorescein itself were measured in 7.5 M aqueous H_2SO_4 and compared with those reported above. The spectra of fluorescein and the ABA–fluorecein derivative are similar in this medium, but not identical; both the emission and excitation spectra are shifted about 4 nm to the red in the tethered compound relative to that of fluorescein itself. In addition, the spectra of the monoanion of the tethered compound could be recovered by neutralizing the sulfuric acid solution with base to pH 3–4, demonstrating that significant hydrolysis did not occur over the course of an experiment (ca. 30 min).

Conclusions

Several potentially useful derivatives of ABA have been prepared and spectroscopically characterized. One of them, a 3′-tethered fluorescein derivative, has been subjected to a full photophysical examination and exhibits properties which make it suitable for binding studies. The compound is soluble in aqueous solution over a wide range of pH. Little interaction between the ABA and the fluorescein moieties is observed spectroscopically in the tethered compound. At pH > 6.7 the system behaves in a particularly simple fashion, with only one species, the dianion, present in significant quantity in both the ground and excited states. The quantum yield of fluorescence is high (0.89) and the fluorescence follows a monoexponential

Scheme 3. Prototropic equilibria of fluorescein in aqueous solution.

temporal decay profile with τ = 4.30 ns. This compound and perhaps others with fluorophores tethered at the 3′ position of ABA would appear to be suitable for hormone binding studies using both time resolved and steady state fluorescence and fluorescence depolarization methods. The fluorescein derivative may be particularly useful because its spectroscopic and temporal decay characteristics vary with pH, and in principle it can therefore be employed to determine the local pH at the ABA binding site in vivo (21).

The 8′-tethered dansyl derivative of ABA could possibly serve as an indicator of binding site polarity, but is not well-suited to quantitatve photophysical studies based on its complex fluorescence decay. The 8′-tethered benzophenone derivative might be useful for photoaffinity labelling if its poor solubility in aqueous media is not a limiting factor.

Experimental section

Synthesis

General

Mps are uncorrected. IR spectra were recorded using KBr pellets on a Perkin–Elmer Paragon 1000. Proton nuclear magnetic resonance (^{1}H NMR) were recorded on a Bruker AMX 500 MHz spectrometer. Unless otherwise stated, $CDCl_3$ was used as solvent in all NMR experiments with $CHCl_3$ as a reference. Chemical shifts (δ) and coupling constants (J) are reported as if they are first order. Low (LRMS) and high (HRMS) resolution mass spectra were recorded in either the electron impact (EI) mode, the chemical ionization (CI) mode, or fast atom bombardment (FAB) mode on a VG

70–250SEQ double-focusing hybrid spectrometer with a Digital PDP 11/73 data system. Mass spectral data are reported in mass to charge units (*m*/*z*).

Flash column chromatography was performed using Merck silica gel 60 (230–400 mesh). Merck silica gel 60 F254 plates (0.2 mm) with aluminum sheet backing were used in analytical TLC. UV active materials were detected under a UV lamp. The plates were then dipped into a solution of phosphomolybdic acid and heated on a hot plate to visualize the spots.

The solvent tetrahydrofuran (THF) was dried by distillation from sodium and benzophenone. Unless otherwise indicated, all reactions were conducted under an atmosphere of dry argon.

Preparation of the 8′-Dansylhydrazone Derivative of ABA (6)

8′-Aldehyde ABA Me ester (4)

Ozone was passed through a solution of Sudan Red 7B (1.4 mL, 0.03% in ethanol) and 8′-methylene ABA Me ester **3** (994 mg, 3.43 mmol, ref. (10)) in ethanol (20 mL) cooled to –78°C for 5 min. Argon was then bubbled through the solution to remove the excess ozone and dimethyl sulphide (2.5 mL) was added. The cooling bath was removed and the mixture was allowed to stir at room temperature for 2 h. The solution was concentrated, and the residue was purified by column chromatography (20% EtOAc in hexane) to provide 434 mg (44%) recovered olefin **3** and 321 mg (32%) of aldehyde **4** (57% based on recovered starting material), mp 159–161.5°C (EtOAc–hexane). IR ν_{max} (cm^{-1}): 3393 (OH), 1715 (CO), 1653 (C=C). ^{1}H NMR δ: 9.58 (s, CHO, 1H), 7.86 (d, *J* = 16.0 Hz, H-4, 1H), 5.95 (br.s, H-3′, 1H), 5.91 (d, *J* = 16.0 Hz, H-5, 1H), 5.76 (br.s, H-2, 1H), 3.68 (s, COOMe, 3H), 2.73 (d, *J* = 18.0 Hz, H-5′, 1H), 2.53 (d, *J* = 18.0 Hz, H-5′, 1H), 1.98 (d, *J* = 1.1 Hz, 6-CH_3 or 7′-CH_3, 3H), 1.98 (d, *J* = 1.3 Hz, 6-CH_3 or 7′-CH_3, 3H), 1.19 (s, 9′-CH_3, 3H). LRFABMS (*m*/*z*) (rel. int.): 293 $[M+1]^+$ (23), 134 (100). HRFABMS (*m*/*z*) $C_{16}H_{20+1}O_5$ requires: 293.1389 $[M+1]^+$; found: 293.1394 $[M+1]^+$.

8′-Dansylhydrazone ABA Me ester (5)

A solution of dansylhydrazine (49 mg, 0.184 mmol) and aldehyde **4** (54 mg, 0.184 mmol) in ethanol and trichloroacetic acid (95:5, 1.5 mL) was heated at 75°C for 10 min. The mixture was cooled, concentrated, and the residue was purified by column chromatography (50% EtOAc in hexane) to provide 89 mg (90%) of hydrazone **5**, mp 94–98°C (EtOAc–hexane). IR ν_{max} (cm^{-1}): 3486 (OH), 3201, 1712 (CO), 1659 (C=C). ^{1}H NMR δ: 8.59 (d, *J* = 8.5 Hz, 1H), 8.28 (dd, *J* = 7.3, 1.2 Hz, 1H), 8.17 (d, *J* = 8.7 Hz, 1H), 7.94 (s, NH, 1H), 7.69 (d, *J* = 16.0 Hz, H-4, 1H), 7.56 (m, 2H), 7.18 (d, *J* = 7.5 Hz, 1H), 7.05 (s, H-8′, 1H), 5.82 (d, *J* = 16.0 Hz, H-5, 1H), 5.69 (br.s, H-3′, 1H), 5.37 (d, *J* = 0.9 Hz, H-2, 1H), 3.66 (s, COOMe, 3H), 2.89 (s, NMe_2, 6H), 2.35 (br.s, H-5′, 2H), 1.91 (d, *J* = 1.2 Hz, 6-CH_3, 3H), 1.53 (d, *J* = 1.3 Hz, 7′-CH_3, 3H), 1.01 (s, 9′-CH_3, 3H). LRFABMS (*m*/*z*) (rel. int.): 540 $[M+1]^+$ (32), 171 (100). HRFABMS (*m*/*z*) $C_{28}H_{33+1}N_3O_6S$ requires: 540.2168 $[M+1]^+$; found: 540.2204 $[M+1]^+$.

8′-Dansylhydrazone ABA (6)

10% KOH (16 mL) was added to a solution of hydrazone **3** (42 mg, 0.078 mmol) in methanol (4 mL) at room temperature and the mixture was stirred overnight. The solution was extracted with EtOAc and discarded, and the remaining aqueous layer was carefully acidified with 10% HCl to pH 3. After stirring for half an hour, the aqueous mixture was extracted several times with Et_2O. The organic layers were combined, washed once with brine, and were dried (Na_2SO_4). The mixture was concentrated to provide 26 mg (64%) of dansylhydrazone **6**, mp 118–121°C (EtOAc–hexane). IR ν_{max} (cm^{-1}): 3462, 3201, 1706 (CO), 1651 (C=C), 1162. ^{1}H NMR δ: 8.56 (d, *J* = 8.6 Hz, 1H), 8.23 (m, 2H), 7.69 (d, *J* = 16.1 Hz, H-4, 1H), 7.42 (m, 2H), 7.19 (s, H-8′, 1H), 7.13 (d, *J* = 7.5 Hz, 1H), 5.89 (d, *J* = 16.1 Hz, H-5, 1H), 5.71 (br.s, H-3′, 1H), 5.41 (br.s, H-2, 1H), 2.87 (s, NMe_2, 6H), 2.41 (d, *J* = 17.6 Hz, H-5′, 1H), 2.33 (d, *J* = 17.6 Hz, H-5′, 1H), 1.97 (s, 6-CH_3, 3H), 1.54 (s, 7′-CH_3, 3H), 1.03 (s, 9′-CH_3, 3H). LRFABMS (*m*/*z*) (rel. int.): 526 $[M+1]^+$ (92), 171 (100). HRFABMS (*m*/*z*) $C_{27}H_{31+1}N_3O_6S$ requires: 526.2011 $[M+1]^+$; found: 526.2012 $[M+1]^+$.

Preparation of the 8′-benzophenone derivative of ABA (10)

THP ABA derivative 7

The Grignard reagent was prepared in situ by reacting magnesium (316 mg, 15.0 mmol) and 2-(6-bromohexoxy)tetrahydro-2*H*-pyran (1.76 mL, 8.0 mmol) in THF (15 mL) at room temperature for 2 h. The mixture was then cooled to –78°C and a solution of dienoic ester **2** (417 mg, 1.6 mmol) in THF (40 mL) was added via syringe. After stirring at –78°C for 10 min, the reaction vessel was put in the freezer (–20°C) overnight. The mixture was quenched with saturated NH_4Cl and extracted with ether (×3). The organic layers were combined, washed once with brine, were dried (Na_2SO_4), concentrated, and the residue was purified by column chromatography (25% EtOAc in hexane) to provide 494 mg (69%) of compound **7**, mp 87–89°C (hexane). IR ν_{max} (cm^{-1}): 3481 (OH), 1717 (CO), 1653 (C=C). ^{1}H NMR δ: 7.85 (d, *J* = 16.1 Hz, H-4, 1H), 6.14 (d, *J* = 16.1 Hz, H-5, 1H), 5.94 (br.s, H-2 or H-3′, 1H), 5.74 (br.s, H-2 or H-3′, 1H), 4.54 (m, 1H), 3.84 (m, 1H), 3.70 (m, 1H), 3.68 (s, COOMe, 3H), 3.49 (m, 1H), 3.34 (m,1H), 2.43 (d, *J* = 17.3 Hz, H-5′, 1H), 2.32 (d, *J* = 17.3 Hz, H-5′, 1H), 1.99 (d, *J* = 0.9 Hz, 6-CH_3, 3H), 1.90 (d, *J* = 7′-CH_3, 3H), 1.80 (m, 1H), 1.69 (m, 1H), 1.56–1.20 (m, 14H), 0.95 (s, 9′-CH_3, 3H). LRESMS (*m*/*z*) (rel. int.): 449 $[M+1]^+$ (90), 366 (78), 365 (100). HRFABMS (*m*/*z*)$C_{26}H_{40}O_6$ requires: 448.2825 $[M]^+$; found: 448.2826 $[M]^+$.

Alcohol 8

A solution of THP ether **7** (235 mg, 0.524 mmol) and pyridinium *p*-toluenesulfonate (13 mg, 0.052 mmol) in EtOH (15 mL) was heated at 60°C for 3 h. The solvent was removed and the residue was purified by column chromatography (33% hexane in EtOAc) to provide 190 mg (99%) of alcohol **8**, mp 126–129°C (hexane). IR ν_{max} (cm^{-1}): 3480 (OH), 1716 (CO), 1653 (C=C). ^{1}H NMR δ: 7.84 (d, *J* = 16.0 Hz, H-4, 1H), 6.14 (d, *J* = 16.0 Hz, H-5, 1H), 5.93

(br.s, H-2 or H-3′, 1H), 5.73 (br.s, H-2 or H-3′), 3.67 (s, COOMe, 3H), 3.60 (t, J = 6.6 Hz, 2H), 2.43 (d, J = 17.1 Hz, H-5′, 1H), 2.32 (d, J = 17.1 Hz, H-5′, 1H), 1.99 (d, J = 1.1 Hz, 6-CH_3, 3H), 1.90 (d, J = 1.3 Hz, 7′-CH_3, 3H), 1.57–1.19 (m, 10H), 0.94 (s, 9′-CH_3). LRFABMS (*m*/*z*) (rel. int.): 365 $[M+1]^+$ (100), 85 (93). HRFABMS (*m*/*z*) $C_{21}H_{32}O_5$ requires: 365.2328 $[M+1]^+$; found: 365.2325 $[M+1]^+$.

*Hydroxy acid **9***

A solution of ester **8** (100 mg, 0.274 mmol) in MeOH (2 mL) and 10% KOH (2 mL) was stirred at 50°C for 1 h. Water was added and the mixture was extracted with EtOAc and discarded. The remaining aqueous layer was then acidified with 10% HCl to pH 3 and was extracted several times with EtOAc. The organic layers were combined, washed with water, brine, and were dried (Na_2SO_4). The solvent was removed and the residue was purified by column chromatography (50% acetone in hexane) to give 66 mg (69%) of the acid **9**. IR ν_{max} (cm^{-1}): 3308 (OH), 1704 (CO). ^1H NMR δ: 7.77 (d, J = 16.1 Hz, H-4, 1H), 6.15 (d, J = 16.1 Hz, H-5, 1H), 5.96 (br.s, H-2 or H-3′, 1H), 5.75 (br.s, H-2 or H-3′), 3.60 (t, J = 6.5 Hz, 2H), 2.44 (d, J = 17.2 Hz, H-5′, 1H), 2.34 (d, J = 17.2 Hz, H-5′, 1H), 2.03 (d, J = 1.2 Hz, 6-CH_3, 3H), 1.90 (d, J = 1.0 Hz, 7′-CH_3, 3H), 1.58–1.17 (m, 10H), 0.96 (s, 9′-CH_3). LRFABMS (*m*/*z*) (rel. int.): 351 $[M+1]^+$ (100), 102 (64). HRFABMS (*m*/*z*) $C_{20}H_{30}O_5$ requires: 351.2171 $[M+1]^+$; found: 351.2150 $[M+1]^+$.

*Benzophenone coupling (**10**)*

A solution of acid **9** (16.0 mg, 0.046 mmol), Et_3N (0.13 mL, 0.914 mmol), and 3′-*O*-(4-benzoyl)benzoyl imidazolide (22) (44.0 mg, 0.138 mmol) in CH_2Cl_2 (1 mL) was stirred at room temperature overnight. The mixture was then quenched with 5% HCl. The organic layer was then separated, and washed with brine, was dried (Na_2SO_4) and was concentrated. Purification of the residue by preparative thin layer chromatography (5% MeOH in CH_2Cl_2) provided 9.6 mg (38%) of the 8′-benzophenone ABA derivative **10**, mp 141–143°C (hexane). ^1H NMR δ: 8.12 (m, 2H), 7.80 (m, 5H), 7.60 (m, 1H), 7.48 (m, 2H), 6.16 (d, J = 16.0 Hz, H-5, 1H), 5.95 (br.s, H-2 or H-3′, 1H), 5.76 (br.s, H-2 or H-3′), 4.31 (t, J = 6.6 Hz, 2H), 2.44 (d, J = 17.3 Hz, H-5′, 1H), 2.34 (d, J = 17.3 Hz, H-5′, 1H), 2.03 (d, J = 0.9 Hz, 6-CH_3, 3H), 1.90 (d, J = 1.0 Hz, 7′-CH_3, 3H), 1.77–1.18 (m, 10H), 0.96 (s, 9′-CH_3). LRFABMS (*m*/*z*) (rel. int.): 558 $[M+1]^+$ (100), 102 (64). HRFABMS (*m*/*z*) $C_{34}H_{38}O_7$ requires: 559.2696 $[M+1]^+$; found: 559.2660 $[M+1]^+$.

Preparation of the 3′-*S*-acetamidofluorescein derivative of ABA (13)

NaH (60% in oil, 20 mg, 0.5 mmol) was added to a solution of 2′,3′-epoxy ABA **11** (100 mg, 0.357 mmol, ref. (12)) in THF (6 mL) at 0°C under nitrogen. Thiol acetic acid (5 drops, ca. 55 mg, 0.7 mmol) and a further portion of sodium hydride (60% in oil, 15 mg, 0.38 mmol) were then added and the reaction mixture was allowed to warm to room temperature. After stirring for an hour, a solution of 0.25 M NaOH (15 mL) was added and stirring continued under nitrogen for another hour. The resultant mixture was concentrated in vacuo to ca. 10 mL, water (25 mL) was added, and was washed with ether (2 × 15 mL). The ether washings were discarded and the aqueous layer was acidified with 1 M citric acid and extracted with EtOAc (3 × 20 mL). The organic extracts were combined, washed with brine, dried (Na_2SO_4), and were concentrated to afford 100 mg (95%) of 3′-thiol ABA **12**, which was used immediately in the next step. IR ν_{max} (cm^{-1}): 3369, 2924, 1671, 1599, 1246. ^1H NMR δ: 7.77 (d, J = 16 Hz, 1H), 6.11 (d, J = 16 Hz, 1H), 5.74 (s, 1H), 4.67 (s, 1H), 2.55 (d, J = 17 Hz, 1H), 2.50 (d, J = 17 Hz, 1H), 2.02 (s, 3H), 1.96 (s, 3H), 1.07 (s, 3H), 1.01 (s, 3H).

A solution of the crude thiol ABA **12** (100 mg, 0.33 mmol) and (iodoacetamido)-fluorescein (200 mg, 0.40 mmol) in MeOH (30 mL) was treated with 1 M NaOH (3 mL) at room temperature under nitrogen. After 2 days the mixture was concentrated in vacuo, and the residue was dissolved in water (100 mL), acidified with 1 M HCl, and was extracted with ethyl acetate (3 × 20 mL). The organic extracts were dried (Na_2SO_4), concentrated in vacuo, and the residue chromatographed (toluene–EtOAc–HOAc, 50:30:2) to afford 3′-*S*-acetamidofluorescein ABA **13** (113 mg, 50%) as a yellow glass. IR ν_{max} (cm^{-1}): 3417, 2922, 1734, 1384, 1113. ^1H NMR (CD_3OD) δ: 7.93 (d, J = 8.5 Hz, 1H), 7.85 (dd, J = 8.5, 1.7 Hz, 1H), 7.54 (d, J = 16.3 Hz, 1H), 7.45 (d, J = 1.7 Hz, 1H), 6.75 (m, 2H), 6.66 (m, 2H), 6.57 (m, 2H), 5.87 (d, J = 16.3 Hz, 1H), 4.89 (s, 1H), 3.57 (d, J = 14.4 Hz, 1H), 3.42 (d, J = 14.4 Hz, 1H), 2.48 (d, J = 16.6 Hz, 1H), 2.18 (d, J = 16.6 Hz, 1H), 2.17 (s, 3H), 1.76 (s, 3H), 0.95 (s, 3H), 0.93 (s, 3H). ESMS *m*/*z*: 301 (100), 684 $[M+1]^+$ (10). HREIMS (*m*/*z*) $C_{37}H_{34}NO_{10}S$ requires: 684.1903 $[M+1]^+$; found: 684.1885 $[M+1]^+$.

Preparation of the 3′-*S*-(2-ethyldansylamide) derivative of ABA

*5-(*N,N-*Dimethylamino)naphthalene-1-sulfon(2-hydroxyethyl)amide*

A solution of pyridine (3 mL) and ethanolamine (281 mg, 4.6 mmol) under N_2 was treated with dansyl chloride (500 mg, 1.9 mmol) and stirred for 17 h. Water (15 mL) was added and stirring continued for a further 1 h followed by extraction of the mixture with EtOAc (3 × 25 mL). The combined organic extract was washed with brine (2 × 75 mL), dried (Na_2SO_4), and concentrated in vacuo to afford the dansyl ethanolamide as a light green oil (545 mg, 100% based on dansyl chloride). The product was homogeneous by TLC (toluene–EtOAc–HOAc, 25:15:2), R_f ca. 0.30 and used without further purification. UV λ_{max} (nm): 217, 250, 335. IR ν_{max} (cm^{-1}): 3509, 3301, 2944, 2871, 2788, 1575, 1456, 1312, 1143, 1060, 940, 790. ^1H NMR ($CDCl_3$) δ: 8.51 (1H, d, J = 8.5 Hz), 8.24 (1H, d, J = 8.6 Hz), 8.21 (1H, d, J = 7.2 Hz), 7.52 (1H, t, J = 8.0 Hz), 7.49 (1H, t, J = 7.8 Hz), 7.15 (1H, d, J = 7.5 Hz), 5.68 (1H, bs), 3.59 (2H, t, J = 4.9 Hz), 3.00 (2H, t, J = 4.9 Hz), 2.86 (6H, s). MS (FIB) (*m*/*z*) (rel. int.): 295 $[MH]^+$ (100), 294 $[M]^+$ (70), 252 (5), 218 (7), 184 (10), 170 (70), 157 (11), 128 (7), 88 (15). HRMS (FIB) calcd. for $C_{14}H_{19}N_2O_3S_1$ $[MH]^+$: 295.1116; found: 295.1113.

*5-(*N,N-*Dimethylamino)naphthalene-1-sulfon(2-mesyloxyethyl)amide*

A solution of dansyl ethanolamide (320 mg, 1.1 mmol) in pyridine (5 mL) was treated with methanesulfonyl chloride

HRMS (FIB) calcd. for $C_{15}H_{21}N_2O_5S_2$ $[MH]^+$: 373.0892; found: 373.0922.

*5-(*N,N-*Dimethylamino)naphthalene-1-sulfon(2-acetothioethyl)amide*

A solution of the dansyl mesyloxyethylamide (149 mg, 0.40 mmol) and thiolacetic acid (57 μL, 0.80 mmol) in freshly distilled THF (5 mL) under N_2, was treated portionwise with sodium hydride mineral oil suspension (60%, 20 mg, 0.80 mmol). The reaction mixture was stirred for 22 h then treated with water (5 mL), made approximately neutral with 0.1 M HCl, and extracted with EtOAc (3 × 25 mL). The extract was dried (Na_2SO_4), concentrated in vacuo, and the residue purified by TLC on silica gel using toluene–EtOAc (90:10) to give the dansyl acetothioethylamide as a yellow oil (55.2 mg, 39%). UV λ_{max} (nm): 212, 328. IR ν_{max} (cm^{-1}): 3293, 2920, 2853, 1740, 1699, 1575, 1456, 1144, 946, 790. ^1H NMR ($CDCl_3$) δ: 8.52 (1H, d, *J* = 8.5 Hz), 8.22 (2H, d, *J* = 8.1 Hz), 7.55 (1H, t, *J* = 8.0 Hz), 7.50 (1H, t, *J* = 7.9 Hz), 7.17 (1H, d, *J* = 7.5 Hz), 4.98 (1H, t, *J* = 6 Hz), 3.08 (2H, q, *J* = 6.3 Hz), 2.87 (6H, s), 2.86 (2H, t, *J* = 6.6 Hz), 2.17 (3H, s). MS (FIB) *m*/*z* (rel. int.): 353 $[MH]^+$ (86), 252 $[M]^+$ (55), 321 (25), 311 (12), 301 (14), 295 (27), 285 (17), 177 (100). HRMS (FIB) calcd. for $C_{16}H_{21}N_2O_3S_2$ $[MH]^+$: 353.0994; found: 353.1002.

3′-ABA-thio(2-ethyldansylamide)

A solution of dansyl acetothioethylamide (59 mg, 0.17 mmol) in methanol (3 mL) under N_2 was treated with N_2-purged 1 M NaOH (1.5 mL). After 45 min ABA 3′-(-epoxide) (23) (50 mg, 0.17 mmol) dissolved in methanol (1 mL) was added dropwise over 2 h. The reaction was heated at 45°C for 1 h followed by stirring at ambient temperature for a further 19 h. Tartaric acid (225 mg) was added and stirring continued for a further 30 min. The resultant suspension was filtered to remove precipitated sodium bitartrate and the filtrate was concentrated in vacuo. The residue was purified via TLC on silica gel using EtOAc–hexane–HOAc (1:1:.025) to give the 3′-dansyl-linked ABA **14** (33 mg, 34%) as a yellow-green film. UV λ_{max} (nm): 216, 250, 327 (sh). IR ν_{max} (cm^{-1}): 3502, 3269, 2952, 1683, 1575, 1456, 1234, 1145. ^1H NMR ($CDCl_3$) δ: 8.49 (1H, d, *J* = 8 Hz), 8.26 (1H, d, *J* = 8.6 Hz), 8.17 (1H, d, *J* = 7.2 Hz), 7.62 (1H, d, *J* = 16 Hz, C-5), 7.51 (1H, t, *J* = 8.1 Hz), 7.46 (1H, t, *J* = 7.6 Hz), 7.14 (1H, d, *J* = 7.5 Hz), 6.08 (1H, d, *J* = 16 Hz, C-4), 6.01 (1H, bs), 5.73 (1H, s, C-2) 3.00 (2H, m), 2.84 (6H, s), 2.75 (2H, m), 2.46 (1H, d, *J* = 16 Hz, C-5′α or C-5′β), 2.32 (1H, d, *J* = 16 Hz, C-5′α or C-5′β), 2.09 (3H, s, C-6), 1.99 (3H, s). HRMS (FIB) calcd. for $C_{29}H_{37}N_2O_6S_2$ $[M]^+$: 573.2093; found: 573.2095.

Spectroscopy and photophysics

Materials

Water was purified by distillation and use of a Millipore filtration system and exhibited negligible fluorescence when excited at the excitation wavelengths used in this study. Fluorescein-labelled ABA dissolves well in water, but the dansyl and benzophenone derivatives are poorly soluble in pure water and were dissolved in either methanol or methanol–water solutions. The pH of aqueous solutions of the fluorescein-labelled derivative was adjusted using either sulfuric acid or aqueous NaOH.

Instrumentation

Absorption spectra were measured with either a Cary 118 or a Cary 1A UV-vis spectrophotometer. Emission and emission excitation spectra and fluorescence quantum yields were measured with a Spex Fluorolog 222 spectrofluorometer at a spectral resolution of 1.8 nm. All spectra were corrected for background and variations of the instrument response with wavelength.

Fluorescence lifetimes were measured by time correlated single photon counting (TCSPC) using a mode-locked, synchronously pumped, cavity-dumped argon ion-dye laser for excitation and a fast microchannel plate detection system both of which have been previously described (23, 24). In these experiments ca. 850 mW of average power in the mode-locked argon ion green line at 514.5 nm was used to synchronously pump either R6G or DCM in an extended-cavity dye-laser, the output of which was tuned with a three-plate Lyot filter and was cavity-dumped with an acousto-optic Bragg cell. For the fluorescein-labeled compound, the fundamental of the cavity-dumped R6G dye laser was frequency-doubled in KDP to obtain between 100–300 μW of cw average power for excitation at ca. 310 nm. For the dansyl derivative the DCM fundamental was frequency doubled to provide excitation wavelengths near 340 nm. The cavity dumper was operated at a repetition rate of 4 MHz and the excitation pulses in the fundamental had widths of 12 ps as measured by autocorrelation. The instrument response function of the detection system has a width of ca. 40 ps FWHM.

Methods

Fluorescence quantum yields were determined by the standard relative method using quinine sulfate in 0.5 M aqueous H_2SO_4 as a standard (ϕ_f = 0.55 in the excitation wavelength range employed (25)) and right angle excitation–emission geometry. In all quantum yield experiments the absorbances of both the sample and standard solutions were matched at a value of ca. 0.05, so that errors due to inner filter effects and spatially nonlinear absorption would be minimized. Because the sample and standard were both prepared

© 2000 NRC Canada

in aqueous solution, corrections for refractive index were unnecessary.

Excited state lifetimes were obtained by an iterative reconvolution process in which trial fluorescence decay functions were convoluted with the measured instrument response function and errors between the resulting synthesized temporal fluorescence decay profile and the measured one were minimized using a least-squares fitting procedure. The distribution of weighted residuals and the value of χ^2 were used as "goodness-of-fit" criteria. These procedures have been described in detail elsewhere (23).

All experiments were carried out at room temperature.

A solid-state ^{133}Cs nuclear magnetic resonance and X-ray crystallographic study of cesium complexes with macrocyclic ligands

Alan Wong, Simon Sham, Suning Wang, and Gang Wu

Abstract: We report solid-state NMR determination of the ^{133}Cs chemical shift anisotropy (CSA) for a series of cesium complexes with macrocyclic ligands. It was found that the isotropic ^{133}Cs chemical shifts are related to the number of oxygen atoms to which the Cs^+ ion is coordinated. The ^{133}Cs chemical shifts were found to correlate with average Cs—O distances. We also attempt to use the established correlation to deduce Cs^+ coordination environment for compounds with unknown structures. We also report the X-ray determination of the crystal structure for $Cs(DB18C6)_2SCN•1/2CH_3OH•1/2H_2O$. The compound crystallizes in monoclinic, a = 14.503(2), b = 15.152(3), c = 39.989(6) Å, β = 90.796(8)°, space group $P2_1/c$, Z = 8. There are two independent molecules in the asymmetric unit cell where each of the two Cs^+ ions is coordinated to two DB18C6 ligand molecules forming a sandwich-type structure.

Key words: solid state NMR, alkali metal, ^{133}Cs chemical shift, macrocyclic ligand, crystal structure.

Résumé : On a mesuré l'anisotropie du déplacement chimique du ^{133}Cs dans les spectres RMN à l'état solide d'une série de complexes du césium avec des ligands macrocycliques. On a trouvé que les déplacements chimiques isotropes du ^{133}Cs sont reliés au nombre d'atomes d'oxygène formant une coordination avec le Cs^+. On a trouvé qu'il existe une corrélation entre les déplacements chimiques du ^{133}Cs et les distances moyennes Cs—O. On a aussi essayé d'établir une corrélation qui permettrait de déduire l'environnement de coordination du Cs^+ dans des composés de structures inconnues. On a aussi déterminé la structure du $Cs(DB18C6)_2SCN•1/2CH_3OH•1/2H_2O$ par diffraction des rayons X. Les cristaux sont monocliniques, groupe d'espace $P2_1/c$, avec a = 14,503(2), b = 15,152(3) et c = 39,989(6) Å, β = 90,796(8)° et Z = 8. Il y a deux molécules indépendantes dans la maille élémentaire asymétrique dans laquelle chacun des deux ions Cs^+ est coordiné à deux molécules de ligand DB18C6 formant une structure de type sandwiche.

Mots clés : RMN à l'état solide, métal alcalin, déplacement chimique du ^{133}Cs, ligand macrocyclique, structure cristalline.

Introduction

Since Pedersen's (1) first synthesis of macrocyclic polyethers, a large number of acyclic, cyclic, and bicyclic crown ethers containing oxygen, nitrogen, and sulfur donor atoms have been prepared and extensively investigated (2). In the past 20 years, alkali metal nuclear magnetic resonance (NMR) spectroscopy has served as a major technique for studying the cation-binding properties of these macrocyclic complexes in solutions; however, relatively few solid-state alkali metal NMR studies were reported in the literature (3, 4). The advantage of solid-state metal NMR is that the alkali metal ions under observation are usually located in a well-defined coordination environment. In contrast, alkali metal ions often undergo rapid exchange between bound and free states in the liquid phase, resulting in averaged NMR parameters. Since a large number of alkali metal complexes have been characterized by X-ray diffraction studies, it is desirable to document NMR parameters for alkali metal ions in various ion-binding environments. In addition, solid-state NMR is capable of yielding the orientation dependence of NMR parameters. This information is usually unavailable from the solution NMR spectra because of the molecular tumbling motion.

Cesium-133 is perhaps the easiest alkali metal nuclide for NMR measurements because of its favorable nuclear properties: 100% natural abundance, I = 7/2, and a small quadrupole moment of $Q = -3 \times 10^{-31}$ m^2. There have been several recent reports on the determination of ^{133}Cs chemical shift anisotropy (CSA) in simple inorganic salts (5–10); however, relatively little is known about solid-state ^{133}Cs NMR data for cesium macrocyclic complexes, except for solid alkalides and electrides studied by Dye and co-workers (11–14). In this contribution, we report the determination of ^{133}Cs CSAs in a number of cesium macrocyclic compounds (Scheme 1). These complexes are used as models for establishing correlation between solid-state ^{133}Cs NMR parameters and Cs^+

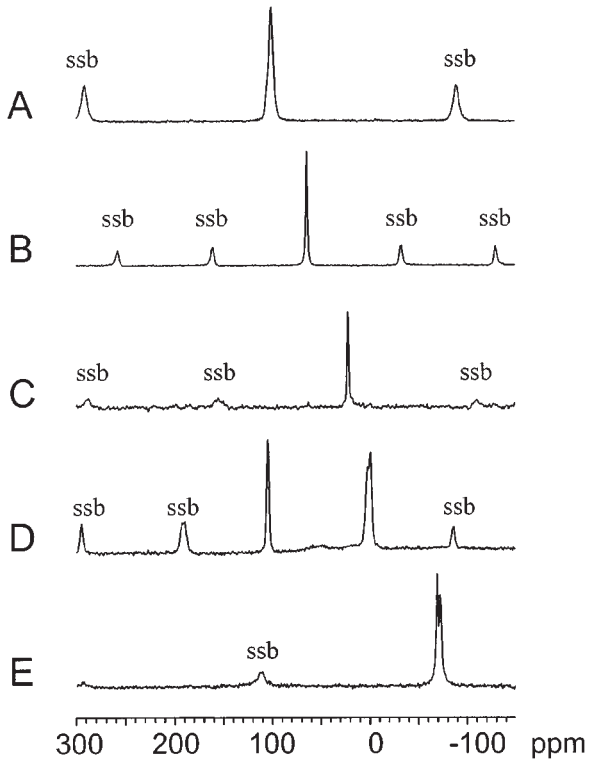
binding environment. We also report the crystal structure for $Cs(DB18C6)_2SCN$.

Experimental

Materials

Cesium thiocyanate, cesium chloride, and macrocyclic ligands were purchased from Aldrich and used without further purification. All complexes were prepared according to the literature methods (15). In general, ligand and cesium salt are mixed in a suitable molar ratio in various solvents (methanol, ethanol, or acetone) and crystallized at either room temperature or 5°C. The melting points of the compounds were consistent with the literature values: mp: 201–202°C for Cs(18C6)SCN, 191–193°C for $Cs(18C6)_2SCN$, 152–153°C for $Cs(DB18C6)_2SCN$, 99–100°C for Cs(C222)SCN, and 146–148°C for Cs(C22)SCN. Nonactin (purchased from Sigma) was mixed with CsSCN in a molar ratio of 1:1.5 in methanol. Gramicidin D [Dubos] was purchased from Sigma (80% gramicidin A, 6% gramicidin B, and 14% gramicidin C). Gramicidin A (25 mg/mL) was crystallized at 5°C from 50 mM solution of CsCl in methanol.

X-ray diffraction analyses



Large colorless crystals of $Cs(DB18C6)_2SCN$ were prepared according to the procedure of Pederson (15) and recrystallized twice from methanol. A crystal of size 0.2 × 0.5 × 0.4 mm was sealed in a glass capillary. The X-ray data were collected on a Siemens P4 single-crystal diffractometer with graphite-monochromated Mo Kα radiation, operated at 50 kV and 40 mA at 296 K. The data were collected over θ = 1.94–22.51°. Data were processed on a Pentium PC using Siemens SHELXTL software package (16) and corrected for Lorentz and polarization effects.

Solid-state ^{133}Cs NMR

Solid-state ^{133}Cs NMR spectra were obtained on two spectrometers: Tecmag Apollo-200 (4.7 T, 26.32 MHz for ^{133}Cs) and Bruker Avance – 500 (11.7 T, 65.59 MHz for ^{133}Cs). Typical MAS frequencies were 5–12.5 kHz with Bruker 4 mm MAS probes. In MAS and central-transition static experiments, a single pulse sequence was used with pulse width of 1 μs (approx. 30° for the central transition). For the satellite-transition static experiments, a Hahn echo sequence was used to avoid acoustic ringing from the probe. Recycle times of 10–30 s were used. All ^{133}Cs chemical shifts were referenced to 0.5 M CsCl (aq.), δ = 0 ppm, by setting the ^{133}Cs NMR signal of solid CsCl to δ = 223.2 ppm. Spectral simulation was performed with the WSOLIDS program provided by Drs. Klaus Eichele and Rod Wasylishen (Dalhousie University, Halifax, Nova Scotia, Canada).

Results and discussion

A. MAS ^{133}Cs NMR spectra

Solid-state ^{133}Cs NMR spectra obtained under the MAS condition are shown in Fig. 1. Since the ^{133}Cs nucleus has a very small quadrupole moment, no second-order quadrupolar broadening was observed at 11.75 T for the compounds studied in the present work. As shown in Fig. 1, each of the ^{133}Cs MAS spectra exhibits sharp isotropic peaks flanked by a large number of spinning side-bands due to the first-order quadrupole interaction. The Cs^+ ion in Cs(C22)SCN exhibits the least chemical shielding, δ_{iso} = 100 ppm. The isotropic ^{133}Cs chemical shift for Cs(18C6)SCN is 64 ppm, which is quite different from the value of 73 ppm reported by Dye and coworkers (11). The reason for this discrepancy is unclear at this time. For the sandwich-type complex, Cs(15C5)$_2$SCN, the Cs^+ ion shows more shielded environment, δ_{iso} = 22 ppm. This chemical shift value is very similar to those found in alkalides, Cs(15C5)$_2M^-$ (M = Na, K, Rb) (12), suggesting that the Cs^+ cation is well shielded by the two 15C5 ligands. For the Cs^+–nonactin complex, the isotropic peak appears at 4 ppm and exhibits some broadening or splitting. Note that the sharp signal at 110 ppm is due to the excessive CsSCN in the sample. The ^{133}Cs NMR experiments performed at a different magnetic field (4.7 T) indicated that the broadening or splitting arises from a chemical shift distribution rather than from the second-order quadrupole interaction. Since the sample was prepared by lyophilizing a mixture containing excessive CsSCN ligand, it is of poorly crystalline nature. Consequently, the observed broadening or slitting may be attributed to either lack of crystallinity or presence of polymorphs. The ^{133}Cs MAS spectrum of Cs(18C6)$_2$SCN exhibits a sharp peak at –72 ppm, which is dramatically different from that for Cs(18C6)SCN, 64 ppm. The structure of Cs(18C6)$_2$SCN was speculated by Pedersen (15) to have a sandwich-type structure. The observation of a ^{133}Cs chemical shift of –72 ppm strongly supports the sandwich structure. Two sharp peaks were observed in the multiple-field ^{133}Cs MAS spectra of Cs(DB18C6)$_2$SCN, δ_{iso} = –70 and –72 ppm, indicating the presence of two crystallographically distinct Cs sites. Since the crystal structure of Cs(DB18C6)$_2$SCN has not been reported in the literature, we decided to carry out an X-ray single crystal diffraction study for this compound.

B. Crystal structure of Cs(DB18C6)$_2$SCN

The crystal structure of Cs(DB18C6)$_2$SCN indicated the presence of two solvent molecules, thus the complete formula is Cs(DB18C6)$_2$SCN•1/2CH_3OH•1/2H_2O. The crystal data are summarized in Table 1. The atomic coordinates with their estimated standard deviations are given in Table 2. Selected bond lengths and bond angles are listed in Table 3. As shown in Fig. 2, there are two molecules in the asymmetric unit cell, giving rise to two crystallographically inequivalent Cs sites. This finding is consistent with the observation of two chemical shifts in the ^{133}Cs MAS spectra. Each cesium ion is coordinated to twelve ether oxygen atoms from the two DB18C6 molecules, forming a hexagonal *anti*-prism coordination geometry around the Cs^+ ion. The Cs—O distances range from 3.188 to 3.586 Å for one site and from 3.206 to 3.787 Å for the other. The planes of the sandwiched cesium complex are approximately perpendicular to one another. The disordered counter ion (SCN^-), and both of the solvent molecules are not in direct contact with the central cesium ion. Interestingly, the crystal structure of Cs(DB18C6)$_2$SCN is very different from that of a closely related compound, Cs(tetramethyl-DB18C6)$_2$SCN. The crystals of Cs(tetramethyl-DB18C6)$_2$SCN are tetragonal with space group of $P4_2/n$ (17). The asymmetric unit cell contains only one dimeric complex. Therefore, one isotropic ^{133}Cs chemical shift would be observed for this complex. The two ligand molecules lie on crystallographic two-fold axis giving rise to the $\bar{4}$ symmetry at the Cs^+ site. The three independent Cs—O distances in Cs(tetramethyl-DB18C6)$_2$SCN, 3.12, 3.27, and 3.36 Å, are much shorter than those in Cs(DB18C6)$_2$SCN.

C. Stationary ^{133}Cs NMR spectra

In order to obtain ^{133}Cs CSAs for the macrocyclic Cs complexes, it is necessary to obtain NMR spectra for stationary powder samples. The stationary ^{133}Cs NMR spectra are shown in Fig. 3. Since the ^{133}Cs second-order quadrupolar broadening is expected to be negligible (vide infra), it is straightforward to analyze the stationary ^{133}Cs NMR line shapes. In general, the ^{133}Cs CSAs for the macrocyclic polyether compounds are quite small, ranging from 50 to 90 ppm. However, a cryptand complex, Cs(C22)SCN exhibits a uniquely large CSA, 208 ppm. It is noted that similarly large ^{133}Cs CSAs have been previously observed in simple inorganic Cs salts. For example, the ^{133}Cs CSAs for the two

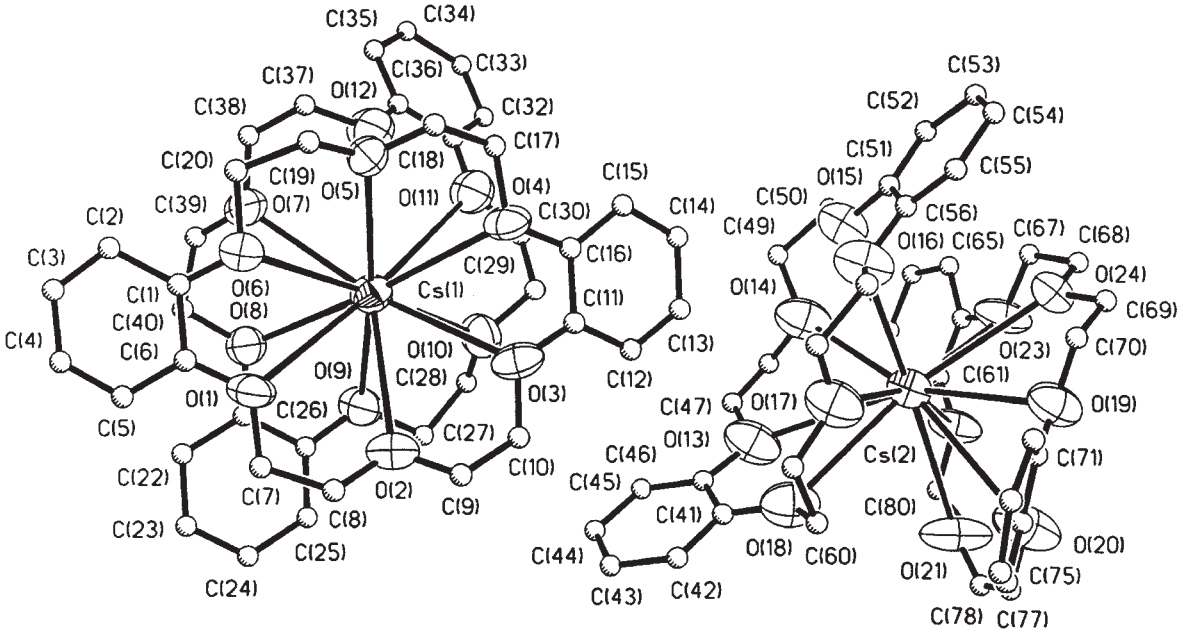
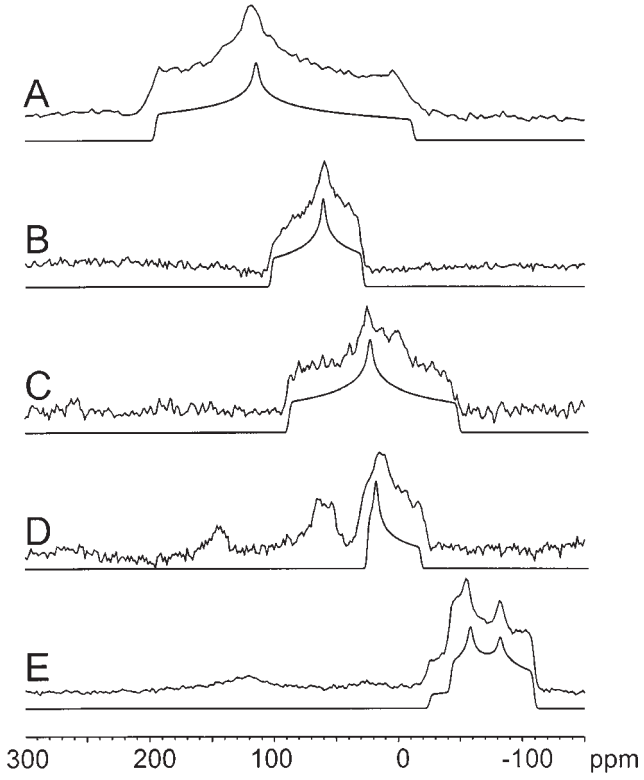
Fig. 2. Diagram illustrating the two crystallographically inequivalent Cs sites in $Cs(DB18C6)_2SCN \cdot 1/2CH_3OH \cdot 1/2H_2O$.





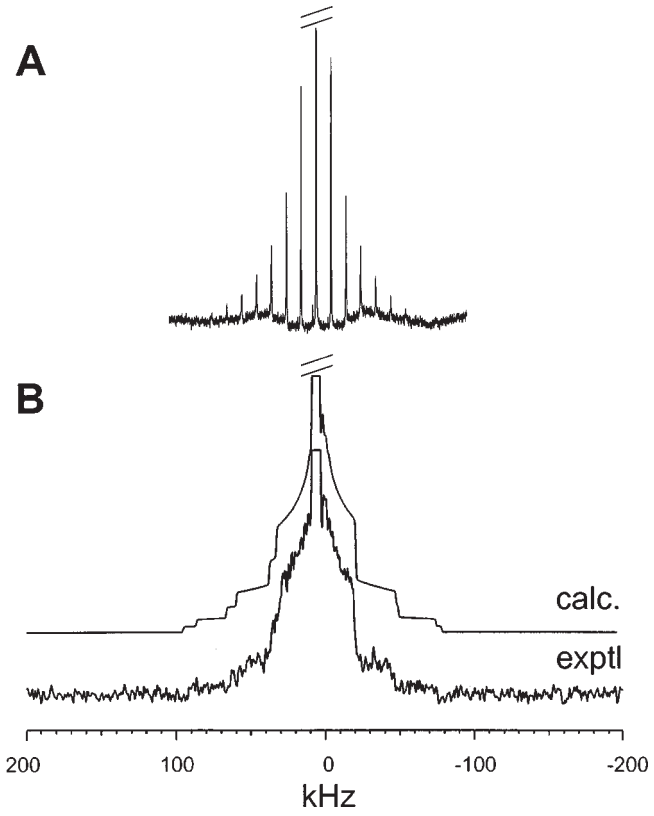


Fig. 3. Experimental (upper trace) and simulated (lower trace) central-transition ^{133}Cs stationary NMR spectra (11.75 T) of (*a*) Cs(C22)SCN, (*b*) Cs(18C6)SCN, (*c*) $Cs(15C5)_2SCN$, (*d*) Cs(Nonactin)SCN, and (*e*) $Cs(DB18C6)_2SCN$.

Cs sites in Cs_2CrO_4 are 337 and 226 ppm (8). We also obtained the ^{133}Cs CSA for another cryptand complex, C222: δ_{11} = 251, δ_{22} = 224, and δ_{33} = 200 ppm. The ^{133}Cs CSA for the Cs^+–nonactin complex is also small. This is consistent with the crystal structure of CsSCN/nonactin where the Cs^+ ion is located approximately at the center of a cube whose eight corners are formed by oxygen donor atoms from the nonactin molecule (18). The stationary ^{133}Cs NMR spectrum of $Cs(DB18C6)_2SCN$ exhibits a complex line shape due to the presence of two Cs sites. Since the isotropic chemical shifts have been determined from analysis of the MAS spectrum of $Cs(DB18C6)_2SCN$, it is straightforward to analyze the stationary spectrum and obtain the principal components of the two ^{133}Cs CS tensors. The ^{133}Cs CSA results for the

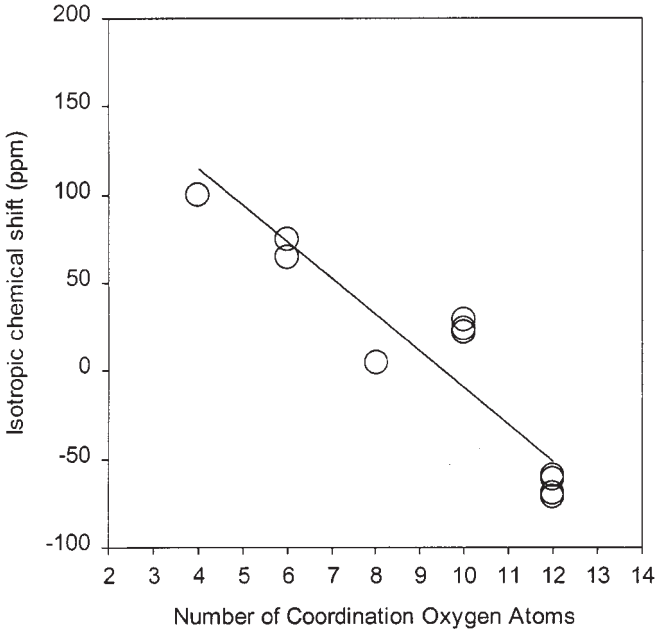
Fig. 4. All-transition 10 kHz-MAS (*a*) and stationary (*b*) ^{133}Cs NMR spectra (11.75 T) of Cs(18C6)SCN. The following parameters were used in the simulation shown in (b): δ_{11} = 103, δ_{22} = 61, and δ_{33} = 29 ppm; QCC = 0.41 MHz; η = 0.85; α = 0; β = 80; and γ = 0°.

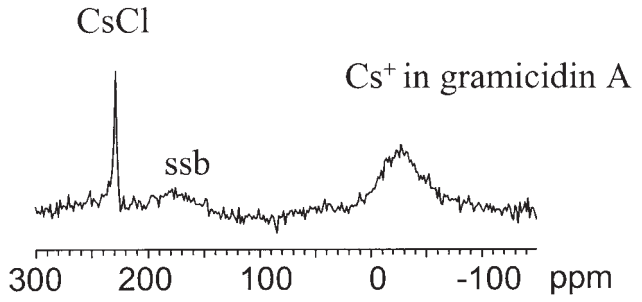


macrocyclic complexes are summarized in Table 4. However, it is also evident from Fig. 3 that some additional features are present in the ^{133}Cs stationary spectra. For example, a broad hump at 120 ppm was observed in the stationary spectrum of Cs(DB18C6)$_2$SCN (Fig. 3d). Since the ^{133}Cs MAS spectra of these complexes did not indicate any impurity, the low-intensity spectral features must arise from the satellite transitions. To obtain an estimate of the ^{133}Cs quadrupole coupling constant (QCC) for Cs-macrocyclic complexes, we recorded a complete stationary spectrum for Cs(18C6)SCN, i.e., both central- and satellite transitions. As shown in Fig. 4, the all-transition ^{133}Cs NMR spectrum covers a range of approximately 200 kHz. Simulation yields that the ^{133}Cs QCC is 0.41 MHz and the asymmetry parameter is 0.85 for Cs(18C6)SCN. At 11.75 T, the second-order ^{133}Cs quadrupolar interaction contributes less than 1 ppm to the stationary central-transition ^{133}Cs spectra and, consequently, can safely be ignored in the spectral analysis, confirming our previous assumptions. The ^{133}Cs MAS spectra of other Cs macrocyclic complexes exhibited similar spinning sideband manifold, suggesting that the QCCs are of similar magnitude as that for Cs(18C6)SCN.

D. ^{133}Cs chemical shifts and ion-binding environment

The origin of ^{133}Cs chemical shielding (σ) can be written as a sum of two contributions (19):

Fig. 5. Correlation between the experimental ^{133}Cs isotropic chemical shift and the number of coordination oxygen atoms for cesium-macrocyclic compounds.



$$\sigma = \sigma_d + \sigma_p$$

where σ_d is the diamagnetic shielding term arising from the induced motion of a spherically symmetric electron cloud at a nucleus, and σ_p is the paramagnetic term caused by mixing of the electronic ground state with excited states in the presence of a strong external magnetic field. To a very crude approximation the paramagnetic shielding (σ_p) is proportional to $-(1/\Delta E) < 1/r^3 > (\rho_e)$, where ΔE is the average energy separation between the ground and excited states of the molecule, $< 1/r^3 >$ is the average distance between electrons and the nucleus of interest, and ρ_e is the relative electron densities in the various *p* orbitals involved in bonding (20-22). In the case of ^{133}Cs NMR, the paramagnetic term is usually a dominant contributor to variations of ^{133}Cs chemical shifts because of the relatively low energy gap (ΔE) and the availability of the outer *p* and *d* orbitals (23).

As shown in Fig. 5, the isotropic ^{133}Cs chemical shifts in macrocyclic compounds exhibit a clear correlation with the number of the oxygen atoms to which the Cs^+ ion is coordinated. It should be pointed out that for complexes with unknown crystal structures, all oxygen atoms in the macrocyclic ligand molecule were assumed to participate the interaction to the Cs^+ ion. Figure 5 suggests that, as the coordination number is increased, the chemical shielded at the Cs center is also increased. A similar correlation has also been observed between the Gutmann donor number (24) of the solvent and NMR chemical shifts of ^{23}Na (25, 26), ^{133}Cs (27), and ^{39}K (28) nuclei. The range of the ^{133}Cs chemical shifts plotted in Fig. 5, 100 ppm to –71 ppm, covers approximately the entire ^{133}Cs chemical shift range for Cs compounds containing oxygen ligands. However, one notable exception is the isotropic ^{133}Cs chemical shift for Cs(C222)SCN, δ_{iso} = 225 ppm. The cage structure of the C222 molecule forces very close contacts between the Cs^+

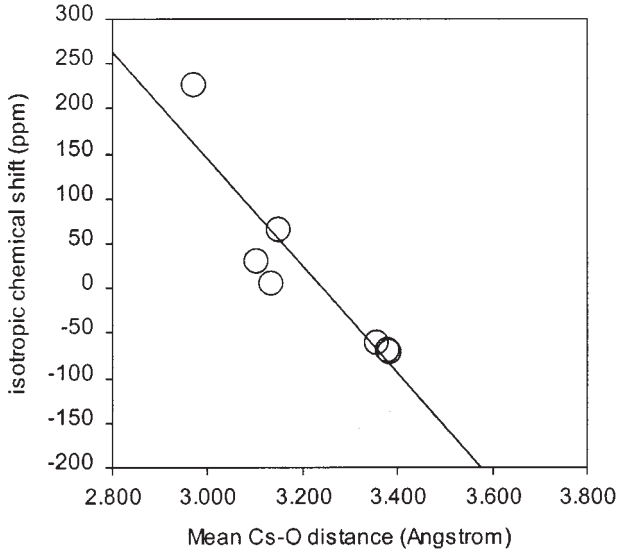
Fig. 6. Central-transition ^{133}Cs MAS spectrum (11.75 T) of gramicidin A/CsCl.



ion and the six oxygen donor atoms, with the average Cs—O distance of 2.970 Å (29). This strong Cs–O overlap is responsible for the unusually large chemical shift in Cs(C222)SCN (vide infra).

Ideally, one would use such a linear correlation to predict Cs^+ binding environments for compounds whose crystal structures are unknown. To test this idea, we obtained the solid-state ^{133}Cs NMR spectra for Cs(HM18C6)SCN•xH$_2$O. The isotropic ^{133}Cs chemical shift for this compound was found to be 0 ppm. Using the correlation curve shown in Fig. 5, we may predict that the Cs^+ ion in Cs(HM18C6)SCN•xH$_2$O is probably coordinated to approximately nine or ten oxygen atoms. This indicates that, in addition to the six oxygen atoms from the 18C6 ring, the hydroxyl side-arm must also be bound to the Cs^+ ion, presumably in a similar fashion as those in sodium and potassium complexes of 16-(2-hydroxyethyl)-1,4,7,10,13-pentaoxa-16-azacyclooctadecane (30). The additional oxygen donors may come from water molecules. It is known that hydration water molecules are also commonly found in metal macrocyclic complexes (30). Therefore, the observed ^{133}Cs isotropic chemical shift of Cs(HM18C6)SCN•xH$_2$O can be rationalized by a Cs^+ ion-binding environment containing nine or ten Cs–O interactions.

A crystalline sample of gramicidin A/CsCl complex was also prepared with the expectation that solid-state ^{133}Cs NMR may shed some light on the Cs^+ binding geometry inside the ion channel. The unit cell dimensions determined for our crystals are 35.565, 35.565, and 62.086 Å with the space group of *P*4222. However, these crystal data are different from all available crystal structures for gramicidin A/CsCl system (31–35). Clearly, our gramicidin A/CsCl crystals represented a new polymorph. Unfortunately, attempts to find the solution of the crystal structure for our gramicidin A/CsCl crystals were unsuccessful. Nevertheless, we obtained the ^{133}Cs MAS NMR spectrum for this crystalline sample. As shown in Fig. 6, a broad peak at 17 ppm is observed in the ^{133}Cs MAS spectrum. The line width of the broad peak is approximately 3.3 kHz. The broadening may be due to the presence of multiple Cs sites in the gramicidin A channel formed by a gramicidin dimer and likely the presence of two independent dimers in the asymmetric unit cell (31–35). In addition, it is also likely that, for each Cs^+ site, there exists a distribution of ^{133}Cs chemical shifts due to the presence of disorder. According to the correlation shown in Fig. 5, the ^{133}Cs chemical shift value of 17 ppm indicates the number of oxygen coordination at the binding sites is approximately 8. This type of binding environment is consistent with those reported for other forms of gramicidin A crystals (31–36). For example, a recent X-ray study of gramicidin A/CsCl (36) revealed that two dimers are present in the asymmetric unit cell and that each gramicidin channel (dimer) contains three Cs^+ binding sites. On average, each Cs^+ ion has eight closest contacts arising from six carbonyl oxygens (3.6–4.5 Å) and two water oxygens (2.8–3.1 Å). Therefore, our solid-state ^{133}Cs NMR observation is in agreement with the crystallographic studies in the Cs^+ binding environment, despite the difference in overall crystal structures. It would be of interest to extend the alkali metal NMR to other gramicidin-cation complexes (Na and K).

Fig. 7. Correlation between the ^{133}Cs chemical shifts and the average Cs—O distance for cesium-macrocyclic compounds.

In the above discussion, we have focused only on the isotropic ^{133}Cs chemical shifts. In the discussion that follows, we briefly comment on the observed tensor components for the Cs complexes with macrocyclic ligands. As seen from Table 4, the span of the chemical shift tensor varied from 26 ppm in Cs(18C6)$_2$SCN to 208 ppm in Cs(C22)SCN. This large difference may be interpreted as due to the structural difference between the two complexes. Clearly, the Cs^+ coordination environment in Cs(18C6)$_2$SCN is more "spherical" than that in Cs(C22)SCN. In principle, the tensor components are more informative than the isotropic value alone. However, for the ^{133}Cs NMR data presented in Table 4, there does not exist any clear trend between δ_{11} and δ_{33} components and ion-binding environment. Interestingly, the δ_{22} components show a nice correlation to the isotropic values. More studies are clearly required to unravel the relationship between individual chemical shift tensor components and ion coordination geometry.

In general, increasing the number of metal-ligand coordination also leads to an increase in the average metal-ligand distance. This is also true in the systems studied here. For example, the average Cs—O distance in Cs(18C6)SCN is 3.150 Å, which compares to 3.382 Å in Cs(DB18C6)$_2$SCN. Dye and coworkers (12) suggested an inverse correlation between ^{133}Cs chemical shifts and the mean Cs—O distance. Figure 7 shows the ^{133}Cs isotropic chemical shift versus the

average Cs—O distance for compounds with known crystal structures. Clearly, large ^{133}Cs chemical shifts are observed at short Cs—O distances. There also exist several examples in the literature where large ^{133}Cs chemical shift values were found for Cs sites exhibiting short Cs—O distances. Skibsted et al. (7) have observed a large ^{133}Cs chemical shift, 178 ppm, in Cs_2CO_3 for a site that is associated with a very short average Cs—O distance, 2.69 Å. Such a short Cs—O distance may allow an efficient electron transfer to occur from the donor oxygen atom in the ligand molecule to a 3*p* orbital of the metal ion (37), thus increasing the paramagnetic shielding contribution.

Conclusions

We have reported the determination of ^{133}Cs CSAs for a series of Cs complexes with macrocyclic molecules. The ^{133}Cs isotropic chemical shifts were found to exhibit a linear dependence on the number of oxygen atoms to which the Cs^+ ion is coordinated. In addition, the ^{133}Cs chemical shifts were also found to correlate with the average Cs—O distances. It would be of interest to find a general bonding parameter that can unify the two aforementioned dependencies. The established correlation may be useful in predicting Cs^+ ion-binding environment for unknown systems based on solid-state ^{133}Cs NMR data alone. We have also determined the crystal structure for $Cs(DB18C6)_2SCN•1/2CH_3OH•1/2H_2O$.

Acknowledgments

This research was financially supported by grants from the Natural Sciences and Engineering Research Council (NSERC) of Canada. We wish to thank Mr. Chris Freure and Dr. Shuan Dong for assistance in sample preparation and Dr. Zongchao Jia for the X-ray measurement of gramicidin A/CsCl crystals.

Supplementary material available

Anisotropic displacement parameters and hydrogen coordinates for $Cs(DB18C6)_2SCN•1/2CH_3OH•1/2H_2O$ (5 pages) have been deposited as supplementary material and may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Ontario, Canada, K1A 0S2.

Isolation of bioactive 5α,8α-epidioxy sterols from the marine sponge *Luffariella cf. variabilis*

Anne Gauvin, Jacqueline Smadja, Maurice Aknin, Robert Faure, and Emile-Marcel Gaydou

Abstract: The lipid extract of the marine sponge *Luffariella cf. variabilis* from Mayotte (Indian Ocean) has proven to be an extraordinarily rich source of a wide variety of unusual steroids belonging to the 5α,8α-epidioxy sterol family. Ten epidioxy sterols have been identified: 5α,8α-epidioxycholesta-6,22-dien-3β-ol, 5α,8α-epidioxycholest-6-en-3β-ol, 5α,8α-epidioxy-24(ξ)-methylcholesta-6,22-dien-3β-ol, 5α,8α-epidioxy-24(*S*)-methylcholest-6-en-3β-ol and its epimer (24*R*), 5α,8α-epidioxy-24(*S*)-ethylcholesta-6,22-dien-3β-ol and its epimer (24*R*), 5α,8α-epidioxy-24(*S*)-ethylcholest-6-en-3β-ol and its epimer (24*R*), along with 5α,8α-epidioxy-24(ξ)-methylcholesta-6,9(11),22-trien-3β-ol. Their structures were determined by nuclear magnetic resonance (^{1}H, ^{13}C) and electron impact mass spectrometry. The mixture of the 10 steroids showed inhibitive activity against the human T-cell leukemia/lymphotropic virus type I (HTLV-I) and also displayed cytotoxic activity against the human breast cancer cell line (MCF_7WT).

Key words: *Luffariella cf. variabilis*, marine sponge, 5α,8α-epidioxy sterols, antitumor and antiviral activities.

Résumé : L'extrait lipidique de l'éponge marine *Luffariella cf. variabilis* de Mayotte (Océan Indien) s'est révélé être une source extraordinairement riche d'une grande variété de stéroïdes particuliers appartenant à la famille des 5α,8α-épidioxy stérols. Dix épidioxy stérols ont été identifiés: 5α,8α-épidioxycholesta-6,22-dien-3β-ol, 5α,8α-épidioxycholest-6-en-3β-ol, 5α,8α-épidioxy-24(ξ)-methylcholesta-6,22-dien-3β-ol, 5α,8α-épidioxy-24(*S*)-methylcholest-6-en-3β-ol et son épimère (24*R*), 5α,8α-épidioxy-24(*S*)-ethylcholesta-6,22-dien-3β-ol et son épimère (24*R*), 5α,8α-épidioxy-24(*S*)-ethylcholest-6-en-3β-ol et son épimère (24*R*), ainsi que le 5α,8α-épidioxy-24(ξ)-methylcholesta-6,9(11),22-trien-3β-ol. Leurs structures ont été déterminées par résonance magnétique nucléaire (^{1}H, ^{13}C) et par spectrométrie de masse en impact électronique. Le mélange des 10 stéroïdes a montré une activité inhibitrice sur le virus de la leucémie–lymphome à cellules-T humain de type I (HTLV-I) et possède également une activité cytotoxique sur les cellules cancéreuses humaines du sein (MCF_7WT).

Mots clés : *Luffariella cf. variabilis*, éponge marine, 5α,8α-épidioxy stérols, activités antitumorale et antivirale.

Marine organisms are an established source of a great diversity of unconventional sterols with unusual functionalization, unique side chains, and nuclei. Several of these steroids, notably those with multiple oxygen functionalities, exhibited a broad range of activities (1, 2). During our ongoing program to isolate novel antiviral and antitumor marine natural products, the lipidic fraction of the sponge *Luffariella cf. variabilis* (family: Thorectidae, order: Dictyoceratida) collected on the coasts of Mayotte Island (Indian Ocean) has been investigated. Although the conventional 3β-hydroxysteroids were totally absent, the crude lipidic extract contained a mixture of 10 bioactive 5α,8α-epidioxy sterols (Fig. 1). In the present paper, we report the isolation and the structure elucidation of these 5α,8α-epidioxy sterols which contain a variety of side chains. This group of steroids with oxygenated functionalities in the nucleus, constitutes a long-recognized class of metabolites isolated from marine organisms such as sponges (3–10), tunicates (6, 11, 12), sea hares (6, 13), gorgonians (14), sea anemones (15), mussels (11, 16), and other marine specimens (12, 16, 17, 18). However, this is the first time that they have been isolated from a sponge of the genus *Luffariella*, and that attention is called to their potential antiviral and antitumor activities.

The crude lipidic extract (2.5%, dry weight of the sponge) of *L. cf. variabilis* collected by SCUBA off the coasts of Mayotte, Indian Ocean, was subjected to the purification procedure as outlined in the Experimental section. The final separation using high-pressure liquid chromatography (HPLC) yielded five fractions (Fig. 2) containing 10 5α,8α-epidioxy sterols (**1**–**10**) (Fig. 1). They were readily identified

in fractions I–V by chromatographic and spectroscopic methods and by comparison with spectral data given in the literature (6, 18, 19). Chemical shifts of proton and carbon resonances of **1**–**10** are respectively given in Table 1 and Table 2; their mass spectra are summarized in Table 3.

Compounds **1**–**9** are characterized by having a steroid nucleus (19 carbon atoms) possessing an endocyclic double bond between the carbons C-6 and C-7, and a peroxy group between the carbons C-5 and C-8. Only the differences in the side chain structures enable the nine compounds to be distinguishable. Two of them (**1**, **2**) have a cholestane skeleton, three others (**3**, **4**, **5**) possess an ergostane skeleton and the last four (**6**, **7**, **8**, **9**) have a stigmastane skeleton. Components **1**, **3**, **6**, and **7** possess a double bond between the carbons C-22 and C-23. The molecular formulas of the epidioxy sterols were determined from the electron impact mass spectra (EIMS) of the five fractions isolated by HPLC. Each of their spectra also displayed an intense ion (M^+-O_2)

Fig. 2. High-performance liquid chromatography of the 5α,8α-epidoxy sterols mixture isolated from the marine sponge *L. cf. variabilis* on a Merck LiChrospher RP-18 column (Darmstadt, Germany; 25 cm × 4 mm i.d.) with 3% aqueous methanol as mobile phase. Elution conditions are given in the Experimental section. Fractions I–V were retrieved as indicated by the dotted lines.

due to the loss of O_2 from the molecular ion, presumably by a retro Diels–Alder fragmentation (6) providing support for the presence of the peroxy group. The presence of this group was also suggested by ^{13}C NMR signals around δ 79.5 (C-8) and 82.2 (C-5) due to quaternary carbons each bearing an oxygen atom. The Δ^6 unsaturation was determined by the ^1H NMR and ^{13}C NMR spectra: H-6 and H-7 were found as a doublet (J = 8.5 Hz) around δ 6.2 and 6.4, respectively, and the chemical shifts of C-6 and C-7 were observed around δ 135.6 and 130.9, respectively. The chemical shifts and AB coupling patterns of the olefinic protons are also indicative of a 5α,8α-epidioxy orientation. The H-6 and H-7 protons are usually found at around δ 6.5 and 6.3, respectively in 5α,8α-epidioxy systems and at δ 5.9 and 5.6 in 5β,8β-epidioxy systems (18). The ^1H NMR signal at δ 3.95 was assigned to H-3, indicating that an hydroxyl group is attached to the C-3 position. The NMR spectra were also useful in characterizing the side chains present in these epidioxy sterols. The Δ^{22} unsaturation in particular was determined for compounds **1**, **3**, **6**, and **7**, by the olefinic proton signals between δ 5.10–5.29 and 5.00–5.17 assigned to H-22 and H-23, respectively. It was also confirmed by ^{13}C NMR signals between δ 137.72–135.52 and 127.03–132.56 due to C-22 and C-23, respectively. Moreover, differences in the chemical shifts of the side chain carbons permitted the determination of the absolute configuration at C-24 for steroids **4**–**9**. Wright et al. (19) have shown indeed that the chemical shift data obtained for the side chain carbons of diastereoisomeric model steroids epimeric at C-24 are insensitive to structural changes remote from the asymetric centre. Thus, the absolute configuration at C-24 for **4**–**9** was deduced by comparing the chemical shifts of their side chain carbons with those given by Wright et al. (19) for several C-24 alkyl 3β-hydroxysterols. Also, as the spin-lattice relaxation times of corresponding carbons in the two epimeric side chains are very similar (19), the composition of mixtures of stereoisomers was obtained from the relative intensities of corresponding carbon signals. So, we found a mixture of 90:10 for the C-24 epimers **4** and **5**, 50:50 for **6** and **7**, and 50:50 for **8** and **9**. ^1H NMR and ^{13}C NMR spectra of fraction II revealed the presence of only one C-24 epimer of the 24-methylepidioxysterol (**3**). However, the absolute configuration at C-24 could not be determined without ambiguity because the chemical shifts of the side chain carbons were not similar enough to those given in the literature (19) for the epimers 24(*R*) or 24(*S*). Therefore, because of these only slight chemical shift differences, we preferred not to assign the stereochemistry at C-24 for compound **3**.

Another minor steroid, 5α,8α-epidioxy-(24ξ)-methylcholesta-6,9(11),22-trien-3β-ol (**10**), (Fig. 1) was also detected along with **1** in fraction I (Fig. 2). This steroid is characterized by a diunsaturated nucleus $\Delta^{6,9(11)}$ and an ergostane side chain having a Δ^{22} unsaturation. As with the nine previously described epidioxy sterols, the Δ^6 unsaturation of **10** was detected by the presence of the two mutually coupled ^1H signals at δ 6.27 (d, J = 8.5 Hz) and δ 6.58 (d, J = 8.5 Hz) due to the olefinic protons H-6 and H-7 respectively. However, the ^{13}C signals of C-6 and C-7, probably concealed by those of compound **1** were not detected. The presence of $\Delta^{9(11)}$ unsaturation was assumed from the ^1H NMR; a doublet of doublet at δ 5.40 was assigned to H-11. In the ^{13}C NMR spectrum, the chemical shifts of C-11 and C-9 at δ 119.80 and 142.60, respectively, was consistent with the presence of a $\Delta^{9(11)}$ unsaturation. Location of the double bond at position 22 was achieved by ^{13}C NMR signals at δ 135.50 (C-22) and 134.40 (C-23). Also, the methyl region of the ^1H NMR spectrum showed a doublet (J = 6.7 Hz) at δ 0.90 suggesting a 24-methyl side chain. However, further investigations are necessary for complete structure elucidation. Indeed, the weak intensity of ^1H and ^{13}C NMR signals prevented the determination of the C-24 stereochemistry.

The determination of relative retention times by HPLC (Table 4) allowed us to confirm NMR and EIMS results by comparison with those given by the literature (6).

Discussion

Many sponges belonging to the order Dictyoceratida (20) are characterized by a very low sterol content. This usually coincides with high content of terpenes indicative of a metabolic shift in this group which favours the continued head-to-tail fusion of isoprene units rather than an enzymatic mechanism for converting two farnesyl pyrophosphate units tail-to-tail to form a sterol precursor. It is nevertheless noteworthy that in *L. cf. variabilis*, the lack of 3β-hydroxysterols seems to be compensated by a high amount of 5α,8α-epidioxy sterols. The precise origin of 5α,8α-epidioxy sterols in marine organisms has not yet been identified. Because of the easy conversion of $\Delta^{5,7}$-sterols into their epidioxides, naturally isolated sterol peroxydes could first be suspected to be artifacts. The conjugated diene system in $\Delta^{5,7}$-sterols is unstable and can easily be oxidized during storage and (or) experiments. Elenkov and co-workers (10) investigated the autooxidation of native $\Delta^{5,7}$-sterols to 5α,8α-epidioxy sterols in the Black Sea sponge *Dysidea fragilis*. They showed that after a rapid extraction and analysis, $\Delta^{5,7}$-sterols are the main constituents of *D. fragilis* sterols and only traces of 5α,8α-epidioxy sterols are present. The crude extract was then stored. After a month, only a low concentration of $\Delta^{5,7}$-sterols remained with a higher concentration of 5α,8α-epidioxy sterols being found, and after three months, no $\Delta^{5,7}$-sterols were detected.

In the present study, we think that the artifactual origin of epidioxides in *L. cf. variabilis* can be excluded. The sponge was indeed rapidly extracted and immediately analyzed by thin layer chromatography showing without ambiguity, the presence of 5α,8α-epidioxy sterols. Moreover, no corresponding $\Delta^{5,7}$-sterols were encountered. In agreement with the findings of others (6, 21) it is felt that the 5α,8α-epidioxy sterols could also be native metabolites. This was confirmed by Serebryakov et al. (21) who isolated these steroids from fungi in the absence of oxygen. Several hypotheses were suggested concerning their biological function in marine organisms and notably that they may act as substrates for various enzyme systems. For example, the cooccurence of epidioxy sterols and $\Delta^{4,7}$-3,6-diketones in the marine sponge *Raphidostila incisa* has led to the proposal that epidioxy sterols may be biosynthetic precursors for the latter group of compounds (5). 5α,8α-Epidioxy sterols could also be biogenetic precursors of polyhydroxylated sterols in *Dysidea* species (10). The isolation of polyketide peroxides from a number of marine sponges of the genus *Plakortis* suggests the possible occurrence of peroxydase enzymes in these organisms (22). The above-mentioned metabolic transformations of epidioxides however are postulated on the basis of the feasibility of certain reactions that proceed well in vitro and on the coexistence in the same animal of epidioxides with those end products. There is no evidence to confirm the suggested hypotheses. Undoubtedly, epidioxy sterols remain an unusual and biosynthetically intriguing group of marine sterols which merits additional biosynthetic investigation.

On the assumption that sponges, which include 5α,8α-epidioxy sterols in their lipid content, have a common (or similar) and specific enzyme system(s), it would have been possible to use these steroids for a chemotaxonomic study. However, this taxonomic consideration turned out to be difficult because it has been found that, in addition to *L. cf. variabilis*, 5α,8α-epidioxy sterols were isolated from seven sponges of completely different genera, families and orders: *(i) Axinella cannabina* (3); (*ii*) *Tethya aurantia* (4); *(iii) Raphidostila incisa* (5); (*iv*) *Thalysias juniperina* (6); (*v*) *Haliclona rubens* (7); (*vi*) *Hyrtios* sp. (8); (*vii*) *Axinissa* sp. (9); and (*viii*) *D. fragilis* (10), and we therefore concluded that contrary to the 3β-hydroxysterols, 5α,8α-epidioxy sterols are not of some chemotaxonomic value. Thus, we were led to think that the metabolites may rather be produced by common symbiotic microorganisms. However, this is one further hypothesis which also requires further investigations as well.

Biological assays

Since the crude lipidic extract of *L. cf. variabilis* was found in a preliminary test (23), to be toxic for the brine shrimp *Artemia salina* (LD_{50} = 50 μg mL^{-1}), the mixture of the 10 5α,8α-epidioxy sterols was submitted to a series of antiviral and antitumoral assays. The metabolites displayed a significant and selective activity against the human T-cell leukemia–lymphotropic virus type I (HTLV-I) which is the cause of both a hematopoietic malignancy and adult T-cell leukemia–lymphoma (24). The reduction until 50% of

Table 4. Composition and HPLC relative retention times of 5α,8α-epidioxy sterols from *L. cf. variabilis*.

Compound	Composition[a] (%)	Relative retention times[b]	
		Exp.[c]	Lit. (6)[d]
(**10**)	18.0	0.74	0.71
(**1**)			0.77
(**3**)	19.5	0.89	0.89
(**2**)	36.6	1.00	1.00
(**4**) + (**5**)	13.3	1.15	1.14
(**6**) + (**7**)			1.16
(**8**) + (**9**)	9.4	1.37	1.36

[a]Quantification of the 5α,8α-epidioxy sterols was based on the area of the HPLC peaks.

[b]Compound **2** has been used as standard for relative retention times.

[c]Obtained on a Merck LiChrospher RP-18 column (25 cm × 4 mm i.d.) with 3% aqueous methanol as mobile phase.

[d]Obtained on a Whatmann Partisil M9 10/50 ODS-2 column (50 cm × 9 mm i.d.) with 8% aqueous methanol as mobile phase.

β-galactosidase whose production is directly related to HTLV-I activity, was observed for a concentration of 0.3 mg mL^{-1}. As far as is known, 5α,8α-epidioxy sterols are the first natural products showing in vitro potency against the HTLV-I virus. Thus, they could be promising agents in the research on natural compounds for therapeutical interventions. These steroids were also assayed on the human imunodeficiency virus (HIV). However, no inhibitory activity was observed. Finally, the mixture was screened for in vitro cytotoxicity against the human breast cancer cell line (MCF_7WT) and 87% inhibition was observed at a concentration of 80 μg mL^{-1}. Other assays are in progress to precisely acscertain the antiviral and antitumor activity of each individual epidioxy sterol isolated in useful quantities. The antiviral (HTLV-I, HIV) and antitumoral assays were performed as described previously (25).

Experimental section

General experimental procedures

All solvents were redistilled before use. Column chromatographic separations were performed on silica gel (Merck, Darmstadt, Germany; type 60, 70–230 or 230–400 Mesh) as the adsorbent. Nuclear magnetic resonance spectra were recorded on a Brucker AMX-400 (Karlsruhe, Germany) in $CDCl_3$, at 400.13 MHz for ^1H NMR spectra and at 100.11 MHz for ^{13}C NMR spectra. Chemical shifts are given in ppm relative to tetramethylsilane as internal standard. Electron impact mass spectra were obtained on a Jeol AX-500 mass spectrometer (Tokyo, Japan) with a source temperature of 200°C and ionization energy of 70 eV. High-pressure liquid chromatography was performed on a Spectraseries P100 (California, U.S.A.) equipped with a Rheodyne injector, a differential refractometer (California, U.S.A.; Thermoseparation products) and a Merck LiChrospher RP-18 column (Darmstadt, Germany ; 25 cm × 4 mm i.d., 5 μm).

Animal material

The sponge sample was collected by SCUBA at a depth between 10–40 m in Passe Longogori (Mayotte Island, northwest of Madagascar, Indian Ocean). The sample was immediately frozen at –20°C and kept in a freezer until extraction. The sponge was identified as *L. cf. variabilis* (Family: Thorectidae, order: Dictyoceratida) by Dr. N. Boury-Esnault (Station Marine d'Endoume, Marseille, France) and Pr. Dr. P. Bergquist (School of Biological Sciences, Auckland, New Zealand). A voucher specimen has been deposited at the Laboratoire de Chimie des Substances Naturelles et des Sciences des Aliments of the Reunion University (Reunion Island, D.O.M, France) under the reference AGL-2–97M.

Extraction and isolation

Frozen sponge tissue (1343 g, dry weight) was cut up and homogenized in a Waring blender in methanol–chloroform (1:2, v/v). After filtration, the solvent was removed under reduced pressure to give the crude material (33.4 g). This lipidic extract was then partitioned between *n*-hexane and 10% aqueous methanol to yield after evaporation of the solvent, 17.1 g of *n*-hexane residue. A part of the *n*-hexane residue (4.8 g) was chromatographed on silica gel (70–230 Mesh) column eluted with a gradient of *n*-hexane–ethyl acetate (5% stepwise elution from *n*-hexane to ethyl acetate). The mixture of 5α,8α-epidioxy sterols eluted with *n*-hexane–ethyl acetate (9:1, v/v) was further purified by chromatography with *n*-hexane–ethyl acetate (9:1, v/v) on silica gel (230–400 Mesh) and isolated as white crystals (59 mg) after

© 2000 NRC Canada

precipitation in *n*-hexane. This fraction was separated by reverse-phase HPLC (1 mL min^{-1} elution with 3% aqueous methanol) to give five fractions I–V (Fig. 2) which respectively contained 5 mg of a mixture of **1** + **10**, 16 mg of **3**, 5 mg of **2**, 4 mg of a mixture of **4** + **5** (90:10, relative % of the epimeric pair) and **6** + **7** (50:50) and 5 mg of a mixture of **8** + **9** (50:50).

Acknowledgements

The authors are grateful to Dr. N. Boury-Esnault and to Pr. Dr. P. Bergquist for the identification of the sponge. The authors also thank the Laboratoire de Chimie Bio-organique de l'Université de Bordeaux II (Bordeaux, France), the Institut National de la Santé et de la Recherche Médicale (INSERM), Fondation Bergognié (Bordeaux, France), the Laboratoire de Virologie, Hôpital Pellegrin (Bordeaux, France) and the Laboratoire de Pharmacologie des médicaments anticancéreux, Fondation Bergonié (Bordeaux, France) for biological assays.

Distribution of microamounts of some M^{2+} ions during $ZnSO_4 \cdot 7H_2O$ crystallization

Marek Smolik

Abstract: Distribution coefficients (*D*) of trace amounts of Ni^{2+}, Co^{2+}, Mg^{2+}, Cd^{2+}, Cu^{2+}, Mn^{2+}, Ca^{2+}, and Fe^{2+} have been determined during crystallization of $ZnSO_4 \cdot 7H_2O$. Their dependencies on the ionic radii of M^{2+} ions, solubilities and structures of the corresponding sulfates as well as their abilities to form solid solutions with $ZnSO_4 \cdot 7H_2O$ have been analyzed. The *D* values are in the range <0.006 (D_{Ca}) – 1.61 (D_{Ni}) and depend mainly on similarity of the structures of the corresponding sulfates and the ability of $MSO_4 \cdot nH_2O$ to form solid solutions with $ZnSO_4 \cdot 7H_2O$. The order of lowering some of the determined distribution coefficients ($D_{Ni} > D_{Mg} > D_{Co} > D_{Fe} > D_{cu}$) exactly agrees with increase of the deformation trend of octahedral coordination of corresponding ions resulting from their electronic configuration. The *D* coefficients do not depend on similarity of size of *ionic radii* of microcomponent ($r_{M^{2+}}$) to macrocomponent ($r_{Zn^{2+}}$), however for ions forming monoclinic sulfate hydrates at 20°C (Co^{2+}, Fe^{2+}, Cd^{2+}, Ca^{2+}) this dependence of distribution coefficients on $r_{M^{2+}}$ is linear in a plot of log *D* against ionic radius. The effect of solubilities of corresponding sulfates in water on the *D* coefficients is complex and clouded by crystal-chemical factors.

Key words: crystallization, zinc(II) sulfate heptahydrate, cocrystallization, distribution coefficients *D* (Henderson-Kraček, Khlopin), distribution of trace impurities.

Résumé : On a déterminé les coefficients de distribution (*D*) de quantités à l'état de traces de Ni^{2+}, Co^{2+}, Mg^{2+}, Cd^{2+}, Cu^{2+}, Mn^{2+}, Ca^{2+} et Fe^{2+} au cours de la cristallisation du $ZnSO_4 \cdot 7H_2O$. On a analysé leurs dépendances sur les rayons ioniques des ions M^{2+}, les solubilités et les structures des sulfates correspondants ainsi que leurs habilités à former des solutions solides avec le $ZnSO_4 \cdot 7H_2O$. Les valeurs de *D* sont comprises entre <0,006 (D_{Ca}) et 1,61 (D_{Ni}) et elles dépendent principalement de la similarité des structures des sulfates correspondants et de l'habilité du $MSO_4 \cdot nH_2O$ à former des solutions solides avec le $ZnSO_4 \cdot 7H_2O$. L'ordre de décroissance de quelques-uns des coefficients de distribution $D_{Ni} > D_{Mg} > D_{Co} > D_{Fe} > D_{Cu}$ est en parfait accord avec une augmentation dans la tendance à la déformation de la coordination tétraédrique des ions correspondants qui résultent de leur configuration électronique. Les coefficients *D* ne dépendent pas de la similarité des tailles des rayons ioniques des microcomposants ($r_{M^{2+}}$) par rapport au macrocomposant ($r_{Zn^{2+}}$); toutefois, pour les ions qui forment des sulfates monocliniques hydratés à 20°C (Co^{2+}, Fe^{2+}, Cd^{2+}, Ca^{2+}) cette dépendance des coefficients de distribution sur $r_{M^{2+}}$ est linéaire lorsqu'on fait une courbe de logD en fonction du rayon ionique. L'effet de la solubilité des sulfates correspondants dans l'eau sur les coefficients D est complexe et il est rendu plus difficile à comprendre en raison de facteurs cristallins et chimiques.

Mots clés : cristallisation, sulfate de zinc(II) heptahydraté, cocristallisation, coefficients de distribution, *D*, (Henderson-Kraček, Khlopin), distribution d'impuretés à l'état de traces.

[Traduit par la Rédaction]

Introduction

Distribution coefficients *D* of microcomponents during crystallization are important indicators of its effectiveness as a purification process. However, the literature data concerning these coefficients are rather scarce. Hence, it seems reasonable to determine the dependence of distribution coefficients on various physicochemical and crystal-chemical factors (such as: ionic charges and radii, similarity of crystal structure and unit cell dimensions, ability to form solid solutions as well as solubilities of corresponding salts), which would allow to predict the values of *D* coefficients for various crystallization systems which have not been investigated so far.

The effect of each of these factors on the *D* coefficients may be predominant for various crystallization systems and as shown by investigations on cocrystallization of microcomponents in several sulfate systems (triclinic: $CuSO_4 \cdot 5H_2O$ (1) and $MnSO_4 \cdot 5H_2O$ at 20°C (2); monoclinic: $FeSO_4 \cdot 7H_2O$ at 20°C (3), at 5°C and 50°C (4), as well as $MnSO_4 \cdot 7H_2O$ at 2°C (2)) very often these influences overlap. There is a lack of data concerning the effect of these factors on *D* coefficients for crystallization of $ZnSO_4 \cdot 7H_2O$, which is one of orthorhombic sulfate hydrates. Cocrystallization of hydrates of M(II) sulfates with zinc(II) sulfate heptahydrate has been recognized to some extent ($FeSO_4 \cdot 7H_2O$ (5–7), $CoSO_4 \cdot 7H_2O$ (8–9), $NiSO_4 \cdot 7H_2O$ (8, 10–11), $CuSO_4 \cdot 5H_2O$ (5, 10, 13), $MgSO_4 \cdot 7H_2O$ (6, 12),

Table 1. Standard conditions of determination of microcomponents by AAS.

Microcomponent	Lamp	Continuous operating current of lamp (mA)	Wavelength (nm)	Slit (nm)	Flame
Ca	HCL[a]	20	422.7	0.7	C_2H_2–N_2O
Cd	EDL[b]	6 watts (power)	228.8	0.7	C_2H_2–air
Co	HCL	30	240.7	0.2	C_2H_2–air
Cu	HCL	30	324.8	0.7	C_2H_2–air
Fe	HCL	30	248.3	0.2	C_2H_2–air
Mg	HCL	20	285.2	0.7	C_2H_2–air
Mn	HCL	30	279.5	0.2	C_2H_2–air
Ni	HCL	30	232.0	0.2	C_2H_2–air

[a]Hollow cathode lamp.

[b]Electrodeless discharge lamp.

$MnSO_4 \cdot 5H_2O$ (14)). However, these investigations concerned mainly macroamounts (>1%) of the mentioned sulfates. Cocrystallization of microamounts of M^{2+} ions was investigated only in a few cases: (*i*) Co^{2+} (D_{Co} = 1.20 at 20°C) (9); (*ii*) Cu^{2+} (D_{Cu} = 0.16 at 20°C)(13); and *(iii)* Mn^{2+} (D_{Mn} = 0.13 at 20°C)(14)).

The purpose of the present study was to determine distribution coefficients, *D*, of trace amounts (10^{-3}–10^{-1}%) of M^{2+} ions {Fe^{2+}, Co^{2+}, Mn^{2+}, Cu^{2+}, Cd^{2+}, Ni^{2+}, Mg^{2+}, Ca^{2+}} during the crystallization of $ZnSO_4 \cdot 7H_2O$ as well as to identify relations between these coefficients and the mentioned physicochemical and crystal-chemical factors.

Experimental

Reagents and solutions

Zinc(II) sulfate heptahydrate, p.a. was additionally purified by crystallization in the presence of H_2O_2. High-purity zinc(II) sulfate heptahydrate, containing less than 1 ppm of each investigated element obtained in the Institute of Chemistry, Inorganic Technology and Electrochemistry Silesian Technical University (Gliwice). Solutions of Fe(II), Co(II), Mn(II), Cu(II), Cd(II), Ni(II), Mg(II) sulfates, and Ca(II) nitrate of determined concentration were used. Ammonia solution (14 mol/dm^3) was obtained by saturating distilled water with ammonia gas. Sodium versenate p.a. (POCh-Gliwice) – 0.1mole/dm^3 water solution, hydrazine sulfate p.a. (POCh-Gliwice), and eriochrome black T ind. (POCh-Gliwice) were used.

Apparatus

Atomic absorption spectrometer model 3300 manufactured by Perkin–Elmer was applied.

Analytical methods

Determination of the macrocomponent

Zinc(II) was determined by complexometric titration with sodium versenate at pH 10 in the presence of eriochrome black T (15).

Determination of microcomponents

Initial concentrations of microcomponents ([ppm] in relation to $ZnSO_4 \cdot 7H_2O$): (*i*) in supersaturated $ZnSO_4$·solution before crystallization (a'_o) (series 1); (*ii*) in saturated solution "purified" (a'_{ro}) and "contaminated" (a''_{ro}) as well as in $ZnSO_4 \cdot 7H_2O$ crystal "purified" (a''_{ko}) and "contaminated" (a'_{ko}) before long-time stirring (series 2); (*iii*) in samples of crystals (a'_k) and mother solutions (a'_r) after crystallization as well as in actually applied washing solution were determined by means of direct atomic absorption spectrometry (AAS) from solutions containing 1.000 g (or less) of $ZnSO_4 \cdot 7H_2O$ in 25 cm^3. All mentioned samples and sets of standards (prepared on the basis of high-purity zinc(II) sulfate), whose $ZnSO_4$ concentrations were the same, were excited in flame and their absorbance measured under the same conditions, which are presented in Table 1.

Method for determination of coefficients D

After crystallization, the crystals were separated from the mother solution by means of filtration through a Büchner funnel with a sintered glass disk, washed with saturated, purified $ZnSO_4 \cdot 7H_2O$ solution, weighed, and dissolved in water. From the zinc(II) content in both solutions, the degree of $ZnSO_4 \cdot 7H_2O$ crystallization α was found from the following formula

$$\alpha = \frac{m_{Ms}}{m_{Mk} + m_{Mr}}$$

where

m_{Ms} = mass of the macrocomponent ($ZnSO_4 \cdot 7H_2O$) in the solid phase

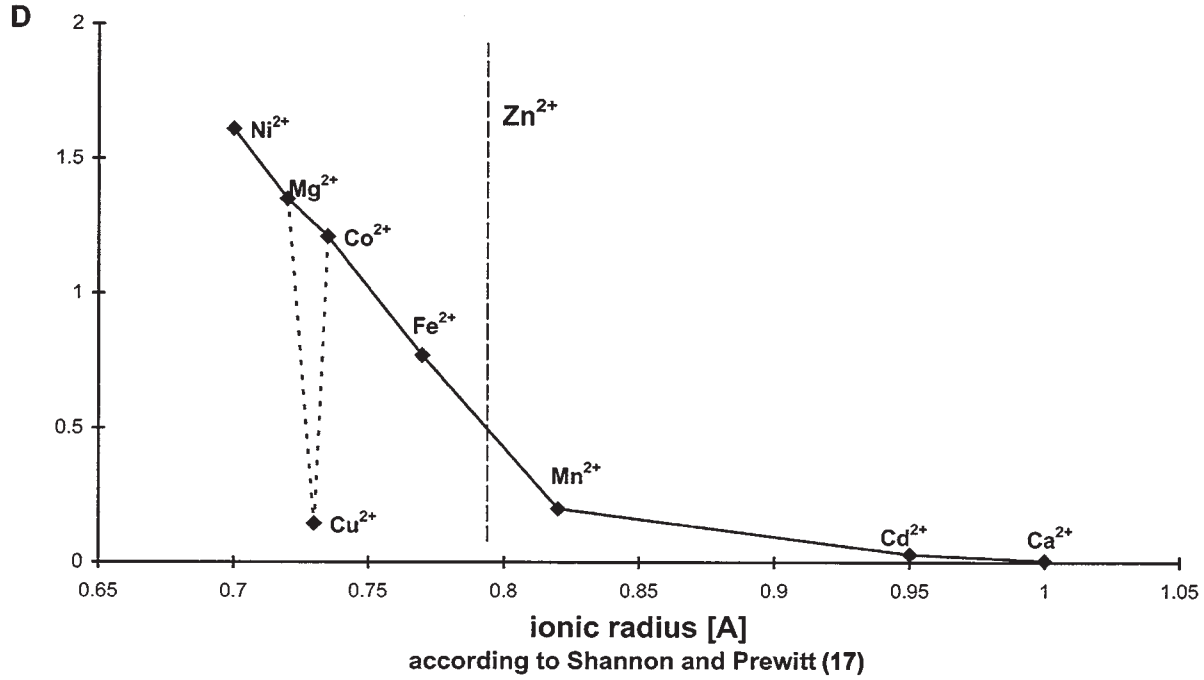
m_{Mk} = mass of the macrocomponent in the crystal

m_{Mr} = mass of the macrocomponent in the mother solution;

$$m_{Ms} = m_k \frac{C_k - C_r}{100 - C_r}$$

m_k = mass of the crystal

C_k = % of the macrocomponent in the crystal; $(100 - C_k)$ – crystal humidity (%)



C_r = % of the macrocomponent in the mother solution

and the volumes of the samples necessary to determine the microcomponents were calculated. The concentration was equal to 1.00 g (or less) of $ZnSO_4 \cdot 7H_2O$ in 25 cm^3.

Relative concentrations of microcomponents ([ppm] in relation to $ZnSO_4 \cdot 7H_2O$) in the mother solution (a'_r) and in the washed crystal (a'_k) determined by direct atomic absorption permitted the calculation of homogeneous distribution coefficient (D) (Henderson-Kraček, Khlopin)) from the following relation

© 2000 NRC Canada

Fig. 1. Dependence of distribution coefficients, *D*, of microcomponents, M^{2+}, during $ZnSO_4 \cdot 7H_2O$ crystallization at 20°C on their ionic radii.

$$D = \frac{a'_k}{a'_r}$$

Conditions of crystallization

1. Establishing the effect of initial concentration of microcomponents on their distribution coefficients, (D) during $ZnSO_4 \cdot 7H_2O$ crystallization at 20°C

The 31–33.5% zinc(II) sulfate solutions of different initial concentrations of microcomponents (a'_o) were cooled to temperatures close to 20°C and then poured into several beakers with water jackets and evaporated while stirring with a magnetic stirrer (~250 rpm) at 20 ± 1°C over 16–25 h. In another series the supersaturated (38–42%) zinc(II) sulfate solutions of different initial concentrations of microcomponents (a'_o) containing hydrazine sulfate were cooled to temperatures close to 20°C and poured into several beakers with water jackets. Having been covered with watch glasses, the solutions were stirred (or evaporated while stirring) with a magnetic stirrer (~250rpm) at 20 ± 1°C over 5–25 h. The applied conditions and obtained results are presented in Tables 2 and 3.

2. Determination of equilibrium distribution coefficients (D) of the microcomponents (M^{2+})

To determine the equilibrium distribution coefficients the method of long-time stirring of crushed crystals in saturated solution was applied (16). The equilibrium was reached starting either from initial concentration ratio of a microcomponent in crystal and in solution exceeding expected value of its equilibrium coefficient (D°_{max}) or from this ratio lower than expected value (D°_{min}). When selecting values D°_{max} and D°_{min} the highest and the lowest values of *D* obtained during crystallization of $ZnSO_4 \cdot 7H_2O$ at 20°C (series 1) were taken into consideration. The experiments were carried out in the following way: "contaminated" $ZnSO_4 \cdot 7H_2O$ crystals (a'_{ko}), crushed to pass a 0.1 mm sieve, were introduced into several beakers together with saturated, "purified" zinc(II) sulfate solution (a'_{ro}). Crystals of purified $ZnSO_4 \cdot 7H_2O$ (a''_{ko}) crushed to pass a 0.1 mm sieve and contaminated saturated solution of zinc(II) sulfate (a''_{ro}) were introduced to some other beakers. Each beaker, covered with watch glass, was placed on the water bath in a closed room. Their contents were stirred for ~360 h with magnetic stirrers. Fluctuations of temperature (which happened) facilitated recrystallization of $ZnSO_4 \cdot 7H_2O$ and helped attain equilibrium and homogeneous partition of microcomponents in crystal. These fluctuations were recorded. Mean value of temperature was equal to 23 ± 1°C. The results are presented in Table 4.

Results and discussion

The data presented in Tables 2 and 3 show that distribution coefficients, *D*, of most microcomponents do not depend essentially on their initial concentration (in the given investigated range).

The distribution coefficients of each of the ions M^{2+} {Co^{2+}, Mn^{2+}, Cu^{2+}, Fe^{2+}, Mg^{2+}, Ni^{2+}, and Cd^{2+}} for two series (D°_{max} and D°_{min}) do not differ from each other considerably, which means that the equilibrium condition was reached for them, and average values for both series are equilibrium values (Table 4). For most microcomponents, those values do not differ essentially from *D* values obtained during isothermal lowering supersaturation or isothermal evaporation at 20 ± 1°C (Table 2 and 3).

The determined partition coefficients, *D*, are diverse: from <0.006 for Ca^{2+} to 1.61 for Ni^{2+}. The determined values of

Note: Other definitions: $\overline{D}$, mean value of D, *sd*, standard deviation; n, number of determinations, $t_{0,05}$, value of Student *t*-test for n – 1 degrees of freedom and for the confidence level of 1 – α = 0.95.

D_{Fe} are lower than those obtained for macroamounts of $FeSO_4 \cdot 7H_2O$ by Balarev and Karaivanova (5) at 25°C and Gorstein (7) at 0°C. In the case of cocrystallization of Co^{2+} ion the determined coefficient D_{Co} is close to that obtained by Gorshtein and Silant'eva (9), but differs considerably from that given by Aslanian et al. (8). The coefficient D_{Ni} is very close to that determined for macroamounts of $NiSO_4 \cdot 7H_2O$ by Oikova et al. (11) and Jangg and Gregori (10), but is slightly lower than that obtained by Aslanian et al. (8) for macroamounts of nickel(II) sulfate heptahydrate. In the case of Mg^{2+} the values of D_{Mg} are slightly smaller than those given by Balarev and co-workers (6, 12) during cocrystallization of macroamounts of $MgSO_4 \cdot 7H_2O$ with $ZnSO_4 \cdot 7H_2O$. The coefficient D_{Cu} differs slightly from that determined by Purkayastha and Das (13) for microamounts of Cu^{2+}, but is considerably lower than that obtained by Jangg and Gregori (10) for macroamounts of Cu^{2+}. In the case of Mn^{2+}, the determined coefficients are slightly lower than those obtained by Purkayastha and Das (14).

The values of determined distribution coefficients D of the microcomponents M^{2+} are a measure of the ability to include ions of guest (M^{2+}) into the crystal lattice of the host ($ZnSO_4 \cdot 7H_2O$) or reciprocal solubility of both sulfate hydrates in the solid phase. According to the generally known principle "similar dissolves in the similar" this ability may be greater, the greater the similarity of radii of substituting ions, their coordination environment in crystal, or crystal structures and unit cell dimensions.

The dependence of D coefficients of the microcomponent on the ionic radius has been presented in Fig. 1. The D coefficients decrease with the increase of the ionic radius $r_{M^{2+}}$. For the most distant ion Ca^{2+}, its value is close to zero ($D <$ 0.006). But there is some irregularity in monotonic run of the $D = f(r_{M^{2+}})$ curve (for Cu^{2+}). It is caused by a considerable difference between the structures of triclinic $CuSO_4 \cdot 5H_2O$ and orthorhombic $ZnSO_4 \cdot 7H_2O$ as well as by a difference in coordination environments of both metal ions in the crystal resulting from their electron configurations. The open-cell Cu^{2+} ions yield highly distorted octahedra due to the Jahn–Teller effect and they can only in slight degree substitute Zn^{2+} ion, on account of the difficulty of acceptance of the coordination environment of the more regular octahedron of Zn^{2+} (18). Furthermore in the run of $D = f(r_{M^{2+}})$ dependence there is not any maximum of D for values of $r_{M^{2+}}$, the most close to the ionic radius of macrocomponent ($r_{Zn^{2+}}$) which often occurred in other crystallization systems (1–4). It means that in this crystallization system similarity of radii of the substituting ions does not influence D coefficients, although their dependence on the $r_{M^{2+}}$ for ions, which form at 20–23°C, (monoclinic sulfate hydrates (Co^{2+}, Fe^{2+}, Cd^{2+}, Ca^{2+})) is linear in a plot of log D against ionic radius with a coefficient of linear correlation $r_{xy} = -0.9941$ (Fig. 2).

The data presented in Table 5 indicate that values of coefficient D are essentially influenced by the similarity of the crystal structure of corresponding sulfate hydrates. The highest distribution coefficients occur for Ni^{2+} and Mg^{2+}, whose s**ulfate hydrates belong to the same orthorhombic crystal system as $ZnSO_4 \cdot 7H_2O$**, have almost the same unit cell dimensions, andcan also form continuous solid solutions ($Zn(Ni)SO_4 \cdot 7H_2O$ and $Zn(Mg)SO_4 \cdot 7H_2O$) without a

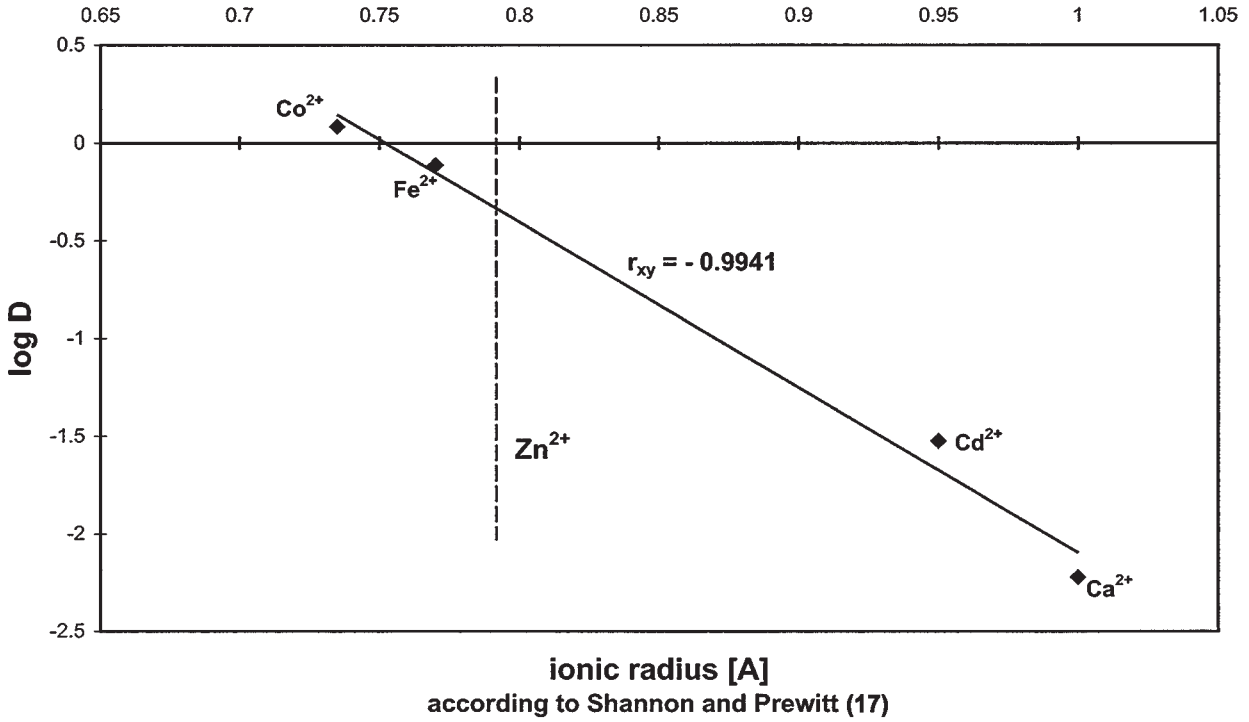
Fig. 2. Dependence of distribution coefficients, *D*, of microcomponents, M^{2+}, forming at 20°C of monoclinic sulfate hydrates on their ionic radii.



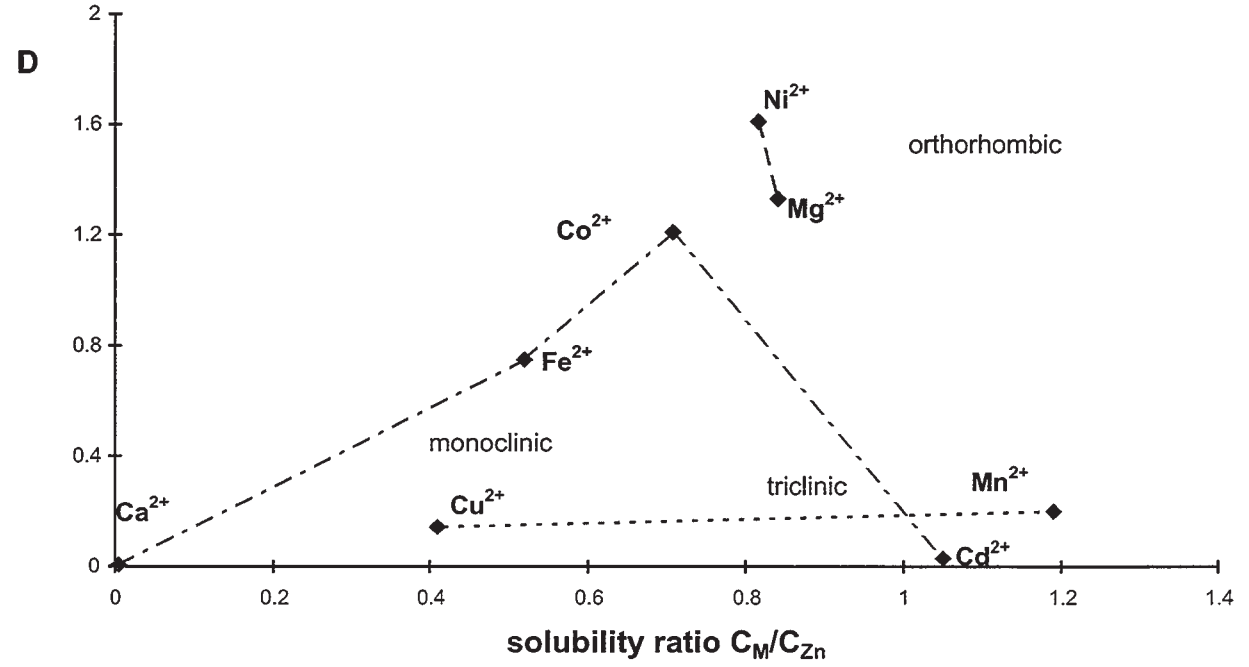


Fig. 3. Relationship between distribution coefficients, *D*, of M^{2+} ions forming at 20°C of sulfate hydrates belonging to the same crystal system and solubility ratio C_M/C_{Zn}.

miscibility gap (6, 8). The coefficients D_{Co} and D_{Fe} are lower, but the similarity of crystal structure of monoclinic $CoSO_4 \cdot 7H_2O$ and $FeSO_4 \cdot 7H_2O$ to $ZnSO_4 \cdot 7H_2O$ is lower as well. Though these monoclinic sulfate hydrates form solid solutions with zinc(II) sulfate heptahydrate ($Zn(Co)SO_4 \cdot 7H_2O$ and $Zn(Fe)SO_4 \cdot 7H_2O$), they are discontinuous. There is a miscibility gap from about 27% $CoSO_4 \cdot 7H_2O$ in the solid to about 46% $CoSO_4 \cdot 7H_2O$ (8) (as well as from about 55% $FeSO_4 \cdot 7H_2O$ in the solid to about 63% $FeSO_4 \cdot 7H_2O$ (6)). In this case, lowering similarity of crystal structure causes lowering reciprocal solubility sulfate hydrates in solid phase. This is accompanied with lowering distribution coefficients of *D*. The smallest *D* coefficients occur for Cd^{2+}, Ca^{2+}, Cu^{2+}, and Mn^{2+}. The first two ions

[c] The highest concentration occurred in goslarite ($ZnSO_4 \cdot 7H_2O$).

have the greatest ionic radii, which hinder their inclusion into the crystal lattice of zinc(II) sulfate heptahydrate. However though Mn^{2+} and Cu^{2+} radii are close to $r_{Zn^{2+}}$, their triclinic sulfate pentahydrates show the lowest symmetry and their crystal structures differ most considerably from structure of $ZnSO_4 \cdot 7H_2O$.

According to Aslanian and Balarev (18) the differences in the crystal structure of the heptahydrate as well as the existence or nonexistence of crystal hydrates of some ions (Co^{2+}, Cu^{2+}, Fe^{2+}, Mg^{2+}, and Ni^{2+}) may be explained with their electron configuration. The deformation trend of octahedral coordination of mentioned ions increases in the following order: $Ni^{2+} < Zn^{2+} < Mg^{2+} < Co^{2+} < Fe^{2+} < Cu^{2+}$. Determined D cocrystallization coefficients of microamounts of these ions with $ZnSO_4 \cdot 7H_2O$ decrease in the same order.

The relationship between D coefficients of M^{2+} ions and solubility ratio C_M/C_{Zn} (where C_M and C_{Zn} are molar solubilities in water of $MSO_4 \cdot nH_2O$ and $ZnSO_4 \cdot 7H_2O$ respectively (19–20)) is very complex (Fig. 3). According to general thermodynamic prediction, D coefficients should decrease with the increasing solubility ratio C_M/C_{Zn}, assuming that activity coefficients ratio of ions in solution as well as activity coefficients ratio of both sulfate hydrates in crystal are unity (21). However they are the lowest in the case of Ca^{2+} for which the solubility ratio is the lowest. Then partition coefficients increase monotonically with the increase of C_M/C_{Zn} ratio (from D_{Ca} to D_{Ni}), and next, they decrease in an irregular way. Based on this dependence for specified groups of M^{2+} ions, which form sulfate hydrates belonging to the same crystal system, we may state that in the case of orthorhombic sulfate hydrates, distribution coefficients, D, obey this thermodynamic prediction, but in the case of monoclinic as well as triclinic sulfate hydrates dependence, $D = f(C_M/C_{Zn})$ does not agree with this prediction. It may result from the great difference between ionic radii of macrocomponent (Zn^{2+}) and microcomponents (Ca^{2+} and Cd^{2+}), causing activity coefficients ratios in solution ($\gamma_{Zn^{2+}}/\gamma_{Ca^{2+}}$ and $\gamma_{Zn^{2+}}/\gamma_{Cd^{2+}}$) are different from unity as well as from the great difference between crystal structure of microcomponents sulfate hydrates ($MnSO_4 \cdot 5H_2O$, $CuSO_4 \cdot 5H_2O$, $CaSO_4 \cdot 2H_2O$, $3CdSO_4 \cdot 8H_2O$) and macrocomponent ($ZnSO_4 \cdot 7H_2O$) causing activity coefficients ratios of corresponding sulfate hydrates in the solid phase to differ from unity.

Conclusions

The coefficients of cocrystallization, D, of investigated microcomponents M^{2+} with zinc(II) sulfate heptahydrate are in the range <0.006 (D_{Ca}) – 1.61 (D_{Ni}). In the case of Ni^{2+}, Mg^{2+} and Co^{2+}, whose D coefficients are greater than 1, crystallization of $ZnSO_4 \cdot 7H_2O$ does not lead to its purification.

The values of D distribution coefficients first of all depend on similarity of the *crystal structure of M(II) sulfate hydrates.* They are the highest for Ni^{2+} and Mg^{2+} (their orthorhombic sulfate heptahydrates are isomorphous with $ZnSO_4 \cdot 7H_2O$, have almost the same unit cell dimensions, and form continuous solid solutions with it). For Co^{2+} and Fe^{2+} they are lower (their sulfate heptahydrates are monoclinic, have different unit cell dimensions, and form solid solutions of limited reciprocal solubility (with miscibility

© 2000 NRC Canada

gap)). The lowest values of D occur for Mn^{2+}, Cu^{2+}, Cd^{2+}, and Ca^{2+} (they do not form sulfate heptahydrates and the structures of their hydrates differ considerably from the structure of $ZnSO_4 \cdot 7H_2O$).

The order of lowering some of the determined distribution coefficients ($D_{Ni} > D_{Mg} > D_{Co} > D_{Fe} > D_{cu}$) exactly agrees with increase of the deformation trend of octahedral coordination of corresponding ions resulting from their electronic configuration.

The D coefficients do not depend on the similarity of ionic radii of microcomponent ($r_{M^{2+}}$) to macrocomponent ($r_{Zn^{2+}}$) since there is no maximum of D for values of $r_{M^{2+}}$ the closest to $r_{Zn^{2+}}$. However, this dependence of D for microcomponents forming at 20°C monoclinic sulfate hydrates (Co, Fe, Cd, Ca) is linear in a plot of log D against ionic radius.

The dependence of D coefficients of M^{2+} ions on the *solubility ratio* C_M/C_{Zn} is very complex. For Ni^{2+} and Mg^{2+} forming isomorphous sulfate hydrates with $ZnSO_4 \cdot 7H_2O$, they get smaller with increasing C_M/C_{Zn} according to general thermodynamic prediction. In the case of the remaining microcomponents, this dependence is disturbed by the influence of ionic radii as well the structure of corresponding sulfate hydrates. They cause activity coefficients ratio of respective ions in solution or activity coefficients ratio of corresponding sulfates in crystal to be different from unity.

Synthesis, characterization, and reactivity of scandium chloro, alkyl, aryl, and borohydride complexes, $Sc(\eta^5\text{-}C_5H_5)R[N(SiMe_2CH_2P^iPr_2)_2]$ (R = Cl, Me, Ph, and BH_4)

Michael D. Fryzuk, Garth R. Giesbrecht, and Steven J. Rettig

Abstract: Reaction of $ScCl_2(THF)[N(SiMe_2CH_2P^iPr_2)_2]$ with NaCp(DME) leads to $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2P^iPr_2)_2]$ (**1**). The X-ray crystal structure shows the scandium centre to reside in a square pyramidal environment with the $[N(SiMe_2CH_2P^iPr_2)_2]$ – ligand bound in a pseudo-meridional fashion. The ^1H NMR spectrum is consistent with a C_s symmetric structure in solution. Metathesis of the chloride ligand with RLi (R = Me, Ph, BH_4) yields the five-coordinate species $Sc(\eta^5\text{-}C_5H_5)R[N(SiMe_2CH_2P^iPr_2)_2]$. Phenyl **3** and borohydride **4** are isolated as crystalline solids, while methyl **2** resisted crystallization. **2**–**4** exhibit ^1H NMR spectra consistent with C_s symmetric solution structures. $Sc(\eta^5\text{-}C_5H_5)Ph[N(SiMe_2CH_2P^iPr_2)_2]$ (**3**) was characterized in the solid state and found to have a similar geometry to that of the parent chloride. Reaction of $Sc(\eta^5\text{-}C_5H_5)Me[N(SiMe_2CH_2P^iPr_2)_2]$ (**2**) with NH_2R (R = Ph, ^{t}Bu) yields the amides $Sc(\eta^5\text{-}C_5H_5)NHPh[N(SiMe_2CH_2P^iPr_2)_2]$ (**5**) and $Sc(\eta^5\text{-}C_5H_5)NH^tBu[N(SiMe_2CH_2P^iPr_2)_2]$ (**6**) via σ-bond metathesis routes; these reactions are accompanied by a competing reaction at the scandium-amide bond to produce the protonated ligand, $HN(SiMe_2CH_2P^iPr_2)_2$. **5** and **6** are also produced by salt-elimination from the chloride **1** and LiNHR (R = Ph, ^{t}Bu). $Sc(\eta^5\text{-}C_5H_5)(BH_4)[N(SiMe_2CH_2P^iPr_2)_2]$ (**4**) reacts with PMe_3 to produce the putative hydride, $Sc(\eta^5\text{-}C_5H_5)H[N(SiMe_2CH_2P^iPr_2)_2]$ (**7**); this species was identified in solution. An equilibrium between **4**, PMe_3, **7**, and $PMe_3{\cdot}BH_3$ exists which greatly favors the starting scandium-borohydride. Crystals of $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2P^iPr_2)_2]$ (**1**) are monoclinic, a = 17.409(2), b = 10.0803(7), c = 17.688(2) Å, β = 94.606(8)°, Z = 4, space group $P2_1/c$; and those of $Sc(\eta^5\text{-}C_5H_5)Ph[N(SiMe_2CH_2P^iPr_2)_2]$ (**3**) are triclinic, a = 10.5129(15), b = 19.124(2), c = 9.114(2) Å, α = 95.582(13), β = 107.047(12), γ = 90.042(11)°, Z = 2, space group P. The structures were solved by Patterson (**1**) and direct (**3**) methods and refined by full-matrix least-squares procedures to R = 0.047 and 0.054 (R_w = 0.042 and 0.049) for 2414 and 2844 reflections with $I \geq 3\sigma(I)$, respectively.

Key words: scandium, σ-bond metathesis, borohydride.

Résumé : La réaction du $ScCl_2(THF)[N(SiMe_2CH_2CH_2P^iPr_2)_2]$ avec le NaCp(DME) conduit à la formation du $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2CH_2P^iPr_2)_2]$ (**1**). La structure cristalline obtenue par diffraction des rayons X montre que le centre scandium se trouve dans un environnement pyramidal carré où le ligand $[N(SiMe_2CH_2CH_2P^iPr_2)_2]$ est lié d'une façon pseudoméridionale. Le spectre RMN du ^1H est en accord avec une structure symétrique $\mathbf{C_s}$, en solution. La métathèse du ligand chlorure avec du RLi (R = Me, Ph, BH_4) fournit des espèces pentacoordinées $Sc(\eta^5\text{-}C_5H_5)R[N(SiMe_2CH_2CH_2P^iPr_2)_2]$. Les dérivés phényle (**3**) et borohydrure (**4**) ont été isolés sous forme de solides cristallins alors que le dérivé méthyle (**2**) n'a pu être cristallisé. Les spectres RMN du ^1H des dérivés **2**–**4** sont en accord avec des structures symétriques $\mathbf{C_s}$ en solution. Le composé $Sc(\eta^5\text{-}C_5H_5)Ph[N(SiMe_2CH_2CH_2P^iPr_2)_2]$ (**3**) a été caractérisé à l'état solide et on a trouvé qu'il possède une géométrie similaire à celle du dérivé chloré qui lui a donné naissance. La réaction du $Sc(\eta^5\text{-}C_5H_5)Me[N(SiMe_2CH_2CH_2P^iPr_2)_2]$ (**2**) avec le NH_2R (R = Ph, *t*-Bu) conduit aux amides $Sc(\eta^5\text{-}C_5H_5)NHPh[N(SiMe_2CH_2CH_2P^iPr_2)_2]$ (**5**) et $Sc(\eta^5\text{-}C_5H_5)NH^tBu[N(SiMe_2CH_2CH_2P^iPr_2)_2]$ (**6**) par le biais de réactions de métathèses impliquant la liaison σ; ces réactions sont accompagnées par une réaction parallèle au niveau de la liaison scandium-amide qui produit le ligand protoné $HN(SiMe_2CH_2CH_2P^iPr_2)_2$. Les composés **5** et **6** se produisent aussi par une élimination de sel à partir du chlorure **1** et du LiNHR (R = Ph, *t*-Bu). Le $Sc(\eta^5\text{-}C_5H_5)BH_4[N(SiMe_2CH_2CH_2P^iPr_2)_2]$ (**4**) réagit avec le PMe_3 et donne lieu à la formation de l'hydrure putatif $Sc(\eta^5\text{-}C_5H_5)H[N(SiMe_2CH_2CH_2P^iPr_2)_2]$ (**7**) qui a été identifié en solution. Il existe un équilibre entre les produits **4**, PMe_3, **7** et $PMe_3{\cdot}BH_3$ qui favorise fortement le borohydrure de scandium de départ. Les cristaux de $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2CH_2P^iPr_2)_2]$ (**1**) sont monocliniques, groupe d'espace $P2_1/c$, avec a = 17,409(2), b = 10,803(7) et c = 17,688(2) Å, β = 94,606(8)° et Z = 4; ceux du $Sc(\eta^5\text{-}C_5H_5)Ph[N(SiMe_2CH_2CH_2P^iPr_2)_2]$ (**3**) sont tricliniques, groupe d'espace P, avec a = 10,5129(15), b = 19,124(2) et

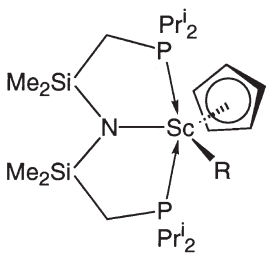
c = 9,114(2) Å, α = 95,582(13), β = 107,047(12) et γ = 90,042(11)° et Z = 2. On a résolu les structures par les méthodes de Patterson et directes et on les a affinées par la méthode des moindres carrés (matrice entière) jusqu'à des valeurs de R = 0,047 et 0,054 (R_w = 0,042 et 0,049) pour respectivement 2414 et 2844 réflexions avec $I \geq 3\sigma(I)$.

Mots clés : scandium, métathèse par liaison-σ, borohydrure.



Introduction

Until recently, the chemistry of scandium was largely unexplored, in part due to the general assumption that the Lewis acidic scandium centre offered little in the way of useful reactivity (1). Although early work with scandium utilized large alkyl (2, 3) or cyclopentadienyl ligands, (4–6) complexes of the general type Cp^*_2ScR (Cp^* = pentamethylcyclopentadienyl, R = hydride, alkyl, aryl) were found to participate in many useful transformations, including olefin polymerization (7–9) and C-H activation (or σ-bond metathesis) (7, 8, 10). Although organoscandium chemistry, and organolanthanide chemistry in general, has been dominated by pentamethylcyclopentadienyl-based ligands, (11) recent work has been directed towards generating reactive scandium alkyl complexes by incorporating nitrogen-containing ligands (12) such as porphyrins, (13–16) amidinates (17), or trispyrazolylborates (18). However, these ligand sets have yet to surpass the unique stabilization provided to the metal centre by either two Cp^* ligands (7, 19, 20) or the combination of a Cp^* ligand and an amide (7, 21–23).

We recently reported the synthesis, characterization, and reactivity of a series of five-coordinate scandium dialkyls, $ScR_2[N(SiMe_2CH_2P^iPr_2)_2]$ (R = Me, Et, CH_2SiMe_3) (**A**) (24). Unfortunately, these scandium dialkyls suffer a similar fate to many lanthanide dialkyls stabilized by a single ancillary ligand (25–27). Although these complexes are stable enough to be isolated, they decompose to multiple, unidentifiable products when reacted with small molecules. One approach to this problem is to replace a chloride with a larger, unreactive ligand, which will result in a more coordinatively saturated complex. Additionally, if the ligand can be chosen to donate more than two electrons to the metal, the compound will have greater electronic stability. This leaves a site at the metal at which to pursue reaction chemistry. In an effort to generate more stable derivatives, and better defined reaction pathways, we metathesized a chloride with NaCp(DME) to generate compounds of the type $Sc(\eta^5\text{-}C_5H_5)R[N(SiMe_2CH_2P^iPr_2)_2]$ (**B**), which have added steric bulk and an additional four electrons, as compared to the $ScR_2[N(SiMe_2CH_2P^iPr_2)_2]$ series. Herein we describe the synthesis, characterization, and reactivity of $Sc(\eta^5\text{-}C_5H_5)R[N(SiMe_2CH_2P^iPr_2)_2]$ (R = Cl, Me, Ph, BH_4).

B

Results and discussion

Synthesis of $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2P^iPr_2)_2]$ (1)

The addition of a THF solution of NaCp(DME) to a solution of $ScCl_2(THF)[N(SiMe_2CH_2P^iPr_2)_2]$ (24) in THF maintained at –78°C results in $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2P^iPr_2)_2]$ (**1**) (eq. [1]). Additionally, the same metathesis can be effected by the addition of solid NaCp(DME) to a toluene solution of the starting dichloride, although this route requires a longer reaction time (1 week).

$$ScCl_2(THF)[N(SiMe_2CH_2PPr^i_2)_2] + NaCp(DME) \xrightarrow[(-\ NaCl)]{THF,\ -78\ ^\circ C} \quad [1]$$

1

Compound **1** is isolated as a slightly yellow, waxy solid and forms colorless crystals upon slow evaporation of a saturated toluene solution. The ^{1}H NMR spectrum of **1** shows a doubling of the ligand resonances, due to the presence of a chloride and a cyclopentadienide ligand. Heating a d_8-toluene solution of **1** to 100°C does not result in the averaging of the diastereotopic ligand resonances, indicating that the positions of the Cp and Cl moieties are fixed, and not subject to exchange via a process such as phosphine dissociation, followed by rotation about the scandium-amide bond and re-coordination. The $^{31}P\{^1H\}$ NMR spectrum of **1** exhibits a broad singlet (δ –1.2 ppm, $\Delta_{1/2}$ = 425 Hz) at all temperatures, due to the interaction with the quadrupolar scandium nucleus (^{45}Sc, I = 7/2, 100% natural abundance) (28). As well, the five equivalent Cp protons couple to two equivalent phosphorous-31 nuclei, exhibiting a triplet in the ^{1}H NMR spectrum at 6.51 ppm ($^3J_{H\text{-}P}$ = 1.3 Hz). The identity of the compound was confirmed by mass spectral, microanalytical and X-ray crystallographic studies.

Synthesis of scandium alkyls $Sc(\eta^5\text{-}C_5H_5)R[N(SiMe_2CH_2P^iPr_2)_2]$ (R = Me (2), Ph (3), BH_4 (4))

Metathesis of the chloride ligand of $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2P^iPr_2)_2]$ (**1**) is undertaken by a number of alkyl, aryl, or borohydride lithium reagents (eq. [2]).

$$\underset{\mathbf{1}}{Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2PPr^i_2)_2]} + RLi \xrightarrow[(-\ LiCl)]{toluene} Sc(\eta^5\text{-}C_5H_5)R[N(SiMe_2CH_2PPr^i_2)_2] \quad [2]$$

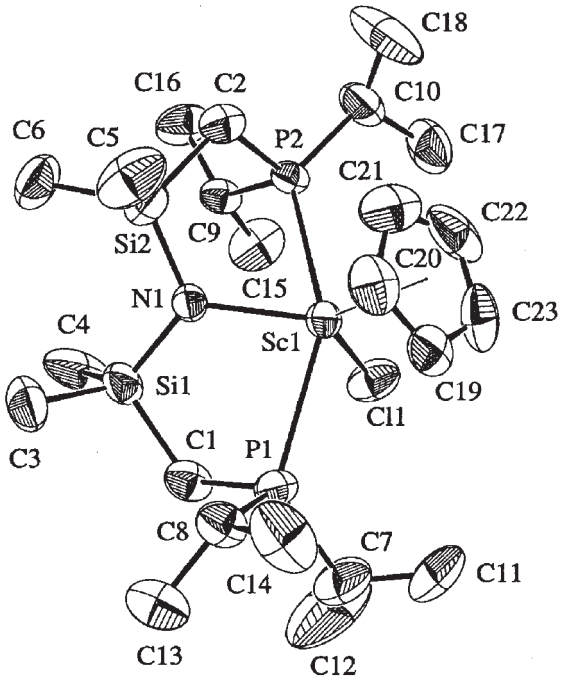
Fig. 1. Molecular structure of $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2P^iPr_2)_2]$ (**1**); 33% probability thermal ellipsoids are shown. Hydrogen atoms are omitted for clarity.



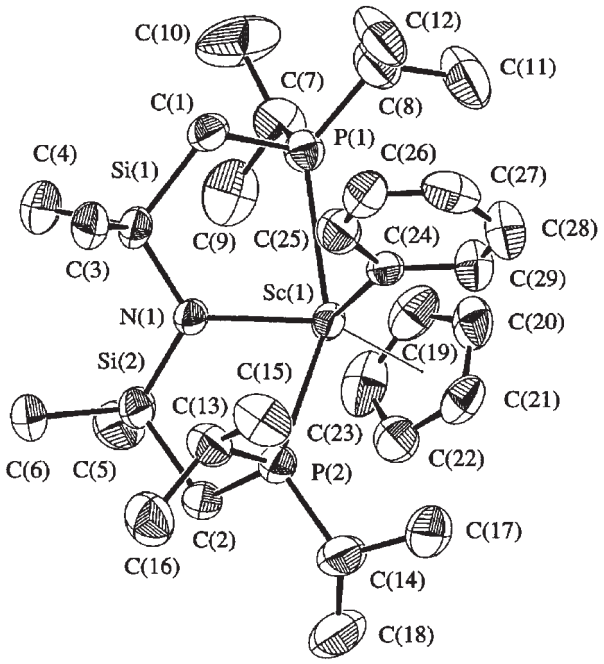


Fig. 2. Molecular structure of $Sc(\eta^5\text{-}C_5H_5)Ph[N(SiMe_2CH_2P^iPr_2)_2]$ (**3**); 33% probability thermal ellipsoids are shown. Hydrogen atoms are omitted for clarity.

The presence of the Cp ring reduces the tendency for these complexes to incorporate LiCl, which was found to occur in the dialkyl species, $ScR_2[N(SiMe_2CH_2P^iPr_2)_2]$ (R = Et, CH_2SiMe_3) (24). The phenyl complex **3** and the borohydride complex **4** were isolated as thermally-stable, off-white solids, which were subsequently obtained as air- and moisture-sensitive colorless crystals from hexamethyldisiloxane solutions. However, methyl **2** resisted crystallization and was used as a yellow, sticky solid. The ^1H NMR spectrum of each complex shows a doubling of the ligand backbone resonances, due to the presence of an alkyl, aryl, or borohydride ligand, and a Cp ligand. In the case of methyl **2**, the methyl protons ($ScCH_3$) resonate as a triplet at –0.19 ppm ($^3J_{H\text{-}P}$ = 4.3 Hz) due to coupling to two equivalent phosphorus-31 nuclei. For all three derivatives, the five Cp protons are equivalent, appearing as a triplet around 6.5 ppm. The $^{31}P\{^1H\}$ NMR spectra of **2**–**4** show broad, temperature invariant singlets at about 0 ppm ($\Delta_{1/2}$ = 100–200 Hz). The structure of the phenyl derivative **3** was investigated by X-ray crystallography.

Structure of $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2P^iPr_2)_2]$ (1) and $Sc(\eta^5\text{-}C_5H_5)Ph[N(SiMe_2CH_2P^iPr_2)_2]$ (3)

The evaporation of a saturated toluene solution of **1** yielded large colorless crystals for X-ray analysis. The molecular structure and numbering scheme are presented in Fig. 1. Complete details of the structural analyses of **1** and **3** are presented in Table 1. Final atomic coordinates and B_{eq} for **1** and **3** are available in Table 2. The scandium centre has a geometry intermediate between trigonal bipyramidal and square pyramidal; if the Cp ligand occupies the apical position, the square pyramidal geometry is completed by the amide, the two phosphines and the chloride.

The angles defined by the Cp—scandium bond, and the four members of the base of the pyramid range from 105.4 to 127.9° (Cp = cyclopentadienyl centroid). The P(1)-Sc(1)-P(2) angle of 147.08(6)° is similar to that in $Sc(CH_2SiMe_3)_2[N(SiMe_2CH_2P^iPr_2)_2]$ (154.92(6)°) (24). The phosphorus-scandium bond lengths (2.804(2) and 2.822(2) Å) are slightly longer than those found for $ScCl_2(THF)[N(SiMe_2CH_2P^iPr_2)_2]$, as is the scandium-amide bond length of 2.116(4) Å (compared to 2.101(7) Å in $ScCl_2(THF)[N(SiMe_2CH_2P^iPr_2)_2]$) (24). The scandium centre is equidistant from all five Cp carbons (2.480(9)–2.511(7) Å), consistent with an η^5-bound cyclopentadienyl ligand. The scandium—Cp bond length (2.21 Å) is similar to that found for $(Cp_2ScCl)_2$ [5] and $(OEP)Sc(\eta^5\text{-}C_5H_5)$ [14] (2.19 and 2.20 Å, respectively) (OEP = octaethylporphyrin). Bond lengths and angles for **1** and **3** are presented in Tables 3 and 4, respectively.

Colorless crystals suitable for X-ray crystallographic analysis were grown from a saturated hexamethyldisiloxane solution of phenyl **3**. Figure 2 shows the numbering scheme and solid state structure. As for the chloride derivative **1**, the scandium centre has a distorted square pyramidal geometry.

In this case, the four angles involving the Cp ring, the scandium centre and the bases of the pyramid range from 104.0 to 130.2°. The P(1)-Sc(1)-P(2) bond angle (149.77(6)°) is in the same range as that determined for **1** and the bis(trimethylsilylmethyl) complex, $Sc(CH_2SiMe_3)_2[N(SiMe_2CH_2P^iPr_2)_2]$ (24). All of the bond lengths involving scandium are normal and show little variation from the parent chloride. The 2.229(6) Å spacing between the scandium centre and the ipso-carbon of the phenyl ring may be compared with distances of 2.242(3) Å for $ScEt_2[N(SiMe_2CH_2P^iPr_2)_2]$ and 2.204(5) and 2.126(4) Å for $Sc(CH_2SiMe_3)_2[N(SiMe_2CH_2P^iPr_2)_2]$. (24)

Values given for R, R_w, and gof are based on those reflections with $I \geq 3\sigma(I)$.

Structure of $Sc(\eta^5\text{-}C_5H_5)(BH_4)[N(SiMe_2CH_2P^iPr_2)_2]$ (4)

Colorless crystals of the borohydride complex **4** remained after the evaporation of a saturated hexamethyldisiloxane solution. Although the basic structural features of the complex were confirmed, a refined structure was not obtained due to disorder. The labile nature of the $[BH_4]^-$ unit, and its proximity to the quadrupolar scandium nucleus, prevented these resonances from being observed in the ^{1}H NMR spectrum. The absence of peaks assignable to BH_4 protons is a characteristic of the ^{1}H NMR spectrum of $[\eta^5\text{-}C_5H_3(SiMe_3)_2]_2Sc(BH_4)$ as well (29). The fluxionality of the $[BH_4]^-$ moiety is readily demonstrated by ^{11}B NMR spectroscopy: at ambient temperature, the spectrum consists of a 1:4:6:4:1 quintet at –27.6 ppm, consistent with coupling to 4 equivalent protons ($^1J_{B\text{-}H}$ = 85 Hz, $\Delta_{1/2}$ = 32 Hz). When a d_8-toluene solution of **4** is cooled to –80°C, the fluxional exchange process between bridge (H_b) and terminal (H_t) hydrogens is retarded; thus, a single broad peak at –27.0 ppm is observed ($\Delta_{1/2}$ = 160 Hz). This is faster than the exchange in $[\eta^5\text{-}C_5H_3(SiMe_3)_2]_2Sc(BH_4)$ which must be heated to 100°C before a quintet is observed ($^1J_{B\text{-}H}$ = 75 Hz) (29).

The solid state infrared spectrum of **4** consists of a sharp, strong band at 2478 cm^{-1} and a broader, weaker signal at 2211 cm^{-1}. These data are consistent with a BH_4 ligand bound in a tridentate fashion (30). These numbers compare favorably with a series of lanthanide tetrahydroborates $[\eta^5\text{-}C_5H_3(SiMe_3)_2]_2M(BH_4)$ (M = La, Pr, Nd, Sm) (29) which feature IR peaks diagnostic of tridentate coordination at 2420 and 2240 cm^{-1}. The band at 2478 cm^{-1} is assigned to the B—H_t stretch (A_1) and the broad band at 2211 cm^{-1} to the B—H_b stretching modes (A_1 and E) (30) In contrast to **4**, the previously characterized scandium tetrahydroborates $[\eta^5\text{-}C_5H_3(SiMe_3)_2]_2Sc(BH_4)$, (29) $[TolC(NSiMe_3)_2]_2Sc(BH_4)(THF)$ (17), and $Sc(BH_4)_3\cdot THF$ (31) bind BH_4 in a bidentate manner. The solution IR spectrum of **4** (hexanes) is identical to that of the solid state.

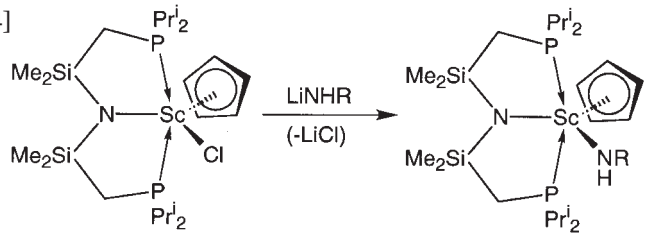
Reactivity of Sc(η^5-C_5H_5)Me[N($SiMe_2CH_2P^iPr_2$)$_2$] (2)

In contrast to the facile decomposition of dialkyls $ScR_2[N(SiMe_2CH_2P^iPr_2)_2]$ (R = Me, Et, CH_2SiMe_3) with H_2, (24) the scandium methyl complex **2** is inert to H_2 (4 atm, 5 days). However, exposure of methyl **2** to H_2NPh or H_2N^tBu (toluene solution, 1 equiv) yields the amides Sc(η^5-C_5H_5)NHPh[N($SiMe_2CH_2P^iPr_2$)$_2$] (**5**) and Sc(η^5-C_5H_5)NH^{t}Bu[N($SiMe_2CH_2P^iPr_2$)$_2$] (**6**) with the elimination of methane (eq. [3]).

[3]

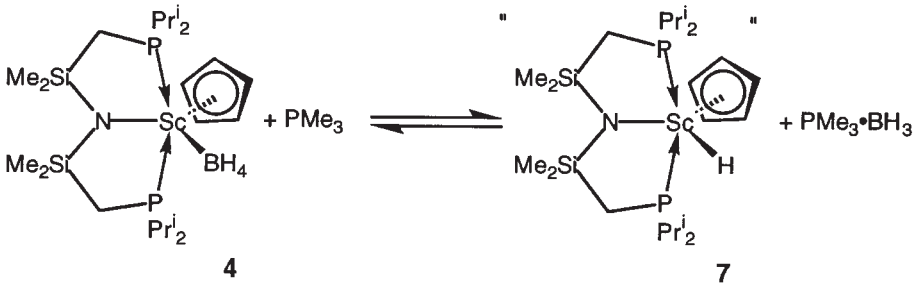


2 **5**: R = Ph; **6**: R = Bu^t

These reactions proceed analogously to those between Cp^*_2ScMe and H_2NR (R = H, Me, Ph, CH_2CMe_3) (32). The syntheses of **5** and **6** are accompanied by a competing decomposition to produce $HN(SiMe_2CH_2P^iPr_2)_2$ and an insoluble scandium-containing precipitate; thus the yields are quite low. (The amides Cp^*_2ScNHR are also produced in low yields (32)). The similar solubility of $HN(SiMe_2CH_2P^iPr_2)_2$ to amides **5** and **6** hindered our attempts to isolate them as pure solids. If a large excess of amine is used (4 equiv), only the protonated ligand is observed. We assume the amine proteolytically attacks the scandium-amide bond, resulting in decomposition accompanied by loss of $HN(SiMe_2CH_2P^iPr_2)_2$.

Cp^*_2ScMe reacts similarly with hydrazine; with 1 equiv, $Cp^*_2ScN(H)NH_2$ is formed although excess NH_2NH_2 results in decomposition to Cp^*H (33). To ensure the identity of the products, **5** and **6** were also synthesized by a salt-elimination route between the chloro species Sc(η^5-C_5H_5)Cl[N($SiMe_2CH_2P^iPr_2$)$_2$] (**1**) and LiNHR (R = Ph, ^{t}Bu) (eq. [4]).

[4]



1 **5**: R = Ph; **6**: R = Bu^t

The ligand backbone and Cp resonances are shifted from the starting methyl complex, and peaks due to the phenyl ring are visible. The N*H* proton resides at 5.55 ppm (br s); by comparison, the N*H* resonance in $[PhC(NSiMe_3)_2]_2Sc(NHC_6H_3$-2,6-^{i}Pr$_2$) is located at 5.86 ppm (17). Even when synthesized from the lithium amides, **5** and **6** are contaminated with $HN(SiMe_2CH_2P^iPr_2)_2$, suggesting that intermolecular cleavage of Sc—N bonds by Sc(η^5-C_5H_5)NHR[N($SiMe_2CH_2P^iPr_2$)$_2$] may also occur. The related hydrazido complex $Cp^*_2ScN(H)NH_2$ also undergoes a concentration dependent decomposition to eliminate Cp^*H (33). The ^{1}H NMR spectrum of *tert*-butylamide **6** contains a NC*Me*$_3$ resonance at 1.37 ppm (s) and a broad peak which integrates for a single

Fig. 3. Variable temperature 96.3 MHz $^{11}B\{^1H\}$ NMR spectra for the reaction between $Sc(\eta^5\text{-}C_5H_5)(BH_4)[N(SiMe_2CH_2P^iPr_2)_2]$ (**4**) and PMe_3 (~100 equiv).

proton at 4.70 ppm. The N*H* peak for the related compound $Cp^*_2Sc(NHCH_2CMe_3)$ resides at 4.75 ppm (32). Phenylamide **5** and *tert*-butylamide **6** exhibit broad peaks ($\Delta_{1/2}$ = 80 and 90 Hz, respectively) around 0 ppm in the $^{31}P\{^1H\}$ NMR spectra.

Reactions between methyl **2** and more acidic substrates such as primary and secondary phosphines were much less well behaved. The reaction of $Sc(\eta^5\text{-}C_5H_5)Me[N(SiMe_2CH_2P^iPr_2)_2]$ with H_2PPh or $HPPh_2$ (1 equiv in THF) results in protonation of the ancillary ligand to yield $HN(SiMe_2CH_2P^iPr_2)_2$ and an insoluble white precipitate. Attempts to generate scandium phosphides of the general formula $Sc(\eta^5\text{-}C_5H_5)(PR_2)[N(SiMe_2CH_2P^iPr_2)_2]$ (R = Ph, ^{i}Pr) via salt metathesis routes from chloride **1** and $LiPPh_2$ or LiP^iPr_2 resulted in unidentifiable mixtures. We also examined the potential of these systems as ethylene polymerization catalysts. Although phenyl **3** and borohydride **4** show no activity towards ethylene, methyl **2** polymerizes ethylene slowly either with or without methylalumoxane present as a co-catalyst.

Reactivity of $Sc(\eta^5\text{-}C_5H_5)(BH_4)[N(SiMe_2CH_2P^iPr_2)_2]$ (4)

Compounds that contain direct metal-hydrogen bonds are important due to their implication in a large number of stoichiometric and catalytic processes (34). In certain cases, transition-metal tetrahydroborate complexes serve as precursors to metal hydride derivatives if BH_3 can be cleaved from the $[BH_4]^-$ unit (35–38). Typically, strong σ-donors such as tertiary phosphines or amines are effective in this regard. The reaction of $Sc(\eta^5\text{-}C_5H_5)(BH_4)[N(SiMe_2CH_2P^iPr_2)_2]$ (**4**) with PMe_3 (~100 equiv) was followed by $^{11}B\{^1H\}$ NMR spectroscopy (Fig. 3).

The spectra consist of a large singlet due to the borohydride complex **4** at –27.6 ppm and a doublet at –47.8 ppm ($^1J_{B\text{-}P}$ = 48 Hz). If the spectrum is collected with proton coupling, this doublet appears as a quartet of doublets ($^3J_{B\text{-}H}$ = 86 Hz). This pattern is due to $PMe_3{\cdot}BH_3$. As the temperature is increased, the relative area of the peak due to $PMe_3{\cdot}BH_3$ increases. This indicates that an equilibrium is present between $Sc(\eta^5\text{-}C_5H_5)(BH_4)[N(SiMe_2CH_2P^iPr_2)_2]$ (**4**), PMe_3, $PMe_3{\cdot}BH_3$, and the putative hydride $Sc(\eta^5\text{-}C_5H_5)H[N(SiMe_2CH_2P^iPr_2)_2]$ (**7**) (Scheme 1).

From the van't Hoff plot, the following thermodynamic parameters were obtained: ΔH° = 8.8 ± 2 kcal mol^{-1} and ΔS° = 10.1 ± 8 cal K^{-1} mol^{-1}. From the equilibrium data, it appears unlikely that a scandium hydride can be isolated via this route. Even with a 100-fold excess of PMe_3 at 68°C, the equilibrium still favors the starting borohydride complex. We should also note that by studying the equilibrium by $^{11}B\{^1H\}$ NMR spectroscopy, we only have indirect evidence for the formation of the scandium hydride **7**. Although the observation of $PMe_3{\cdot}BH_3$ implies the existence of this species, we were not able to observe the scandium-hydride signal in the ^1H spectrum due to quadrupolar broadening; however new ligand and Cp resonances were evident (see Experimental Section). The positive entropy term indicates a monomeric species, as opposed to a dimeric or base-stabilized complex, which would be reflected in a significantly negative value of ΔS°.

Conclusions

In an attempt to generate more stable scandium-alkyls, a chloride in the starting complex $ScCl_2(THF)[N(SiMe_2CH_2P^iPr_2)_2]$ was replaced with a cyclopentadienyl ligand, to generate a more sterically and electronically saturated metal centre. The rationale for this was that the resulting alkyl complexes $Sc(\eta^5\text{-}C_5H_5)R[N(SiMe_2CH_2P^iPr_2)_2]$ should exhibit more controlled reactivity patterns as compared to the previously reported series $ScR_2[N(SiMe_2CH_2P^iPr_2)_2]$ (R = Me, Et, CH_2SiMe_3). Metathesis of the remaining chloride ligand in $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2P^iPr_2)_2]$ (**1**) was easily undertaken. The methyl complex **2** was inert to H_2, but found to react with amines via C-H activation to yield phenylamide **5** and *tert*-butylamide **6** although a competing decomposition to $HN(SiMe_2CH_2P^iPr_2)_2$ was observed. The borohydride complex **4** reacts with PMe_3 to form a putative scandium-hydride complex **7**, as studied by $^{11}B\{^1H\}$ NMR spectroscopy. The presence of a single Cp ligand results in more

© 2000 NRC Canada

stable scandium alkyls, although reaction at the scandium-amide bond, as well as the scandium-alkyl bond, is still observed.

Experimental section

Procedures

Unless otherwise stated all manipulations were performed under an atmosphere of dry, oxygen-free dinitrogen or argon by means of standard Schlenk or glovebox techniques. The glovebox used was a Vacuum Atmospheres HE-553-2 model equipped with a MO-40-2H purification system and a –40°C freezer. ^{1}H, ^{31}P{^{1}H}, and ^{11}B{^{1}H} NMR spectroscopy were performed on a Varian XL-300 instrument operating at 299.9, 121.4, and 96.3 MHz, respectively. ^{1}H NMR spectra were referenced to internal C_6D_5H (7.15 ppm) or $C_6D_5CD_2H$ (2.09 ppm). ^{31}P{^{1}H} NMR spectra were referenced to external $P(OMe)_3$ (141.0 ppm with respect to 85% H_3PO_4 at 0.0 ppm). ^{11}B{^{1}H} NMR spectra were referenced to neat BEt_3 (0.0 ppm). Mass spectral studies were carried out on a Kratos MS 50 using an EI source. Infrared spectra were recorded on a BOMEM MB-100 spectrometer. Solution samples were recorded on a 0.1 mm KBr cell and solid samples were recorded as KBr pellets. Microanalyses (C, H, N) were performed by Mr. P. Borda of this department.

Materials

$ScCl_2(THF)[N(SiMe_2CH_2P^iPr_2)_2]$ was prepared by a published procedure (24). MeLi (1.4 M solution in ether) was purchased from Aldrich and used as received. $LiBH_4$ and $NaBH_4$ were purchased from Strem and used as received. H_2NPh and H_2N^tBu were purchased from Aldrich and distilled over sodium benzophenone. PMe_3 was purchased from Aldrich and vacuum transferred over sodium benzophenone. LiNHPh and $LiNH^tBu$ were prepared by the addition of BuLi to an ether solution of the amine. NaCp(DME) (39) and PhLi (40) were prepared according to published procedures.

Toluene, Et_2O, THF, and hexamethyldisiloxane were refluxed over CaH_2 prior to a final distillation from either sodium metal or sodium benzophenone ketyl under an argon atmosphere. Deuterated solvents were dried by distillation from sodium benzophenone ketyl; oxygen was removed by 3 freeze-pump-thaw cycles.

Syntheses

*Sc(η^5-C_5H_5)Cl[N(SiMe$_2$CH$_2$P^{i}Pr$_2$)$_2$] (**1**). Method 1*: To a solution of $ScCl_2(THF)[N(SiMe_2CH_2P^iPr_2)_2]$ (572 mg; 0.985 mmol) in toluene (10 mL) was added solid NaCp(DME) (176 mg; 0.985 mmol). The reaction mixture was stirred at room temperature for 1 week. The reaction mixture was then passed through a frit lined with Celite to remove NaCl. The solvent was removed in vacuo to yield a yellow waxy solid. The residue was taken up in a minimum amount of toluene (approx. 5 mL). Slow evaporation of the solvent afforded large colorless plates (358 mg; 68% yield). *Method 2*: 10 mL of a THF solution of NaCp(DME) (400 mg, 2.25 mmol) was added dropwise to a THF solution (10 mL) of $ScCl_2$ $(THF)[N(SiMe_2CH_2P^iPr_2)_2]$ (1.270 g; 2.19 mmol) maintained at –78°C. This was stirred overnight and left to warm to room temperature. The THF was then removed in vacuo and the residue extracted with toluene (3 × 10 mL) and passed through a frit lined with Celite to remove NaCl. The solvent was removed in vacuo to yield a white waxy solid, which resulted in colorless plates upon crystallization from toluene (655 mg; 56% yield). ^{1}H NMR (C_6D_6) δ: 6.51 (t, 5H, C_5H_5, $^{3}J_{H\text{-}P}$ = 1.3 Hz), 2.15 and 1.78 (d of sept, 4H, C*H*Me$_2$, $^{3}J_{H\text{-}H}$ = 7.7 Hz, $^{2}J_{H\text{-}P}$ = 3.4 Hz), 1.34, 1.14, 1.11, and 1.06 (dd, 24H, CH*MeMe′*, $^{3}J_{H\text{-}H}$ = 7.7 Hz, $^{3}J_{H\text{-}P}$ = 6.5 Hz), 0.88 and 0.65 (dd, 4H, C*H*$_2$P, $^{2}J_{H\text{-}H}$ = 14.5 Hz, $^{2}J_{H\text{-}P}$ = 7.8 Hz), 0.28 and 0.24 (s, 12H, Si*Me*$_2$). ^{31}P{^{1}H} NMR (C_6D_6) δ: –1.2 (425 Hz peak width at half height). MS: *m/e* 538 (M^+). Anal. calcd. for $C_{23}H_{49}ClNP_2ScSi_2$: C 51.33, H 9.18, N 2.60; found: C 51.40, H 8.98, N 2.83.

*Sc(η^5-C_5H_5)Me[N(SiMe$_2$CH$_2$P^{i}Pr$_2$)$_2$] (**2**).* To a toluene solution (5 mL) of $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2P^iPr_2)_2]$ (**1**) (302 mg; 0.561 mmol) was added MeLi (0.40 mL of a 1.4 M Et_2O solution, 0.560 mmol), dropwise. The reaction mixture became cloudy and was stirred overnight, after which time it was filtered through a frit lined with Celite to remove LiCl. The solvent was removed in vacuo to yield an orange-yellow waxy solid (187 mg; 65% yield). Because the product was low melting, elemental analysis was not possible. ^{1}H NMR (C_6D_6) δ: 6.49 (t, 5H, C_5H_5, $^{3}J_{H\text{-}P}$ = 1.1 Hz), 2.04 and 1.79 (d of sept, 4H, C*H*Me$_2$, $^{3}J_{H\text{-}H}$ = 7.4 Hz, $^{2}J_{H\text{-}P}$ = 4.1 Hz), 1.22, 1.15, 1.13 and 1.06 (dd, 24H, CH*MeMe′*, $^{3}J_{H\text{-}H}$ = 7.4 Hz, $^{3}J_{H\text{-}P}$ = 7.0 Hz), 0.83 and 0.69 (dd, 4H, C*H*$_2$P, $^{2}J_{H\text{-}H}$ = 14.0 Hz, $^{2}J_{H\text{-}P}$ = 4.0 Hz), 0.31 and 0.28 (s, 12H, Si*Me*$_2$), –0.19 (t, 3H, ScC*H*$_3$, $^{3}J_{H\text{-}P}$ = 4.3 Hz). ^{31}P{^{1}H} NMR (C_6D_6) δ: –2.0 (135 Hz peak width at half height). MS: *m/e* 502 (M^+ – Me).

*Sc(η^5-C_5H_5)Ph[N(SiMe$_2$CH$_2$P^{i}Pr$_2$)$_2$] (**3**).* To a toluene solution (10 mL) of $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2P^iPr_2)_2]$ (**1**) (300 mg; 0.558 mmol) maintained at –60°C was added an ethereal solution of PhLi (1.2 mL of a 0.57 M solution; 0.684 mmol). The reaction mixture was left to warm up and stir overnight, and then filtered through a frit lined with Celite to remove LiCl, followed by solvent removal in vacuo. The residue was taken up in a minimum amount of hexamethyldisiloxane (approx. 5 mL). Subsequent slow evaporation resulted in the formation of colorless prisms (104 mg; 32% yield). ^{1}H NMR (C_6D_6) δ: 7.93 (d, 2H, *o*-Ph, $^{3}J_{H\text{-}H}$ = 8.2 Hz), 7.23 (t, 1H, *p*-Ph, $^{3}J_{H\text{-}H}$ = 8.0 Hz), 7.15 (m, 2H, *m*-Ph), 6.62 (t, 5H, C_5H_5, $^{3}J_{H\text{-}P}$ = 1.3 Hz), 1.71 (d of sept, 4H, C*H*Me$_2$, $^{3}J_{H\text{-}H}$ = 7.3 Hz, $^{2}J_{H\text{-}P}$ = 2.3 Hz), 1.05, 1.03, 0.85, and 0.55 (dd, 24H, CH*MeMe′*, $^{3}J_{H\text{-}H}$ = 7.3 Hz, $^{3}J_{H\text{-}P}$ = 7.0 Hz), 1.00 and 0.67 (dd, 4H, C*H*$_2$P, $^{2}J_{H\text{-}H}$ = 13.5 Hz, $^{2}J_{H\text{-}P}$ = 5.0 Hz), 0.42 and 0.32 (s, 12H, Si*Me*$_2$). ^{31}P{^{1}H} NMR (C_6D_6) δ: –2.8 (100 Hz peak width at half height). MS: *m/e* 580 (M^+). Anal. calcd. for $C_{29}H_{54}NP_2ScSi_2$: C 60.07, H 9.39, N 2.42; found: C 59.62, H 9.17, N 2.08.

*Sc(η^5-C_5H_5)(BH$_4$)[N(SiMe$_2$CH$_2$P^{i}Pr$_2$)$_2$] (**4**). Method 1*: Solid $LiBH_4$ (37 mg; 1.70 mmol) was added to a solution of $Sc(\eta^5\text{-}C_5H_5)Cl[N(SiMe_2CH_2P^iPr_2)_2]$ (**1**) (200 mg; 0.372 mmol) in toluene (10 mL). The reaction mixture was stirred at room temperature for 1 week and then passed through a frit lined with Celite to remove LiCl and excess $LiBH_4$. The solvent was removed in vacuo to yield a yellow waxy solid. The residue was taken up in a minimum amount of hexamethyldisiloxane (approx. 5 mL). Slow evaporation of the solvent

© 2000 NRC Canada

yielded large colorless plates (45 mg; 23% yield). *Method 2*: Sc(η^5-C_5H_5)Cl[N($SiMe_2CH_2P^iPr_2$)$_2$] (**1**) (130 mg; 0.242 mmol) and $NaBH_4$ (90 mg; 2.38 mmol) were placed in a bomb. 10 mL THF was distilled onto the mixture and left to stir overnight. The solvent was removed under vacuum and the residue extracted into toluene (3 × 5 mL). The reaction mixture was then passed through a frit lined with Celite to remove NaCl and excess $NaBH_4$. The solvent was then removed in vacuo to yield a white solid. The residue was taken up in a minimum amount of hexamethyldisiloxane (approx. 2 mL). Slow evaporation of the solvent gave large colorless plates (83 mg; 66% yield). ^{1}H NMR (C_6D_6) δ: 6.41 (t, 5H, C_5H_5, $^3J_{H-P}$ = 1.3 Hz), 1.99 and 1.80 (d of sept, 4H, C*H*Me$_2$, $^3J_{H-H}$ = 7.0 Hz, $^2J_{H-P}$ = 5.1 Hz), 1.23, 1.11, 1.08, and 1.03 (dd, 24H, CH*MeMe′*, $^3J_{H-H}$ = 7.0 Hz, $^3J_{H-P}$ = 6.0 Hz), 0.90 and 0.65 (dd, 4H, CH_2P, $^2J_{H-H}$ = 14.5 Hz, $^2J_{H-P}$ = 4.8 Hz), 0.31 and 0.28 (s, 12H, SiMe_2). ^{31}P{^{1}H} NMR (C_6D_6) δ: 0.5 (200 Hz peak width at half height). ^{11}B NMR (C_6D_6, 20°C) δ: –27.6, quint, BH_4, $^1J_{B-H}$ = 85 Hz, 32 Hz peak width at half height), (C_7D_8, –80°C) δ: –27.0 (br s, BH_4, 160 Hz peak width at half height). ^{11}B{^{1}H} NMR (C_6D_6, 20°C) δ: –27.6 (s, BH_4, 32 Hz peak width at half height). IR (KBr disc): ν_{B-H} = 2478 (H_t), 2211 cm^{-1} (H_b), (hexanes solution): ν_{B-H} = 2476 (H_t), 2212 cm^{-1} (H_b). MS: *m/e* 516 (M^+ – H). Anal. calcd. for $C_{23}H_{53}BNP_2ScSi_2$: C 53.38, H 10.32, N 2.71; found: C 53.79, H 10.40, N 2.86.

*Sc(η^5-C_5H_5)NHPh[N($SiMe_2CH_2P^iPr_2$)$_2$] (**5**). Method 1*: To Sc(η^5-C_5H_5)Me[N($SiMe_2CH_2P^iPr_2$)$_2$] (**2**) (92 mg; 0.178 mmol) in toluene (10 mL) was added a toluene solution (10 mL) of aniline (23 mg, 0.247 mmol). The yellow color of the solution gradually dissipated and the solution became cloudy. The reaction mixture was stirred overnight, and the contents of the flask filtered through Celite to remove a white precipitate, followed by solvent removal. **5** was isolated as an oil; the presence of HN($SiMe_2CH_2P^iPr_2$)$_2$ (by NMR spectroscopy) did not allow for a pure sample to be obtained (30 mg; 28% yield (estimated)). *Method 2*: An ethereal solution (5 mL) of LiNHPh (14 mg, 0.141 mmol) was slowly added by cannula to a toluene solution (10 mL) of Sc(η^5-C_5H_5)Cl[N($SiMe_2CH_2P^iPr_2$)$_2$] (**1**) (75 mg, 0.139 mmol) maintained at –78°C. The solution was allowed to warm to room temperature, during which time it became cloudy. The solution was filtered to remove LiCl and the solvent removed in vacuo to yield a yellow oil (25 mg; 30% yield (estimated)). ^{1}H NMR (C_6D_6) δ: 7.20 (t, 2H, *m*-Ph, $^3J_{H-H}$ = 6.0 Hz), 6.78 (d, 2H, *o*-Ph, $^3J_{H-H}$ = 6.0 Hz), 6.66 (t, 1H, *o*-Ph, $^3J_{H-H}$ = 6.0 Hz), 5.55 (br s, 1H, N*H*), 6.48 (t, 5H, C_5H_5, $^3J_{H-P}$ = 1.5 Hz), 1.87 and 1.73 (d of sept, 4H, C*H*Me$_2$, $^3J_{H-H}$ = 6.8 Hz, $^2J_{H-P}$ = 1.5 Hz), 1.13, 1.09, 0.99 and 0.92 (dd, 24H, CH*MeMe′*, $^3J_{H-H}$ = 6.8 Hz, $^3J_{H-P}$ = 6.5 Hz), 0.75 and 0.68 (dd, 4H, CH_2P, $^2J_{H-H}$ = 13.4 Hz, $^2J_{H-P}$ = 4.3 Hz), 0.30 and 0.28 (s, 12H, SiMe_2). ^{31}P{^{1}H} NMR (C_6D_6) δ: –1.0 (80 Hz peak width at half height).

*Sc(η^5-C_5H_5)NH^{t}Bu [N($SiMe_2CH_2P^iPr_2$)$_2$] (**6**). Method 1*: To Sc(η^5-C_5H_5)Me[N($SiMe_2CH_2P^iPr_2$)$_2$] (**2**) (90 mg; 0.174 mmol) in toluene (10 mL) was added a toluene solution (10 mL) of *tert*-butylamine (17 mg, 0.232 mmol). The yellow color of the solution dissipated and the solution became cloudy. The reaction mixture was stirred overnight, the contents of the flask filtered through Celite to remove a white precipitate, and the solvent removed. **6** was isolated as an oil; the presence of HN($SiMe_2CH_2P^iPr_2$)$_2$ (by NMR spectroscopy) did not allow for a pure sample to be obtained (41 mg; 41% yield (estimated)). *Method 2*: An ethereal solution (5 mL) of LiNH^{t}Bu (11 mg, 0.149 mmol) was slowly added by cannula to a toluene solution (10 mL) of Sc(η^5-C_5H_5)Cl[N($SiMe_2CH_2P^iPr_2$)$_2$] (**2**) (75 mg, 0.139 mmol) maintained at –78°C. The solution was allowed to warm to room temperature, during which time it became cloudy. The solution was filtered to remove LiCl and the solvent removed in vacuo to yield a yellow oil (20 mg; 25% yield (estimated)). ^{1}H NMR (C_6D_6) δ: 6.48 (s, 5H, C_5H_5), 4.70 (br s, 1H, N*H*), 1.80 and 1.71 (d of sept, 4H, C*H*Me$_2$, $^3J_{H-H}$ = 7.4 Hz, $^2J_{H-P}$ = 3.4 Hz), 1.37 (s, 9H, NMe_3), 1.15, 1.06, 1.04 and 1.00 (dd, 24H, CH*MeMe′*, $^3J_{H-H}$ = 14.8 Hz, $^3J_{H-P}$ = 7.4 Hz), 0.67 (other peak obscurred, dd, 4H, CH_2P, $^2J_{H-H}$ = 10.2 Hz, $^2J_{H-P}$ = 4.8 Hz), 0.42 and 0.35 (s, 12H, SiMe_2). ^{31}P{^{1}H} NMR (C_6D_6) δ: 1.0 (90 Hz peak width at half height).

*Sc(η^5-C_5H_5)H[N($SiMe_2CH_2P^iPr_2$)$_2$] (**7**).* A sealable NMR tube equipped with a Kontes valve was loaded with a 1 mL d_8-toluene solution of Sc(η^5-C_5H_5)(BH_4)[N($SiMe_2CH_2P^iPr_2$)$_2$] (**4**) (approx. 0.1 M). The NMR tube was attached via a glass bridge to a bomb containing PMe_3. The contents of the NMR tube were frozen and the head space evacuated. The head space was then opened to the bomb of PMe_3 and allowed to fill with vapour. The bomb was closed, and the vapour condensed into the NMR tube. The NMR tube was flame-sealed and carefully allowed to warm to room temperature. This method resulted in the exposure of Sc(η^5-C_5H_5)(BH_4)[N($SiMe_2CH_2P^iPr_2$)$_2$] to ~1 mL PMe_3 (approx. 100 equiv). Due to the large excess of PMe_3, the reaction was followed by ^{11}B{^{1}H} NMR spectroscopy. ^{1}H NMR (C_6D_6) δ: 6.30 (t, 5H, C_5H_5, $^3J_{H-P}$ = 1.1 Hz), 1.95 and 1.85 (d of sept, 4H, C*H*Me$_2$, $^3J_{H-H}$ = 7.1 Hz, $^2J_{H-P}$ = 4.5 Hz), 1.15, 1.13, 1.12 and 1.03 (dd, 24H, CH*MeMe′*, $^3J_{H-H}$ = 7.2 Hz, $^3J_{H-P}$ = 10.5 Hz), 0.22 and 0.16 (s, 12H, SiMe_2), methylene protons obscured by PMe_3. ^{31}P{^{1}H} NMR (C_6D_6) δ: 0.3 (430 Hz peak width at half height). ^{11}B{^{1}H} NMR (C_6D_6) δ: –27.6 (s, Sc(η^5-C_5H_5)(BH_4)[N($SiMe_2CH_2P^iPr_2$)$_2$]), –47.8 (d, PMe_3·*B*H_3, $^1J_{B-P}$ = 48 Hz). ^{11}B NMR (C_6D_6) δ: –27.6 (quint, Sc(η^5-C_5H_5)(BH_4)[N($SiMe_2CH_2P^iPr_2$)$_2$]), –47.8 (q of d, PMe_3·*B*H_3, $^1J_{B-P}$ = 48 Hz, $^3J_{B-H}$ = 86 Hz). The peak at –47.8 ppm increased in area as the temperature was elevated.

X-ray crystallographic analyses of Sc(η^5-C_5H_5)Cl[N($SiMe_2CH_2P^iPr_2$)$_2$] (1) and Sc(η^5-C_5H_5)Ph[N($SiMe_2CH_2P^iPr_2$)$_2$] (3)

Crystallographic data appear in Table 1. The final unit-cell parameters were obtained by least-squares on the setting angles for 25 reflections with 2θ = 31.3–47.0° for **1** and 20.1–27.4° for **3.** The intensities of three standard reflections, measured every 200 reflections throughout the data collection, showed only small random fluctuations for **1** and decayed linearly by 13.4% for **3**. The data were processed (41), corrected for Lorentz and polarization effects, decay (for **3**), and absorption (based on azimuthal scans).

The structure of **1** was solved by the Patterson method and that of **3** by direct methods. The structure analysis of **3** was initiated in the centrosymmetric space group *P* on the basis of the *E*-statistics, this choice being validated by subsequent

© 2000 NRC Canada

calculations. All nonhydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were fixed in calculated positions with C—H = 0.98 Å and B_H = 1.2 $B_{\text{bonded atom}}$. A correction for secondary extinction was applied for **1** (Zachariasen type, isotropic, gaussian), the final value of the extinction coefficient being 7.1(7) × 10^{-7}. No correction for secondary extinction was necessary for **3**. Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from the International Tables for X-Ray Crystallography (42). Final atomic coordinates and equivalent isotropic thermal parameters, selected bond lengths, and selected bond angles appear in Tables 2–4, respectively. Tables of full crystallographic data, final atomic coordinates, bond lengths, bond angles, anisotropic thermal parameters, and torsion angles are available as supplementary material.[2]

Influence of the temperature on the viscosity measurements of solutions of a soil fulvic acid

Francisco Rey and Adelio A.S.C. Machado

Abstract: The influence of the concentration (ca. 45 to 300 mg L^{-1}), the pH (3.0 to 8.0), the ionic strength (0.005 to 0.10 M), and the temperature (283 to 303 K) on the viscosimetric behaviour of solutions of a soil fulvic acid has been analysed, and their molecular parameters (length, thickness, and molecular volume) calculated. The results indicate that the polyelectrolytic behaviour of the fulvic acid is similar at all the temperatures, i.e., increasing the viscosity when reducing the ionic strength and to increase the temperature. With respect to the pH an initial decrease in the viscosity is obtained followed by a rise to the highest pH values. These variations have been interpreted by their molecular parameters as due to modifications of the structure of the molecules of the fulvic acid.

Key words: fulvic acid, viscosity, temperature.

Résumé : L'influence de la concentration (ca. 45 à 300 mg L^{-1}), du pH (3.0 à 8.0), de la force ionique (0.005 á 0.10 M) et de la température (283 à 303 K) sur le comportement viscosimétrique de solutions d'acides fulviques de sol a été analysée, et leurs paramètres moléculaires (longueur, épaisseur et volume moléculaire) ont été calculés. Les résultats montrent que le comportement polyélectrolytique des acides fulviques est semblable à toutes les températures; plus précisément, la viscosité augment avec la diminution de la force ionique et l'augmentation de la température. L'influence du pH se traduit par une diminution initiale de la viscosité suivie ensuite par une augmentation celle-ci dans les valeurs de pH les plus élevées. Ces variations ont été interprétées, en fonction de leurs paramétres moléculaires, comme dues aux modifications de la structure des molécules d'acides fulviques.

Mots clés : acides fulviques, viscosité, température.

Introduction

Humic substances play a very important role in the environment because of their interaction with the particles of soils, trace metals and nutrients, their biological effects on plants and micro-organisms, and their influence on the quality of superficial and underground waters. It is well known that the pH, the concentration, and the presence of inert inorganic species, which alter the ionic strength, influence the behaviour of humic substances to a large extent (1). However, although temperature varies markedly in natural systems, its influence has been rarely considered in the study of the properties of these substances.

The measurement of the viscosity of fulvic or humic acid solutions can provide information about of the size and the shape of their molecules in solution, and the literature contains several studies in which the behavior of this type of substances is analysed by viscosimetric techniques (2 and references therein). However, in most of these cases the results are either incomplete or not comparable, due to differences in the extraction or purification methods or to the fact that values of the pH and of the ionic strength of the solutions studied were not the same or were not controlled.

Moreover, in spite of its importance, the analysis of the influence of the temperature on the viscosity of the humic material solutions (and consequently on the size and shape of their molecules) has not been approached in a systematic way. As far as the authors know, only Adhikari et al. (3) have measured the viscosities of humic acid solutions between 30 and 50°C, explaining the differences obtained in the reduced viscosity by the decrease of the viscous drag or by high-temperature coiling. These results are in agreement with those in Orlov's book (4). Finally, Stevenson (5) points out the influence of the temperature on the viscosimetric behavior of the humic substances when dissolved, but neither present nor refer to any published data.

In conclusion, the data in the literature do not clarify the influence of the temperature on the viscosity of humic materials in solution. Therefore, it was decided to include the viscosimetric measurements in a project in progress in our departments to study the behavior of the fulvic acids in solution (6–10). In a previous work (2), the influence of the concentration, the pH, and the background electrolyte concentration on the viscosimetric solution properties of a soil fulvic acid at low concentrations and constant temperature of 298 K were analysed. In the present work, the influence of temperature (283–303 K) on this behavior is reported. The dimensions of the molecules of the fulvic acid

were calculated, and their temperature-induced variations are discussed.

Experimental

Reagents and materials

All the reagents were for analysis quality and were used without further purification. For the preparation of the solutions deionised water Millipore Alpha Q was employed.

The fulvic acid sample used in the present work was isolated from a Portuguese soil of forest, collected in Famalicao (near Porto, 30 km to the Northeast), by the standard procedure proposed by the IHSS (11). For this purpose, portions of the soil dried in air were treated with hydrochloric acid (2 M, pH ≈ 2) by shaking during 15 days. The solid was separated by filtration and the liquid was concentrated in a column filled with Amberlite XAD-8 resin. The column was washed with water until free of chloride ions and then eluted with 0.1 M NaOH. The fulvic acid in the eluate was converted to its acidic form in a column with a cationic exchange resin (Merck Ion Exchanger I) and then freeze-dried to obtain a powder. The yield of the process was of the order of 0.5% of the fulvic acid – soil weights. Characterization parameters: elemental analysis: C 43.0, H 3.8, and N 1.7%; S and heavy metals not detected, O (51.5%) obtained by difference; Total acidity 11.9 meq g^{-1}, carboxylic acidity 5.3 meq g^{-1}; ash content lower than 0.5%.

To adjust the pH of the solutions, 0.1 M HCl and (or) 0.1 M NaOH solutions were used. $NaNO_3$ was used as support electrolyte to adjust the total ionic strength to desired values (see below).

Equipment

Free H^+ values (expressed as pH) were measured with a Crison μ-pH 2002 pH-meter (±0.1 mV) and an Ingold combined electrode, calibrated at each ionic strength by standard HCl–NaOH titrations (12). The viscosity measures were made with an Ostwald type viscosimeter (the flow time with deionised water at 298 K was 345.4 ± 0.2 s) at constant temperatures between 283 and 303 K, in 5 K steps (Tectron 4373200 thermostat, ±0.1 K). The density was measured with a glass picnometer calibrated with water at each temperature studied.

To obtain the average molecular weight (*M*) of the samples (used here as the average value of the heterogeneous mixture named fulvic acid), the semi-empirical equation obtained by Chin (13)

$$[1] \qquad M = 3.99\ \varepsilon + 490$$

where ε is the molar absorbtivity at 280 nm, was used. For this purpose, plots of the absorbance vs. concentration of the sample (in mg L^{-1}) buffered with 0.1 M sodium hydrogen carbonate were obtained at constant temperature using a Kontron Uvikon 930 UV–V spectrophotometer.

Procedure

The samples for the viscosimetric measurements were prepared by diluting aliquots of a 1000 mg L^{-1} stock solution of fulvic acid, and adjusting the pH and the total ionic strength to the required values. The experiments were done at twelve values of fulvic acid concentration, six pH values, and five temperatures (Table 1). The measurements of flow time were repeated at least twenty times and their mean values (after rejecting outlier values by a standard statistical technique (14)) were used to calculate the values of the absolute viscosities (standard deviations were always found to be less than 0.5%).

189.0		
236.0		
289.0		

Theory

The values of the relative (η_r), specific (η_{sp}), and reduced (η_z) viscosities were obtained from the experimental values of the absolute viscosity (η) by their respective definitions (eqs. [2]–[4]) (15)

$$[2] \qquad \eta_r = \frac{\eta}{\eta_0}$$

$$[3] \qquad \eta_{sp} = \frac{\eta - \eta_0}{\eta_0}$$

$$[4] \qquad \eta_z = \frac{\eta_{sp}}{c}$$

where η_0 is the absolute viscosity of the water and *c* the concentration of the solute in the solution. As intrinsic viscosities ([η]) are the base for molecular parameters calculation two different approaches were used to obtain their values, namely the extrapolation to zero concentration of the linear part of the plots of the reduced viscosity against concentration and the Fuoss and Cathers equation (16)

$$[5] \qquad \frac{c}{\eta_{sp}} = \frac{1}{A} + \frac{B}{A}\sqrt{c}$$

The results obtained by two methods are very similar (differences less than 2%) and mean values were used in calculations.

As the intrinsic viscosity can be related to the molecular weight (*M*) by Staundinger's equation of

$$[6] \qquad [\eta] = KM^{\alpha}$$

where *K* and α are coefficients depending on the temperature, the solvent and the polyelectrolyte, but are independent of the pH and of the ionic strength (15), values of the molecular weight at each pH and ionic strength are required for

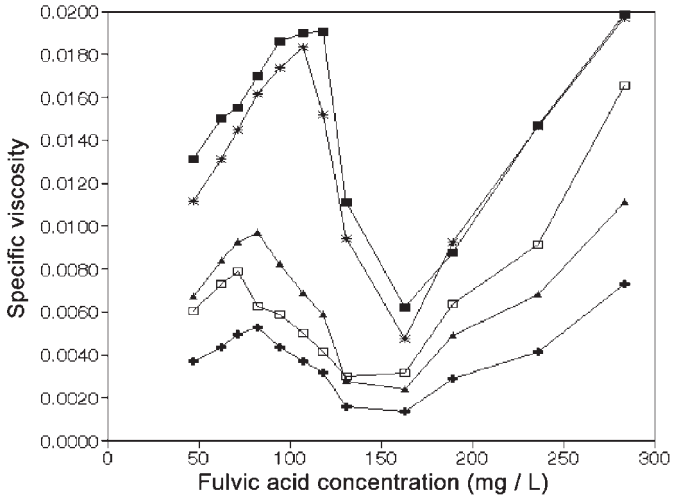
Fig. 1. Variation of the specific viscosity with the fulvic acid concentration for the following experimental conditions: (■) pH = 5.0, I = 0.005 M, T = 283 K; (▲) pH = 4.0, I = 0.01 M, T = 288K; (+) pH = 5.0, I = 0.03 M, T = 293K; (*) pH = 6.0, I = 0.01, T = 298K; (□) pH = 4.0, I = 0.005, T = 303 K.



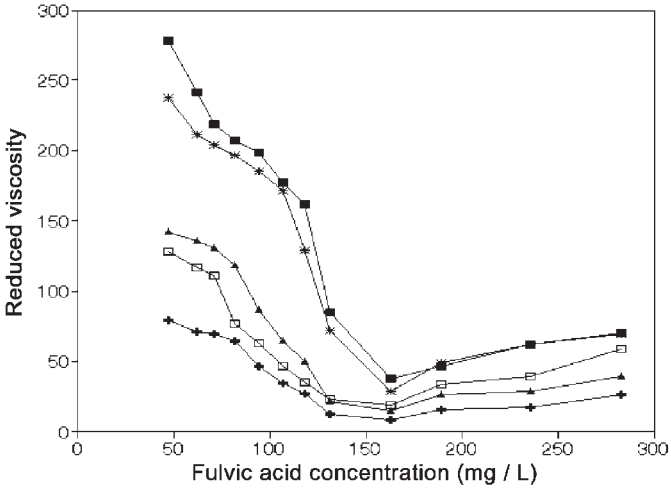


Fig. 2. Variation of the reduced viscosity with the fulvic acid concentration (same conditions as Fig. 1).

calculation of K and α. To estimate these values, absorbances at 280 nm were measured at the five temperatures used in the work (see eq. [1]), but were found to be constant within 2% maximum error. This shows that, under the present experimental conditions, M at each pH and ionic strength can be considered as constant over the whole temperature range. Therefore, values of molecular weights at 298 K, obtained in previous work at the same pH and ionic strength conditions (2), were used for the calculations of K and α, using the plots of the reduced viscosity against the molecular weight (see Fig. 4 below in "Results and Discussion").

The mean shape and the dimensions of the acid fulvic particles are important magnitudes when the physicochemical behaviour of these substances is analysed. The viscosity values can be used for their calculation, provided a model for such particles is used. In the bibliography, different shapes have been used, especially spheres, disks, and rods (15). In the analysis of the data obtained at 298 K it was concluded that from these three only the rod model, corresponding to a flexible linear colloid, was compatible with the experimental data (17). Therefore, this model was used in the present work, from which two relevant parameters were calculated, the length (a) and the thickness (b) of the rod, which are related to a function [k] through the equation (15)

$$[7] \qquad [k] = \frac{(a/b)^2}{15(\ln 2ab - 3/2)} + \frac{3(a/b)^2}{15(\ln 2ab - 1/2)} + \frac{14}{15}$$

This equation can be solved by numerical iteration to calculate the a/b ratio. The individual values of a and b can be determined from this ratio and the expression for the molecular volume given by

$$[8] \qquad V = \frac{\pi b^2 a}{4}$$

Results and discussion

Viscosimetric data for humic substances obtained at different temperatures can not be compared if the existence of a common general behaviour is not demonstrated. As it was stated at 298 K (2), the shape of the variation of the specific and reduced viscosity with the fulvic acid concentration are practically the same, despite of the composition of the solutions. Consequently, these plots can be used for an adequate verification of the constancy of this behaviour. So, in the figures 1 and 2 several examples of that type of plots are shown. As it can be seen, the shape of the curves is practically unalterable, and the range of values is similar to the reported for 298 K (2), which strongly suggest that the viscosimetric structure of this fulvic acid molecules is independent of the temperature, and, therefore, the same model can be applied to the data obtained at the five temperatures studied here. Moreover, this assumption is also confirmed when the variations of the intrinsic viscosity with the pH at constant ionic strength (Fig. 3) are analysed. A decrease of the intrinsic viscosity of the solutions of the fulvic acid when the pH is increased until about 5.0, followed by an increase in the neutral and alkaline pH ranges, is observed. This variation (also found at 298 K (2)) is a common fact for weak acid polyelectrolytes of the fulvic acid type, and it has been explained as a consequence of the existence of weaker binding forces at lower pH values [3] and the occurrence of aggregation due to cationic bridges and intermolecular interactions above pH 6 [4]. However, in absence of a more

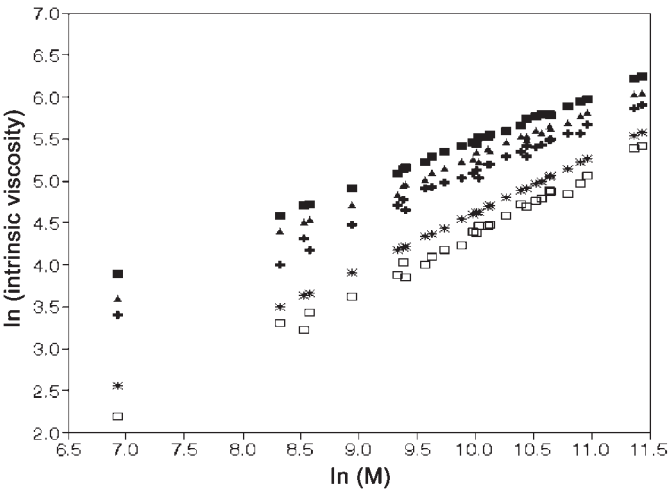
complete characterisation of the sample, it must be considered only hypothetical for the present fulvic acid.

When data of intrinsic viscosity are compared at different temperatures (at constant pH), an important decrease when temperature rises was obtained. Because the size and shape of fulvic acid rods are the main factors that control the movement of these molecules in solution (and, hence, the viscosity) further discussion requires numerical values of length and thickness (see comments about Table 4) below.

In Table 2 the results for the intrinsic viscosity of the solutions of the fulvic acid at the values of pH, ionic strength and temperature studied in the present work are collected. Because the values of the absolute viscosity for the total ionic strength 0.1 M do not differ significantly from the viscosities of pure water at all temperatures, they were excluded from the table.



In Fig. 4, plots of ln ([η]) vs. ln M are presented. As shown, the plots are practically linear (r > 0.995 for all the

Fig. 4. Plot of ln (intrinsic viscosity) vs. ln (molecular weight) at different temperatures: (■) 283 K; (*) 288 K; (▲) 293 K; (+) 298 K; (□) 303 K.

temperatures) which also confirm the assumption of the existence of an unique general behaviour, and allow the calculation of the parameters *K* and α; the values obtained are collected in Table 3. The results indicate an increase of the value of α and a decrease of *K* upon increasing the temperature, which can be attributed to the relative poorness of the solvent (18). Moreover, values of α fall in the range between 0.5 and 0.8, as for most of the polyelectrolyte–solvent systems (19).

In Table 4 the molecular parameters (i.e., molecular volume (*V*), length (*a*) and thickness (*b*)) for the molecules of the fulvic acid obtained at the different temperatures are collected (for values at 298 K, see reference 2). Although the values of *b* are of the same order of magnitude as those published (15), the values of *a* are larger. This is perhaps due to the different origin of the fulvic acids and to the lower concentrations range used (2). As shown by the data tables, these values depend markedly on the ionic strength, the pH, and the temperature, and therefore these three factors will be analysed separately.

As a rule, upon increasing the ionic strength a decrease in the molecular weight is observed as described before (2, 20), as well as a decrease of the size of the molecules of the fulvic acid due to the decrease in the values of both *a* and *b*. This can be attributed to further coiling of the fulvic acid

© 2000 NRC Canada

molecules (widely illustrated in the bibliography (5), due to the repulsion by the counterions or to the neutralisation of the superficial charges by the added salt (3).

With reference to the influence of the pH, an initial decrease of the values of both *a* and *b* upon increasing the pH is observed, until minima at pH ≈ 6 are reached, followed by a growth at higher pH values. This result is similar to others in the literature (15). The variation decreases when the ionic strength decreases (two to four times), and suggests that the presence of the counterions plays a very important role in the modifications of the structure of the molecules of fulvic acids.

A different variation is obtained when the temperature changes. In this case, at constant pH and ionic strength, a decrease of the length of the acid fulvic rods, probably due to coiling accompanied by increase of their thickness, is observed. As far as we know, this behaviour has not been described previously, though it has been suggested (3) that a decrease of the viscosity of solutions of humic substances upon increasing of the temperature is expected, due to the more extensive ionisation of these substances at higher temperatures. Since the length of the particles is the main variable responsible for the viscosity, its decrease explains why the viscosity decreases upon increasing the temperature and the consequent decrease of the viscous drainage.

As shown by the results of the present work, the external factors of the solutions (pH, ionic strength and, in particular, the temperature) can influence markedly the size of the molecules of fulvic acids in solution, and, consequently, their viscosimetric behaviour. However, the molecular weight, although changing with the ionic strength and the pH, keeps its value when the temperature is varied.

The photoequilibration of the *ortho*-, *meta*-, and *para*-isomers of substituted benzenes in acetonitrile and the photoaddition of 2,2,2-trifluoroethanol (TFE) to the same isomers: a survey

J. Foster, A.L. Pincock, J.A. Pincock, S. Rifai, and K.A. Thompson

Abstract: The phototransposition (*ortho, meta, para*) in acetonitrile of a number (25) of disubstituted benzenes have been examined. For some cases (methylbenzonitriles, trifluoromethyltoluenes, and trifluoromethylbenzonitriles) photostationary states could be reached but others (methylanisoles, methoxybenzonitriles, dicyanobenzenes, and methy 4-toluyl sulfone) were unreactive. The photoaddition of 2,2,2-trifluoroethanol (TFE) to the same compounds as well as 5 monosubstituted cases was also examined. The products obtained for reactive compounds were all TFE ethers of bicyclo[3.1.0]hex-3-en-2-ol derivatives. For benzene and alkylbenzenes (toluene, *ortho*-xylene) these photoadducts are formed by ground state addition of TFE to benzvalene derivatives. For others (methylbenzonitriles), bicyclic diradicals or carbenes are likely intermediates. Many substituted compounds (anisole, fluorobenzene, methyl benzoate, methylanisoles, methoxybenzonitriles, dicyanobenzenes, trifluoromethylbenzonitriles, and fluorotoluenes) did not react with TFE. The trifluoromethylbenzonitriles did however undergo phototransposition in TFE, the only compounds to do so.

Key words: substituted benzenes, phototransposition, photoaddition.

Résumé : On a étudié la phototransposition (*ortho, méta, para*), réalisée dans l'acétonitrile, d'un certain nombre (environ 25) benzènes disubstitués. Dans certains cas (méthylbenzonitriles, trifluorométhyltoluènes et trifluorométhylbenzonitriles), il a été possible d'atteindre des états stationnaires, mais les autres méthylanisoles, méthoxybenzonitriles, dicyanobenzènes et méthyl(4-méthylphényl)sulfone] ne sont pas réactifs. On a aussi étudié la photoaddition du 2,2,2-trifluoroéthanol (TFE) à ces mêmes composés ainsi qu'aux cinq produits monosubstitués. Avec chacun des composés réactifs, les produits obtenus sont les éthers TFE des dérivés bicyclo[3.1.0]hex-3-én-ols. Pour le benzène et les alkylbenzènes (toluène, *ortho*-xylène), ces photoproduits se forment par une addition à l'état fondamental du TFE aux dérivés benzvalènes. Pour les autres composés (méthylbenzonitriles), les intermédiaires sont vraisemblablement des radicaux ou des carbènes bicycliques. Plusieurs composés substitués (anisole, fluorobenzène, benzoate de méthyle, méthylanisoles, méthoxybenzonitriles, dicyanobenzènes, trifluorométhylbenzonitriles et fluorotoluènes) ne réagissent pas avec le TFE. Toutefois, dans le TFE, les trifluorométhylbenzonitriles subissent une phototransposition; ce sont les seuls composés à le faire.

Mots clés : benzènes substitués, phototransposition, photoaddition.

Introduction

Recently, we reported on both the phototransposition reactions of *para*-, *meta*-, and *ortho*-methylbenzonitrile, **1**, **2**, and **3**, in acetonitrile (1) and the photoaddition reactions of the same isomers upon irradiation in 2,2,2-trifluoroethanol (TFE) (2). The photolysis of benzonitrile (**4**), 2,4,6-trideuteriobenzonitrile (**4(*d*$_3$)**), and 2,6-dideuterio-4-methylbenzonitrile (**1(*d*$_2$)**) in both acetonitrile and TFE proved to be very helpful in understanding the major pathway(s) for both phototranspositions and alcohol photoadditions. These pathways are shown for **1(*d*$_2$)** in Scheme 1.

In acetonitrile, the results can be summarized as follows: first, the phototransposition reaction converting **1**, **2**, and **3** leads to a steady state mixture of *para*:*meta*:*ortho* = 3:20:77 for irradiation of both **1** and **2**. For the *ortho* isomer, **3**, the phototransposition is considerably slower and the steady state composition is not reached; second, both 1,2- and 1,3-transpositions occur in the primary photochemical step; third, the relative reactivity of the three isomers in the phototransposition reaction is *para*:*meta*:*ortho* = 32:4:1; fourth, the quantum yield (at low conversion) of phototransposition for the *para* isomer is 0.025; fifth, quenching studies with 2,3-dimethyl-1,3-butadiene have shown the reactions to occur from the excited singlet state for both the *para* and *ortho* isomers; sixth, ^{13}C NMR analysis of the phototransposition products **2(*d*$_2$)** and **3(*d*$_2$)** from **1(*d*$_2$)** demonstrated that the cyano-substituted carbon was always involved in the phototransposition step. These six observations can be rationalized by the left-hand part of Scheme 1. For instance, the

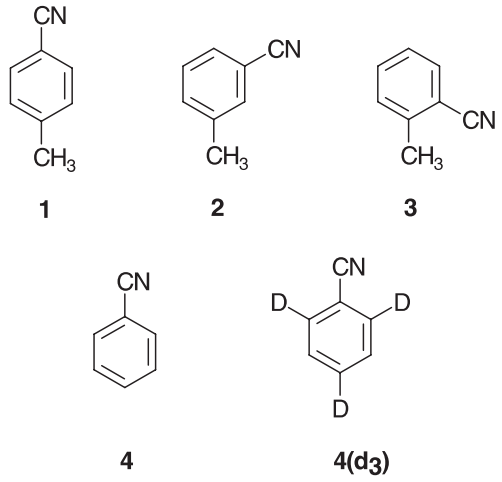


Scheme 1. Mechanistic scheme for the phototransposition and the photoaddition of TFE for the methylbenzonitriles, **1**, **2**, **3** using **1(d_2)** as the example.

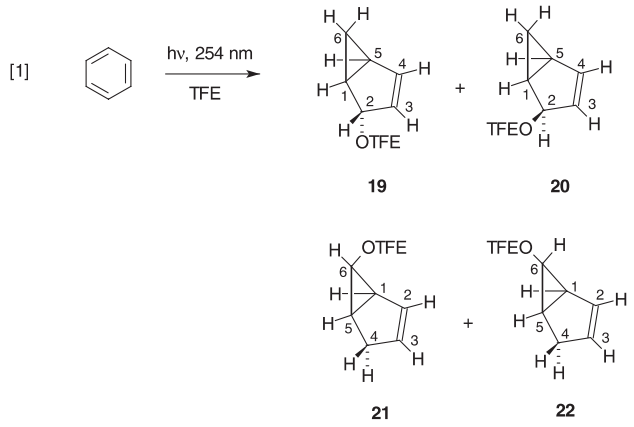
excited singlet state of **1(d_2)** gives the bicyclo[3.1.0] intermediate **5** by *meta* bridging between C2 and C6. This intermediate singlet state is written as a zwitterion with the negative charge on the cyano-substituted carbon and the delocalized positive charge shown on only one of the two ends of the allylic part. Migration of the cyano-substituted carbon around the other five results in formation of the isomeric intermediates, **6** and **7**, which can return to **2(d_2)** and **3(d_2)**, respectively.

The potential energy surface connecting the three intermediates, **5**, **6**, and **7**, may not be as simple as implied in Scheme 1. First, as mentioned above and for convenience in describing the next results in TFE, the intermediates are shown as zwitterions but clearly, and depending on the substituents, they could have considerable biradical character. More important, for the unsubstituted derivative, e.g., C_6H_6, high level MO calculations (3) have shown that species other than these biradicals, such as the carbene structure 5-methylene-1,3-cyclopentadiene, are important. In fact, the carbene structures are of considerably lower energy than the biradicals. We are in the process of doing similar calculations for several substituted cases. Second, because we have no evidence that would require them, the corresponding benzvalene structures that would result from exergonic closure of the intermediate **5**, such as **8**, are not included in Scheme 1. Benzvalene itself can be prepared by photolysis of benzene (4) and, as will be discussed in more detail below, has been strongly implicated in phototranspositions of

© 2000 NRC Canada

deuterium substituted benzenes (5) and in the photoadditions of alcohols (6, 7, 8) and acids (7) to benzene. For the methyl benzonitriles, **8** could proceed thermally or perhaps, photochemically, to **6**, and hence to **2(d_2)**, by breaking the bond indicated in Scheme 1.

Photolysis of both the *para* and *meta* isomers, **1** (and the deuterated compound, **1(d_2)**) and **2**, in TFE resulted in six major addition products, **9**–**14**; the *ortho* isomer was unreactive. These six products are separated into two groups, the four that have a proton *endo* at C6 and the two that have the same proton *exo*; the ratios of the yields of the two groups are 79:21 from **1** and 64:36 from **2**, respectively. As shown in Scheme 1, these products can all be rationalized by nucleophilic trapping of the bicyclo[3.1.0]hexenyl cations, **17** and **18**. These cations are formed directly from the *meta* isomer (**2**) by *endo* and *exo* protonation, respectively, on C6 of **6** but indirectly via rearrangement of the cations **15** and **16** first formed from the *para* isomer. The driving force for the rapid rearrangement of **15** to **17** and **16** to **18** was ascribed to the enhanced stability of **17** and **18** as a result of methyl substitution at the terminal carbon, rather than at the node, of the allylic system. Very rapid rearrangements of bicyclo[3.1.0]hexenyl cations have been observed previously (7, 9).



These phototranspositions and photoaddition reactions of nitrile-substituted benzenes indicate that the electron withdrawing substituent is critical in determining the efficiency of the reactions as well as the structures of the addition products. Clearly, the effect of other substituents is of interest. We now report a more general study of these reactions for a variety of substituted benzenes.

Results and discussion

Photolysis of benzene

The unimolecular photoreactivity of benzene was first discovered in 1957 for its conversion to fulvene. This observation stimulated considerable interest in benzene photochemistry which resulted in the observation of other photoisomerizations to benzvalene, Dewar benzene, and prismane as well as the photoaddition reactions of acids, alcohols, and water. This material has been reviewed a number of times (10–12). Particularly relevant to the present work is the observation that irradiation at 254 nm of 1,3,5-trideuteriobenzene gave the 1,2,4-d_3 isomer both in solution (hexadecane) and in the gas phase with quantum yields of 0.025 and 0.012, respectively, (5). The proposed intermediate was a deuterated benzvalene. In addition, irradiation of benzene in TFE gave the addition products **19**–**22**, eq. [1]. The initial publication (6) reported only formation of **19** and **21** in a ratio of 2:1. These compounds were isolated by preparative GC; ^{1}H NMR spectra were used to assign the structures. No information was provided to assign the stereochemistry given for the TFE group at C2 in **19** but, for **21**, the *endo* stereochemistry was assigned by the appearance of H6 as a pseudo triplet with J = ~7 Hz, typical of the *cis* H-H coupling constant in cyclopropanes. In a later publication (8), **19** and **20** were demonstrated to be the primary photoproducts and **21** and **22** were formed from them by benzene sensitization. In addition, **21** was converted to **22** as the photolysis of either **19** or **20** proceeded. These results were rationalized by formation of benzvalene in the primary photochemical event followed by ground state addition of TFE to give **19** and **20**. Confirmation of this was obtained by reacting benzene solutions of independently synthesized benzvalene with TFE and observing, as products, only **19** and **20**. Another important clue for the intermediacy of benzvalene was the observation, using deuterium incorporation, of exclusive *endo* protonation at C6 (7), as expected for addition to the strained cyclopropyl sigma bond in benzvalene.

We have repeated the photolysis of benzene in TFE to confirm these results and to obtain higher field ^{1}H and ^{13}C NMR spectra. Photolysis of benzene (2.81×10^{-2} M) in TFE for 4 h resulted in 53% conversion of the benzene to three addition products (GC and GC-MS) in the ratio of 3.6:1:1 and a total yield of 45%. At 10% conversion, this ratio was 6.1:1.7:1. The structures of these three compounds (**19**–**21** respectively, in eq. [1]) were confirmed by ^{1}H NMR (normal

and COSY) and ^{13}C NMR (normal and HMQC) of the mixture at 400 MHz. Chemical shifts and coupling constants are given in the Experimental Section. At these conversions, no evidence was obtained for the presence of **22**. The distinction between **21** and the other two isomers is easily made because there are only two signals, H2 and H3, above δ 4.4 in the ^{1}H NMR for **21**. Moreover, **19** and **20** both have two signals at δ 1.0 or less (H6 *endo* and *exo*) whereas **21** has none. The stereochemistry at C2 of the major product, **19**, was established by coupling because H2 appears as a

© 2000 NRC Canada

broadened singlet indicating a small coupling between H2 and H1 as is typical for the *endo* hydrogen at C2 in this ring system (2); in contrast, H2 in **20** appears as a doublet with splitting equal to 6.7 Hz. The stereochemistry at C6 in **21** was confirmed, as before, by the appearance of H6 as a pseudo triplet with splitting equal to 6.3 Hz, as expected for a cyclopropane hydrogen *cis* to the two hydrogens, H1 and H5 (6, 8).

A comparable photolysis of benzene-d_6 in TFE gave the same three products but with very simple ^{1}H NMR spectra because now only one diagnostic hydrogen (and the CH_2 from TFE) is observable. This hydrogen is clearly H6 *endo* (H6 *endo* : H6 *exo* > 50:1) in the major product, **19**, and in **20**. The situation is not so clear for the minor product **21** because of overlap of signals but the ratio of H4 *exo* to H4 *endo* is approximately 2:1.

All of these results are in agreement with the previously proposed mechanism (6–8) which suggested that the primary photoproducts (**19** and **20**) are formed by *endo* protonation of benzvalene followed by *exo* (major) and *endo* (minor) trapping of the allylic cation by TFE. The third product (**21**) results from benzene sensitized isomerization of the primary products. This observation of highly selective *endo* protonation contrasts with our results for benzonitrile derivatives where products resulting from *exo* and *endo* protonation at C6 are formed in almost equal amounts (2). The conclusion is that photochemical addition of TFE to benzene proceeds through benzvalene but that substituted benzvalenes are not involved in the photoaddition of TFE to benzonitriles.

A general comment about the TFE addition reactions to benzene and other aromatics would be useful at this point. The addition products that we obtained from the benzonitriles were stable and could be separated by silica gel chromatography, presumably because the nitrile functional group provides enough polarity to create differing R_f values. For benzene and the other aromatics discussed below, separation on silica gel was not achieved. Moreover, the addition products were not consistently stable so that the composition of mixtures would sometimes change on standing or on evaporation of the TFE solvent. At times, ^{1}H NMR spectra revealed that removal of the solvent left no characterizable products even though GC analysis had given well defined peaks. Most NMR spectra reported are therefore of crude reaction mixtures which always contained a broad, unidentified cluster of signals between δ 1 and 2 in the ^{1}H NMR (probably oligomers or polymers). As a consequence, well-defined NMR spectra for pure compounds could not be obtained. However, in the ^{1}H NMR spectra of the addition products, the high field region of the cyclopropyl hydrogens and the low field region of the hydrogens on the alkene and oxygen-substituted carbons could usually be analyzed. Fortunately, these two regions provide enough information about the structure of the addition products so that assignments can be made with considerable confidence.

Photolysis of monosubstituted benzenes in TFE

Because photolysis of benzonitriles in TFE gave four well characterized addition products, other mono substituted benzenes were also examined in TFE as described above for benzene. These included toluene, anisole, fluorobenzene, trifluoromethylbenzene, and methyl benzoate. Of these, only toluene and trifluoromethylbenzene reacted to any significant extent.

For toluene, after 4 h, 59% had reacted to give at least 12 addition products (23% total by GC), with two being the major (40% of the mixture) products. The ^{1}H NMR of the crude reaction mixture revealed that the major products were like that for benzene because of the observation of two *endo* protons at C6 ("quartet" at δ –0.05 and –0.12, respectively) of the bicyclo[3.1.0]hexene ring system; also the methyl group must be at C4 (lack of olefin doublet of doublets and no signal typical of H4 at ~ δ 6). Attempts to purify this compound by silica gel chromatography were unsuccessful. Photolysis of toluene-d_8 in TFE resulted in the same products (GC) and the ^{1}H NMR revealed again that protonation by TFE was highly preferred at C6 *endo*. These observations suggest that the major pathway for photoaddition of TFE is by protonation at C1 or C6 (identical by symmetry) of an intermediate methylbenzvalene (*x*-methyltricyclo[3.1.0.0^{2,6}]-3-hexene) that is not methyl substituted at C1 or C6. As observed previously, rapid isomerization of this bicyclo[3.1.0]-3-hexen-2-yl cation will result in the methyl substituent being at the terminal end of the allylic moiety (C2 or C4) so that, after *exo* and *endo* nucleophilic trapping by TFE, the major products will be 4-methyl-2-(2,2,2-trifluoroethyl) derivatives.

For trifluoromethylbenzene, 4 h photolysis gave 57% conversion of starting material to six additions products (GC and GC-MS) with one of them accounting for 53% of the mixture. At this point, the mass balance was still 72%. Again, silica gel chromatography gave no characterizable products from this mixture. Moreover, the ^{1}H NMR of the crude reaction mixture did not provide clear signals for any one compound. There were, however, no high field signals around δ 0 indicative of a cyclopropyl -CH_2-. Therefore, the photoaddition products are probably similar in structure to those of the benzonitriles, i.e., resulting from protonation at the CF_3 substituted carbon.

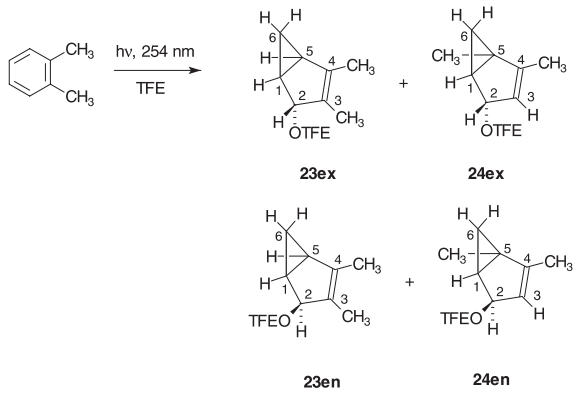
Photolysis of disubstituted benzenes

Xylenes

Alkyl substituted benzenes have been important in the understanding of aromatic phototransposition reactions. The gas phase isomerization of *o*-xylene to *m*-xylene and of *m*-xylene to both *o*- and *p*-xylene (ratio 1:4) and the isomerization of *m*-xylene in the pure liquid and in isohexane solvent were first reported in 1964 (13). In the same year, a study appeared on the photoequilibration of the di-*t*-butylbenzenes in ether (14). Later, for the solution (isohexane) photochemistry of *o*-xylene, the primary photochemistry was reported to give both *m*- and *p*-xylene in a ratio of 14:1 (15). Thus, both 1,2- and 1,3-transpositions are occurring simultaneously in solution for *o*-xylene.

More extensive results on the solution transposition photochemistry of the xylenes were reported by Anderson in 1970 (16). The phototranspositions were found to be independent of solvent (hexane and EPA (5:5:2 mixture of ether, isopentane, and ethanol)) and wavelength of excitation. Irradiation in the 230–280 nm range gave disappearance quantum yields in hexane of 0.00775, 0.0111, and 0.00274 for

© 2000 NRC Canada



o-, *m*-, and *p*-xylene, respectively. At very low conversions, the ratio of *meta*:*para* from *ortho* was 8.8:1 indicated that again both 1,2- and 1,3-transpositions were occurring as a primary photochemical event. The ratio of *para* to *ortho* from *m*-xylene was 4.1 but no ratio of *ortho* to *meta* was reported for the very unreactive *para* isomer.

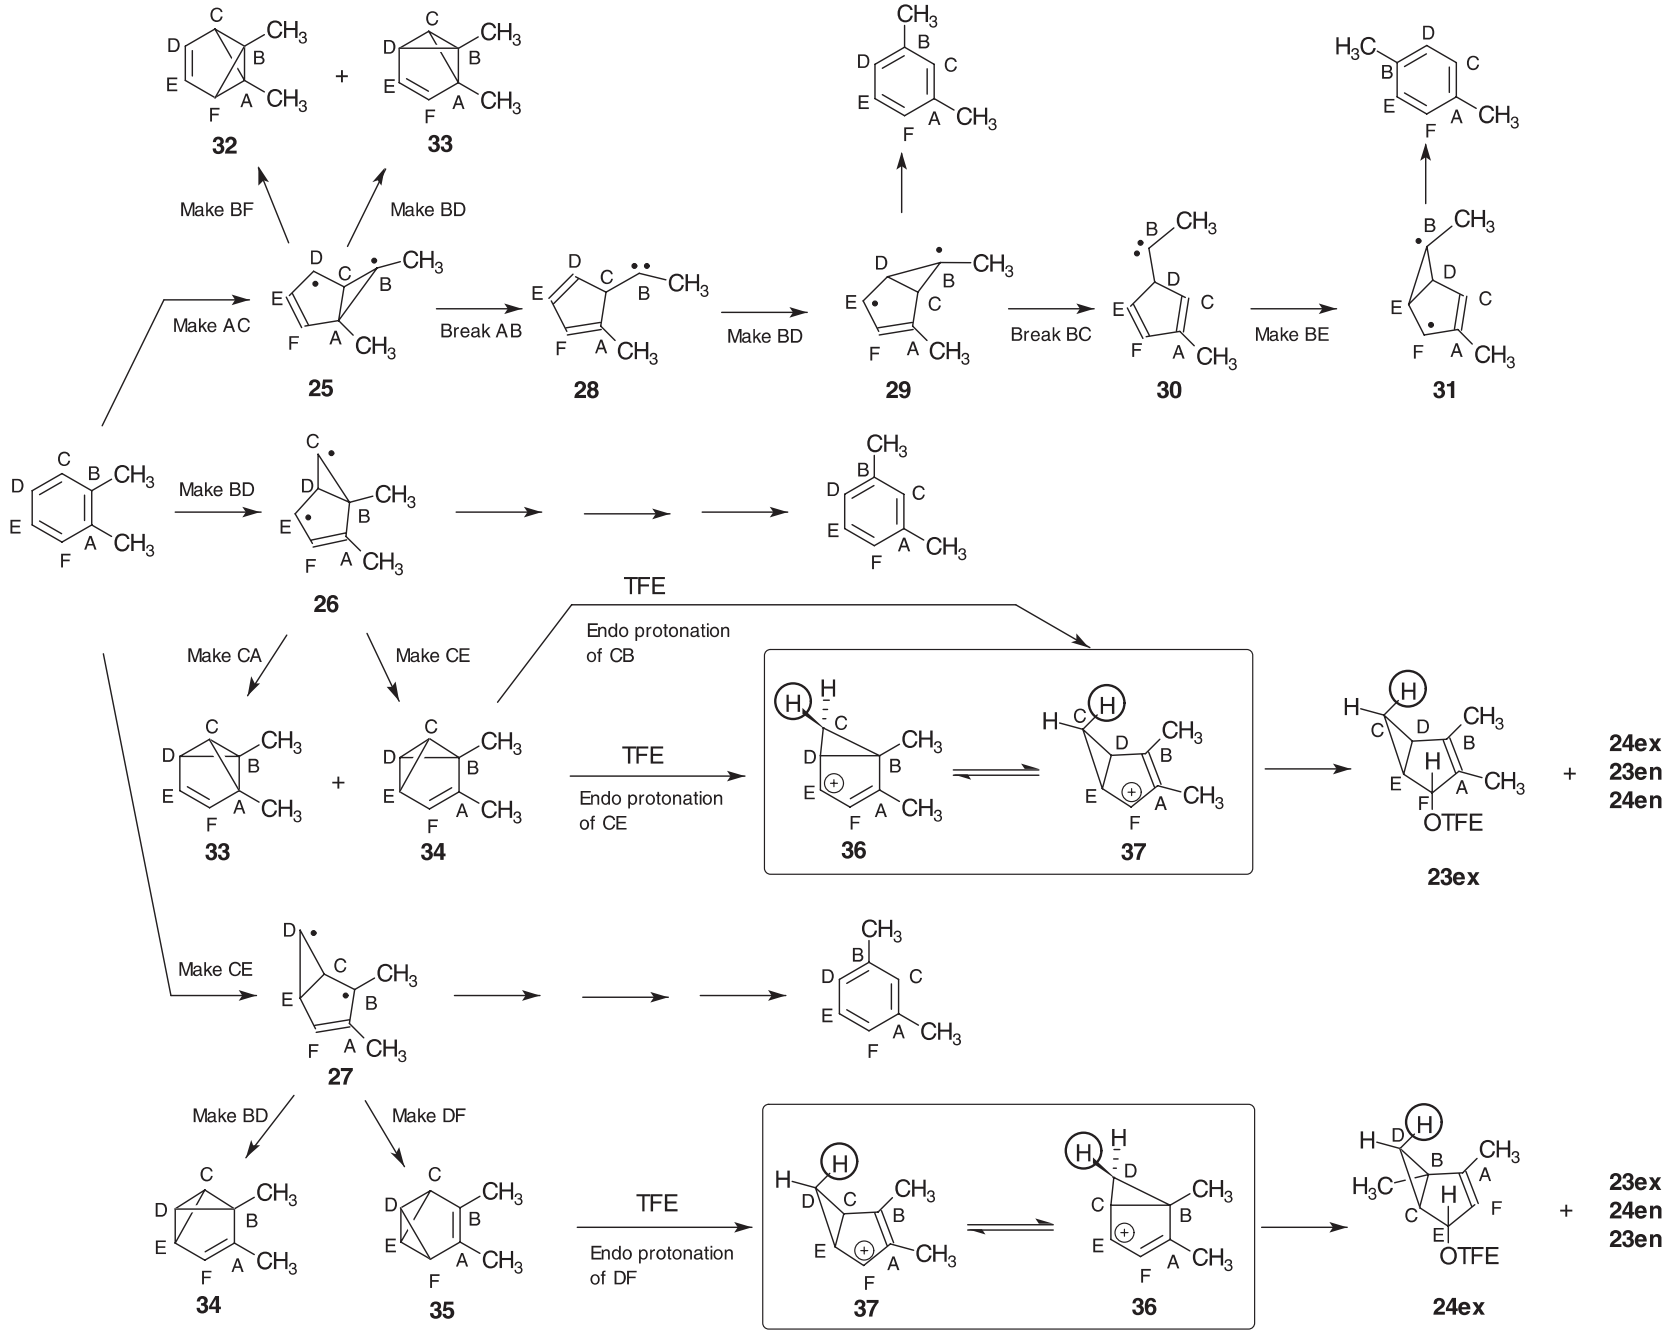
We have examined the xylene isomers in acetonitrile and observed similar results. By taking samples as a function of time under 1.5% conversion, primary product ratios were obtained by extrapolation to zero time. The values obtained are: *meta*:*para* = 11:1 for *ortho*; *ortho*:*para* = 6.0:1 for *meta*; and *meta*:*ortho* > 25:1 for *para*. The last value was difficult to obtain reliably because the *para* and *meta* isomers have very similar GC retention times on the column used. They can be resolved to the baseline when they are present in comparable amounts, but not when the ratio is greater than 100 to 1. Therefore, the *meta* isomer appears as a shoulder on the tail of the large *p*-xylene signal and quantifying its intensity is difficult. In agreement with the previous results, the *meta* isomer is the most reactive in the phototranspositions in acetonitrile and the *para* isomer, the least. Relative reactivities are approximately 1:1.4:0.3 for *ortho*:*meta*:*para*.

Irradiation of the xylenes in TFE gave characterizable products only for *o*-xylene. For both the *meta* and the *para* isomers, the starting material disappeared but no significant signals at the appropriate retention times appeared. In contrast, irradiation of a 2.52×10^{-2} M solution of *o*-xylene in TFE for 5 h resulted in 83% conversion to eight addition products in a total yield of 50%. Two of these eight accounted for 65% of the products formed, and two others, 21%. An important observation is that the photoaddition reaction in TFE is about 25 times more efficient than the phototransposition reaction in acetonitrile. Not surprisingly, therefore, no phototransposition was observed in TFE. The reported quantum yield of *o*- to *m*-xylene in hexane of ~0.007 suggests that the quantum yield for photoaddition is about 0.18.

Removal of the solvent allowed the identification of these major products, **23ex** and **24ex**, by ^{1}H NMR (normal and COSY) at 400MHz, eq. [2]. These assignments are made

[2]

with considerable confidence even though the cyclopropyl hydrogen at C1 and C5 were not observable as they fall underneath the broad, uncharacterizable signal between δ 1 and 2.5 (see above). Both clearly have a cyclopropyl CH_2 at C6 on the basis of the high field signal for H6 *endo* at δ –0.40 for **23ex** and δ 0.14 for **24ex**. Moreover for **23ex**, this signal is a pseudo-quartet (~3.6 Hz) as expected if there are hydrogens at both C1 and C5; in contrast, this signal is a pseudo-triplet (~4.0 Hz) for **24ex**, indicating methyl substitution at C1, C5, or C6 (It is actually at C5.). Neither compound has the expected doublet of doublets for hydrogens at both C3 and C4. For **23ex** there is only one signal in the low field region (δ 4.32) corresponding to H2 and it is a broad singlet indicating that the TFE group is *exo*. Moreover, the two methyl groups (δ 1.78 and 1.56) are broadened by the expected homoallylic coupling. For **24ex**, these are two low field signals at δ 4.38 (H2) and 5.02 (H3); again the TFE group is *exo*. The methyl groups are now more separated in chemical shift, δ 1.82 for 4-CH_3 and 1.28 for 5-CH_3, indicating cyclopropyl substitution for the latter. Finally, the other two major products in the mixture are very likely the corresponding *endo* isomers **23en** and **24en**, eq. [1], on the basis of the similarities in their ^{1}H NMR spectra to those for the *exo* isomers: δ 0.05, "q" and –0.19, "t," respectively, for H6 *endo* and the splitting of the signals for H2 into doublets (~8 Hz) by coupling to H1.



A similar photolysis of *o*-xylene-d_{10} in TFE gave the same products and the ratio of *endo*:*exo* protonation at C6 by TFE could easily be determined by ^{1}H NMR integrals of the corresponding hydrogens. For both **23** and **24**, the ratio was ~9:1.

The results for the *o*-xylene photochemistry in both acetonitrile and TFE can be rationalized by the mechanism outlined in Scheme 2. Photochemical excitation to S_1 leads to the pre-fulvene biradicals **25**, **26**, and **27**. For benzene itself, by MO calculations (17), this process proceeds over a small activation barrier to a conical intersection so that the biradical is on the ground state surface. For benzene there is only one such biradical but for *o*-xylene, three are possible. Each of these biradicals can collapse to one pair of the four possible benzvalene structures, **32**–**35**. A previously proposed and possible mechanism for *ortho* to *meta* phototransposition is then the return of the dimethylbenzvalene to xylene either thermally or, as has been suggested, by photochemical sensitization (13, 15). These dimethylbenzvalenes allow for phototransposition because two carbons of the original *o*-xylene can now switch positions on the return pathway. For instance, **33** was formed by AC plus BD bond formation. By next breaking bonds AB and CD, carbons B and C have been interchanged so that *o*-xylene has isomerized to *meta*. For *o*-xylene only one of the four dimethylbenzvalenes, i.e., **33**, leads to isomerization; the other three lead to undetectable carbon-carbon transpositions.

This mechanism for phototransposition cannot be the exclusive one for *o*-xylene because both 1,2- and 1,3-transpositions, in a ratio of 10.5:1, are observed in the primary photochemical process. Our preference is therefore for the pathway of migration in the biradicals. Thus **25**, rather than collapsing to benzvalenes **32** and **33**, ring-opens by AB bond cleavage to the cyclopentadienylcarbene, **28**. MO calculations (3) for benzene itself have shown that structures like **25** are not as stable as structures like **28**. We are in the process of doing similar calculations for substituted benzenes. This pathway of migration of a single carbon around the cycle formed by the other five has been strongly implicated in our previous study (1) on the phototransposition reactions of the

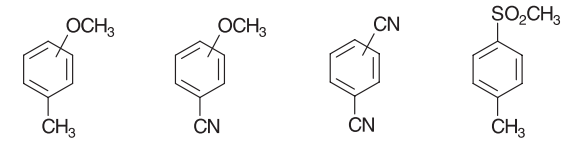
© 2000 NRC Canada

Scheme 2. Mechanism for the phototransposition and the photoaddition of TFE for *o*-xylene.

© 2000 NRC Canada

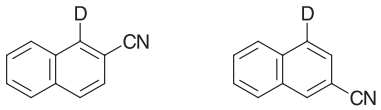
methylbenzonitriles in acetonitrile. Thus, **25** proceeds to **28** and then to **29** which can ring-open to *m*-xylene or proceed to **30** and finally to *p*-xylene. Similar pathways for the initially formed biradicals **26** and **27** (intermediates not shown in Scheme 2) can lead only to *m*-xylene. Because the efficiency of phototransposition for *o*-xylene is low, the major fate of the first-formed biradicals must be return to *o*-xylene or collapse to benzvalene.

The photoaddition reaction of *o*-xylene in TFE provides additional information about benzvalene formation. In contrast to the photoadditions to benzonitriles where both *exo* and *endo* protonation at C6 of the bicyclo[3.1.0] derivatives was observed, the products, like those from both benzene and *o*-xylene, exhibit a marked preference for *endo* protonation. Because the products formed from *o*-xylene are not methyl substituted at C6, benzvalene **32** cannot be a major intermediate and **33** is also unlikely because protonation at the methyl substituted carbon of the bonds AB or BD would be expected to occur some of the time. Therefore, **34** and **35** are the major benzvalenes most likely formed. By symmetry, **34** has only two observable modes of *endo* protonation: at CE, giving the bicyclic cation **36** and at CB, giving **37**. It is not possible to determine which of these is preferred because these cations will again equilibrate rapidly by thermally allowed 1,4-sigmatropic rearrangement, with retention of configuration of the migrating carbon (2). Thus, the *endo* H (circled) remains *endo*, as demonstrated by the results using deuterated *o*-xylene. In a similar way, *endo* protonation of the benzvalene **35** can only lead to the bicyclic cation **37** but again it should rapidly equilibrate with **36**.



The products **23** and **24**, eq. [2], are clearly derived from *exo* (major) and *endo* (minor) trapping of the cations by TFE. The *exo* attack is presumably preferred for steric reasons. In principle, three such cations are possible (symmetry reduces the total from five to three) with the CH_2 group bridging any one of the five bonds in the dimethylcyclopentyl ring. However, only **36** and **37** have the allyl cation methyl substituted at the end. Therefore, these two are expected to be more stable; products from the other one are formed, if at all, in minor amounts. A similar observation was made in the photochemical TFE addition to *m*- and *p*-methylbenzonitrile (2). Finally, the TFE quenching of the cations **36** and **37** occurs mainly at the hydrogen substituted end. This may reflect the increased stability of the methyl substituted alkene in **23** and **24**.

The conclusion from this section on xylene photochemistry is that *o*-xylene most likely undergoes phototransposition through the biradical/carbene pathway and photoaddition through a much more efficient benzvalene pathway. *m*-Xylene undergoes phototransposition with comparable efficiency to both *o*- and *p*-xylene (ratio 6.0:1) but, for reasons that are unknown, the photoaddition products with TFE are not stable. Finally, *p*-xylene is very unreactive for either process and only very slow phototransposition is observe with a high preference for 1,2-transposition to *m*-xylene.



Other disubstituted benzenes

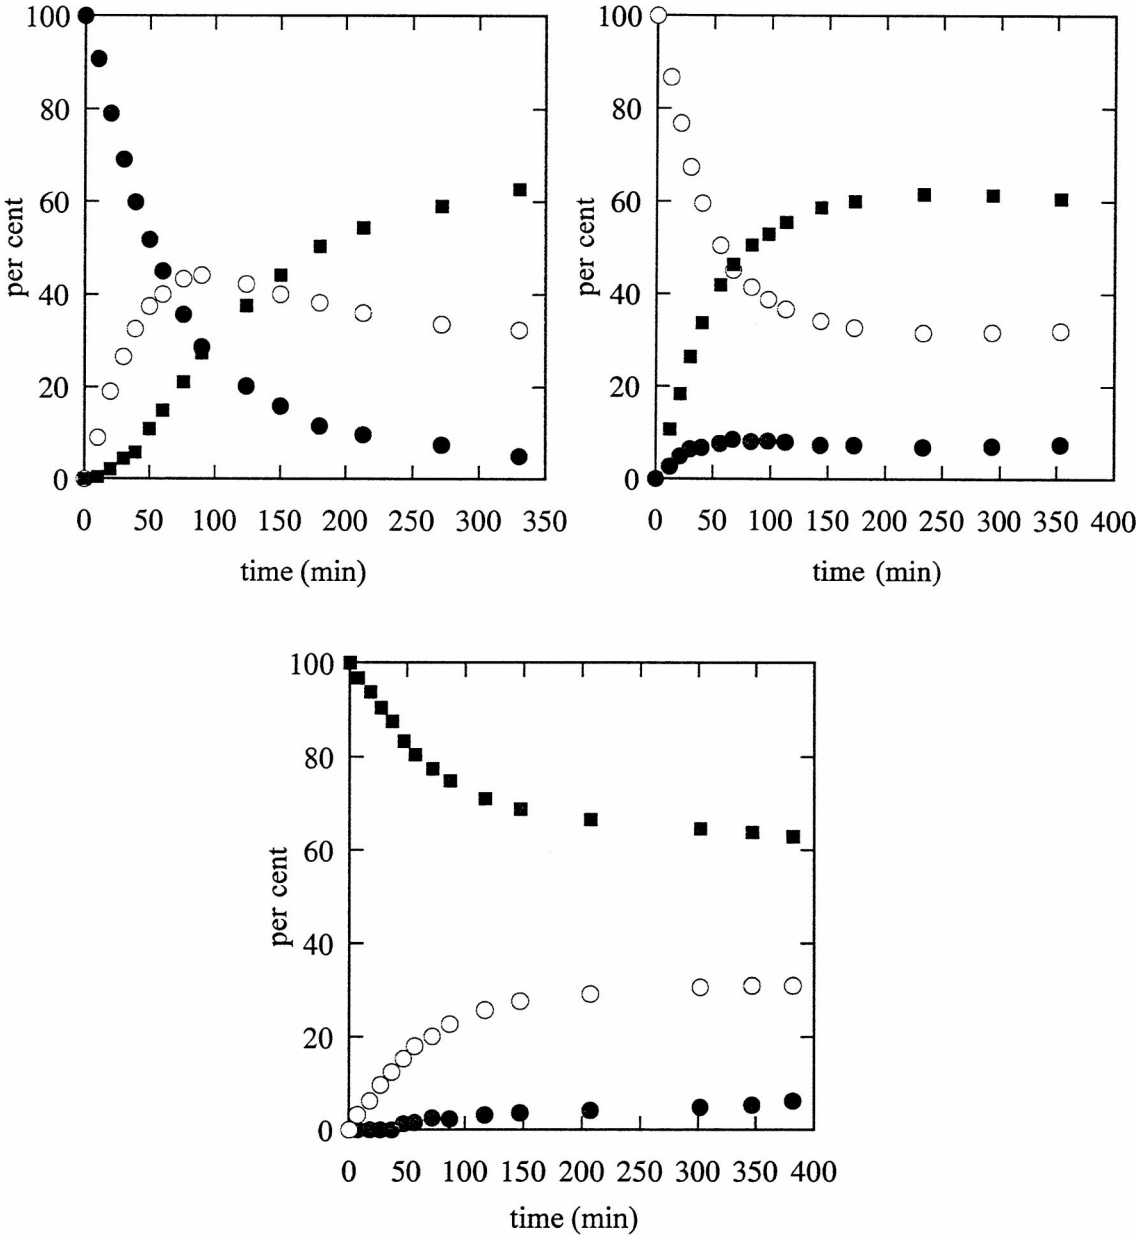
As a consequence of the observation of phototransposition and photoaddition of TFE to the methyl benzonitriles and xylenes, a survey of other disubstituted compounds was made. The compounds **38**–**42** were all found to be unreactive. Compound **42** was made from 2-aminonaphthalene by exchange at C1 with D_2O followed by Sandmeyer reaction to the nitrile. The idea was that if isomerization occurred by cyano-substituted carbon migration, as is the case of the methylbenzonitriles by bridging between C1 and C3, then 1-deuterio-2-cyanonaphthalene would be converted to 4-deuterio-2-cyanonaphthalene, **43**, a rearrangement that would be invisible without deuterium substitution. No reaction was observed by ^1H NMR analysis.

In contrast to these unreactive compounds, the substituted derivatives, **44**–**46**, showed photoreactivity but in ways that were different from the previously examined cases. The structures of **38**–**46** suggest that electron-withdrawing groups facilitate this type of aromatic photochemistry.

38 (*o, m, p*) **39** (*o, m, p*) **40** (*o, m, p*) **41**

42 **43**

*Trifluoromethyltoluenes, **44** (*o, m, p*)*



The plots for the photochemical interconversion of these three isomers are shown in Figs. 1*a*, *b*, and *c*. The reactions are considerably more efficient than the corresponding methylbenzonitriles, the steady state for photoequilibration being reached in about 200 min, about 10 times faster than for 4-methylbenzonitrile. More interesting is the observation that the steady state composition of *o*:*m*:*p* = 7:32:61 is essentially reversed from that observed for the methylbenzonitriles, *o*:*m*:*p* = 77:20:3. This occurs because for the CF_3 compounds, **44**, the *para* isomer is the least reactive and the *ortho* isomer is the most; the reverse order of reactivity holds for the methyl benzonitriles, **1**, **2**, and **3**.

The second major difference can be seen most clearly from Fig. 1*a* for the reactivity of the *ortho* isomer. At low conversions, as the *ortho* isomer disappears and the *meta* grows, the *para* is seen to have an induction period. The ratio of *para* to *meta* for the first sample taken at 10 minutes is greater than 10:1 but has dropped to 3:1 by 50 min. This implies that 1,2-transpositions are preferred to 1,3-transpositions in contrast to the observation for 4-methylbenzonitrile where the yields of the 3- and 2-substituted isomers increased simultaneously. The same is true for the *para* isomer, the ratio of *m*:*o* being greater than 20:1, Fig. 1*c*.

Photolysis of either **44*o*** or **44*m*** in TFE resulted in rapid formation of a complex mixture of at least 9 addition products (GC-MS); the major product accounted for 41% of the mixture. As in the case of the *m*- and *p*-methylbenzonitriles the product composition was essentially independent of the starting material. The mass balance was again good; 90%

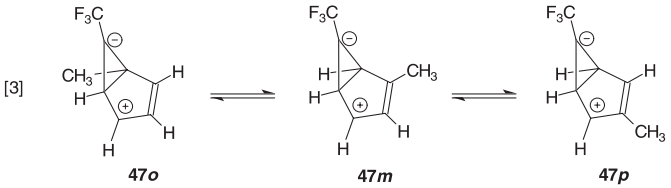
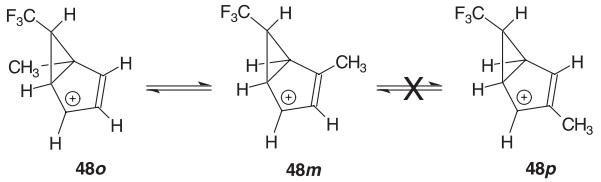
Fig. 1. Plots of the phototransposition in acetonitrile of *o*-, *m*-, and *p*-trifluoromethyltoluenes, **44*o*** (●), **44*m*** (○), and **44*p*** (■): 1*a*, starting with **44o**; 1*b*, starting with **44*m***; and 1*c*, starting with **44*p***.



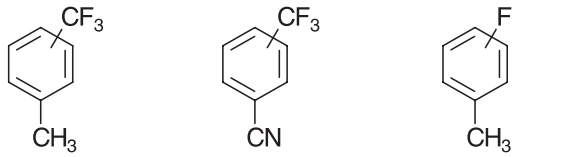
after 86% conversion for the *ortho* isomer and 81% after 85% conversion for the *meta* isomer. Unfortunately, evaporation of the solvent gave a residue whose ^{1}H NMR spectrum showed only a broad, unstructured signal covering the range of δ 2.5 to 0.5 ppm.

In contrast to the *ortho* and *meta* isomers, the *para* compound did not form any addition products in TFE. Moreover, the isomerization reaction occurred at a rate that was approximately 10 times slower than in acetonitrile, Fig. 1*a*. We conclude that some intermediate in the photochemistry of the *para* isomer is quenched by TFE (probably by protonation) but that this unknown species returns to starting material rather than leading to photoaddition products.



By analogy with the methylbenzonitriles, Scheme 1, we would expect the first formed intermediates to be bicyclic biradicals, perhaps **47o**, **47*m***, and **47*p*** from **44*o***, **44*m***, and **44*p***, respectively, eq. [3], and that these would form the

[3]



protonated species **48*o***, **48*m***, and **48*p*** in TFE, eq. [4]. The phototransposition in acetonitrile is explained by eq. [3] and the photoaddition in TFE by trapping of the cations, **48**. Surprisingly, **48*p***, if formed, does not lead to photoadducts.

© 2000 NRC Canada

[4] 

Moreover, **48*o*** and **48*m*** must again rapidly equilibrate because the product mixture obtained in TFE is identical for both **44*o*** and **44*m***; most of the products may be formed from the more stable cation, **48*m***.

Finally, for the methylbenzonitriles, we demonstrated by deuterium labelling and TFE trapping, that the cyano group was attached at C6 in the bicyclic intermediates. We have no evidence that the same is true for the trifluoromethyltoluenes (**44**) because we were unable to observe the ^{1}H NMR spectra of the photoadducts with TFE and have not attempted, nor thought of a convenient way, to synthesize specifically deuterated substrates.

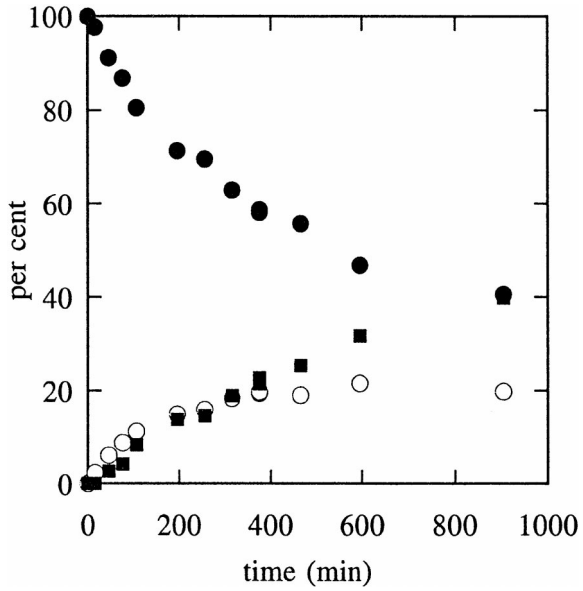
44 (*o, m, p*) **45 (*o, m, p*)** **46 (*o, m, p*)**

*Trifluoromethylbenzonitriles, **45** (*o, m, p*)*

Photolysis in acetonitrile of both **45*m*** and **45*p*** resulted in photoequilibration to all three isomers, with the steady-state composition being similar for both; *o*:*m*:*p* = 40:20:40. The *meta* isomer was slightly more as reactive than the *para*. In contrast, the *ortho* isomer was considerably less reactive and a photostationary state was not reached. For the *para* isomer, product ratios for the *meta* and *ortho* isomers indicated that both 1,2- and 1,3-tranpositions were occurring simultaneously.

Surprisingly, irradiation in TFE gave essentially the same results as in acetonitrile. The plot is shown for the *para* isomer in Fig. 2. No products resulting from the addition of TFE were observed. These compounds are the only examples where we have observed efficient phototransposition reactions rather than photoadditions in TFE.

*Fluorotoluenes, **46** (*o, m, p*)*



These compounds showed very low reactivity in either acetonitrile or TFE. However, **46*m*** did slowly react to form the *ortho* and *para* isomers in a ratio of 5:1 at low conversion but a steady-state mixture was not reached.

Summary

The results for the photochemistry reported in this work and for previously reported methylbenzonitriles (1, 2) and benzene-1,3,5-d_3 (5) are given in Table 1.

For benzene and alkyl benzenes (toluene, xylene) benzvalenes are probably the important intermediates, certainly for the TFE additions on the basis of the preference for *endo* protonation at C6 and probably for the phototranspositions

Fig. 2. Plot for the phototransposition in TFE of 4-trifluoromethylbenzonitrile, **45*p*** (●) to **45*m*** (○), and **45*p*** (■).

in acetonitrile because of the preference for 1,2-versus 1,3-transpositions.

For the disubstituted compounds that do react efficiently, namely the methylbenzonitriles (**1**, **2**, and **3**), the trifluoromethyltoluenes (**44(*o*, *m*, *p*)**), and the trifluorobenzonitriles (**45(*o*, *m*, *p*)**), three very different kinds of reactivity are observed. For the methylbenzonitriles in acetonitrile, clearly simultaneous 1,2- and 1,3-transpositions are occurring; in TFE both *endo* and *exo* protonation at C6 are observed. Therefore, bicyclic intermediate radicals (like **5**, **6**, and **7** in Scheme 1) and (or) carbenes (like **28** and **30** in Scheme 2) are the critical intermediates. Benzvalenes (like **8**b in Scheme 1) are of minor importance. For the trifluoromethyltoluenes, (**44(*o*, *m*, *p*)**), 1,2-transpositions dominate 1,3-transpositions (most clearly seen in Fig. 1*a*). Unfortunately, the structures of the photoaddition products in TFE could not be determined. For the trifluoromethylbenzonitriles (**45(*o*, *m*, *p*)**), essentially identical phototransposition results (but no photoadditions) were observed in both acetonitrile and TFE.

The other major observation to be made from the results in Table 1 is that many compounds, both mono- and disubstituted are photochemically very unreactive to either process, with the indication that electron withdrawing groups, either by inductive (CF_3) or resonance (CN) effects, are important.

Finally, even after completing the survey of compounds given in Table 1, no clear trends are obvious that would allow reliable prediction of the results for a new compound. Perhaps MO calculations for a variety of substituents will help to clarify these obviously complicated potential energy surfaces. Such calculations are in progress.

Experimental

Chemicals

The following compounds were obtained from Aldrich and were distilled before use: anisole; 2-, 3- and 4-methylanisole;

1,2-, 1,3-, and 1,4-dimethoxybenzene; methylbenzoate; α,α,α-trifluorotoluene; *o*-, *m*-, and *p*-xylene; 4-trifluoromethyltoluene; *o*-, *m*-, and *p*-trifluoromethylbenzonitrile; and 4-biphenylcarbonitrile. Both 2-trifluoromethyl and 3-trifluoromethyltoluene were synthesized by the Huang-Minlon (18) modification of the Wolff–Kishner reduction from the corresponding aldehydes, available from Aldrich. The deuterated substrates, benzene-d_6, toluene-d_8, and *o*-xylene-d_{10} were also obtained from Aldrich.

Photolysis

All photolysis were carried out in a Rayonet reactor, using 254 nm lamps, as described previously. The GC column used was also described previously (2). Because pure compounds could not be obtained for the addition of TFE, product yields were estimated by GC/FID peak areas without calibration.

An expeditious synthesis of (±)-decahydro-5*H*-dipyrrolo [1,2-*a*:1′,2′-*c*]pyrimidine-5-carbonitrile: a formal synthesis of (±)-tetraponerines-1, -2, -5, and -6

M. Plehiers, S. Heilporn, D. Ekelmans, S. Leclercq, M. Sangermano, J.C. Braekman, and D. Daloze

Abstract: A short and practical synthesis of (±)-decahydro-5*H*-dipyrrolo[1,2-*a*:1′,2′-*c*]pyrimidine-5-carbonitrile (**17**), a pivotal intermediate in the synthesis of (±)-tetraponerines-1 (**5**), -2 (**6**), -5 (**7**), and -6 (**8**), in three steps and 24% overall yield, from simple and inexpensive starting materials, is reported. The key step of our synthesis is a one pot stereoselective multistep process, whereupon two molecules of Δ^1-pyrroline (**9**) react with diethyl malonate (**10**) to afford the tricyclic lactam ester **13**, possessing the tetraponerine skeleton. Hydrolysis of the carboethoxy group of **13** followed by decarboxylation yields lactam **15**, which is converted into α-aminonitrile **17**. Our fruitless efforts to transform lactam **15** into the tetraponerines through reductive alkylation are also discussed.

Key words: alkaloids, tetraponerines, stereoselective synthesis, Robinson–Schöpf reaction, lactams, ants.

Résumé : Opérant à partir de produits de départ peu coûteux et facilement disponibles, on a mis au point une synthèse courte et pratique, en trois étapes et un rendement global de 24%, du (±)-décahydro-5*H*-dipyrrolo[1,2-*a*-:1′,2′-*c*]pyrimidine-5-carbonitrile (**17**), un intermédiaire dans la synthèse des (±)-tétraponérines-1 (**5**), -2 (**6**), -5 (**7**) et -6 (**8**). L'étape clé de notre synthèse est une réaction unipot stéréosélective à plusieurs étapes par laquelle deux molécules de la Δ^1-pyrroline (**9**) réagissent avec du malonate d'éthyle (**10**) pour conduire à la formation de l'ester lactame tricyclique **13** qui possède le squelette de la tétraponérine. L'hydrolyse du groupe carboéthoxy du composé **13**, suivie d'une décarboxylation, conduit au lactame **15** qui est finalement transformée en α-aminonitrile **17**. On discute aussi de nos vains efforts pour transformer le lactame **15** en tétraponérines par le biais d'une alkylation réductrice.

Mots clés : alcaloïdes, tétraponérines, synthèse stéréosélective, réaction de Robinson–Schöpf, lactames, fourmis.

Introduction

The tetraponerines are a group of eight tricyclic alkaloids isolated from the poison gland of the Neo Guinean ant *Tetraponera* sp. (1). These compounds are distributed into two families, which are based either on the 5-alkyldecahydro-5*H*-pyrido[1,2-*c*]pyrrolo[1′,2′-*a*]pyrimidine[3] skeleton ("6–6–5" skeleton) [T-3 (**1**), T-4 (**2**), T-7 (**3**), and T-8 (**4**)] or on the 5-alkyldecahydro-5*H*-dipyrrolo[1,2-*a*:1′,2′-*c*]pyrimidine[3] skeleton ("5–6–5" skeleton) [T-1 (**5**), T-2 (**6**), T-5 (**7**), and T-6 (**8**)] (Fig. 1) (2). In each family, the compounds differ from each other by the length of the alkyl chain (*n*-propyl or *n*-pentyl) and (or) by the configuration of the carbon atom to which it is attached.

Whereas several syntheses of tetraponerines **1**–**4** have been described (for a recent review see ref. (3)), only one synthesis of (±)-**7** and (±)-**8** (2), and one asymmetric synthesis of (+)-**5** to (+)-**8** (4) have been reported up to now. In the course of our work on the biosynthesis of the tetraponerines (5, 6), we needed a practical way to synthesize the tetraponerines **5**–**8** belonging to the "5–6–5" skeleton. In this context, we envisioned that a modified Robinson–Schöpf condensation between Δ^1-pyrroline (**9**) and diethyl malonate (**10**) could lead to the diester intermediate **11** which, through reaction with a second Δ^1-pyrroline unit, would afford **12**. Finally, the latter could lactamize into compound **13** having the required tricyclic skeleton (Scheme 1). This scheme is only a working hypothesis, since the order of the steps could

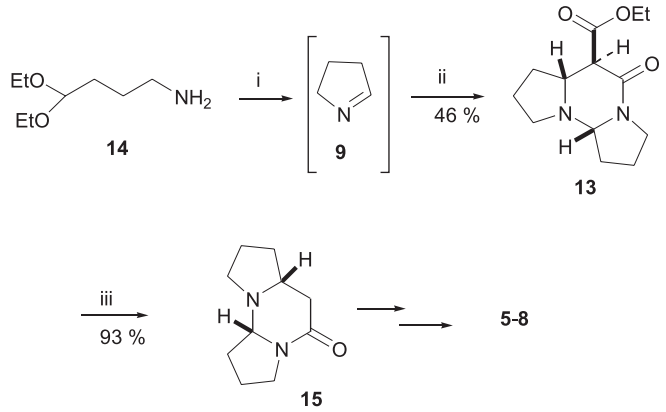
be reversed or several competitive processes could take place.

Results and discussion



Our initial attempts along these lines, however, were disappointing. When Δ^1-pyrroline (**9**), generated through treatment of 4-aminobutanal diethylacetal (**14**) with an excess of 10% HCl (7), was reacted with 0.5–4 equiv of **10** in a citrate–phosphate buffer (pH 5.4) at 20°C for 24 h, as described by Stevens and Lee (8) for the synthesis of coccinelline, the reaction mixture showed only traces of the desired compound **13**. Instead, large amounts of **9** and **10** were still present, accompanied by polar compounds which were not investigated. The influence of different parameters, such as temperature, proportions of reactants, and pH, on the outcome of the reaction was studied. It turned out that an increase of pH had a beneficial effect because the yield of compound **13** reached 20% at pH 8 and 27% at pH 10, after work-up and silica gel chromatography. The optimum conditions we have found (2:1 ratio of **10** and **14**, pH 12, 20°C for 14 h, vigorous stirring) furnished **13** in a reproducible 46% yield (based on **14**) (Scheme 2). The structure of **13** was assigned on the basis of its spectral properties, particularly 1D and 2D NMR spectra at 600 MHz. The *trans*-relationship between H-9 and H-10 was based on the coupling constant $J_{9,10}$ = 10 Hz, whereas we assumed a *cis*-relationship between H-4 and H-10 based on the results of previous cyclization reactions in this series (2–4). This assignment was later confirmed by the conversion of **13** into **17**. Next, lactam ester **13** was decarboxylated into lactam **15** in a 93% yield, by treatment with 5% KOH–MeOH at 20°C for 2 h, followed by addition of 10% HCl to pH 4–5, and heating the resulting mixture for 2 h at 70°C (Scheme 2).

With compound **15** easily available in two steps, we turned our attention to the conversion of its lactam group

Scheme 1. Synthetic strategy towards tricyclic lactam **13**.

Scheme 2. Synthesis of tricyclic lactam **15**. Reagents and conditions: (*i*) 10% HCl, 20°C, 30 min; (*ii*) (*a*) 1 M KOH → pH 12; (*b*) **10** (2 equiv), 0°C → 20°C, 14 h; (*iii*) (*a*) 5% KOH–MeOH, 20°C, 2 h; (*b*) 10% HCl → pH 4–5, 0°C; (*c*) 70°C, 2 h.

into an α-alkylamine. Compounds bearing this functionality are important synthetic targets (3, see for example ref. (9)). One way to synthesize them is through reductive alkylation of lactams, which involves the addition of an alkyl organometallic reagent onto the lactam carbonyl, followed by iminium ion formation and reduction of the latter by an hydride reagent. Despite the well-known lack of reactivity of lactam carbonyls towards nucleophilic reagents, several examples of this process are nevertheless described in the literature (10–16). In this context, it is interesting to note that all our efforts to repeat the reductive alkylation described by Jones (13) as a key step in his short synthesis of tetraponerine-8 (**4**) failed. Indeed, when the conditions described by Jones (13) (pentylmagnesium chloride or bromide, TMEDA, followed by $LiAlH_4$ or $LiAl(Ot\text{-}Bu)_3H$) were applied to his bicyclic lactam, we observed only the reduction of the carbonyl group.[4] Other conditions were subsequently tried, such as *n*-BuLi, with or without TMEDA, pentylmagnesium chloride in the presence of Ce(III) salts (17), or preformed *n*-$BuCeCl_2$ (17), again without success.[4] Despite these negative results, we submitted lactam **15** to a reductive alkylation using *n*-$BuCeCl_2$ but, again, the results

were disappointing. When the reducing step was performed with $NaBH_4$, most of starting **15** was recovered unchanged whereas with $LiAlH_4$ complex mixtures were obtained. Several authors have already reported that the addition of alkyl organometallic reagents to lactam carbonyls is fraught with difficulties (11, 12, 15, 16). This problem seems to be attributable to competitive enolate formation (15). Indeed, a close look at successful examples reported in the literature showed either that the lactam carbonyl is not sterically hindered (10), that it is activated towards nucleophilic attack (11, 14, 16), or still, that the organometallic reagents used [aryllithium (11), furyllithium (12), and alkylcerium (15) reagents] are less basic than alkylmagnesium or alkyllithium reagents. In agreement with this interpretation, Yamaguchi and Hirao (18) have described the successful synthesis of α-alkynylamines through the addition of alkynyllithium reagents to the carbonyl group of lactams in the presence of $BF_3{\cdot}Et_2O$, followed by $LiAlH_4$ reduction.

We thus submitted **15** to these conditions, using 1-pentynyllithium (Scheme 3). This procedure indeed furnished a 70:30 ratio of the two diastereomers **16a** and **16b** in a 49% yield. Unfortunately, the last step, namely, the reduction of the triple bond of **16** to afford T-5 (**7**) and T-6 (**8**) proved unsatisfactory. Several hydrogenation catalysts and various conditions of temperature and pressure were tried but with limited success. Either the reaction was not complete and stopped at the alkene stage (W_2 grade RaNi, with or without KOH), or overreduction was observed (Pd-C, PtO_2), leading to complex mixtures containing small amounts of **7** and **8**. The latter were accompanied by secondary products arising from hydrogenolysis of the aminal (5), or of the propargyl amine (19) functionalities of **16**. The best results (ca. 16% of a 54:46 mixture of T-5 (**7**) and T-6 (**8**)) were obtained with Wilkinson's catalyst (20) (Scheme 3), but the yield could not be improved. Thus, to circumvent this problem, we turned to an indirect alkylation method, namely the α-aminonitrile methodology of Stevens (21, 22). Accordingly, the iminium ion, resulting from partial reduction of **15** with DIBAL-H at –78°C followed by acid treatment, was trapped with cyanide ion to furnish in a 56% yield the α-aminonitrile **17** (Scheme 3), identical in all respects (except rotation power) with the pivotal intermediate described by Yue et al. (4) in their tetraponerine synthesis.

Conclusions

In conclusion, the results reported here constitute a short and convenient procedure to synthesize the four tetraponerines **5–8**. The key intermediate **15** was obtained from readily available and inexpensive starting materials in three steps and 24% overall yield. Through its simplicity and conciseness, this approach compares favourably with our previous one (2). On the other hand, the synthesis of Yue et al. (4) leads to enantiomerically pure compounds and good overall yields, but requires seven steps. It is noteworthy that all our attempts to directly transform lactam **15** into the tetraponerines through reductive alkylation failed, whatever the conditions used.

Scheme 3. Conversion of **15** into the tetraponerines. Reagents and conditions: (*i*) (*a*) 1-pentynyllithium (3 equiv), $BF_3{\cdot}Et_2O$ (3 equiv), –40°C, 4 h; (*b*) EtOH (3 equiv), then $LiAlH_4$ (excess), –40°C, 1 h; (*ii*) H_2, Wilkinson catalyst, atm. pressure, 20°C, 41 h; (*iii*) (*a*) DIBAL-H (1.2 equiv), –78°C, THF, 2 h; (*b*) $HClO_4$–EtOH → pH 3; (*c*) KCN (5.5 equiv), 14 h.

Experimental section

General

EIMS and EIHRMS were performed with a Fisons VG Micromass Autospec instrument (70 eV) and GC–EIMS analyses with the same instrument coupled to a Carlo Erba 8065 MS gas chromatograph equipped with a capillary column (carrier gas He). In all cases, peak intensities are expressed as % relative to the base peak. The ^1H NMR spectra were recorded in $CDCl_3$ at 250 MHz with a Bruker WM 250 spectrometer or at 600 MHz with a Varian UNITY 600 spectrometer and are reported in ppm from internal TMS on the scale. Data are reported as follows: chemical shift [multiplicity (s, singlet; bs, broad singlet; d, doublet; bd, broad doublet; t, triplet; q, quartet; sex, sextet; dd, double doublet; td, double triplet; m, multiplet; ms, massif), coupling constants in Hz, integration]. The IR spectra were recorded with a Bruker IFS 25 instrument. GLC analyses were performed with a Varian 3400 apparatus equipped with capillary columns (column 1, 25 m × 0.32 mm fused-silica column coated with OV1; column 2, 30 m × 0.53 mm fused-silica column coated with OV1701), carrier gas N_2. Thin layer chromatography analyses (TLC) were performed on 0.25 mm Polygram silica gel SILG–UV_{254} precoated plates (Macherey–Nagel). Column chromatographies were performed over silica gel (MN Kieselgel 60 0.04–0.063 mm) using the flash technique. Melting points are uncorrected.

Synthesis of 13

Compound **14** (0.52 g, 3.25 mmol) was dissolved with gentle heating in 10% HCl (10 mL) and left at 0°C for 20 min. Then, a 1 M KOH solution was added until the pH reached 12, and **10** (1.05 g, 6.5 mmol) was added in one portion. The mixture was vigorously stirred for 14 h and progressively allowed to warm from 0 to 20°C. After

© 2000 NRC Canada

addition of 50 mL of 10% NH_4OH solution, the mixture was extracted three times with CH_2Cl_2 (25 mL). The combined organic layers were filtered on a WA filter paper and evaporated in vacuo to give a residue which was purified by flash chromatography on a silica gel column (CH_2Cl_2–MeOH, 98:2) to afford **13** as an oil which crystallized on standing. Recrystallization in acetone–pentane (1:1) yielded 0.380 g of white crystals (1.5 mmol, 46%).

13: mp 100–102°C. Hydrolysis and decarboxylation of 13 into 15

Compound **13** (150 mg, 0.6 mmol) was stirred in 5 mL of 5% aqueous KOH solution for 2 h at 20°C. Then, an aqueous 10% HCl solution was added dropwise at 0°C till pH 4–5, and the resulting mixture was heated at 70°C for 2 h. After basification with NH_4OH, the mixture was extracted three times with CH_2Cl_2 (25 mL). The combined organic layers were filtered on a WA filter paper and evaporated in vacuo to give 100 mg of **15** (0.56 mmol, 93%). Compound **15** is hygroscopic and must be carefully dried before being engaged in the next reaction.

Reductive alkynylation of 15: compounds 16a and 16b

To 1-pentyne (82 μL, 0.83 mmol) in 1 mL of anhydrous THF was added under a nitrogen atmosphere at –78°C, *n*-BuLi (0.55 mL, 0.84 mmol) followed by $BF_3{\cdot}Et_2O$ (105 μL, 0.83 mmol). After stirring at –78°C for 1 h, lactam **15** (51 mg, 0.28 mmol) in 1 mL of THF was added dropwise and the stirring maintained at –40°C for 4 h. The reaction mixture turned progressively red. Then, EtOH (50 μL, 0.86 mmol) and $LiAlH_4$ (50 mg, 1.32 mmol) were added at –40°C and the mixture was stirred for 1 h. After addition of water, the mixture was extracted three times with CH_2Cl_2 (25 mL). The combined organic layers were dried over $MgSO_4$ and evaporated in vacuo. The residue was chromatographed on an alumina column (hexane:EtOAc, 98:2 – 95:5) to afford **16a** (22.5 mg, 0.097 mmol) and **16b** (9.5 mg, 0.041 mmol) (70:30 ratio, total yield 49%).

One *sp* carbon signal was not detected.

Catalytic hydrogenation of 16a and 16b: synthesis of T-5 (7) and T-6 (8)

To a mixture of **16a** and **16b** (6.0 mg, 0.026 mmol) in toluene (10 mL) was added Wilkinson's catalyst (11.6 mg, 0.012 mmol) and the mixture was left under stirring for 41 h under an atmospheric pressure of hydrogen. After 23 h, a GC (column 2, from 180 to 260°C, programmed at 5°C/min) of the crude reaction mixture showed the presence of T-5 (**7**) and T-6 (**8**) in an approximately 70:30 ratio, along with 25% of starting material. After 41 h, the latter had disappeared, but secondary compounds were found besides a 54:46 mixture of T-5 (**7**) and T-6 (**8**). The reaction mixture was then evaporated in vacuo and the residue chromatographed on an

© 2000 NRC Canada

alumina column (hexane:AcOEt, 50:50), yielding T-5 and T-6 as a mixture (1 mg, 0.0042 mmol, 16%). The two compounds were identical in ^{1}H NMR and capillary GC with reference compounds (2).

Formation of 17

To lactam **15** (59.3 mg, 0.33 mmol) in anhydrous diethyl ether (4.0 mL) was added a 1 M solution of DIBAL-H in hexane (0.40 mL, 0.4 mmol), and the mixture stirred under a nitrogen atmosphere at –78°C for 2 h. Then, the mixture was acidified using a 10% ethanolic perchloric acid solution, till the pH reached about 3. Finally, KCN (118 mg, 2.15 mmol) in 1 mL of H_2O was added and the mixture left overnight at 20°C. After addition of a saturated $NaHCO_3$ solution to pH 8, the mixture was extracted three times with CH_2Cl_2. The combined organic phases were dried on $MgSO_4$, filtered, and evaporated in vacuo. Chromatography on a silica gel column (eluent hexane:AcOEt, from 8:2 to 7:3) yielded nitrile **17** (35 mg, 0.18 mmol, 56%). Compound **17** displayed MS, IR, ^{1}H, and ^{13}C NMR spectra identical with those reported by Yue et al. (4).

17: HRCIMS (*m*/*z*): 192.1491 (100, [M + H^+], $C_{11}H_{18}N_3$), (calcd. for $C_{11}H_{18}N_3$: 192.1500); 191.1416 (12, [M^+], $C_{11}H_{17}N_3$), (calcd. for $C_{11}H_{17}N_3$: 191.1422); 165.1399 (20, $C_{10}H_{17}N_2$), (calcd. for $C_{10}H_{17}N_2$: 165.1392); 138.1154 (20, $C_{10}H_{17}N_2$), (calcd. for $C_{10}H_{17}N_2$: 138.1157).

Ab initio analysis of C—H and C—C stretching intensities in Raman spectra of hydrocarbons

Kathleen M. Gough, Jason R. Dwyer, and Richard Dawes

Abstract: Molecular polarizability and changes in the polarizability associated with the stretch of C—C and C—H bonds have been calculated for thirty-four saturated hydrocarbons, including the series of *n*-alkanes to C15, as well as several cyclo- and bicycloalkanes, propellanes, prismanes, and hedranes. The ab initio results (HF/D95(d,p)) are compared to experimental Raman trace scattering intensities where such information is available. Possible factors governing trends in the magnitude of the derivatives are considered. For the C—C stretches, chain length and position along the chain are the most important factors for the *n*-alkanes, whereas strain appears to be significant for the ring and caged structures. For the C—H stretches, the most significant factors are the same as those found in our earlier work: location, type, and orientation relative to the carbon skeleton.

Key words: hydrocarbons, Raman scattering intensities, molecular polarizability, polarizability derivatives, theory of atoms in molecules.

Résumé : On a calculé la polarisabilité moléculaire ainsi que les changements de polarisabilité associés à l'élongation des liaisons C—C et C—H de trente-quatre hydrocarbures saturés comprenant les alcanes normaux jusqu'en C15 ainsi que plusieurs cyclo- et bicycloalcanes, propellanes, prismanes et hédranes. Dans les cas où de telles données étaient disponibles, on a comparé les résultats des calculs ab initio (HF/D95(d,p)) avec les intensités de dispersion des spectres Raman expérimentaux. On a considéré les facteurs qui peuvent influencer les tendances dans l'amplitude des dérivées. Pour les élongations C—C, la longueur de la chaîne ainsi que la position le long de la chaîne sont les facteurs les plus importants des alcanes linéaires alors que, pour les structures cycliques ou en cage, la tension semble le facteur le plus important. Pour les élongations C—H, les facteurs les plus importants sont les mêmes que ceux observés dans notre travail antérieur: position, type et orientation relative par rapport au squelette carboné.

Mots clés : hydrocarbures, intensités de dispersion Raman, polarisabilité moléculaire, dérivées de polarisabilité, théorie des atomes dans les molécules.

Introduction

In the course of our study on Raman trace scattering intensities in hydrocarbons (1–4), we have shown that the polarizability derivative associated with the C—H bond stretching motion is not a readily transferable parameter. The principal geometric factors that correlate with the magnitude of the derivative are type and location of the bond, alignment relative to the carbon skeleton and local steric hindrance (1). To date, our theoretical study has been confined to C—H stretching vibrations which can be readily compared to experimental Raman scattering intensities (1–5). We have now extended the theoretical study to include symmetric C—C stretching vibrations in straight chain hydrocarbons, as well as in some ring and caged molecules exhibiting various degrees of strain (Fig. 1). The goals are

(1) to identify suitable molecules for in-depth experimental and theoretical study (preferably small molecules with high symmetry, only one or two different types of C—H and C—C bonds, and unusually high or low predicted intensities)

(2) to obtain theoretical data on molecules which are not amenable to experimental analysis, but which may provide us with more insight into the factors governing scattering intensities.

Experimental data for absolute Raman trace scattering intensities are quite limited, particularly for molecules with more than about 10 atoms. This is not surprising, given the requirements for obtaining reasonably accurate results. Nonresonant Raman trace scattering spectra must be acquired for the relatively isolated system, hence molecules should be in the gas phase. A force field analysis is required to convert the measured band intensities, first to derivatives of the polarizability with respect to normal coordinates, and then to derivatives with respect to internal coordinates. Experimental intensities are subject to considerable error margins, especially for the very weak modes. Thus, it is also important to obtain spectra for several isotopomers, on the

assumption that the derivatives with respect to internal coordinates will be unchanged by isotopic substitution, while the composition of the normal modes will be different. This is achieved by recording the Raman spectra for the parent molecule and for several different deuterated species (2, 5–8). The problem is thus over-determined, with more items of independent data than there are parameters to be fit. This approach reduces the error in the final results, but limits the molecules for study to those with sufficient vapor pressure for gas phase work, and necessitates synthesis of specifically deuterated species.

More recently, we have focussed on the use of ab initio quantum chemistry calculations for the prediction of polarizability derivatives. The molecules we have chosen to investigate here include a homologous series of *n*-alkanes, small branched and ring alkanes as well as several strained ring systems. The latter have unusual structures such as the inverted tetrahedral geometry about the bridgehead carbon at-

© 2000 NRC Canada

oms in the propellanes and the curved bonds in small rings (9). Recent studies have shown that the C—H bond in tetrahedrane can act as a hydrogen donor (10), while the C—C bonds can function as proton acceptors (11). Detailed analyses (9) using the theory of atoms in molecules (AIM) developed by Bader (12) to characterize bond order, bond ellipticity, and charge concentrations of strained ring systems have underscored the unusual electronic character of these systems.

Observed trends in the intensities of hydrocarbon C—H stretching modes led to our present interpretations of intensity dependence (1). We now report the results of calculations on the C—C stretches and on those C—H stretches not previously reported, for these candidate molecules. The most significant variations and trends in this expanded set are discussed in relation to geometrical features of the molecules.

Calculation method

The procedures followed were identical to those used in our earlier work (1–4, 13) and are only briefly summarized here. The geometry of each molecule was optimized at the HF/D95(d,p) level with Gaussian 94 (14). This basis set provides a reasonable core size and balanced polarization functions necessary for good results (9, 13). The molecular polarizability was calculated at the optimized geometry with the coupled perturbed Hartree–Fock (CPHF) option in Gaussian 94 (14). The equations are solved analytically for this basis set. The polarizability was then recalculated for geometries in which symmetrically equivalent bonds were extended or compressed by $\Delta r = 0.010$ Å. The derivative was determined by finite difference

$$[1] \qquad \frac{\partial\bar{\alpha}}{\partial \mathrm{r}} \cong \frac{\Delta\alpha}{\Delta r} = \frac{1}{\mathrm{n}}\left(\frac{\bar{\alpha}' - \bar{\alpha}}{\Delta r}\right)$$

where $\bar{\alpha} = 1/3$ (trace of the polarizability tensor) = mean molecular polarizability, and n = number of symmetrically equivalent bonds stretched. The derivative reported is the average of those for $\pm\Delta r$; individual values differed from the average by 2% at most. This process was repeated for each unique bond type in the molecule.

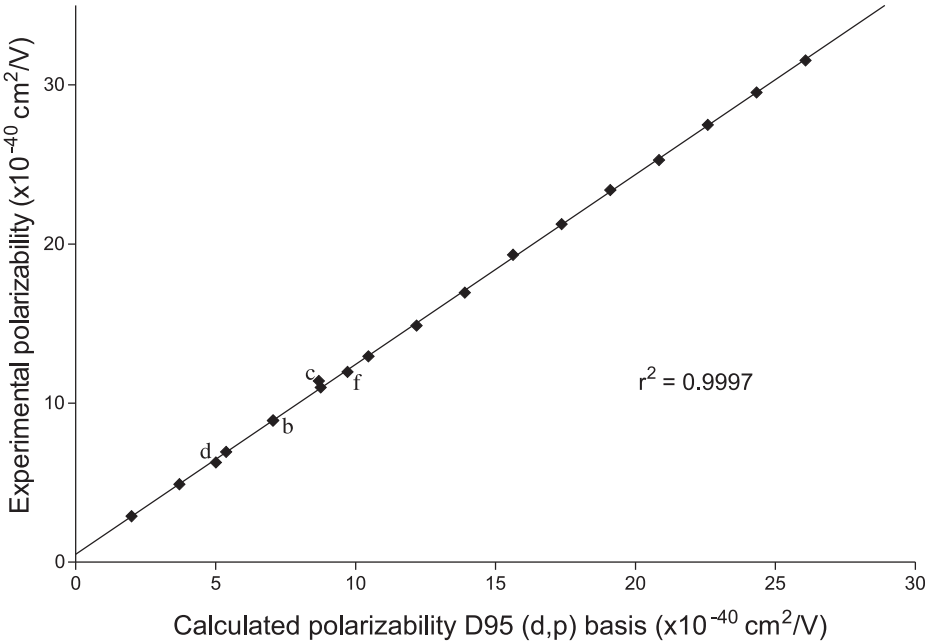
We tested several variables with which the variations in C—C stretch derivatives might be correlated, including optimized bond length, strain energy and several AIM parameters reported by Wiberg et al. (9): charge density at bond critical point, bond ellipticity, and average electron population. The most useful descriptor was the strain energy, estimated in the manner described by Wiberg et al. (9). The molecular energy was calculated, after optimization with the *very tight* convergence criterion, for a set of standard molecules and for all the molecules in the study. The "strain-free" energy of individual components was determined from the standard reference set

(*i*) CH_3 = 1/2 E (ethane) = –39.6246205 au
(*ii*) CH_2 = 1/2 {[E (propane) – 2 × E (CH_3)] + [E (cyclohexane)/6]} = –39.0431489 au
(*iii*) CH = E (isobutane) – [3 × E (CH_3)] = –38.4623977 au
(*iv*) quaternary C = E (neopentane) – [4 × E (CH_3)] = –37.8810579 au

These values are quite similar to those calculated in the same way with a larger basis set (15). The strain energy of any molecule was then found as the difference between the energy of the given molecule and the sum of the energies of its strain-free components. The total strain energy was partitioned equally among the carbons in the molecule, in most cases. For the methylcycloalkanes, it was assumed that all the strain was located in the ring, hence strain energy for the methyl carbons was set to zero. The calculated strain energy was then divided equally among the ring carbons. The sum of strain energies for both carbons in a bond was compared to the magnitude of the polarizability derivative for the stretch of that bond. The equipartition is not strictly valid for the bicycloalkanes, propellanes, prismanes, and adamantane, but is regarded as a useful first approximation. Individual cases are discussed below.

Results

The structures of all the molecules in this study are presented in Fig. 1. The experimental molecular polarizability values are available for only some of the molecules: straight chain alkanes to C15 (16, 17), as well as isobutane (**b**) (16), neopentane (**c**) (18), cyclopropane (**d**) (19), and cyclohexane (**f**) (16). These experimental values are compared to the calculated equilibrium molecular polarizability in Fig. 2. As expected from previous work (1–4, 13, 15, 20–22), the calculated values are lower than those from experiment, but the correlation here is excellent ($r^2 = 0.9997$ for $n = 19$), giving us confidence in the level of theory.



The derivatives of the mean molecular polarizability ($\partial\bar{\alpha}/\partial \mathrm{r}_{CC}$) with respect to the stretch of the C—C bonds have been calculated for the straight chain alkanes C2 to C15, and all the molecules in Fig. 1 except octahedrane (**s**) and decahedrane (**t**). The data for the straight chains are listed in Table 1. The derivatives calculated for the straight chain C—C stretches exhibit marked trends that are illustrated graphically in Fig. 3. The derivatives for the remaining molecules are shown in Table 2. The propellanes (**k** and **l**) represent special cases, since the variables cannot be strictly separated. For [1.1.1] propellane, all C—C bonds were stretched simultaneously, and the mixed result is reported. For the [2.2.2] propellane, shown below, the angle β is very nearly a right angle, at 91°. The 0.01 Å stretch of the nearly independent C—C bonds, labelled *b*, resulted in an increase of only about 0.0002 Å in the bonds labelled *a*. The derivative obtained is thus, to a very good approximation, the isolated stretch of bond *b*. The remaining bonds, *a* and *c*, cannot be disassociated, thus the derivative reported is for their simultaneous stretch.

The average strain energy per carbon is given in the last column of Table 2. The strain energy for each bond has been plotted against the derivative of each bond (Fig. 4). A moderate correlation is observed (see Discussion).

The C—H stretch polarizability derivatives for many of these molecules have been presented in an earlier paper (1). The calculated derivatives of the mean molecular polarizability expressed relative to the internal coordinate for CH stretch ($\partial\bar{\alpha}/\partial \mathrm{r}_{CH}$) are presented in Table 3 for the 10 new molecules. All of the derivatives have been calculated as described above, according to eq. [1].

Fig. 2. Correlation between experimental and calculated (HF/ D95(d,p), this work) mean molecular polarizability for the *n*-alkanes and molecules **b**, **c**, **d**, and **f**. See also Fig. 1 and Tables 1 and 2.

Discussion

Our previous work (1–4) has focused exclusively on C—H stretches. The current work addresses the C—C stretches in the same series of molecules and engenders some fundamental differences in our discussion. The C—H bonds are exterior to the carbon framework, consequently our correlations involved descriptors of their relation to that framework (e.g., axial–equatorial, endo–exo, bridgehead, etc.). We now turn our attention to the nature of the framework, to the location of the bond within the framework and their roles in determining the magnitude of the polarizability derivative for stretching C—C bonds.

The calculated equilibrium molecular polarizabilities are somewhat lower than the experimental values. This was not considered surprising, given that these are Hartree–Fock calculations, with neither configuration interaction nor electron correlation, and are static, not dynamic, polarizabilities (13, 20, 21). Nevertheless the excellent correlation between calculated and experimental mean molecular polarizability (Fig. 2) gives us confidence in the results. For discussion purposes, we group the C—C and C—H stretches separately. In the C—C stretch category, we consider first the unstrained hydrocarbons: straight and branched alkanes, and cyclohexane; and then the strained cyclic systems.

C—C bond stretches

Straight chain

Of the homologous series studied here, the experimental polarizability derivatives for the C—C stretch are available only for ethane (23), propane (8), and *trans*-butane (5) (Table 1). The level of calculation is sufficient to capture the relative magnitudes of the derivatives, though not the absolute values. This was also the case for the C—H stretches studied previously, and again, the ab initio results are convincingly parallel to those obtained experimentally.

In each molecule, the derivative of the terminal C—C bond is always greater than that for the first interior bond (Table 1, any individual row). The derivatives then *increase* for bonds that are located closer to the centre of the chain, reaching a maximum at the central bond. When chains of different length are compared (Table 1, any column) the magnitude of the derivative increases with chain length for any given position. The pattern that emerges (Fig. 3) is somewhat different from that observed for the C—H stretches. For the latter, it has been shown both by experiment and theory that the derivative for the terminal in-plane methyl C—H stretch increases monotonically with chain length. The derivatives for the methylene C—H bonds along the length of the chain are much smaller and decrease slightly with chain length and with position along the chain. Thus, there are two features to be explained for the C—C stretches: (a) the overall increase in the derivative with chain length; and (b) the relative ordering of the derivatives according to position within a single chain. Some factors are considered below.

Our interpretations of the CH-stretching intensities have been based on an analysis of the charge density with AIMPAC (11, 24). This software yields an atom by atom analysis of electron populations, both in the presence and absence of an applied field. The polarizability may be determined from these data. It is not possible to repeat the full AIMPAC analysis for C—C stretches in the longest chain molecules where the greatest differences are predicted. Not only is this time-consuming but the accumulated integration error can be at least as great as the small differences that are sought. In some cases, the calculations fail to converge due to problems with correct identification of the distorted interatomic surfaces when a field is applied.

Fig. 4. Variation of calculated polarizability derivative for the C—C stretch with estimated strain energy in some cyclic and caged molecules. See Table 2 for data.

The important results from the AIM analysis of the C—H stretches provide a guide for the C—C stretch intensities and are reviewed here (1–4, 13). For a straight chain molecule placed in an electric field, analysis of the charge distribution revealed that there was an end-to-end transfer of charge between terminal methyl hydrogen atoms (1–4, 13, 15). This dipole, induced along the molecule, was opposed by the atomic dipoles of the carbon atoms. The charge transfer term increased dramatically with chain length, and was the principal factor governing the magnitude of the unusually large derivative for the in-plane methyl C—H bond (1). For the stretch of the methylene C—H bonds, the charge transfer term remained fairly constant, in accord with the similar structure of the methylenes and their alignment relative to the molecular framework. Those derivatives were all quite similar, regardless of chain length or position along the chain.

We note that when any C—C bond is stretched, the overall chain length is being increased. We suspect that the charge transfer term, which was the most important factor in the large in-plane methyl CH derivative, above, is again playing the crucial role. This would also account for the overall increase in $\partial\bar{\alpha}/\partial r_{CC}$ with chain length. The ordering within any given chain is more puzzling. The stretch of the central C—C bond results in the separation of two equivalent halves of the molecule, with increased charge separation and increased polarizability. When bonds to either side of the centre are stretched, there is always a central portion that remains unchanged and may dampen the charge transfer effect. Certainly, the derivative decreases for bonds located further from the centre. It is only at the end of the chain that this effect is reversed, where the terminal methyl groups are stretched away from the methylene chain. The C1-C2 derivative is consistently larger than that for C2-C3. There is no immediately obvious reason for this difference. We are now attempting a complete AIM analysis of intermediate chains (*n*-heptane and *n*-nonane) that may provide some explanation.

Branched hydrocarbons and simple unstrained rings

The derivatives for the branched hydrocarbons isobutane and neopentane are shown in Table 2 along with those for the cyclic molecules. The two, branched hydrocarbons provide references for unstrained methine and quaternary carbons, respectively. Both derivatives are slightly smaller than but comparable to that of propane, and much smaller than those for the *n*-butane to *n*-hexane series. We conclude that the derivative is on the order of the longest chain segment in cases of branched connectivity.

Table 3. Values of $\partial\bar{\alpha}/\partial r_{CH}$ for branched and cyclic alkanes calculated with HF/D95 (d,p) basis set.

Molecule[a]	Bond[b]	$\partial\bar{\alpha}/\partial r_{CH}$[a] ($10^{-30}$ cm/V)

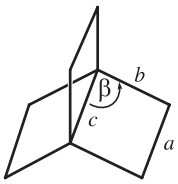
Dodecahedrane (**u**)		1.220

[a]Bold letter in parentheses identifies structure in Fig. 1.
[b]Labels follow codes in Fig. 1.

It is anticipated that dimension should also have some effect on the derivatives in ring systems. In the simple, unstrained cyclohexane ring, the AIM analysis of the C—H stretch derivatives (3) showed the typical dependence of the derivative on end-to-end charge transfer cross the ring, giving rise to a much larger derivative for the equatorial C—H stretch compared to axial. The molecule lacks the open chain character that is associated with monotonic increase of $\partial\bar{\alpha}/\partial r_{CC}$ with chain length, but it is likely that charge transfer continues to play an important role. While the derivative is much smaller than those in *n*-hexane, it is the same as that of the interior C—C bond in *n*-butane, which it does resemble in projection.

Strained hydrocarbons



Both dimension and strain, which is determined by the local and global molecular and electronic structure, are anticipated to be significant qualifiers for the prediction of the polarizability derivatives for these molecules. The importance of strain seems apparent upon examination of the propyl series (units: 10^{-30} cm/V):

Propane	1.329
Cyclopropane	(d)1.196
Cyclopropyl ring in tetrahedrane (m)	0.981
Cyclopropyl ring in prismane (n)	0.978

Similarly, the derivative for cyclobutane is much smaller than derivatives for the C—C bonds in ethane, propane or *n*-butane. In Fig. 4, we have plotted strain energy, against C—C stretch derivative for most of the molecules in Table 2. Data were omitted where assignment of strain energy was ambiguous. Dimension and location of a bond within a molecule are thereby excluded, however the fact that the smallest derivative is found in the largest molecule indicates that

© 2000 NRC Canada

Scheme 1.

dimension is not the predominant factor here. While the correlation is not large, it is still significant, given the varied group. We conclude that there is a large reduction in intensity primarily associated with increased strain.

One of the problems with the strain energy correlation is that it is calculated for the entire molecule. The amount of strain associated with one bond or its stretch cannot be assigned in a straightforward manner. For example, in bicyclo[2.2.2]octane, there is surely more strain at the bridgehead carbons than at the methylene carbons. The derivative for the methylene–methylene bond (labelled a) is larger than for the bridgehead–methylene bond (labelled b), but the same strain energy term is used. It is possible that separate parameters could be obtained from an AIM analysis, but further restrictions occur in the prismane series (**n**–**q**). Each molecule may be described as a sandwich of two identical rings of 3, 4, 5. or 6 bonds (a) connected by vertical bonds (b). In each case, all carbon atoms are identical, and all the vertical bonds are very similar in length. If strain and size are the principal factors, then it is not surprising that the derivatives for the ring bonds increase with ring size, from 0.978 to 1.172 × 10^{-30} cm/V. However we are then unable to explain why the derivatives for the vertical bonds decrease, from 1.085 to 0.904 × 10^{-30} cm/V. Since all carbons are identical, the strain energy term is of no use here.

Previous studies on the C—H bonds have proven that the changes in the molecular polarizability cannot be attributed solely to changes in the bonds being stretched. Equilibrium structure dictates the measurable equilibrium properties but the polarizability and the derivative are dynamic responses of the entire molecule. The response cannot be thought of as something localized within a single structural alteration: the entire molecule and charge redistribution must be considered. Thus, while strain may be considered to be a useful general predictor, it cannot be considered as an analytical probe. Without a proper analysis of the total molecular charge distribution, we cannot attempt a more definitive explanation. This work is now in progress on those molecules amenable to the AIM analysis.

C—H stretch

The magnitude of $\partial\bar{\alpha}/\partial r_{CH}$ has been shown to be dependent on the location of the bond within the molecule, the alignment relative to the structure and the strain in the system (1). The derivatives calculated here (Table 3) continue to exhibit this behavior. Apart from the C—H bonds in neopentane (**c**) and methylene C—H in adamantane (**r**), all are classified as bridgehead. In (**c**), the derivative is small, and comparable to that of the methylene C—H in straight chain alkanes. This fits within the general pattern of the larger derivative being associated with a methyl C—H bond

Scheme 2.

lying in the plane of the carbon chain, for the *n*-alkanes. In propane, $\partial\bar{\alpha}/\partial r_{CH}$ is 1.18 (units: 10^{-30} cm/V) for the in-plane methyl C—H, and only 1.05 for the out-of-plane C—H (1). These values drop, and the difference is reduced, in isobutane (1): C—H (in-plane) 1.107; C—H (out-of-plane) 1.00. The value for the unique C—H bond in neopentane (**c**) fits nicely into this pattern, at 1.032. As the shape of the molecule becomes more spherical, the distinction between the C—H bonds vanishes, and the magnitude of the derivative falls to that of a typical methylene. At 1.106 × 10^{-30} cm/V, the derivative for the methylene C—H in (**r**) is similar to those in unstrained cycloalkanes with no axial–equatorial distinctions (1).

It was previously observed that $\partial\bar{\alpha}/\partial r_{CH}$ was unusually large for any bridgehead C—H (1). All the values for bridgehead C—H bonds studied here are large, with derivatives ranging from 20% to 30% higher than that of a methylene. The hedranes may be visualized as being formed by bonding three stacked rings: octahedrane (**s**) (3:6:3), decahedrane (**t**) (4:8:4), and dodecahedrane (**u**): (5:10:5). We now have two different types of bridgehead C—H: one attached to the carbon of the smaller ring, and one attached to the carbon of the larger, middle ring. In (**s**) and (**t**), the derivative is about 10% greater for the C—H attached to the smaller ring, perhaps reflecting the greater strain in that portion. In (**u**), all the C—H bonds are actually equivalent, there is much less strain in this larger system, and the derivative is only moderately elevated.

Conclusions

The C—C and C—H stretch polarizability derivatives have been calculated for straight chain and branched hydrocarbons as well as for a number of cyclic hydrocarbons exhibiting varying degrees of strain. In the straight chain hydrocarbons, the derivatives for the C—C stretch exhibit distinct and in some ways unexpected trends. There is an overall increase in magnitude of the derivative with increasing chain length. The derivatives, $\partial\bar{\alpha}/\partial r_{CC}$, are predicted to be larger for the bonds located closer to the centre of the chain, reaching a maximum with the central bond. The C—C stretch derivatives for the cyclic hydrocarbons are slightly smaller than those in comparable straight chain molecules, and decrease with increasing ring strain. The magnitudes of $\partial\bar{\alpha}/\partial r_{CH}$ calculated here follow the patterns already observed in our previous study. In cyclic molecules, the ordering of the derivatives is always axial << equatorial and endo << exo. Derivatives for undifferentiated methylene C—H bonds are quite similar, regardless of the molecule in which they are found. Derivatives for bridgehead C—H are 20–30% larger than for methylene C—H. It is interesting that strain is associated with a decrease in $\partial\bar{\alpha}/\partial r_{CC}$ and yet an increase in $\partial\bar{\alpha}/\partial r_{CH}$.

Calculations indicate that the derivatives for the bridgehead C—H bonds in bicyclo[1.1.1]pentane should be much larger than for the methylene CH, while $\partial\bar{\alpha}/\partial r_{CC}$ should be much smaller than that in either *n*-pentane or neopentane. This molecule exhibits many other useful characteristics: it

is small, has high symmetry, and is gas phase at room temperature. Work has begun on acquisition of the experimental absolute Raman trace scattering intensities along with complete AIM analysis of the charge distribution.

Hydrogen bonding interaction of diphenylbarbituric acid and 9-ethyladenine. Crystal structure of a 1:1 complex

Arthur Camerman, Donald Mastropaolo, Andrew Hempel, and Norman Camerman

Abstract: There are several different types of adenosine receptors found in the brain and molecules capable of interacting with the adenine ring system may have an effect on brain activity. Phenobarbital and diphenylhydantoin, two commonly used antiepileptic drugs have been shown to form hydrogen bonded complexes with adenine derivatives. Although 5,5-diphenylbarbituric acid has anticonvulsant properties equivalent to phenobarbital, neither its structure nor possible interactions with adenine have been investigated. 5,5-Diphenylbarbituric acid and 9-ethyladenine were, therefore, cocrystallized and the three-dimensional 1:1 hydrogen bonded complex was determined by X-ray diffraction. The crystals are monoclinic, *C*2/*c*, a = 28.457(9), b = 10.633(3), c = 13.995(4) Å, β = 100.20(2)°, Z = 8, R = 0.067 for 1680 reflections with $I > 3\sigma(I)$. The molecules propagate along the b crystallographic axis in an alternating fashion in which adjacent adenine and barbiturate molecules interact through a pair of hydrogen bonds. Two-fold symmetry related barbiturate carbonyl groups in neighboring planes of hydrogen bonded ribbons are involved in dipole–dipole attractive interactions. This hydrogen bonding pattern is compared to patterns found in other barbiturate–adenine complexes.

Key words: hydrogen bonding, crystal structure, barbiturates, adenine, anticonvulsants.

Résumé : On connaît plusieurs types différents de récepteurs de l'adénosine et de molécules capables d'interagir avec le système cyclique de l'adénine qui peuvent avoir un effet sur l'activité cérébrale. On a démontré que deux médicaments fréquemment utilisés contre l'épilepsie, le phénobarbital et la diphénylhydantoïne, forment des complexes avec les dérivés de l'adénine par le biais de liaisons hydrogènes. Même si l'acide 5,5-diphénylbarbiturique possède des propriétés anticonvulsantes équivalentes à celles du phénobarbital, aucune étude n'a été faite sur sa structure ou sur ses interactions possibles avec l'adénine. On a donc cocristallisé de l'acide 5,5-diphénylbarbiturique et de la 9-éthyladénine et, faisant appel à la diffraction des rayons X, on a déterminé la nature tridimensionnelle du complexe 1:1 lié par liaisons hydrogènes. Les cristaux sont monocliniques, groupe d'espace *C*2/*c*, avec a = 28,457(9), b = 10633(3) et c = 13,995(4) Å, β = 100,20(2)°, Z = 8, R = 0,067 pour 1680 réflexions avec $I > 3\sigma(I)$. Les molécules se propagent le long de l'axe cristallographique d'une façon alternée dans laquelle les molécules adjacentes d'adénine et de barbiturate interagissent par le biais d'une paire de liaisons hydrogènes. La symétrie binaire apparentée aux groupes carbonyles du barbiturate de plans voisins des rubans de liaisons hydrogènes est impliquée dans les interactions d'attraction dipôle–dipôle. Ce patron de liaison hydrogène se compare à ceux retrouvés dans d'autres complexes barbiturate–adénine.

Mots clés : liaison hydrogène, structure cristalline, barbiturates, adénine, anticonvulsant.

[Traduit par la Rédaction]

Introduction

5,5-Diphenylbarbituric acid (DPB) is chemically very similar to diphenylhydantoin (DPH) and phenobarbital (PB), two of the drugs most widely used for the control of epileptic seizures. All three compounds possess two hydrophobic (phenyl, ethyl) groups attached to the tetrahedral carbon of a heterocyclic ring which contains at least two hydrogen bond acceptor atoms (see Fig. 1). Placement of these atoms with respect to each other in three-dimensional space is considered an important stereochemical factor in determining anticonvulsant activity (1). Despite its similarities with DPH and PB, early pharmacological studies of DPB (2–4) reported only weak anticonvulsant activity and dismissed DPB as a potentially new agent for the treatment of epilepsy. However, more than 25 years later another study (5) compared the anticonvulsant activity of DPB, DPH, and PB in the mouse by gavage administration of the drugs in conjunction with two standard laboratory tests most commonly used for the measurement of anticonvulsant efficacy, pentylenetetrazol (PTZ), and maximal electroshock (MES) induced seizures. The results showed that DPB when administered

Fig. 1. Chemical drawings and numbering scheme of the heterocyclic rings of 5-5-diphenylhydantoin, 5,5-diphenylbarbituric acid, phenobarbital, and 9-ethyladenine.

by gavage has anticonvulsant properties comparable to PB. Experiments with intraperitoneally administered DPB also concluded that poor solubility of DPB in the gastrointestinal lumen was a major factor in limiting potency. These results suggest that solubility problems were most likely responsible for the weak anticonvulsant activity reported for DBP in the early trials.

At present the mechanisms of action of the antiepileptic drugs PB and DPH are not completely understood. Although the inhibition of membrane sodium channels has been shown to be a basic action of DPH (6) there is no single action of DPH that can account for all its effects on both neuronal and nonneuronal tissue. Other mechanisms of action could include regulation and inhibition of voltage-dependent neurotransmitter release at synapses and regulation of calmodulin and cyclic nucleotide second messenger systems (7). PB shows similar but less potent effects on Na^+ channels and also interacts with GABA-mediated receptors (8). Early on, the similarity of barbiturates to uracil was recognized and prompted several investigations into whether and how barbiturates and similar drugs might associate with adenine in an attempt to explain their pharmacological effects. Such studies have observed selective hydrogen bond interactions between barbiturates and adenine derivatives (9–14) and between substituted hydantoins and 9-ethyladenine (EtAd) (15, 16) in the solid state and in solution. As yet it is still unclear whether these specific hydrogen bond interactions can be correlated with any pharmacologic activity. However, these interactions have gained added significance with the more recent discovery of adenosine receptors in brain membranes (17) and the evidence of the anticonvulsant action of endogenous adenosine (18, 19). Thus it has been suggested that modification or modulation of this purinergic system might also provide a basis for a possible antiepileptic drug mechanism. For example, barbiturates and benzodiazepines have been shown (20, 21) to inhibit adenosine uptake in rodent brain synaptosomes which results in elevated synaptic adenosine levels. Similarly, DPH has been shown to inhibit adenosine uptake in rat cerebral cortical neurons (22). These increased levels of adenosine could be correlated with some of the depressant effects these compounds have on neuronal tissue. The complementarity that DPH and PB have shown to the purine ring system through hydrogen-bond formation might well be an indicator of their ability to effect changes in the purinergic system that has been postulated to be linked to antiepileptic drug action.

In light of the role adenosine may play in regulation of seizure activity, the more recent results showing DPB to be a better anticonvulsant than previously thought and the fact that DPH and PB form hydrogen-bonded complexes with adenine derivatives, we decided to investigate DPB's three-dimensional structure and its hydrogen bonding capabilities with adenine molecules. We successfully cocrystallized DPB and EtAd with the aim of elucidating the structure of the intermolecular complex which can then be compared to the structures of adenine complexes with DPH, with PB, and with other barbiturates. In addition, DPB's three-dimensional stereochemistry obtained from the crystal structure determination can be used for comparisons with known structures of the other anticonvulsants. Such information may prove helpful in understanding some modes of action of this important class of drugs.

Experimental

Equimolar amounts of DPB and EtAd were dissolved in a 50:50 acetone–water mixture. Slow solvent evaporation yielded colorless, thin, plate-like crystals. Weissenberg photographic methods revealed the monoclinic space group *C*2/*c* which was confirmed by structural analysis.

The crystal data including data collection and refinement parameters are summarized in Table 1. The data were corrected for Lorentz and polarization factors; no absorption correction was applied.

MULTAN 80 (23) was used to solve the structure. An E-map calculated with the phases from the solution with the best combined figure of merit revealed all 33 non-hydrogen atoms of the asymmetric unit. Hydrogen atoms were located from subsequent difference Fourier electron density maps and their positional parameters were refined along with nonhydrogen positional and anisotropic temperature factors. Hydrogen atoms were given fixed isotropic temperature factors equal to $B = 3.6$ Å^2. The refinement converged to a final residual of $R = 0.067$. The program used in the refinement was from the XRAY76 System (24). Table 2 lists the atom fractional coordinates.[2]

Results and discussion

The crystal asymmetric unit contains one molecule of DPB and one molecule of EtAd. The adenine and barbiturate molecules are highly planar. The standard deviation of the nine atoms of the purine group from the least-squares plane defined by these atoms is 0.02 Å with the amino nitrogen situated only 0.01 Å from this plane. The standard deviation of the barbiturate atoms N(1), C(2), N(3), C(4), and C(6) from their least-squares plane is 0.05 Å with atoms O(4), C(5), and O(6) exhibiting the maximum deviations of –0.11, 0.06, and 0.09 Å, respectively. The phenyl groups are planar to within 0.01 Å. Bond distances and angles for DPB and EtAd are all within the normal range and are typical of barbiturate and adenine derivatives.

The pyrimidine ring of DPB is decidedly more planar than those of other barbiturates in which one of the C(5) substituents is a phenyl ring (11, 25 and refs. therein). Those

structures contain pyrimidine rings described as envelope-shaped with C(5) 0.30–0.43 Å out of the plane in the direction of the phenyl group and atoms O(4) and O(6) displaced by more than 0.10 Å from the plane in the direction away from the phenyl group. It is not known whether the more planar conformation of the barbiturate ring observed in the crystal structure of DPB is a chemical effect related to the presence of two phenyl rings attached to C(5) or is a consequence of the crystal packing forces. It should be pointed out that others (26) have found no correlation between the chemical nature of the C(5) substituent and the extent of barbiturate ring puckering. Furthermore, the variation in barbiturate ring puckering reported in crystal structures all containing 5,5-diethylbarbituric acid (12, 27–30) indicates that the puckering in the solid state is dominated by crystal packing forces. Other than these small differences in the barbiturate ring planarity, DPB and PB are very similar in overall structural geometry and stereochemistry. In the reported three-dimensional structures of DPH (16,31) the hydantoin rings are planar to within experimental error.

DPB and EtAd form a 1:1 complex organized into infinite ribbons of alternating adenine and barbiturate residues in which adjacent adenine and barbiturate molecules interact through pairs of hydrogen bonds. The dihedral angle between the adenine and barbiturate planes is only 1.2°. DPB donates its N(1) hydrogen to N(7) of EtAd and the DPB carbonyl oxygen O(6) accepts a hydrogen from the EtAd amino group forming a Hoogsteen type pair of hydrogen bonds. The second pair of hydrogen bonds is of the Watson–Crick type and involves the N(3) hydrogen and O(4) carbonyl of DPB with N(1) and the other amino hydrogen of EtAd. The hydrogen bonding scheme is illustrated in Fig. 2 and Table 3 gives the hydrogen bonding geometry. The basic structural pattern is very similar to those of the crystalline complexes EtAd–5-isopropyl-5-bromoallylbarbiturate (I) (11) and EtAd–5,5-diethylbarbituric acid (II) (12). Figure 3 (Top) is a schematic drawing which summarizes the hydrogen bonding features of I, II, and the current structure. A unique feature of these structures is the positioning of two symmetry related barbiturate carbonyl groups, C(2)-O(2), which lie in neighboring planes of the hydrogen bonded ribbons with their bond vectors pointing in opposite directions as is shown in Fig. 2. The C(2)— O(2)′ intermolecular contact of 3.090(9) Å found in the present study is shorter than the same contact found in I (3.165(20) Å) and longer than that found in II (2.983(4) Å). Such an arrangement of carbonyl groups has also been observed in crystal structures of hydrated barbiturate derivatives (25). These noncovalent contacts which are less than or approximately equal to the normal van der Waals distance of 3.1 Å appear to be due to an attractive dipole–dipole interaction. The differences in the contact distances observed in these structures are most likely due to crystal packing requirements of the different sized barbiturate C(5) substituents which fill the spaces between the planar hydrogen-bonded layers. One other significant difference between the current structure and structures I and II is the dihedral angle between the hydrogen-bonded barbiturate and adenine ring planes. In I and II this angle is 10.5 and 10.2° respectively compared with just 1.2° found for the DPB–EtAd structure.

In all three structures the carbonyl oxygens adjacent to the C(5) atom of the barbiturates form extremely weak hydrogen bonds and the N(3) of EtAd and O(2) of the barbiturates are not involved in any hydrogen bonds. As previously suggested (11), the long contacts involving the adenine N(6) hydrogens and barbiturate O(4) and O(6) carbonyls might be explained by geometrical constraints placed on the molecular arrangement due to translational symmetry which propagates the 1:1 complex and forms the infinite hydrogen-bonded ribbon. Since there is one independent molecule of EtAd and one of DPB, any change in the contact on one side of N(6) will effect a change in the opposite direction on the other side. The observed distances are thus a result of a compromise between crystal packing symmetry and hydrogen bond forces. As we will see below, when there is a greater degree of freedom with two crystallographically independent molecules involved in forming the adenine–barbiturate hydrogen bonded pair, the N(6)—carbonyl oxygen hydrogen bond distances are less than 3.2 Å and in the more normal range. In structures I and II there was some speculation about hydrogen bond formation between adenine C2

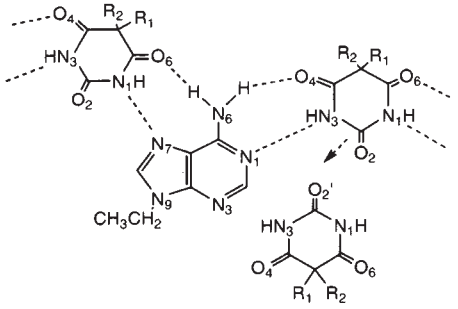
Fig. 2. Stereoscopic drawing showing hydrogen bonding and bond–dipole interactions in the 1:1 EtAd–DPB crystal. Hydrogen bonds are represented by dashed lines and the C(2)—O(2) dipole interaction is indicated by arrows. Hydrogen atoms have been omitted for clarity.

and C8 hydrogens with the barbiturate O2. In the DPB–EtAd complex we find these C—O distances to be 3.34 Å with the C-H-O(2) angles less than 140° suggesting only normal van der Waals contacts. In I the adenine C8 and C2 distances to the barbiturate O2 are 3.28 and 3.31 Å, respectively which also indicate relatively weak interactions. In II the adenine C8 and barbiturate O2 distance is 3.18 Å indicating a stronger hydrogen bond-like interaction but the C-H-O(2) angle is only 129°. The adenine C2—barbiturate O2 distance of 3.37 Å found in II is more typical of a normal van der Waals contact.

In the structures of the complexes 8-bromo-9-ethyladenine–phenobarbital (III) (10) and 8-bromo-9-ethyladenine–5-allyl-5-isobutylbarbituric acid (IV) (13) a different hydrogen bonding scheme is found with no evidence of carbonyl dipole interactions (see Fig. 3 (Bottom)). In III and IV the barbiturate molecules form separate Watson–Crick-type hydrogen-bonded pairs with each of two crystallographically independent adenine derivatives utilizing the barbiturate hydrogen bond donors N(1) and N(3) and acceptors O(2) and O(4). In structure IV there is a second barbiturate molecule which hydrogen bonds to two independent adenine derivatives as depicted in Fig. 3. Also in IV there is no hydrogen-bonded dimer formed between the second of the two independent adenine molecules.

It should be pointed out that structure III is the only 2:1 adenine to barbiturate complex observed which might account for its different hydrogen bonding pattern. However the major factor in determining the two different hydrogen bonding schemes shown in Fig. 3 is the presence of the 8-bromo-substituent on the adenine molecules in the III and IV structures. This bulky substituent prevents the formation of the Hoogsteen-type pair that is observed in structures I, II, and the DPB–EtAd structure due to a sterically forbidden contact it would make with the barbiturate O(2) carbonyl oxygen. Since adenine moieties of nucleic acids and coenzymes are not usually substituted at the 8-position (especially with a bromine atom), it seems reasonable to suggest that if barbiturates complex with adenine bases or interact with similar receptors in vivo, the likely hydrogen bonding scheme is that found between DPB and EtAd



The comparisons made between the present structure and the others cited above thus indicate that the presence of the C(2)-O(2) dipole interaction is dependent on the adenine derivative and its hydrogen bonding requirements while the strength of the interaction appears to be balanced against the packing requirements of the different sized C(5) barbiturate substituents.

Unlike DPH (16), barbiturate molecules do not form self-associated hydrogen-bonded dimers when a complementary alternative molecule is available in the structure even if in some cases the other molecule happens to be water (25). Given an unrestricted choice of hydrogen bond pair formation with adenine molecules, barbiturates seem to prefer a mixed Watson–Crick, Hoogsteen-type pairing leaving the C(2)-O(2) available for dipole–dipole type interactions. Our crystal structure results along with the others discussed above suggest that in addition to hydrogen bonding these nonbonded carbonyl associations may also be important in determining molecular packing. Whether such dipole interactions might be involved in barbiturate–receptor binding or pharmacological signal transmission is not known.

It is of interest to note that primidone, the phenobarbital congener with the C(2)=O(2) replaced by CH2, is also a useful antiepileptic agent. Its spectrum of anticonvulsant effects resembles that of phenobarbital except that it is much less potent in antagonizing PTZ induced seizures. As barbiturate C(2)=O(2) carbonyls do not hydrogen bond to EtAd, it is likely that primidone could interact with adenine by forming the same pairs of hydrogen bonds as observed in the DPB–EtAd complex. Thus if some barbiturate anticonvulsant or other pharmacologic actions are mediated through this type of interaction they are likely to be those actions common to both phenobarbital and primidone.

Reactions of the radical cation derived from 2,2′-azinobis(3-ethylbenzothiazoline-6-sulfonic acid) ($ABTS^{\cdot+}$) with amino acids. Kinetics and mechanism

C. Aliaga and E.A. Lissi

Abstract: Stable free radicals derived from 2,2′-azinobis(3-ethylbenzothiazoline-6-sulfonic acid) ($ABTS^{\cdot+}$) have been extensively employed to monitor the antioxidant capacity of biological fluids and beverages. Besides reacting with typical antioxidants (such as phenols or thiols) these radicals react with a variety of hydrogen or electron donors. The present work reports on the kinetics and mechanism of these radical reactions with several amino acids. Reaction rates notably increase when the pH of the media increases and, when measured under similar conditions, follows the order

cysteine > > tryptophan > tyrosine > histidine > cystine

The kinetics of the process is interpreted in terms of a mechanism comprising an initial pH dependent reversible step, followed by secondary reactions of the substrate derived radical with itself or with another $ABTS^{\cdot+}$; this simple three-step mechanism leads to very complex kinetic expressions. The specific rate constants of several of the elementary steps were determined by working under a wide range of substrate, radical, and ABTS concentrations. The values obtained for the initial interaction between the ABTS derived radical and the substrate range from 0.5 M^{-1} s^{-1} to 1.9×10^6 M^{-1} s^{-1} for histidine and cysteine, respectively.

Key words: ABTS radical cation, 2,2′-azinobis(3-ethylbenzothiazoline-6-sulfonic acid), amino acids, kinetics.

Résumé : On a fait appel à des radicaux libres stables dérivés de l'acide 2,2′-azinobis(3-éthylbenzothiazoline-3-sulfonique) ($ATBS^{\cdot+}$) pour de déterminer la capacité antioxydante de boissons et de fluides biologiques. En plus de réagir avec les antioxydants typiques (tels que les phénols et les thiols), ces radicaux réagissent avec un certain nombre de donneurs d'hydrogène ou d'électron. Dans le présent travail, on a déterminé la cinétique et le mécanisme de ces réactions radicalaires avec plusieurs acides aminés. Les vitesses de réaction augmentent beaucoup avec une augmentation du pH du milieu et, lorsqu'on les mesure dans des conditions identiques, elles suivent l'ordre suivant

cystéine > > tryptophane > tyrosine > histidine > cystine

On interprète la cinétique du processus en fonction d'un mécanisme impliquant une étape initiale réversible qui dépend du pH et qui est suivie par des réactions secondaires du radical dérivé du substrat soit avec lui-même soit avec une autre molécule de $ATBS^{\cdot+}$; ce mécanisme simple en trois étapes conduit à des expressions cinétiques très complexes. On a déterminé les constantes de vitesse spécifique de plusieurs étapes élémentaires en utilisant une grande variété de concentrations de substrats, de radicaux et d'ABTS. Les valeurs obtenues pour l'interaction initiale entre le radical provenant de l'ABTS et le substrat vont de 0,05 M^{-1} s^{-1} à $1{,}9 \times 10^6$ M^{-1} s^{-1} pour l'histidine et la cystéine respectivement.

Mots clés : cation radical ABTS, acide 2,2′-azinobis(3-éthylbenzothiazoline-3-sulfonique), acides aminés, cinétique.

Introduction

The capacity of additives to diminish the formation of the 2,2′-azinobis(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS) derived radical cation ($ABTS^{\cdot+}$), when the parent compound is incubated in presence of a free radical source, has been extensively studied to evaluate the free radical trapping capacity of pure compounds and complex mixtures (1–4). Interpretation of the data in these systems is not straightforward, since the decrease in radical cation concentration observed in the presence of the additives can be due to trapping of the primary radicals and (or) to the bleaching of the formed radical cations by the additives. In this regard, it is interesting to evaluate the capacity of compounds of

biological interest to react with this stable free radical. Furthermore, methods have been proposed to evaluate the total antioxidant capacity of complex samples, from the bleaching extent of preformed radical cations (5, 6), and hence it is interesting to know which compounds, and at which rates, are able to react with the ABTS radical cation. This radical cation can be easily formed by the one electron oxidation of the colourless parent compound ABTS (**1**).

MnO_2, potassium persulfate, HRP, or any free radical source (i.e., azo compounds) under aerobic conditions can be employed as oxidant. The resulting radical cation is a long-living species with high extinction coefficients at 416, 650, and 734 nm. The concentration of the radical cation can be readily monitored by its absorbance at these long wavelengths (6, 7).

It has been reported that small molecules such as phenols, hydroperoxides, bilirubin, thiols, amines, and uric and ascorbic acids are capable of reducing this radical cation (5, 6), but a thorough kinetic study has been carried out only with a family of monophenols (7) and hydroperoxides (8) as substrates. The mechanism of the process was rationalized in terms of a first preequilibrium between $ABTS^{\cdot+}$ and the substrate, involving a reversible pH-dependent back reaction. Secondary reactions of the produced radicals lead to the final products.

Amino acids and serum albumin give positive responses when their antioxidant capacity is assayed by monitoring the extent of ABTS radical cation formation in the H_2O_2–Peroxidase–ABTS system (4, 6). Furthermore, it has been shown that proteins, such as albumin, are able to bleach ABTS preformed radical cations (5), but it has not been established which amino acids are reactive and (or) the kinetics, mechanism, and stoichiometry of the process. In the present work, we address this problem by studying the reaction between ABTS radical cations and several amino acids, which have a labile hydrogen atom in the side-chain group. The selected amino acids were cysteine (-SH), tryptophan (-NH), histidine (-NH), and tyrosine (-OH). Their reactivity was compared to that of amino acids that do not possess a reactive hydrogen atom.

Materials and methods

ABTS was purchased from Sigma and used as received. The radical cation was prepared by the reaction of ABTS (150 M) with MnO_2 (25 mg/mL) at room temperature. In this system, formation of the radical is almost instantaneous. After centrifugation and filtration to remove unreacted MnO_2, the $ABTS^{\cdot+}$ solution was stable for several hours at room temperature. The radical cation derived from it was prepared by the reaction of ABTS (150 μM) with 1.5 mM potassium peroxodisulphate (Merck). The reaction was carried out at 50°C during 2 h. After cooling to room temperature, the absorbance of the solution remains stable for several hours. The concentration of $ABTS^{\cdot+}$ was evaluated from the absorbance at 734 nm ($\varepsilon = 0.015\ M^{-1}\ cm^{-1}$). Along the kinetic runs the concentration of the parent compound was deduced from its absorbance at 340 nm ($\varepsilon = 0.039\ M^{-1}\ cm^{-1}$). The results obtained were independent of the method employed to produce the radical cations.

The amino acids L-tyrosine and L-tryptophan were purchased from Merck, L-cysteine from Sigma, and L-histidine from Eastman. This latter compound was purified prior to its use by recrystallization from methanol.

Each solution was prepared in buffer phosphate (Merck) at the desired pH and the kinetics of the reactions measured at 23 ± 1°C by monitoring absorbance changes in an UV–vis Chem Station Hewlett–Packard (diode array) spectrometer. The components of the reaction mixture were added to the reaction cell in the order $ABTS^{\cdot+}$, ABTS, and substrate. The additions were carried out under strong mixing to minimize mixing times. The mixing was maintained during all the reaction. The concentration ranges employed were: (*i*) $ABTS^{\cdot+}$ (9–60 M); (*ii*) ABTS (10–450 M), and (*iii*) amino acid (2 M–0.2 mM).

The pH was controlled with 100 mM phosphate (pH 6 and 7) and citrate (100 mM, pH 5). Some experiments were carried out employing water pretreated with Chellex-100 to remove metals from the medium.

Results

The addition of micromolar amino acid concentrations to an ABTS radical cation solution readily bleaches the sample absorbance at 734 nm. The effect of the additive depends upon the experimental conditions and the amino acid considered. Results obtained for several amino acids under similar conditions are shown in Fig. 1. The data given in Fig. 1 show that, under similar conditions, the reactivity follows the order

$$Cys >>> Trp > Tyr > His >>> Cystine$$

This different reactivity indicates that the rate is determined by the characteristics of the pendant group, with the aliphatic backbone totally unreactive. Relative reactivities are in close agreement with those reported by Lissi et al. (9) regarding the ability of amino acids to trap peroxyl radicals. Furthermore, they are also in fair agreement with the data reported by Meucci and Mele (4) on amino acid antioxidant capacity. These authors concluded, from experiments carried out in the ABTS/HRP system, that the best antioxidant was cysteine, with tyrosine and tryptophan showing rather similar antioxidant patterns.

To obtain kinetic information on the reaction between the amino acids and the ABTS radical cation, the rate of the reaction employing Cys, Trp, Tyr, and His was measured over a wide range of experimental conditions. In particular, we examined the effect of pH, $ABTS^{\cdot+}$, ABTS, and amino acid concentration on the rate of the process.

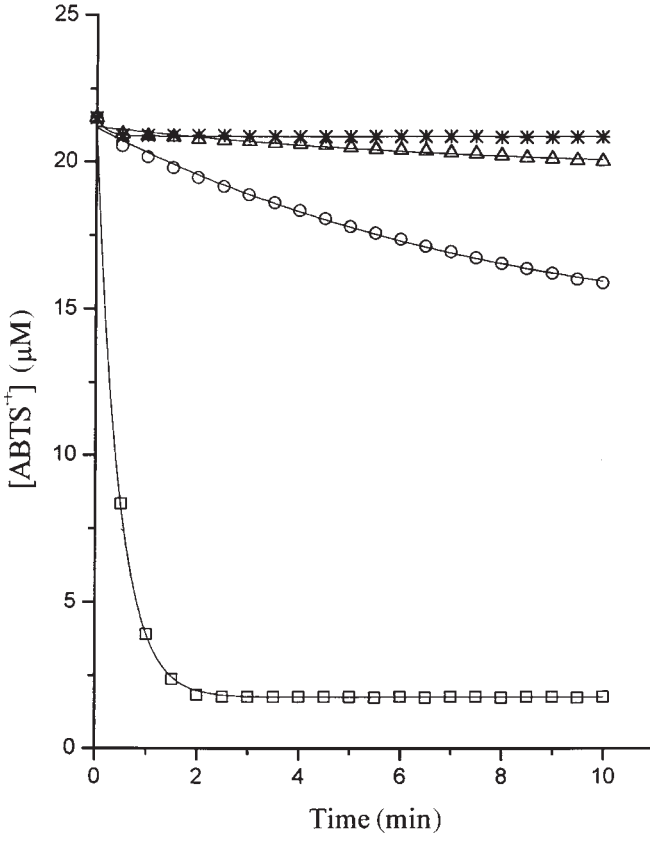

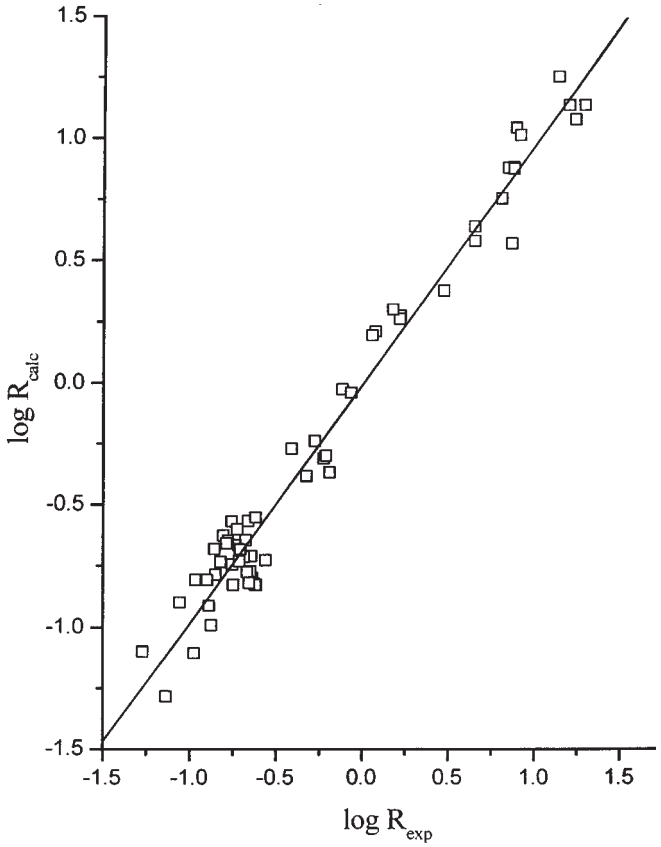

Fig. 2. Data obtained in the Cys–$ABTS^{\cdot+}$ system at pH 5. Correlation between experimental and calculated reaction rate obtained from eq. [3] with the parameters included in Table 1. Slope = 0.97, R = 0.985, N = 61, and P < 0.0001.

Cysteine

The reaction of cysteine with ABTS radical cations presents features similar to those previously reported for *tert*-butylhydroperoxide: the reaction rate increases with pH, increases both with cysteine and $ABTS^{\cdot+}$ concentrations, and is partially inhibited by ABTS. When initial rates (Ro) at different pH are measured employing a constant set of concentrations of ABTS, $ABTS^{\cdot+}$, and cysteine, the measurements can be fitted to an equation such as

$$[1] \qquad \log R_0 = k - \delta \text{ pH}$$

where k includes the contribution of all the reactants and products to the rate of the process. A plot of log R_0 vs. pH allows then an evaluation of the reaction order in protons (δ). The value obtained was ca. 0.22. This value, measured between pH 5 and 7, is bound to a rather large uncertainty because the high rate of the process hinders a precise evaluation of the initial rate, particularly at the higher pH.

Reaction rates over a wide range of conditions can be only measured at pH 5, due to the occurrence of a very fast reaction at higher pH. The values of Ro, were fitted to a kinetic law such as

$$[2] \qquad R_0 = k\,[\text{ABTS}]^{\alpha}\,[\text{ABTS}^{\cdot+}]^{\beta}\,[\text{Cys}]^{\chi}$$

The pseudo rate constant and apparent reaction orders were obtained by the best fit of the data to a lineal multiparametric equation

$$[3] \qquad \log Ro = \log k + \alpha \log [\text{ABTS}] + \beta \log [\text{ABTS}^{\cdot+}] + \chi \log [\text{Cys}]$$

The best values of the reaction orders obtained by this procedure are given in Table 1. The indicated values of k are those obtained when the concentrations are expressed in μM and the time in seconds.

The agreement between R_0 values calculated with this set of parameters and those experimentally determined is shown in Fig. 2. This figure shows that eq. [3] reproduces the data within a factor ca. 1.5 over all the conditions employed. The fractional orders and the dispersion of the data beyond that expected from the experimental errors, implies that the mechanism is complex and not completely represented by a simple rate law such as that given in eq. [3].

To test if air and (or) traces of metals influence the rate of the process, experiments were carried out under nitrogen. No significant differences were observed (data not shown). Similarly, no differences in reaction rates were observed when water was pretreated with chelex-100 (data not shown).

Formation of ABTS (as measured by the increase in absorbance at 340 nm, Fig. 3) is almost quantitative to the radical cation consumption over all the reaction process, both in presence of excess radical cation or cysteine.

The stoichiometry of the reaction between the radical cation and cysteine was measured only with excess radical

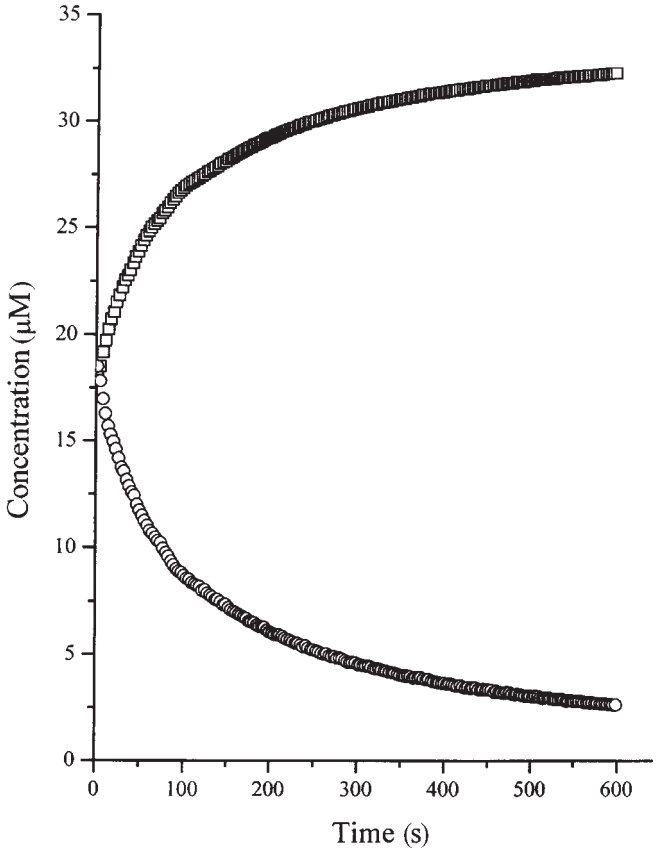
Fig. 3. Time course of the Cys + $ABTS^{\cdot+}$ reaction, followed by the growth of ABTS (from the sample absorbance at 340 nm) (□) and the consumption of $ABTS^{\cdot+}$ (from the decrease in absorbance at 734 nm) (○).



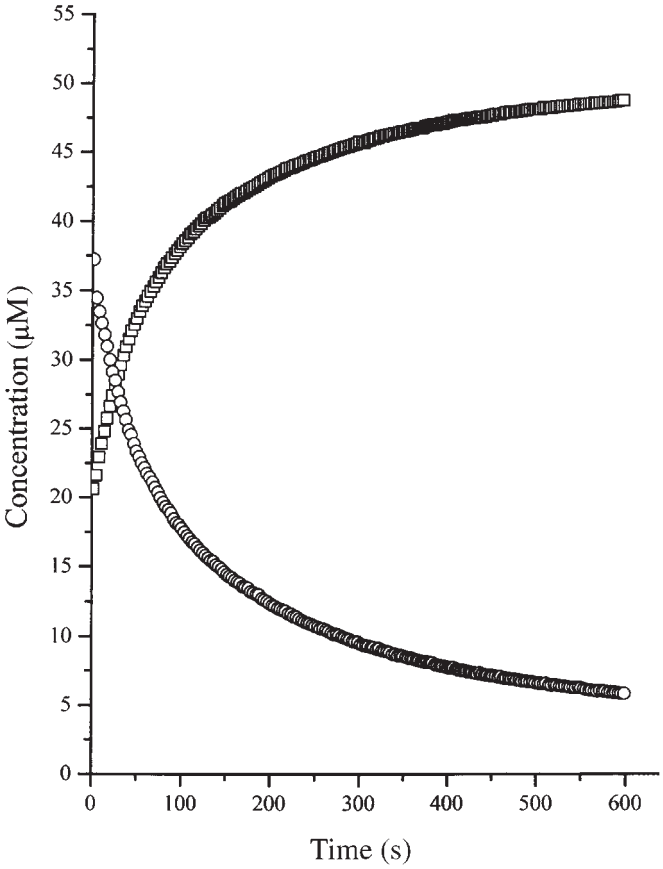


Fig. 4. Time course of the Trp + $ABTS^{\cdot+}$ reaction, followed by the growth of ABTS (from the sample absorbance at 340 nm) (□) and the consumption of $ABTS^{\cdot+}$ (followed by decrease in absorbance at 734 nm) (○).

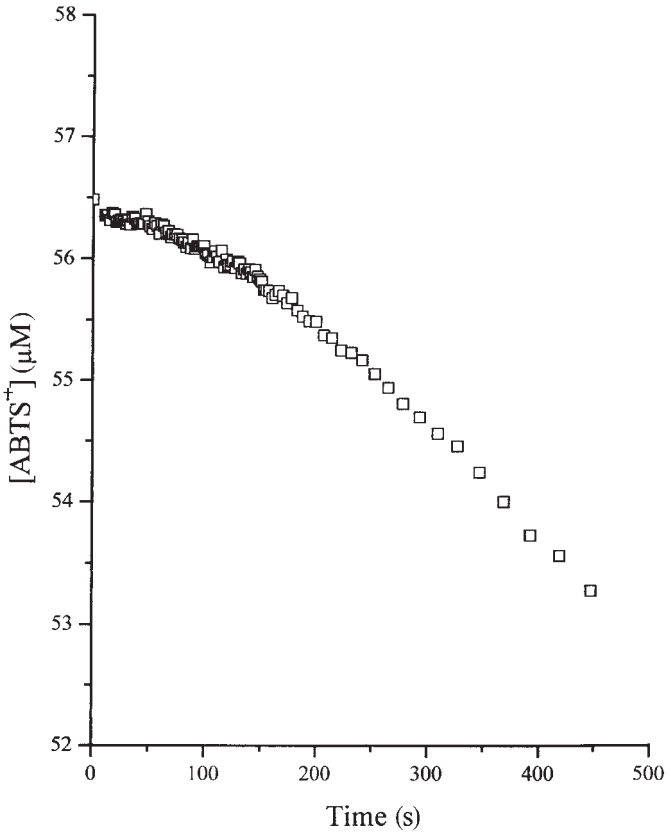
cation. Nearly 1.8 radical cations were consumed by each cysteine introduced into the system. The overall reaction, in excess of radical cation, can be then represented by

[4] $2\ ABTS^{\cdot+} + Cys \rightarrow 2\ ABTS + products$

Tryptophan

The data obtained employing Trp conform to the same pattern than that of Cys. However, since the rate of the process is considerably slower, initial rates can be obtained over a wider range of conditions. The kinetic data obtained at pH 5 and 7, fitted to eq. [3], provide the pseudo-reaction orders included in Table 1. As with the other amino acids, the rate of the process is not influenced by traces of metals.



The consumption of the radical cation is accompanied by noticeable oxygen consumption (as measured with the selective oxygen electrode). In fact, nearly 0.33 mol of oxygen are consumed per each reacted mole of radicals. Since formation of ABTS, evaluated from the increase in absorbance at 340 nm, is almost quantitative (Fig. 4) and, in excess of radical cation, nearly three radicals are consumed by each Trp molecule introduced into the system, the overall stoichiometry of the process can be represented by

[5] $3\ ABTS^{\cdot+} + Trp + O_2 \rightarrow 3\ ABTS + \text{oxidation products}$

The fluorescence of the reacted sample (Excitation = 340 nm, Emission = 450 nm) would suggest the presence of kynurenine and formylkynurenine) among the products. These are the normal products associated to the free radical mediated oxidation of tryptophan (10).

© 2000 NRC Canada

Fig. 5. Kinetic profile of $ABTS^{\cdot+}$ bleaching by His at pH 7.0. This profile corresponds to a complex kinetic behaviour, with noticeable autoacceleration at long reaction times.

In spite of the relatively high oxygen uptake associated to the process (indicative of Trp oxidation), the rate of ABTS radical consumption induced by Trp measured at pH 7 is nearly independent of the presence of oxygen. Reactions carried out under nitrogen give the same initial rate than when the runs are carried out under air. This would indicate that oxygen is only involved in fast (not rate-limiting) secondary reactions of Trp derived radical intermediates.

Tyrosine and histidine

Tyrosine and histidine induced ABTS radical cation consumption present similar characteristics to those previously mentioned for Cys and Trp. Pseudo-reaction orders obtained when the data (measured at pH 5.0 for tyrosine and pH 7.0 for histidine) are fitted to eq. [1] are included in Table 1. When Tyr and His are employed, back formation of ABTS is also almost quantitative. However, the consumption of ABTS with His does not follow a simple pattern, presenting a very small fast initial reaction, followed by a slow process with significant autoacceleration at longer times (Fig. 5). No attempts were carried out to elucidate the origin of this complex reaction profile. Furthermore, and due to the slow rate of the process, the reaction can only be measured at pH 7.0. At lower pH, the reaction is extremely slow, while at higher pH, the ABTS radical cation becomes unstable even in the absence of additives. The rates measured correspond to the slow phase of the reaction.

Cystine (0.2 mM) and methionine (0.2 mM) did not produce any consumption of the ABTS radical cation (50 μM) during 1 h at pH 7.0. Complete lack of reaction was also observed when *N*-methyltryptophan (0.1 mM) and *O*-methyltyrosine (0.1 mM) were employed.

Discussion

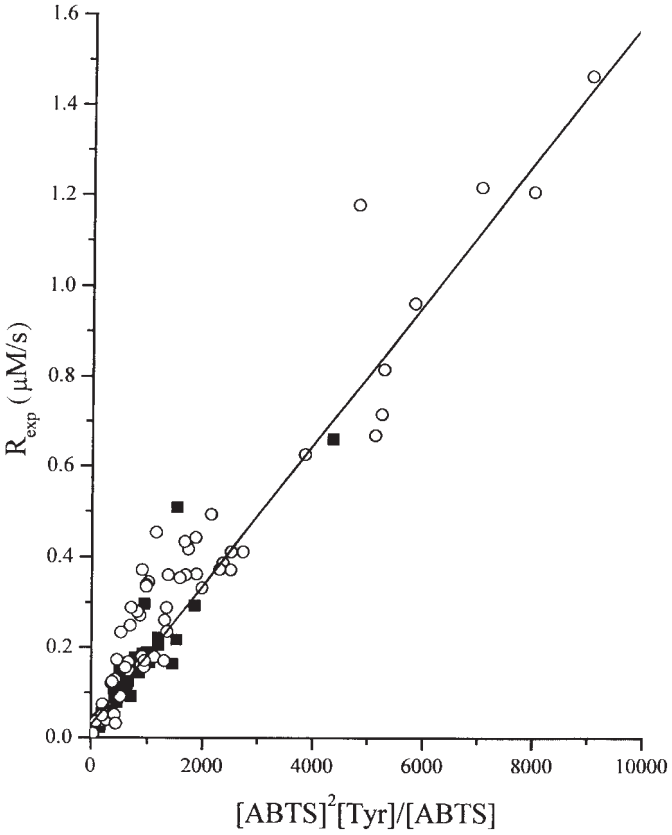
The main features of the reaction between ABTS radical cations and phenols (7) and hydroperoxides (8) have been explained in terms of the following simplified mechanism where XH is a compound bearing a labile hydrogen atom.

[6] $ABTS^{\cdot+} + XH \rightleftharpoons ABTS + X\cdot + H^+$

[7] $ABTS^{\cdot+} + X\cdot \longrightarrow$ non–radical products

[8] $X\cdot + X\cdot \longrightarrow$ non–radical products

This simple scheme also explains the main features of the results obtained in the present work, at least when Cys, Trp, and Tyr are considered. The requirement of a labile hydrogen atom for the reaction is compatible with the lack of reactivity of cystine, methionine, *N*-methyltryptophan, and *O*-methyltyrosine. Reactions of the amino acid derived radical ($X\cdot$) with O_2 would provide an extra reaction channel for $X\cdot$ consumption, particularly when Trp and Cys are employed. However, the fact that the kinetic of $ABTS^{\cdot+}$ bleaching by the amino acid is nearly independent of oxygen pressure would suggest that oxygen/radical reactions are not kinetically relevant.



This simple mechanism predicts that the order of the inhibition by protons and ABTS must be similar. Furthermore, the magnitude of these orders must be related to the extent of reversibility of the initial step, ranging from zero (lack of reversibility) to two (complete reversibility and rxn. [8] as main reaction channel for removal of the $X\cdot$ radicals). The higher apparent reaction orders in ABTS and $ABTS^{\cdot+}$ obtained in the reaction of Trp at pH 5 than at pH 7 are compatible with a higher contribution of the back reaction when the proton concentration increases. Regarding cysteine, the low reaction orders obtained for protons and ABTS, as well as their similarity, would imply that the initial step is far from equilibrium. This is compatible with the fast rate of the total process measured for this amino acid, and could be related to the relative lability of the S—H bond. These criteria would indicate that in the reactions of the other amino acids, the initial hydrogen transfer is more reversible. However, the fact that both orders are significantly different implies that a simple mechanism, such as that depicted by eqs. [6]–[8], must be considered only as a first approximation.

The orders obtained employing tyrosine are close to those expected if the initial step were totally reversible, as reported for other phenols (7). To test this possibility, the experimental rates are plotted against $[ABTS^+]^2$ [Tyr]/[ABTS] in Fig. 6. The results show that, over all the conditions employed, the data conform to the kinetic law expected if rxn. [6] reaches equilibrium and rxn. [7] is the main step in the removal of Tyr derived radicals. For this compound the rate law can then be considered to be

[9] $\text{Rate} = k_{exp}\,[ABTS^+]^2\,[\text{Tyr}]/[\text{ABTS}]$

© 2000 NRC Canada

Fig. 6. Fit of Tyr data to a completely reversible mechanism. Following eq. [3], experimental rates are plotted against $[ABTS^{\cdot+}]^2[Tyr]/[ABTS]$. Correlation: $R = 0.9$. (O) $ABTS^{\cdot+}$ prepared with persulfate, (■) $ABTS^{\cdot+}$ prepared with MnO_2.

with

$$[10] \quad k_{exp} = K_6\, k_7$$

At pH 7, the best value of the k_{exp}, obtained from the slope of the plot shown in Fig. 6, is $1.65 \times 10^2\ M^{-1}\ s^{-1}$.

If the initial step is partially reversible, the kinetic law (and the stoichiometry of the process) will be determined by the relative rates of rxns. [7] and [8]. If it is assumed that the radical X· reaches a steady state condition, the two limiting situations above mentioned lead to the following rate laws (8)

Mechanism I (rate of rxn. [7] > > than rate of rxn [8])

$$[11] \quad R_{exp} = 2R_7 = 2k_7 \frac{k_6[XH][ABTS^{\cdot+}]^2}{k_{-6}[ABTS] + [ABTS^{\cdot+}]}$$

Mechanism II (rate of rxn. [7] < < than rate of rxn. [8])

$$[12] \quad R_{exp} = R_8 = k_8[X^{\cdot}]^2 = k_8\left(\frac{-k_{-6}[ABTS] + ((k_6[ABTS])^2 + 4k_8k_6)^{1/2}}{2k_8}\right)^2$$

Equation [11] can be arranged to

Table 2. Parameters derived from eq. [15].

$$[13] \quad \frac{[ABTS^{\cdot+}][XH]}{R_{exp}} = \frac{1}{k_6} + \frac{k_{-6}[ABTS]}{k_7k_6[ABTS^{\cdot+}]}$$

A plot of the left-hand side of this equation against $[ABTS]/[ABTS^{\cdot+}]$ can be employed to test if the data conform to this mechanism.

To fit the data to Mechanism II, eq. [12] can be arranged to

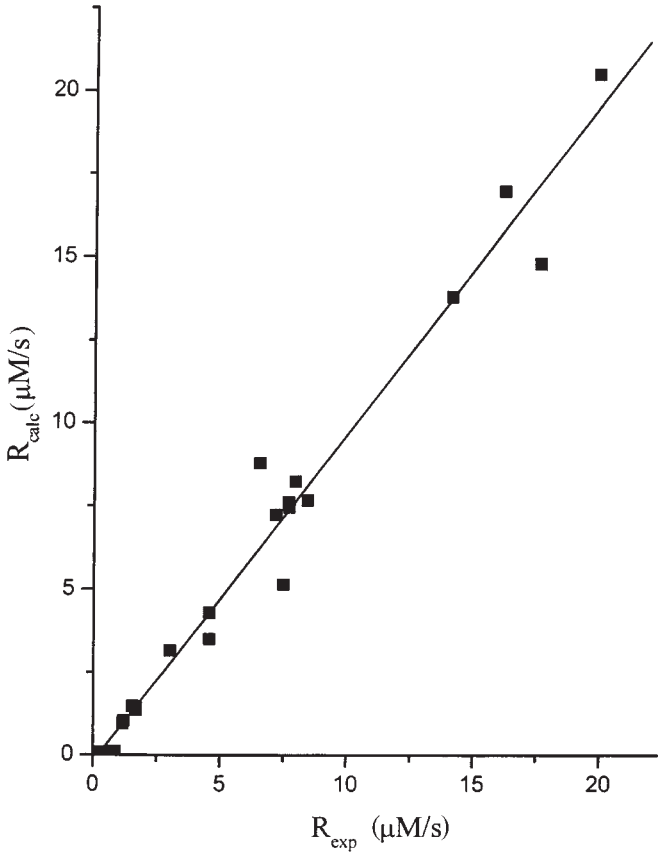
$$[14] \quad \frac{R_{exp}}{[ABTS^{\cdot+}][XH]} = k_6 - \frac{k_{-6}}{k_8} \quad \frac{k_{-6}\, R_{exp}^{1/2}[ABTS]}{k_8[ABTS^{\cdot+}][XH]}$$

and a plot of the left-hand side of this equation against $R_{exp}^{1/2}$ $[ABTS]/[ABTS^{\cdot+}][XH]$ can be employed as a mechanistic test (8).

The data obtained with Cys, Trp, and His do not conform to eq. [13] or eq. [14], implying that the whole mechanism must be considered to interpret the kinetic data. In spite of the apparent simplicity of this mechanism, it can not be reduced to a simple rate law and must be numerically solved. Applying the steady state hypothesis, the rate law can be expressed by a five-parameter eq. [8]

$$[15] \quad R = Ak_6^2\left[\frac{[ABTS^{\cdot+}]^2[XH]^2}{[ABTS]^2}\right] - Ak_6\left[\frac{2[ABTS^{\cdot+}][XH]R}{[ABTS]^2}\right] + A\left[\frac{R^2}{[ABTS]^2}\right] + Bk_6\left[\frac{[ABTS^{\cdot+}]^2[XH]}{[ABTS]}\right] - B\left[\frac{[ABTS^{\cdot+}]R}{[ABTS]}\right]$$

where:



$$[16] \quad A = \frac{k_8}{k_{-6}^2} \quad \text{and} \quad \frac{k_8}{k_{-6}}$$

The best values of the five parameters (Ak_6^2, Ak_6, A, Bk_6, and B) of eq. [15] were obtained numerically by a minimum square methodology using a MAPLE-V software. This procedure allows an estimation of k_6, A, and B. The values obtained are collected in Table 2. Although these values, and particularly the A and B ratios, are subject to rather high uncertainties, some conclusions can be derived from the data collected in Table 2.

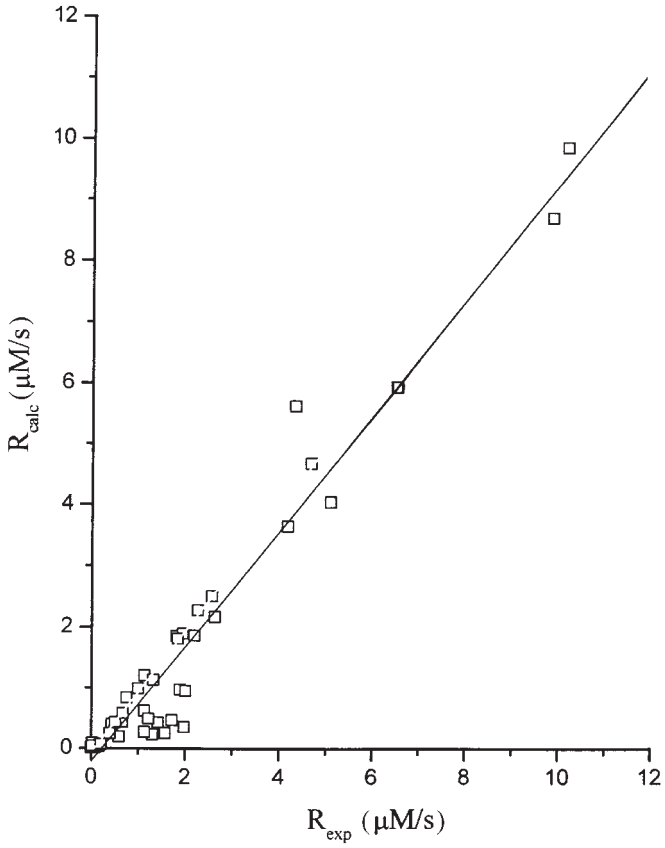
The derived values show that the reactivity of a given compound is directly related to the value of the specific rate constant of the initial step. In fact, this rate constant is highest for cysteine (the most reactive amino acid) and lowest for

© 2000 NRC Canada

Fig. 7. Correlation between measured and calculated reaction rates. Rates were calculated according to eq. [15] with the parameters given in Table 2. Data obtained employing (*a*) Cys, pH 5 (R = 0.99), (*b*) Trp, pH 5 (R = 0.97), and (*c*) His, pH 7 (R = 0.85).

the less reactive compound (histidine). Furthermore, relative values of k_6 are in agreement with the expected trend for a free radical hydrogen abstraction. In fact, two possible extreme mechanisms can be proposed for the postulated first step (rxn. [6]. In the first one, an initial hydrogen transfer

[17] $ABTS^{\cdot+} + XH \rightarrow ABTSH^{+} + X\cdot$



is followed by deprotonation of the $ABTSH^{+}$. If this is the limiting process, the relative rates could be expected to parallel those of other radical processes (9), in agreement with the relative values of k_6 found in the present work

Cys > Trp > Tyr

and the lack of reactivity of *N*-methyltryptophan, *O*-methyltyrosine, and cystine.

The other extreme mechanism involves an electron transfer followed by deprotonation of the substrate derived radical, followed by deprotonation of the amino acid. This first step would inversely correlate with the amino acid ionization potentials. However, semiempirical calculations (AM1 methodology (11)) and applying Koopman's theorem (12) gives lower *IP*, for Trp (8.38 eV) than for Cys (9.35 eV, in fair agreement with reported data (13)), suggesting that an initial limiting step mediated by an electron transfer could not be operative, at least for cysteine.

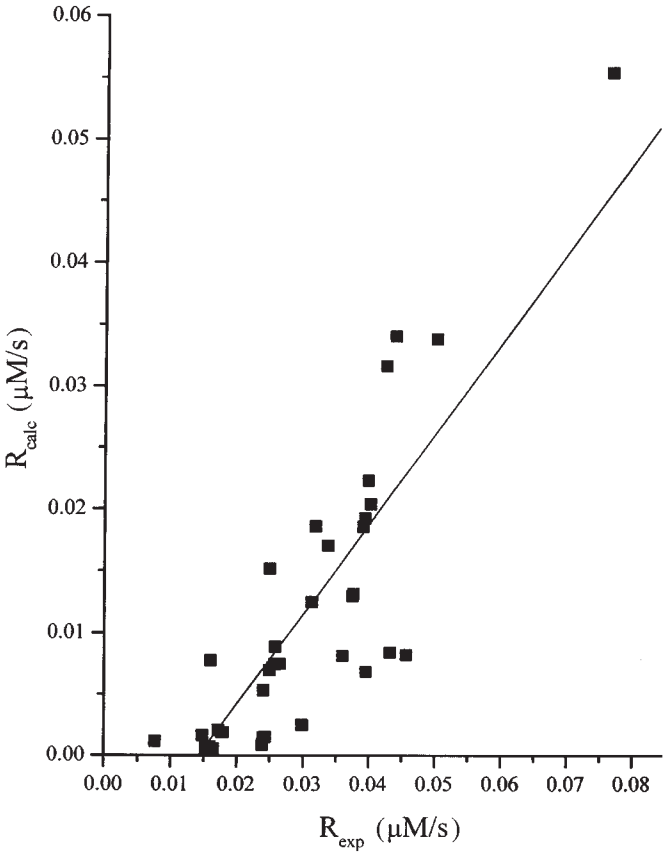
Fig. 7 (*Continued*).

The values of A and B given in Table 2 are compatible with those expected from the proposed mechanism and the characteristics of processes [6]–[8]. In fact, since the concentrations of ABTS and its radical cation are of the same order of magnitude, values of k_7/k_{-6} between 0.2 and 1.0 are consistent with a partial reversibility of step [6].

The data obtained for Trp show that the decrease in reaction rate when the pH decreases can be mostly ascribed to a decrease in k_{-6}, in agreement with the proposed mechanism. This would imply that ABTS radical cations are reacting with the neutral molecule and not with a small fraction of deprotonated compound in equilibrium. In this sense, the initial step can be represented by

[18] $ABTS^{\cdot+} + TrpH \leftrightarrow ABTS + TrpH^{+} \leftrightarrow ABTS + Trp\cdot + H^{+}$

and not by deprotonation of the amino acid



[19] $TrpH \rightarrow Trp^{-} + H^{+}$

followed by a reaction of the deprotonated compound with the ABTS radical cation.

The suitability of the parameters given in Table 2 to reproduce the experimental data under all the conditions employed can be assessed by plotting the calculated rates against the experimentally determined values. The data obtained employing Cys, Trp, and His are given in Fig. 7. These data show that the proposed equation reasonably fits experimental data obtained over a wide range of conditions.

© 2000 NRC Canada

Fig. 7 (*Concluded*).

This would indicate that the complete mechanism is able to interpret the main features of the kinetic process.

In conclusion, our data show that amino acids are able to bleach preformed ABTS radical cations with almost quantitative back formation of the parent ABTS. The rate of the process is mainly determined by the presence of labile hydrogen atoms in the amino acid side chain. The main features of the kinetic law can be explained in terms of a mechanism involving a partially reversible initial step. The relevance of the back reaction depends on the solution pH.

Several puzzling aspects are evidenced from a close examination of the data: (*i*) the lack of oxygen effect on the rate; (*ii*) the almost total recovery of the parent ABTS irrespective of the relevance of eq. [7]; and (*iii*) the dispersion of the data even when the whole mechanism is considered. Also, the lack of the relationship between the rate law and stoichiometric factors (related to the relative importance of process [7] and [8]) previously reported for a series of phenols (7). All these factors suggest that the mechanism depicted by eqs. [6]–[8] is an oversimplification and that some of the products (most likely those resulting from eq. [7]) are not stable. The decomposition of these initial products could consume oxygen, increase the ABTS yield, and modify the stoichiometry without altering the initial rates evaluated in the present work. Interestingly, in some compounds such as Trolox and Catechin, it was observed an overshoot in $ABTS^{\cdot+}$ consumption with a significant recovery after a few minutes (to be published). This could be explained by a transformation of the cross-adducts from rxn. [7] into the products of the type produced in rxn. [8].

The results obtained in the present work show that the mechanism of $ABTS^{\cdot+}$ reactions are extremely complex. This implies that extreme care must be exercised in the evolution of antioxidant capacities by procedures based on its bleaching (5, 14) or lack of formation (3), particularly when the information is derived from measurements carried out of a single reaction time (3, 14).

The use of the Ramberg–Bäcklund rearrangement for the formation of aza-macrocycles: a total synthesis of manzamine C

David I. MaGee and Ellen J. Beck

Abstract: A total synthesis of the marine alkaloid manzamine C has been accomplished. A Ramberg–Bäcklund reaction was used as a key step to construct the required azacycloundecene ring.

Key words: alkaloid, macrocycle, Ramberg–Bäcklund, manzamine C.

Résumé : On a effectué une synthèse totale de la manzamine C, un alcaloïde marin. L'étape clé implique une réaction de Ramberg–Bäcklund qui permet de fabriquer le cycle azacycloundécène requis.

Mots clés : alcaloïde, macrocycle, Ramberg–Bäcklung, manzamine C.

[Traduit par la Rédaction]

Introduction

Manzamines are a growing family of novel oncolytic marine alkaloids isolated from several different genera of sponge off the coast of Okinawa, Japan. Manzamines A (**1**), B (**2**), and C (**3**) were first isolated and characterized by Higa and coworkers from *Haliclona* sp. (Scheme 1) (1, 2). Structurally, the manzamines consist of a β-carboline unit, at least one aza-macrocycle, several additional nitrogen atoms, and usually a complex array of rings of various sizes. The exception to this is manzamine C (**3)**, which contains only the β-carboline unit and an azacycloundecene ring. Despite the contrast in structures, manzamine C is just as potent as the other members, having an IC_{50} value of 3 μg/mL on P388 mouse leukemia cells (2). In comparison, manzamine B has an IC_{50} value of 6 μg/mL on the same cell line (2). Their challenging structural features as well as their potent biological activity have made the manzamines very attractive targets for synthesis (3, 4).

Our group is particularly interested in the development of novel methods for forming medium and large heterocycles and their application to natural product synthesis. This desire, as well as the potent biological activity of the manzamines, made them ideal targets. Due to the relative simplicity of manzamine C our investigations began there, because the knowledge gained from the construction of this alkaloid could then be applied to the synthesis of the more complex congeners.

Manzamine C **3** was seen to arise from two basic fragments, the β-carboline unit **4** and azacycloundec-6-ene **7**, as shown in Scheme 2. In contrast to previous syntheses (5, 6), our route to β-carboline **4** began with the known alkaloid harmane **5** (7). This strategy was very appealing since the starting alkaloid could be efficiently prepared in gram quantities from cheap starting materials, and, in principle, only one other synthetic step would be needed to generate **4**. To construct the azacycloundecene ring we envisaged the use of an efficient procedure developed in our laboratories (8, 9) which involved the in situ formation and trapping of a ketene. With this methodology in mind, azacycloundecene **7** could be formed from alkynyl ether **8**, which in turn could be generated by a Wittig reaction between hydroxy phosphonium salt **10** and aldehyde **9**. Although this route appeared inviting, it was not without concern because preparation of aldehyde **9** was seen to arise from the oxidation of alcohol **14** (see Scheme 3) and, due to lack of literature precedent, it was not known whether the alkynyl ether would survive. Regardless, it was felt that suitable conditions could be found.

Results and discussion

There have been several reports of the formation and reaction of the dianion of harmane **5** with simple aldehyde and ketone electrophiles (10, 11). Following one of these protocols (11), the dianion was formed with *n*BuLi at room temperature and then subjected to several electrophiles including: *p*-formaldehyde, methylchloroformate, CO_2, ethyl isocyanate, and dimethylcarbonate. Regardless of the electrophile used to quench the dianion, a significant amount of starting material was always recovered, as well as a by-product that appeared to have an incorporated butyl group. To try and solve this problem we turned to the use of strong amide bases, and after much experimentation, it was found that the dianion could be efficiently generated by the use of 4 equivalents of LDA at –78°C for 1 hour. When the dianion

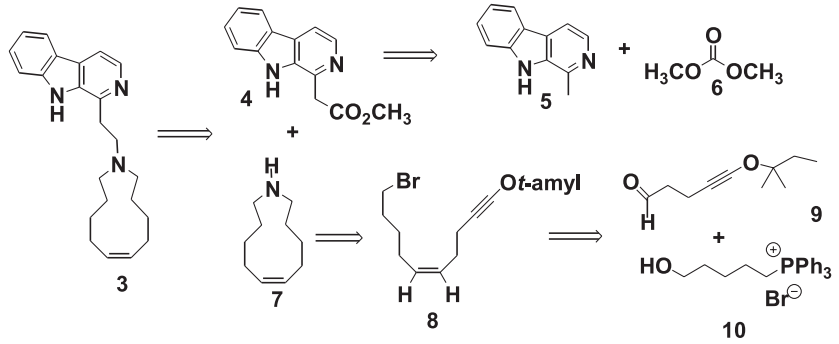
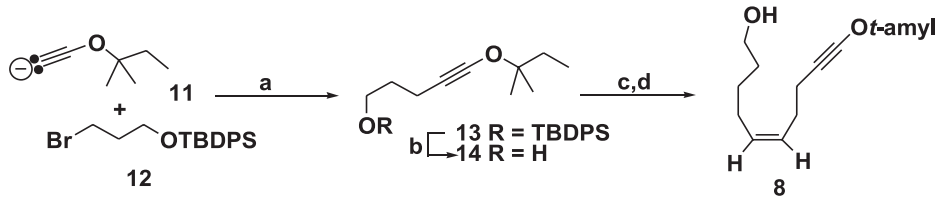
Scheme 1. Manzamine A (**1**), Manzamine B (**2**), Manzamine C (**3**).

formed under these conditions was reacted with excess dimethylcarbonate (3 equiv) for 50 min, ester **4** (5) was obtained in 78% (Scheme 2). Significant amounts of the malonate was formed if longer reaction times were used.



Construction of ketene precursor **8** began with the addition of lithium (2-methyl-2-butoxy) acetylide **11** to 3-bromo-1-(*tert*-butyldimethylsilyloxy)propane **12** to generate **13** in 70% yield (Scheme 3) (12). Deprotection of the silyl group with tetrabutylammonium fluoride proceeded uneventfully to give alcohol **14** in 75% yield. A variety of oxidizing agents were then analyzed for their effectiveness to achieve the desired transformation; these included PDC (13), Swern (14), DMS-NCS (15), Dess–Martin periodinane (DMP) (16), and SO_3·pyridine complex (17). While PDC and Swern led only to complete destruction of the starting material, presumably due to the acid lability of the alkynyl ether, DMS-NCS and DMP gave small amounts of aldehyde contaminated by a significant amount of an unknown byproduct. Fortunately, reaction with SO_3·pyridine complex in DMSO gave what appeared by ^{1}H NMR spectroscopy to be predominantly the desired aldehyde which, due to its sensitivity to purification by SiO_2 chromatography, was directly reacted with phosphorane **10** (18) to give alkene **8** in a disappointing 15–25% overall yield. Extensive experimentation proved that the low yield was a result of inefficient production of the aldehyde; however, attempts to try and improve this have thus far proved fruitless.

A new strategy



With our failure to secure the ketene precursor in useful yield, an alternative cyclization strategy was sought.[2] Ever mindful of our ultimate goal of a general aza-macrocyclization strategy that could be applied to the synthesis of the other manzamines, one method which appeared viable was the Ramberg–Bäcklund rearrangement (19–21). This option was inviting because synthesis of the requisite macrocycle should be straightforward and, more importantly, the site of the newly created olefin would be fixed by the position of the sulfone group and would not isomerize under the reaction conditions (22). Although the stereospecificity of the Ramberg–Bäcklund reaction was of concern, it was known that in acyclic systems the reaction leads to predominantly *cis*-olefins (22) and that in certain ring systems only *cis*-alkenes are produced (23–27). Surprisingly, we have not found any examples that address this stereospecificity question in flexible macrocyclic arrays.

With this strategy in mind, synthesis of the azacycloundecene ring began with condensation of 5-amino-1-pentanol **15** with δ-valerolactone **16** to afford amide-diol **17** quantitatively (Scheme 4). The amide **17** was directly reduced to the amine using BH_3–DMS (28) and isolated as the amine hydrochloride salt **18**, again in quantitative yield. Subsequent protection of the amino functionality as its *t*BOC-carbamate, followed by conversion of diol **19** to dibromide **21** via dimesylate **20**, generated the analogue

Scheme 2. Retrosynthetic analysis of manzamine C.

Scheme 4. (**a**) xylenes, reflux (92%); (**b**) (*i*) BH_3·DMS, THF, reflux, (*ii*) MeOH, anhyd. HCl, RT (100%); (**c**) Boc_2O, TEA, MeOH, reflux (83%); (**d**) methanesulfonyl chloride, pyridine, CH_2Cl_2, RT (94%); (**e**) LiBr, acetone, reflux (90%); (**f**) $Na_2S·9H_2O$, EtOH, reflux (86%); (**g**) (*i*) NCS, CCl_4, reflux, (*ii*) mCPBA, CH_2Cl_2, RT (58%); (**h**) KO*t*Bu, DMSO, RT (97%); (**i**) OsO_4, NMO, THF-*t*BuOH-H_2O, RT (84%); (**j**) (*i*) KO*t*Bu, THF, 0°C, (*ii*) 2,4,6-triisopropylbenzenesulfonyl chloride, 0°C–RT, (*iii*) KOtBu, RT (65%); (**k**) Rh(II) octanoate dimer, dimethyl diazomalonate, benzene, reflux (65%); (**l**) HCl(g), EtOAc, 0°C (100%).

required for cyclization in 71% overall yield. Attempts to effect cyclization of dibromide **21** with $Na_2S·9H_2O$ at high concentrations (29) only led to loss of starting material and little product formation. Fortunately refluxing **21** with $Na_2S·9H_2O$ in ethanol at high dilution (1.5×10^{-4} M) gave sulfide **22** in excellent yield (86%). Using these conditions, no dimer was observed, however, significant dimer formation was observed if the concentration was increased (e.g., 1.5×10^{-3} M) or if the diiodide was used in place of the dibromide. Sulfide **22** was then converted in a standard fashion to α-chlorosulfone **23** in 58% overall yield (30).

With **23** now in hand, investigations into the stereospecificity of the rearrangement began. Treatment of α-chlorosulfone **23** with potassium *t*-butoxide produced *trans*-olefin **24** with high stereospecificity (98:2 *trans*:*cis* ratio) and in a 97% yield! Although it had been noted in several acyclic examples that the use of strong bases, such as KOtBu, in the Ramberg–Bäcklund reaction predominantly gave *E*-olefins (22), it was nevertheless a surprise to get the *trans*-alkene almost exclusively in this cyclic system. Several milder, less bulky bases (2 M KOH, DBU, TEA, urea) were used in an attempt to predominantly form the *cis*-olefin, however, the results were not encouraging.

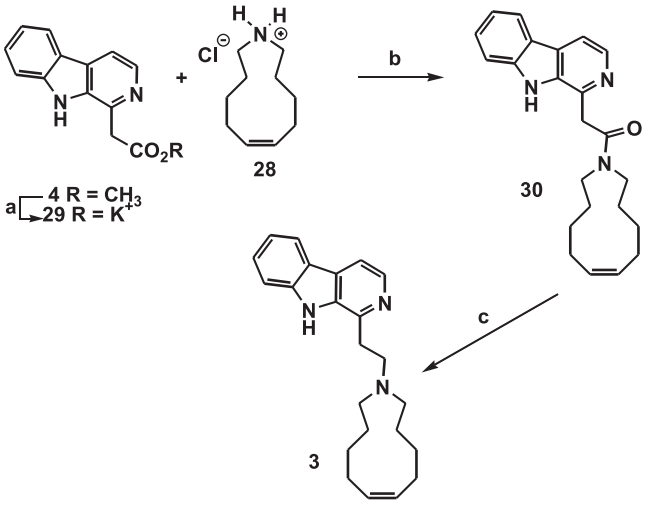

Table 1. Results of Ramberg–Bäcklund rearrangement using a variety of bases. The *E*:*Z* ratios were determined by GC analysis.

Reaction conditions	Yield (%)	% *Trans*	% *Cis*
KO*t*Bu, DMSO, RT, 10 min	97	98	2
aq. KOH, H_2O, 100°C, 1 h	57	61	39
DBU, toluene, 110°C, 1 h	56	57	43
TEA, toluene, 110°C, 1 h	NR	—	—
urea, H_2O, 100°C, 1 h	NR	—	—
NBu_3, toluene, 110°C, 1 h	NR	—	—

In acyclic systems it is known that aqueous hydroxide gives predominantly *cis*-olefins (22), therefore it was somewhat surprising to get principally *trans* in this case. In these systems, the *cis*-alkene is favored because of lower gauche interactions in the *cis*-episulfone formation when compared to the *trans*-episulfone formation (22). Presumably, it appears in the cyclic version that these gauche interactions are

Scheme 5. (*a*) KOH, EtOH, RT; (*b*) DPPA, TEA, amine **28**, RT (70% over 2 steps); (*c*) $LiAlH_4$, THF, 0°C–RT (42%).

not the only major contributor to determining the geometry, but also the transannular interactions that arise as a result of the ring trying to adopt the proper conformation for episulfone formation. These two factors appear to oppose one another because the degree of *trans*-episulfone formation in our example, as inferred from the amount of *trans*-alkene formed, is unusually high. This suggests that there are less unfavorable transannular interactions during the formation of the *trans*-episulfone, therefore it is the *trans*-alkene which is formed as the major product.

Although conditions were not found that would generate stereochemically pure *Z*-alkene, we were able to produce the *E*-alkene stereospecifically and in high yield. For our synthetic endeavours this was almost as good because a simple olefin inversion would furnish the required *Z*-azacycloundecene. To pursue this, a *trans*-epoxide was initially formed and then attempts were made to open the epoxide to a *cis*-diol. Unfortunately, endeavours to effect epoxide opening either under aqueous acidic (pTSA, $HClO_4$, H_2SO_4, HOAc) or basic conditions (NaOH or KOH in DMSO, RT–150°C) only led to recovered starting material or complete destruction. Replacement of the carbamate with a benzenesulfonamide group produced no better results. From molecular models it appears that the lack of reactivity is undoubtedly due to the conformation of the ring; that is for a nucleophile to add in an S_N2 manner, as it would in an epoxide opening, it would have to essentially add from "inside" the ring. Coupled with this, it appears that the nitrogen, although far less nucleophilic, may still be participating in assisted opening of the epoxide and hence leading to significant loss of material.

To alleviate this problem, an approach that did not involve epoxide opening was developed. Olefin **24** was oxidized to *trans*-diol **25** with OsO_4 in excellent yield, 84% (31). A monosulfonate was then generated from diol **25** under anionic conditions using 2,4,6-triisopropylbenzenesulfonyl chloride and KOtBu (32, 33). This intermediate was then treated in situ with an additional equivalent of KO*t*Bu, to obtain *cis*-epoxide **26** in 65% overall yield. Interestingly, no disulfonate was observed, presumably due to the bulkiness of the electrophile. Finally, deoxygenation (34) of *cis*-epoxide **26** with Rh(II) octanoate dimer and dimethyl diazomalonate furnished *cis*-olefin **27** in 65%. A solution of carbamate **27** in ethyl acetate was then treated with HCl gas to remove the *t*BOC protecting group and generate the amine hydrochloride salt **28** (5) in 100% yield.

With both segments (ester **4**, amine **28**) in hand, completion of the synthesis was straightforward. Following the procedure of Hino (5), ester **4** was first hydrolyzed with KOH in EtOH to obtain the potassium salt **29** (Scheme 5) which was then combined with amine hydrochloride **28** in DMF in the presence of diphenylphosphoryl azide and triethylamine to give the corresponding amide **30** (5) in 70% yield. Direct reduction of amide **30** with LAH afforded the natural product, which was identical to all spectral data reported by Higa (2), in 42% yield.

In conclusion, a straightforward and concise synthesis of manzamine C has been accomplished. The requisite *Z*-azacycloundecene was produced in a stereospecific manner by utilizing a Ramberg–Bäcklund rearrangement followed by olefin inversion. The generality of this approach for synthesizing other flexible macro-heterocycles found in the manzamines and other natural products is currently being investigated.

Experimental[3]

All reactions were carried out in flame-dried glassware under argon atmosphere using dry, freshly distilled solvents. Reagents were purchased from Aldrich Chemicals and used without further purification.

Melting points were obtained using a Gallenkamp melting point apparatus and are uncorrected. Infrared spectra were recorded on a Perkin–Elmer 598 infrared spectrophotometer, with all spectra run in NaCl cells with $CHCl_3$ as solvent or on a 3M polyethylene type 61 IR card with 19 mm aperture. Mass Spectra were recorded on a KRATOS MS50TC. ^1H NMR and ^{13}C NMR were recorded using a Varian Unity 400 (400 MHz) spectrometer. All NMR samples were run in $CDCl_3$ with 0.05% Me_4Si as internal reference, or methanol-d_4 at room temperature, or in DMSO-d_6 at higher temperatures (50°C, 90°C, or 100°C), as indicated. Purification of compounds by flash column chromatography was done using E. Merck silica gel 60 (particle size 0.040–0.062 mm). Preparative thin-layer chromatography was carried out on 0.25, 0.50, or 1 mm E. Merck silica gel plates.

N-*(5′-hydroxypentyl)-5-hydroxypentanamide (**17**)*: To a solution of δ-valerolactone **16** (1.7 mL, 18.3 mmol) in xylenes (50 mL) at 30°C was added 5-amino-1-pentanol **15** (2 mL, 18.3 mmol). The resulting mixture was refluxed for 18 h, followed by evaporation of the solvent in vacuo and recrystallization (hexane – ethyl acetate) to yield amide-diol **17** (3.61 g, 92%) as a colourless solid (mp 38.5–41.3°C). IR (IR Card): 3300, 3100, 2910, 2850, 1640, 1550, 1050 cm^{-1};

[3] Spectra have been deposited as supplementary material and may be purchased from the Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, ON, Canada K1A 0S2 (http://www.nrc.ca/cisti/irm/unpub_e.shtml).

^{1}H NMR (CD_3OD): 1.38 (m, 2 H), 1.52 (m, 6 H), 1.65 (m, 2 H), 2.19 (t, J = 7.5 Hz, 2 H), 3.16 (t, J = 7.0 Hz, 2 H), 3.54 (t, J = 6.7 Hz, 2 H), 3.55 (t, J = 6.5 Hz, 2 H); ^{13}C NMR (CD_3OD): 22.0, 22.8, 28.8, 31.6, 31.8, 35.4, 38.9, 61.1, 61.3, 174.5; HRMS (EI): $C_{10}H_{21}NO_3$(calc) = 203.15214, $C_{10}H_{21}NO_3$(obs) = 203.1526 (m^+).

*Bis(5-hydroxypentyl)amine hydrochloride (**18**)*: A 2.0 M borane – dimethyl sulfide solution in THF (57.1 mL, 0.114 mol) was added dropwise to a refluxing solution of amide-diol **17** (5.95 g, 29.3 mmol) in THF (100 mL). After addition of the BH_3–DMS was complete, the reaction mixture was refluxed for one hour. After cooling to room temperature, methanol (13.9 mL, 0.342 mol) was added dropwise over 15 min and the reaction mixture was then stirred until all the precipitate had dissolved. Anhydrous HCl in diethyl ether (24.8 mL, 0.117 mol, 4.72 M) was added and the reaction was stirred for 10 min at room temperature. Finally, the solvent was evaporated in vacuo, the residue was washed three times with Et_2O, and then dried under vacuum to furnish amine-diol-hydrochloride **18** (6.60 g, 100%) as a colourless solid (mp 60.1–61.0°C). IR (IR Card): 3330, 2920, 1450, 1040 cm^{-1}; ^{1}H NMR (CD_3OD): 1.46 (m, 4 H), 1.56 (m, 4 H), 1.73 (m, 4 H), 3.00 (t, J = 7.9 Hz, 4 H), 3.57 (t, J = 6.3 Hz, 4 H); ^{13}C NMR (DMSO-d_6, 90°C): 23.2, 25.9, 32.3, 47.5, 60.9; HRMS (EI): $C_{10}H_{24}NO_2Cl$(calc) = 225.1496, m^+/z-Cl(calc) = 190.1807, $C_{10}H_{24}NO_2$(obs) = 190.1808 (m^+-Cl).

N-*(*t-*butyloxycarbonyl)-bis(5-hydroxypentyl)amine (**19**)*: To a solution of amine-diol **18** (6.4 g, 28.3 mmol) in methanol (100 mL) was added triethylamine (15.8 mL, 113.0 mmol), followed by di-*tert*-butyl dicarbonate (7.4 g, 33.9 mmol). The reaction was then heated to reflux for 2 h and the solvent was then evaporated in vacuo. The residue was taken up in dichloromethane (100 mL), washed quickly with cold 1 M HCl and then brine, dried over $MgSO_4$, filtered, and the solvent evaporated. The residue was purified by SiO_2 chromatography (ethyl acetate) to yield carbamate-diol **19** (6.82 g, 83%) as a clear, colourless oil. IR (NaCl cells): 3610, 3440, 2930, 1670, 1160 cm^{-1}; ^{1}H NMR ($CDCl_3$): 1.32 (m, 4 H), 1.42 (s, 9 H), 1.54 (m, 8 H), 2.30 (s, 1 H), 2.51 (s, 1 H), 3.14 (m, 4 H), 3.60 (t, J = 6.5 Hz, 4 H); ^{13}C NMR (DMSO-d_6, 100°C): 23.3, 28.4, 28.6, 32.7, 47.1, 61.3, 78.5, 155.2; HRMS (EI): $C_{15}H_{31}NO_4$(calc) = 289.2252, m^+/z-$C_5H_9O_2$(calc) = 188.1650, $C_{10}H_{22}NO$(obs) = 188.1652.

N-*(*t-*butyloxycarbonyl)-bis(5-methanesulfonyloxypentyl)amine (**20**)*: Pyridine (2.6 mL, 31.6 mmol) was added to a solution of carbamate-diol **19** (2.3 g, 7.9 mmol) in dichloromethane (50 mL). This mixture was then cooled in an ice bath and methanesulfonyl chloride (2.5 mL, 31.6 mmol) was added. The reaction was stirred at room temperature for 18 h. The reaction mixture was then diluted with ether (75 mL); washed with cold 10% HCl, 10% NaOH (×2), H_2O, and brine; dried over $MgSO_4$; filtered; the solvent evaporated in vacuo; and the residue was purified by SiO_2 chromatography (2:1 hexane : ethyl acetate) to provide dimesylate **20** (3.31 g, 94%) as a colourless oil. IR (NaCl cells): 2940, 1675, 1350, 1160, 950 cm^{-1}; ^{1}H NMR ($CDCl_3$): 1.42 (m, 4 H), 1.46 (s, 9 H), 1.57 (m, 4 H), 1.79 (m, 4 H), 3.02 (s, 6 H), 3.19 (m, 4 H), 4.24 (t, J = 6.5 Hz, 4 H); ^{13}C NMR (DMSO-d_6, 70°C): 22.7, 27.9, 28.6, 28.7, 37.2, 46.6, 70.7, 78.7, 155.2; HRMS (EI): $C_{17}H_{35}NO_8S_2$(calc) = 445.1804, m^+/z-C_4H_9O(calc) = 372.1151, $C_{13}H_{26}NO_7S_2$(obs) = 372.1151.

N-*(*t-*butyloxycarbonyl)-bis(5-bromopentyl)amine (**21**)*: Dimesylate **20** (8.1 g, 18.1 mmol) was combined with lithium bromide (15.8 g, 0.181 mol) in acetone (150 mL) and refluxed for 18 h. The solvent was then removed in vacuo. The residue was taken up in diethyl ether (100 mL), washed with H_2O and brine, dried over $MgSO_4$, filtered, and then concentrated and purified by silica gel chromatography (10:1 hexane:ethyl actetate) to furnish dibromide **21** (6.74 g, 90%) as a clear, pale yellow oil. IR (NaCl cells): 2930, 1670, 1300, 1155, 555 cm^{-1}; ^{1}H NMR ($CDCl_3$): 1.44 (m, 4 H), 1.46 (s, 9 H), 1.54 (m, 4 H), 1.88 (m, 4 H), 3.17 (m, 4 H), 3.41 (t, J = 6.8 Hz, 4 H); ^{13}C NMR (DMSO-d_6, 90°C): 25.4, 27.6, 28.6, 32.4, 35.0, 46.7, 78.7, 155.2; HRMS (EI): $C_{15}H_{29}NO_2Br_2$(calc) = 413.0565, m^+/z-C_4H_9O(calc) = 339.9912, $C_{11}H_{20}NOBr_2$(obs) = 339.9917, 312 (m^+/z-$C_5H_9O_2$).

N-*(*t-*butyloxycarbonyl)-1-thia-7-azacyclododecane (**22**)*: Dibromide **21** (50 mg, 0.12 mmol) was combined with sodium sulfide nonahydrate (30 mg, 0.12 mmol) in absolute ethanol (500 mL) and refluxed for 18 h. The ethanol was then evaporated in vacuo. The residue was taken up with diethyl ether (50 mL) and washed with 5% sodium hydroxide (×3) and then water, dried with $CaCl_2$, filtered and then concentrated. Purification on a 1 mm preparatory plate (10:1 hexane : ethyl acetate) furnished the monomer sulfide **22** (30 mg, 86%) as a clear colourless oil. IR (NaCl cells): 2930, 1675, 1455, 1410, 1365, 1285, 1150, 990 cm^{-1}; ^{1}H NMR ($CDCl_3$): 1.47 (s, 9 H), 1.59 (m, 8 H), 1.67 (m, 4 H), 2.58 (t, J = 6.0 Hz, 4 H), 3.29 (m, 4 H); ^{13}C NMR (DMSO-d_6, 90°C): 22.9, 27.6, 27.7, 28.6, 30.9, 48.0, 78.6, 156.1; HRMS (EI): $C_{15}H_{29}NO_2S$(calc) = 287.1919, m^+/z -$C_5H_9O_2$(calc) = 186.1316, $C_{10}H_{20}NS$(obs) = 186.1320.

N-*(*t-*butyloxycarbonyl)-2-chloro-1,1-dioxo-1-thia-7-azacyclododecane (**23**)*: Sulfide **22** (0.22 g, 0.76 mmol) and *N*-chlorosuccinimide (0.10 g, 0.76 mmol) were combined in carbon tetrachloride (20 mL) and refluxed for 3 h. The reaction mixture was then cooled in an ice bath, the precipitate was filtered and the solvent was removed from the filtrate in vacuo. The residue was taken up in dichloromethane (20 mL) and cooled in an ice bath. *m*-Chloroperbenzoic acid (85%, 0.34 g, 1.99 mmol) was then added and the reaction was stirred for 18 h at room temperature. The reaction mixture was then cooled in an ice bath and the precipitate was filtered off. The filtrate was washed with 1 M NaOH (×2) and then brine, dried over $MgSO_4$, filtered, and the solvent removed. The crude product was purified by column chromatography (2:1 hexane : ethyl acetate) to supply chlorosulfone **23** (0.156 g, 58%) as a colourless solid (mp 147.8–149.5°C). IR (NaCl cells): 2930, 1680, 1450, 1410, 1365, 1310, 1150, 900 cm^{-1}; ^{1}H NMR ($CDCl_3$) 1.48 (s, 9 H), 1.50–1.85 (m, 7 H), 1.86–2.10 (m, 2 H), 2.10–2.30 (m, 2 H), 2.99 (m, 1 H), 3.19 (m, 1 H), 3.28 (m, 2 H), 3.47 (m, 2 H), 4.76 (dd, J = 4.1, 7.5 Hz, 1 H); ^{13}C NMR ($CDCl_3$): 21.3, 21.6, 23.1, 25.5, 25.8, 28.4, 31.6, 47.0, 47.2, 48.9, 73.1, 79.9, 156.5; HRMS (EI): $C_{15}H_{28}NO_4SCl$(calc) = 353.1428, m^+/z-$C_5H_9O_2$(calc) = 252.0825, $C_{10}H_{19}NO_2SCl$(obs) = 252.0830.

N-*(*t-*butyloxycarbonyl)-6-(*E*)-azacycloundecene (**24**)*: To a solution of chlorosulfone **23** (0.156 g, 0.44 mmol) dissolved in methyl sulfoxide (10 mL) was added potassium *tert*-butoxide (2.2 mL, 1.0 M solution in THF, 2.2 mmol). The reaction was then stirred at room temperature for 10 min. The reaction was diluted with diethyl ether (10 mL) and then poured into water (10 mL). The aqueous phase was extracted twice with diethyl ether. The combined organic phase was washed twice with water and then brine, dried over $MgSO_4$, filtered, and the solvent removed in vacuo. The residue was purified by silica gel chromatography (10:1 hexane : ethyl acetate) to provide *trans*-olefin **24** (0.108 g, 97%) as a clear, colourless oil. IR (NaCl cells): 2930, 1665, 1455, 1365, 1300, 1165, 1125, 980, 890 cm^{-1}; ^1H NMR ($CDCl_3$): 1.32 (m, 4 H), 1.42 (s, 9 H), 1.50 (m, 4 H), 2.15 (m, 4 H), 3.15 (m, 2 H), 3.25 (m, 2 H), 5.44 (t-like, J = 4.3 Hz, 2 H); ^{13}C NMR (DMSO-d_6, 90°C): 23.6, 25.7, 28.6, 33.8, 44.3, 78.4, 131.0, 154.7; HRMS (EI): $C_{15}H_{27}NO_2$(calc) = 253.2042, m^+/z -$C_5H_9O_2$(calc) = 152.1439, $C_{10}H_{18}NO_2$(obs) = 152.1451.

N-*(*t-*butyloxycarbonyl)-6,7-*trans-*azacycloundecandiol (**25**)*: To a stirred solution of *t*-butanol (32 mL), water (4 mL), THF (12 mL), 4-methylmorpholine-*N*-oxide (0.43 mL, 2.5 mmol), and *trans*–olefin **24** (0.52 g, 2.1 mmol) was added 2–3 crystals of osmium tetraoxide. The reaction was allowed to stir at room temperature for 18 h, then 2 g of florisil and 2 g sodium dithionite were added. This mixture was stirred for 5 min and then filtered through a pad of Celite. The solvent was removed in vacuo, the residue was taken up in ethyl acetate (20 mL); washed with 10% HCl, H_2O, and brine; dried over $MgSO_4$; filtered; and the solvent evaporated. The crude diol was purified by column chromatography (ethyl acetate) to furnish *trans*–diol **25** (0.498 g, 84%) as an off-white solid (mp 110.1–112.2°C). IR (NaCl cells): 3580, 2920, 1670, 1365, 1155 cm^{-1}; ^1H NMR ($CDCl_3$): 1.47 (s, 9 H), 1.5–1.7 (m, 8 H), 1.70 (s, 2 H), 1.84 (m, 2 H), 2.37 (m, 2 H), 3.25 (m, 4 H), 3.66 (s, 2 H); ^{13}C NMR (DMSO-d_6, 90°C): 20.5, 26.6, 27.8, 30.6, 49.0, 72.1, 77.8, 155.1; HRMS (EI): $C_{15}H_{29}NO_4$(calc) = 287.2097, m^+/z -$C_5H_9O_2$(calc) = 186.1494, $C_{10}H_{20}NO_2$(obs) = 186.1489.

N-*(*t-*butyloxycarbonyl)-6,7-*cis-*epoxyazacycloundecane (**26**)*: To a cooled solution of *trans*–diol **25** (0.087 g, 0.30 mmol) in THF (7 mL) was added potassium *tert*-butoxide (0.30 mL, 1.0M solution in THF, 0.30 mmol). After the reaction mixture was stirred for 15 min in an ice bath, 2,4,6-triisopropylbenzenesulfonyl chloride (0.092 g, 0.30 mmol) was added in THF (3 mL) and the reaction was allowed to stir at room temperature for 15 min. A second aliquot of potassium *tert*-butoxide (0.30 mL, 1.0 M solution in THF, 0.30 mmol) was added and the reaction was stirred for 10 min at room temperature. The reaction was diluted with diethyl ether (10 mL); washed with 1 M HCl, 10% NaOH, H_2O, and then brine; dried over $MgSO_4$; filtered; and the solvent evaporated. The crude product was purified by column chromatography (10:1 hexane : ethyl acetate to 2:1 ethyl acetate : hexane) to furnish *cis*–epoxide **26** (0.045 g, 65%) as a white solid (mp 81.4–83.8°C) and recovered *trans*–diol **25** (0.013 g). IR (NaCl cells): 2960, 2930, 1670, 1450, 1410, 1365, 1150, 900 cm^{-1}; ^1H NMR ($CDCl_3$): 1.36 (m, 2 H), 1.46 (s, 9 H), 1.58 (m, 4 H), 1.74 (m, 4 H), 1.92 (m, 2 H), 2.75 (m, 2 H), 2.92 (d, J = 10.3 Hz, 2 H), 3.66 (m, 2 H); ^{13}C NMR (DMSO-d_6, 90°C): 22.0, 23.9, 26.5, 28.6, 49.9, 57.2, 78.7, 155.6; HRMS (EI): $C_{15}H_{27}NO_3$(calc) = 269.1991, m^+/z -$C_5H_9O_2$(calc) = 168.1389, $C_{10}H_{18}NO$(obs) = 168.1388.

N-*(*t-*butyloxycarbonyl)-6-(*Z*)-azacycloundecene (**27**)*: To a refluxing solution of *cis*-epoxide **26** (0.054 g, 0.20 mmol) and 5 mg of Rh (II) octanoate dimer in benzene (3 mL) was added dimethyl diazomalonate (0.063 g, 0.40 mmol) in benzene (2 mL) slowly over ten minutes. After the addition was complete the reaction was refluxed for 30 min more, then cooled to room temperature, filtered through silica, and the solvent removed in vacuo. The crude product was purified by column chromatography (10:1 hexane : ethyl acetate) to furnish *cis*-olefin **27** as a clear, colourless oil (0.033 g, 65%). IR (NaCl cells): 2955, 1665, 1450, 1410, 1360, 1290, 1150, 1110, 885 cm^{-1}; ^1H NMR ($CDCl_3$): 1.47 (s, 9 H), 1.50 (m, 4 H), 1.68 (m, 4 H), 2.19 (m, 4 H), 3.27 (m, 4 H), 5.40 (m, 2 H); ^{13}C NMR (DMSO-d_6, 90°C): 24.4, 26.0, 26.1, 28.6, 48.9, 78.6, 130.7, 155.4; HRMS (EI): $C_{15}H_{27}NO_2$(calc) = 253.2042, m^+/z -$C_5H_9O_2$(calc) = 152.1439, $C_{10}H_{18}N$(obs) = 152.1447.

*6-(*E*)-azacycloundecene hydrochloride (**28**)*: HCl gas was bubbled into a cooled solution of *cis*-olefin **27** (0.1 g, 0.41 mmol) in ethyl acetate (10 mL) for 10 min. The reaction mixture was then stirred for 5 min more at room temperature before the solvent was evaporated in vacuo. The residue was washed with Et_2O (3×) and then dried under vacuum to provide the amine-hydrochloride salt **28** (0.078 g, 100%) as a white solid (mp 132.0–135.1°C). IR (IR card): 2890, 1590, 1435 cm^{-1}; ^1H NMR (CD_3OD): 1.60 (m, 4 H), 1.77 (m, 4 H), 2.32 (m, 4 H), 3.10 (t, J = 7.7 Hz, 4 H), 5.48 (t, J = 5.3 Hz, 2 H); ^{13}C NMR (CD_3OD): 22.4, 23.7, 25.0, 41.4, 130.8; HRMS (EI): $C_{10}H_{20}NCl$(calc) = 189.1284, m^+/z -Cl(calc) = 154.1596, $C_{10}H_{20}N$(obs) = 154.1580.

*1-methoxycarbonylmethyl-β-carboline (**4**)*: To a solution of LDA (4.4 mmol) in THF (20 mL) at –78°C was added harmane **5** (0.2 g, 1.1 mmol) in THF (10 mL). After stirring the resulting solution for 15 min at –78°C, dimethylcarbonate (0.28 mL, 3.3 mmol) was added and the solution was stirred at –78°C for 50 min. The cold bath was then removed and the reaction allowed to stir for 10 min, before quenching with a saturated solution of NH_4Cl. The aqueous phase was then extracted twice with dichloromethane. The combined organic phase was washed with brine, dried over $MgSO_4$, filtered, and the solvent evaporated in vacuo. Purification by flash chromatography (ethyl acetate) followed by crystallization (hexane – ethyl acetate) furnished harmane ester **4** (0.207 g, 78%) as an amorphous yellow solid (mp 109–111°C). IR (NaCl cells): 3420, 2950, 1720, 1630, 1430, 1380, 1310, 1120, 1005 cm^{-1}; ^1H NMR ($CDCl_3$): 3.76 (s, 3 H), 4.26 (s, 2 H), 7.31 (m, 1 H), 7.56 (m, 2 H), 7.92 (d, J = 5.3 Hz, 1 H), 8.13 (d, J = 7.7 Hz, 1 H), 8.41 (d, J = 5.3 Hz, 1 H), 9.17 (s, 1 H); ^{13}C NMR ($CDCl_3$): 42.5, 52.6, 111.9, 114.3, 120.2, 121.7, 121.7, 128.5, 129.7, 135.1, 137.2, 138.9, 140.6, 171.6; HRMS (EI): $C_{13}H_{12}N_2O_2$(calc) = 240.0899, $C_{13}H_{12}N_2O_2$(obs) = 240.0894.

*Manzamine amide (**30**)*: A 1.5 M aqueous solution of potassium hydroxide (0.26 mL, 0.39 mmol) was added to a solution of harmane ester **4** (0.049 g, 0.21 mmol) in ethanol

© 2000 NRC Canada

(2 mL) and the resulting solution was stirred for 2 h at room temperature. The solvent was then removed in vacuo and the residue was dried under vacuum for several hours. The residue was then dissolved in *N*,*N*-dimethylformamide (2 mL) and to this solution was added amine-olefin **28** (0.04 g, 0.21 mmol) in DMF (1 mL), diphenylphosphoryl azide (0.09 mL, 0.41 mmol), and triethylamine (0.06 mL, 0.41 mmol). The reaction mixture was stirred for 18 h at room temperature and then 10% aqueous NaOH solution was added until the reaction mixture was alkaline. The reaction mixture was extracted twice with dichloromethane. The combined organic phase was washed with H_2O (×5), dried over $MgSO_4$, filtered, and the solvent was evaporated in vacuo. Purification by flash chromatography (1:1 hexane : ethyl acetate) provided manzamine amide **30** (0.052 g, 70%) as an amorphous yellow solid (mp 138–140°C). IR (NaCl cells): 3450, 2930, 1610, 1430, 1365, 1315 cm^{-1}; ^1H NMR ($CDCl_3$): 1.46 (m, 4 H), 1.69 (m, 4 H), 2.18 (t-like, J = 5.6 Hz, 4 H), 3.32 (m, 2 H), 3.55 (m, 2 H), 4.25 (s, 2 H), 5.34 (t-like, J = 5.8 Hz, 2 H), 7.25 (m, 1 H), 7.52 (m, 2 H), 7.85 (d, J = 5.3 Hz, 1 H), 8.08 (d, J = 7.7 Hz, 1 H), 8.33 (d, J = 5.3 Hz, 1 H), 10.16 (s, 1 H); ^{13}C NMR ($CDCl_3$): 24.2, 24.5, 24.9, 25.1, 25.3, 26.1, 43.3, 46.3, 48.6, 112.2, 113.9, 119.8, 121.4, 121.6, 128.3, 129.0, 130.7, 130.7, 135.8, 138.2, 138.7, 140.6, 169.8; HRMS (EI): $C_{23}H_{27}N_3O$(calc) = 361.2154, $C_{23}H_{27}N_3O$(obs) = 361.2153, 181 (m^+-$C_{11}H_{18}NO$), 152 (m^+-$C_{13}H_9N_2O$), 209 (m^+-$C_{10}H_{18}N$).

*Manzamine C (**3**)*: To a cooled solution of $LiAlH_4$ (0.08 g, 2.15 mmol) in THF (10 mL) was added manzamine amide **30** (0.155 g, 0.43 mmol) in THF (5 mL). The reaction was stirred for 3 h at room temperature and then quenched by the addition of 10% aqueous NaOH (1–2 mL) until the organic layer was clear. The reaction mixture was then extracted with dichloromethane twice, dried over K_2CO_3, and the solvent evaporated in vacuo. Purification by flash chromatography (40:1 diethyl ether:methanol to 10:1 diethyl ether:methanol) furnished manzamine C **3** (0.055 g, 42%) as a pale yellow solid (88.5–90.5°C). IR (NaCl cells): 2920, 2850, 1615, 1450, 1370, 1315 cm^{-1}; ^1H NMR ($CDCl_3$): 1.54 (m, 4 H), 1.80 (m, 4 H), 2.31 (m, 4 H), 2.92 (t, J = 7.7 Hz, 4 H), 3.00 (t, J = 5.9 Hz, 2 H), 3.43, (t, J = 5.9 Hz, 2 H), 5.48 (t-like, J = 5.4 Hz, 2 H), 7.25 (m, 1 H), 7.53 (m, 2H), 7.84 (d, J = 5.4 Hz, 1 H), 8.13 (d, J = 7.9 Hz, 1 H), 8.29 (d, J = 5.4 Hz, 1 H), 12.54 (s, 1 H); ^{13}C NMR ($CDCl_3$): 22.9, 24.6, 26.0, 33.9, 48.6, 52.5, 112.0, 113.3, 119.2, 121.6, 121.8, 127.8, 128.4, 131.0, 135.4, 137.5, 140.7, 144.6; HRMS (EI): $C_{23}H_{29}N_3$(calc) = 347.2361, $C_{23}H_{29}N_3$(obs) = 347.2345, 166 (m^+-$C_{12}H_9N_2$).

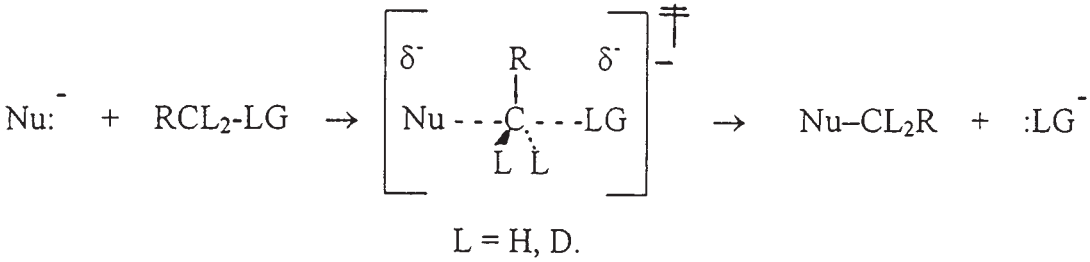
An unusually large secondary α-deuterium kinetic isotope effect in hydride ion S_N2 reactions

Terry Koerner, Kenneth Charles Westaway, Raymond A. Poirier, and Y. Wang

Abstract: Theoretical calculations at the HF/6–31+G* level suggest the secondary α-deuterium kinetic isotope effects for hydride ion S_N2 reactions are much larger than expected for the structure of the transition state. The secondary α-deuterium kinetic isotope effects for the S_N2 reactions between sodium borohydride (hydride ion) and *para*-methyl- and *para*-chlorobenzyl chlorides are much larger than expected as the theoretical calculations suggest. It appears the secondary α-deuterium isotope effects are larger than expected for the structure of the S_N2 transition state because the hydride ion is too small to affect the C_α—H(D) out-of-plane bending vibrations in the transition state.



Key words: secondary α-deuterium kinetic isotope effects, S_N2, nucleophilic substitution, transition state, substituent effects.

Résumé : Des calculs théoriques au niveau HF/6–31+G* suggèrent que les effets isotopiques cinétiques secondaires des atomes deutérium en α dans les réactions S_N2 des ions hydrures sont beaucoup plus importants que ceux auxquels on pourrait s'attendre à partir de la structure de l'état de transition. Les effets isotopiques cinétiques secondaires des atomes deutérium en α dans les réactions S_N2 entre le borohydrure de sodium (ion hydrure) et les chlorures de *para*-méthyl- et *para*-chlorobenzyles sont beaucoup plus élevés que ceux auxquels on pourrait s'attendre sur la base des calculs théoriques. Il semble que les effets isotopiques cinétiques secondaires des atomes deutérium en α sont beaucoup plus élevés que ceux auxquels on pourrait s'attendre sur la base de l'état de transition S_N2 en raison du fait que l'ion hydrure est beaucoup trop petit pour affecter les vibrations de déformation hors-plan C_α—H(D) dans l'état de transition.

Mots clés : effets isotopiques cinétiques secondaires des atomes deutérium en α, S_N2, substitution nucléophile, état de transition, effets de substituant.

Introduction

In a theoretical study of the secondary α-deuterium kinetic isotope effects (KIEs) for S_N2 reactions, eq. [1], by Poirier et al., (1) the KIE was expressed as the

[1] 

product of a translational, a rotational, a vibrational, and a tunneling term (eq. [2]).

[2] $(k_H/k_D)_\alpha = (k_H/k_D)_{trans}\ (k_H/k_D)_{rot}\ (k_H/k_D)_{vib}\ (k_H/k_D)_{tunnelling}$

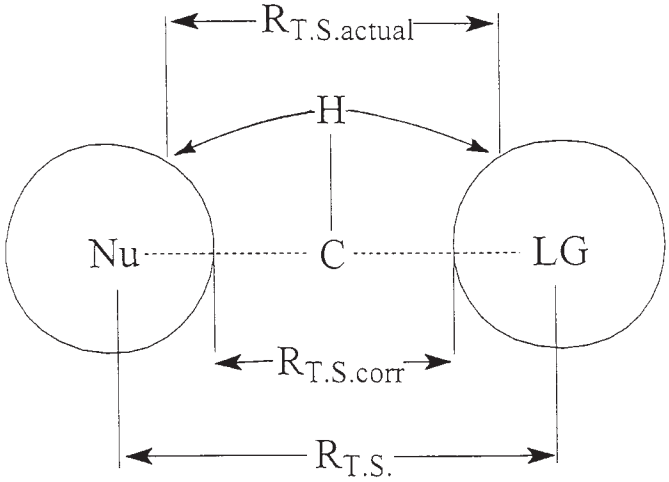
Table 1. A comparison of the bending and stretching contributions to the secondary α-deuterium KIE for hydride ion and other nucleophiles with a similar nucleophile-leaving group distance in the transition state.

	Methyl chloride			Methyl fluoride		
	OH^-	H^-	% Difference	F^-	H^-	% Difference
$(k_H/k_D)_\alpha$	0.907	0.983	8.4	0.846	1.013	20.0
Nu···LG distance (Å)	4.37	4.32	1.1	3.69	3.65	1.1
$(k_H/k_D)_{stretching}$	0.714	0.707	1.0	0.677	0.653	3.5
$(k_H/k_D)_{bending}$	1.112	1.288	15.9	0.978	1.389	42.0

The vibrational term was factored into three terms (eq. [3]),

$$[3] \quad (k_H/k_D)_{vib} = (k_H/k_D)_{stretching}\,(k_H/k_D)_{bending}\,(k_H/k_D)_{other}$$



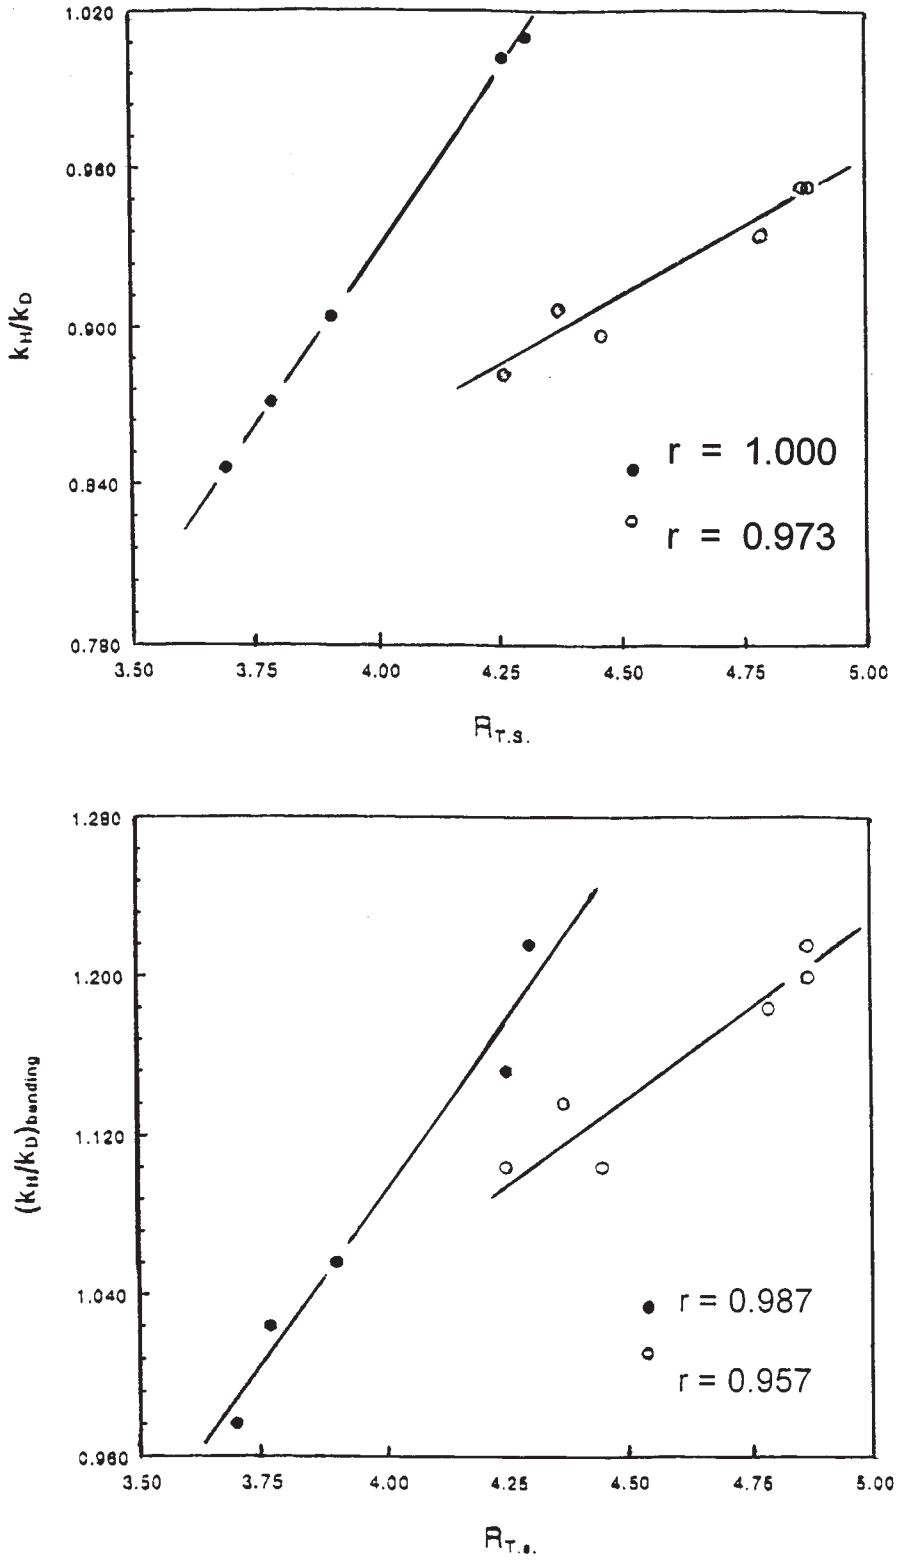
where $(k_H/k_D)_{stretching}$ is due to the changes that occur in the three C_α—H(D)stretching vibrations, $(k_H/k_D)_{bending}$ is the contribution due to the changes that occur in the seven C_α—H(D) bending (primarily the out-of-plane bending) vibrations, and $(k_H/k_D)_{other}$ is due to the changes that occur in the other vibrations, when the reactant is converted into the S_N2 transition state (1). The $(k_H/k_D)_{stretching}$ and $(k_H/k_D)_{bending}$ contributions to the KIE were calculated to determine how these vibrations affected the magnitude of the secondary α-deuterium KIE and to determine how the $(k_H/k_D)_{stretching}$ and $(k_H/k_D)_{bending}$ contributions to the KIE were related to the structure of the S_N2 transition state. The initial study (1) showed that the large and inverse stretching component of the KIEs was constant, but different, for each leaving group. For example, the stretching component of the secondary α-deuterium KIE for the S_N2 reactions between several nucleophiles and methyl chloride or methyl fluoride, were $(k_H/k_D)_{stretching}$ = 0.701 ± 0.014 and 0.677 ± 0.013, respectively. The bending contributions to the KIE on the other hand, varied markedly with the nucleophile and the nucleophile-leaving group (Nu···LG) distance ($R_{T.S.}$) in the transition state[2]. For instance, the $(k_H/k_D)_{bending}$ varied from 1.098 to 1.221 in the methyl chloride reactions and from 0.978 to 1.215 in the methyl fluoride reactions.

Since the $(k_H/k_D)_{stretching}$ contribution to the KIE is constant for a particular leaving group, the magnitude of both the total KIE and the bending contribution to the KIE were related to the Nu···LG distance in the S_N2 transition state (1) (Fig. 2).

Results and discussion

When the calculations described above were extended to the secondary α-deuterium KIEs for both the methyl chloride and methyl fluoride S_N2 reactions with hydride ion, the results showed that the hydride ion KIEs were significantly larger than expected, i.e., the KIE was much larger than expected given the Nu···LG distance in the transition state (Fig. 3).

Fig. 1. The relationship between $R_{T.S}$, $R_{T.S.corr}$, and $R_{T.S.actual}$ for the C_α—H(D) bending vibrations in the S_N2 transition state.



The results (Table 1) show that the KIE for the methyl chloride reaction with hydride ion is 8.4% larger (less inverse) than the hydroxide ion reaction that has an almost identical (4.37 rather than 4.32 Å) Nu···LG distance. In the methyl fluoride S_N2 reactions, the KIE for the hydride ion reaction is 20% larger than the KIE for the fluoride ion (identity reaction) even though both reactions have almost identical (3.65 vs. 3.69 Å) Nu···LG distances in the transition state. The stretching and bending contributions to the KIEs for the methyl chloride and methyl fluoride reactions with hydride ion were calculated in an effort to understand why the hydride ion reaction KIEs were so large. The stretching contribution to the methyl chloride and methyl fluoride reactions with hydride ion are virtually identical to those found for the reactions with other nucleophiles, i.e., the stretching vibration contribution to the KIEs for the H^- and OH^- reactions with methyl chloride and for the H^- and F^- reactions with methyl fluoride only differ by 1.0 and

[2] Glad and Jensen (2) suggested that the Nu···LG (internuclear) distance ($R_{T.S.}$) is not the correct parameter to use but that the Nu···LG distance minus the radius of both the nucleophile and the leaving group atoms ($R_{T.S.corr}$) should be used for determining the energy of the bending vibrations (the magnitude of the secondary α-deuterium KIE). We tried correlating the calculated KIE with $R_{T.S.corr}$ before publishing our first paper (1) but found the relationship between the $(k_H/k_D)_\alpha$ and $R_{T.S.corr}$ was worse than the correlation between $(k_H/k_D)_\alpha$ and $R_{T.S.}$ A possible explanation for this is that the α-hydrogen only approaches the nucleophile and the leaving group in the C_α—H(D) bending vibration approximately 0.8 Å above the internuclear axis joining the nucleophile, the α-carbon and the leaving group in the S_N2 transition state (Fig. 1). The curvature of the surfaces of the spherical nucleophile and leaving group nucleophilic atoms means $R_{T.S.actual}$ (the space available for the C_α—H(D) out-of-plane bending vibrations in the transition state) is greater than $R_{T.S.corr}$ and the higher correlation with $R_{T.S.}$ suggests $R_{T.S.actual}$ is closer to $R_{T.S.}$ than to $R_{T.S.corr}$.

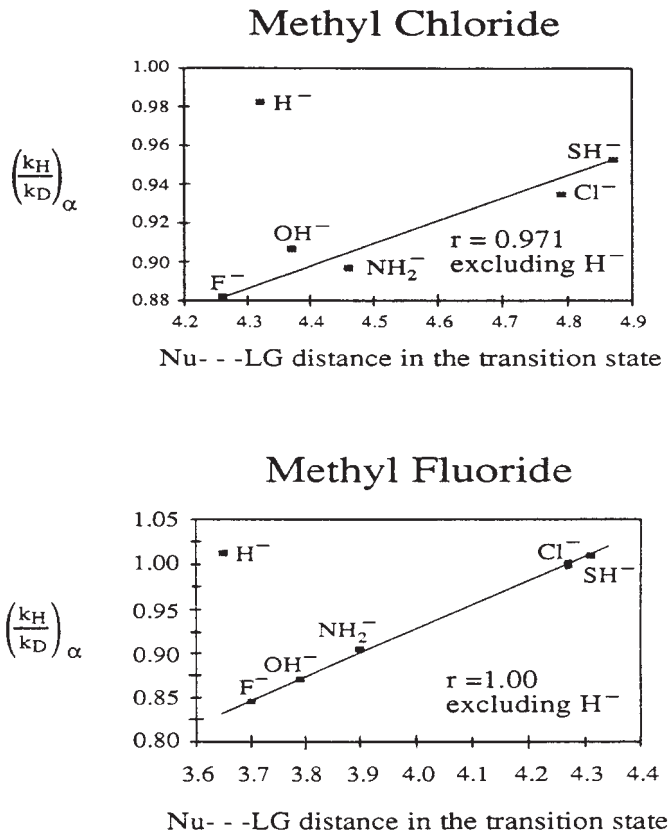

Fig. 2. The total KIE (curve a) and the bending vibration contribution to the KIE (curve b) vs. $R_{T.S.}$ for the S_N2 reactions of methyl chloride and methyl fluoride with various nucleophiles. The open circles are for the methyl chloride reactions and the solid circles are for the methyl fluoride reactions.

3.5%, respectively (Table 1). The major difference between the KIEs with the almost identical Nu···LG distances in the transition state, is due to the bending contribution to the KIE, i.e., the bending contribution to the H^- KIE is 15.9% larger than the bending contribution to the OH^- KIE when the substrate is methyl chloride. The effect is even more

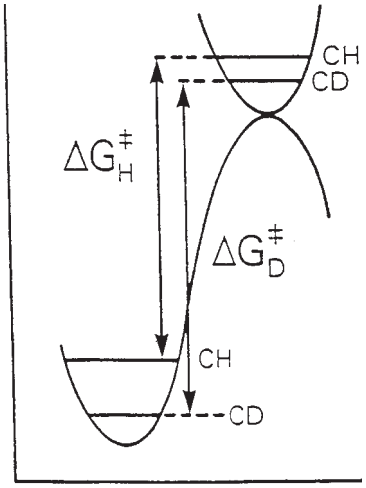
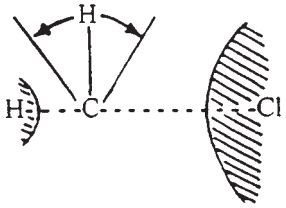
Fig. 3. The secondary α-deuterium KIE as a function of the Nu···LG distance in the transition states for the S_N2 reactions of methyl chloride and methyl fluoride with various nucleophiles.

dramatic for the methyl fluoride reactions. Here, the bending contribution to the H^- KIE is 42.0% larger than the bending contribution to the F^- KIE.

The larger bending vibration contribution to the H^- KIEs obviously occurs because the zero-point energy difference in the C_α—H(D) out-of-plane bending vibrations is lower than expected in the S_N2 transition state (Fig. 4). The unusually large $(k_H/k_D)_{bending}$ contribution to the KIE means the C_α—H(D) bending vibrations in the transition state are low energy. One possible explanation for this is that the hydride ion is too small to affect the C_α—H(D) vibrations in the transition state (Fig. 5), i.e., the hydride ion is too small to sterically hinder the C_α—H(D) out-of-plane bending vibrations. This means the bending vibrations are low energy, the ZPE difference in the transition state is smaller than expected, and the KIE is larger than expected. It is interesting to note that the effect of the small hydride ion is greater in the methyl fluoride reactions which have a shorter Nu···LG distance in the transition state. Removing the effect of the hydride in a tighter transition state would be expected to have a greater effect on the C_α—H(D) out-of-plane bending vibrations and, therefore, on the KIE.

Fig. 4. A reaction coordinate diagram for an S_N2 reaction with low energy out-of-plane bending vibrations in the transition state.





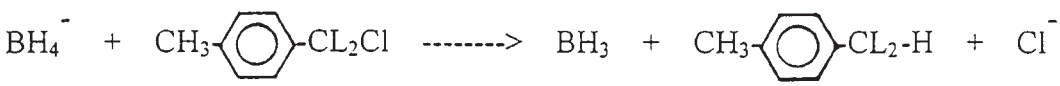


Fig. 5. The transition state for the hydride ion S_N2 reactions showing that the hydride ion is too small to affect the C_α—H(D) out-of-plane bending vibrations.

Although the above rationale for the larger secondary α-deuterium KIEs in the hydride ion reactions seems reasonable, experimental confirmation of this phenomenon is needed. The secondary α-deuterium KIE for the S_N2 reaction between sodium borohydride (hydride ion) and *para*-methylbenzyl chloride (eq. [4]), was determined to learn whether the KIE for the hydride ion reaction was, indeed, larger than expected.

Three labelled and three unlabelled reactions were done simultaneously. The three rate constants (3) for the unlabelled (k_H) and labelled (k_D) substrates were averaged and divided to obtain the secondary α-deuterium KIE. Each KIE was determined twice and all the second order (first order in $BH4^-$ and in substrate) kinetic plots were linear to at least 90% of completion and had correlation coefficients ≥0.998.

The average secondary α-deuterium KIE at 30.000 ± 0.002°C (Table 2), is 1.091 ± 0.002 or approximately 1.044/$_{\alpha\text{-D}}$. The $(k_H/k_D)_\alpha$ per α-deuterium for a carbenium ion S_N reaction of an alkyl chloride where the first step is fully rate-determining, is 1.11 (4–6). If dissociation of the intimate ion pair or formation of the free carbocation is rate-determining, the $(k_H/k_D)_\alpha$ would be approximately 1.15 per α-deuterium (5). The much smaller secondary α-deuterium KIE of

[a]Standard deviation for three separate kinetic runs.

[b]The error is $1/k_D[(\Delta k_H)^2 + (k_H/k_D)^2 \times (\Delta k_D)^2]^{1/2}$, where Δk_H and Δk_D are the standard deviations for the average rate constants for the reactions of the undeuterated and deuterated nucleophiles, respectively.

[c]Standard deviation.

$1.044/_{\alpha\text{-D}}$ found in this study, confirms that the reaction is an S_N2 process.

The secondary α-deuterium KIE = 1.091 or $1.044/_{\alpha\text{-D}}$ found for this reaction is near the maximum secondary α-deuterium KIE = $1.06/_{\alpha\text{-D}}$ found for an S_N2 reaction of an alkyl chloride (7–11). Thus, the hydride ion KIE is large. However, interpreting the KIE is difficult. Two explanations are possible. One possibility is that the large secondary α-deuterium KIE of 1.091 means that the transition state is loose, and symmetric, with long nucleophile—α- carbon *and* α-carbon—leaving group bonds. A large KIE would be observed in this case because the C_α—H(D) out-of-plane bending vibrations will be low energy in the transition state.

The second possibility is that the hydride ion – *p*-methylbenzyl chloride reaction has an unsymmetric transition state and an unusually large secondary α-deuterium KIE. Westaway et al. (12) suggested that some benzyl substrates react via an unsymmetric S_N2 transition state. In all the reactions where unsymmetric S_N2 transition states have been characterized in enough detail so that one knows the relative lengths of the nucleophile—α-carbon and the α- carbon—leaving group bonds in the transition state, the stronger reacting bond has always been short and the weaker reacting bond has been long. Since the H—C bond is much stronger than the C_α—Cl bond (the stretching frequencies are 2960 and 650 cm^{-1}, respectively), (13) an unsymmetric transition state should have a short H—C_α and a long C_α—Cl bond. If this is the case, one would expect a very small secondary α-deuterium KIE because the out-of-plane bending vibrations in the transition state will be determined by only the out-of-plane bending vibrations to the short reacting bond (12). In fact, the secondary α-deuterium KIEs in reactions with unsymmetric S_N2 transition states are all small because the out-of-plane bending vibrations in the reactant or the product and in the transition state are similar (12). In fact, this behaviour has been found experimentally. For instance, in the *p*-substituted benzyl chloride – cyanide ion reactions and in the cyanide ion – *m*-chlorobenzyl-*p*-substituted benzyl benzenesulphonate reactions which are believed to have unsymmetric S_N2 transition states, the secondary α-deuterium KIEs are small, i.e., they range from 1.008 to 1.011 and from 1.009 to 1.028, respectively (12, 14). Therefore, if the hydride ion – *p*-methylbenzyl chloride transition state is unsymmetric with a short H—C_α bond, one would expect a small secondary α-deuterium KIE to be found. The observed KIE of 1.091, which is near the maximum possible secondary α-deuterium KIE for an alkyl chloride, would be unusually large as the theoretical calculations suggest.

The problem then, is to determine whether the KIE is large because the S_N2 transition state is loose but symmetric or unsymmetric with a short H—C_α bond in the transition state. Westaway et al. (12) proposed that one could determine the symmetry of the S_N2 transition state if one varied a substituent on the benzene ring of the substrate. If the transition state is symmetric, the structure of the transition state and therefore, the KIE, would change with a change in substituent. If, on the other hand, the transition state was unsymmetric with a short H—C_α bond, changing the substituent on the benzene ring of the substrate would not alter the stronger H—C_α transition state bond significantly (the Bond Strength Hypothesis (15)) and therefore, the KIE, which is determined by the short H—C_α bond, will not change with substituent, i.e., the change in the long C_α—Cl transition state bond will occur too far away to affect the C_α—H(D) out-of-plane bending vibrations in the transition state (the KIE).

The secondary α-deuterium KIE for the S_N2 reaction between *p*-chlorobenzyl chloride and sodium borohydride was determined to learn if the S_N2 transition state was symmetric or unsymmetric. The secondary α-deuterium KIE of 1.092 ± 0.001 (Table 3), for the *p*-chlorobenzyl chloride hydride ion reaction at 30.000 ± 0.002°C is identical to the KIE = 1.091 ± 0.002 for the reaction with *p*-methylbenzyl chloride. Therefore, these S_N2 transition states must be unsymmetric with short H—C_α and long C_α—Cl transition state bonds.

Since the H—C_α bond is short in the S_N2 transition states of hydride ion reactions, one would expect the secondary α-deuterium KIE to be small (vide supra). However, the secondary α-deuterium KIE is large. The experimental KIEs, therefore, are larger than expected, presumably because the hydride ion in the transition state is too small to affect the C_α—H(D) out-of-plane bending vibrations (Fig. 5). This means the C_α—H(D) out-of-plane bending vibrations will be very low energy in the transition state of any hydride ion S_N2 reaction and therefore, the KIE will be much larger than one would expect given the H—C_α or Nu···LG distance in the S_N2 transition state.

Experimental

The *p*-methylbenzyl- and *p*-chlorobenzyl chlorides (Aldrich) were distilled before use. The preparation of the *p*-methyl- and *p*-chloro-1,1-d_2-benzyl chlorides has been described

CP/MAS NMR and X-ray crystallographic characterization of *trans*-$PdX_2(PPh_2vinyl)_2$ (X = Cl, I); UV and $Et_2O{\cdot}BF_3$ reaction studies, including the formation of $[Pd(\mu\text{-}Cl)(PPh_2vinyl)_2]_2[BF_4]_2$

Michael B. Hursthouse, David G. Kelly, Mark E. Light, and Andrew J. Toner

Abstract: The complexes $PdCl_2(PPh_2vinyl)_2$ and $PdI_2(PPh_2vinyl)_2$ have been prepared and crystallographically characterized as their *trans* square planar isomers. *Trans*-$PdCl_2(PPh_2vinyl)_2$ exists in a centrosymmetric structure with a planar $PdCl_2P_2$ core whereas *trans*-$PdI_2(PPh_2vinyl)_2$ shows no local Pd-centred symmetry and significant distortion of the PdI_2P_2 core from planarity. Crystallographic data is in accord with the $^{31}P\{^1H\}$ CP/MAS NMR spectra of the two complexes, which display a single resonance for the chloro-complex and two resonances for the iodo-complex. UV irradiation of CH_2Cl_2 solutions of $PdCl_2(PPh_2vinyl)_2$ followed by re-dissolution in $CDCl_3$ indicates no permanent chemical change. However, post-irradiation CP/MAS $^{31}P\{^1H\}$ NMR spectroscopy demonstrates the presence of *trans*-$PdCl_2(PPh_2vinyl)_2$ in two solid state structures, plus *cis*-$PdCl_2(PPh_2vinyl)_2$. $PdI_2(PPh_2vinyl)_2$ exists only in its *trans* form in both solid state and solution. Irradiation results in phosphine displacement and the formation of *sym*-$[PdI_2(PPh_2vinyl)]_2$ and free phosphine, the latter being characterized as $Ph_2P(O)$vinyl following aerobic oxidation. $PdCl_2(PPh_2vinyl)_2$ reacts in the presence of $Et_2O{\cdot}BF_3$ to afford $[Pd(\mu\text{-}Cl)(PPh_2vinyl)_2]_2[BF_4]_2$ whereas $PdI_2(PPh_2vinyl)_2$ is recovered in 95% yield, with the remaining material undergoing phosphine abstraction to form *sym*-$[PdI_2(PPh_2vinyl)]_2$.

Key words: palladium, phosphine, alkene, isomerization, CP/MAS.

Résumé : On a préparé les complexes $PdCl_2(PPh_2vinyl)_2$ et $PdI_2(PPh_2vinyl)_2$ et sur la base de la cristallographie, on a établi qu'il s'agit des isomères plans carrés *trans*. Le *trans*-$PdCl_2(PPh_2vinyl)_2$ existe dans une structure centrosymétrique comportant une unité centrale $PdCl_2P_2$ plane alors que le *trans*-$PdI_2(PPh_2vinyl)_2$ est fortement déformé par rapport à la planéité. Les données cristallographiques sont en accord avec le spectre RMN CP/MAS du $^{31}P\{^1H\}$ des deux complexes qui ne présentent qu'une seule résonance pour le complexe chloré et deux résonances pour le complexe iodé. L'irradiation UV de solutions de CH_2Cl_2 du complexe $PdCl_2(PPh_2vinyl)_2$ suivie d'une redissolution dans le $CDCl_3$ indique qu'il n'y a pas de changement chimique permanent. Toutefois, la spectroscopie RMN CP/MAS du $^{31}P\{^1H\}$ démontre la présence de *trans*-$PdI_2(PPh_2vinyl)_2$ dans deux structures à l'état solide en plus de *cis*-$PdI_2(PPh_2vinyl)_2$. Le $PdI_2(PPh_2vinyl)_2$ n'existe que dans sa forme *trans* tant à l'état solide qu'en solution. L'irradiation provoque un déplacement de la phosphine et la formation de *sym*-$[PdI_2(PPh_2vinyl)]_2$ et de phosphine libre; cette dernière est caractérisée sous la forme de $Ph_2P(O)$vinyl après une oxydation aérobique. Le *trans*-$PdCl_2(PPh_2vinyl)_2$ réagit en présence de $Et_2O{\cdot}BF_5$ pour conduire à la formation de $[Pd(\mu\text{-}Cl)(PPh_2vinyl)_2]_2[BF_4]_2$ alors que le $PdI_2(PPh_2vinyl)_2$ est récupéré avec un rendement de 95%, le reste du produit subissant une abstraction de phosphine avec formation de la *sym*-$[PdI_2(PPh_2vinyl)]_2$.

Mots clés : palladium, phosphine, alcène, isomérisation, CP/MAS.

[Traduit par la Rédaction]

Introduction

Increasing interest exists in the formation of high molecular weight materials from metal complexes and the incorporation of such complexes into organic polymers. Pendant alkene moieties incorporated into phosphine ligands and their complexes have demonstrated polymerization in the presence of UV radiation and Lewis acids (1, 2). The potential for similar polymerization or alternative metal-centred reaction pathways is assessed in the present work for palladium(II) complexed diphenylvinylphosphine. Palladium(II) readily forms PdX_2P_2 (X = halide, *P* = tertiary phosphine) complexes with monodentate and bidentate phosphines. These complexes have formed the focus of numerous studies as a vehicle for probing *cis*/*trans* isomerization (3) and

ligand/anion exchange processes (4), and as potential stoichiometric and catalytic reagents in synthesis (5). The principal modes of characterization have been solution $^{31}P\{^1H\}$ NMR spectroscopy and single crystal X-ray diffraction studies. The former technique demonstrates that monodentate phosphine complexes generally exist as *cis*/*trans* mixtures in solution, although modification of P and X can lead to the *trans* isomer being overwhelmingly thermodynamically favored (6). Crystallization generally leads to the isolation of *trans* complexes; indeed 45 of the 55 reported PdX_2P_2 single crystal X-ray diffraction structures of monodentate phosphine complexes are of the *trans* isomer.[2] Solid state distortion from square planar geometries in these crystallographic studies is known but is not universal. In contrast, such distortion is not observed by solution $^{31}P\{^1H\}$ NMR spectroscopy.

Cross-polarization magic-angle-spinning (CP/MAS) NMR spectroscopy offers an increasingly available and complementary characterization technique that probes the solid state structure of non-crystalline materials. The study of solid samples by conventional NMR apparatus and experiments yields at best broad signals or a rolling baseline. Two principal factors contribute to this uninformative data; dipole-dipole nucleur interactions and chemical shift anisotropy (CSA). The former is removed in solution by molecular motion, which is sufficiently rapid to afford an averaged molecular orientation and thus zero local field. The effect of CSA, the directional influence of chemical bonds on nucleur shielding, is reduced to zero by the same motion in solution. Both factors vary in magnitude as a function of $3\cos^2\theta - 1$, where θ is the orientation to the applied field. Thus, spinning samples at a frequency larger than the CSA linewidth (usually a few kilohertz), and at an angle where the term $3\cos^2\theta - 1$ becomes zero (54° 44′) allows the observation of sharp solid state spectra. Such 'magic angle spinning' when coupled with the sensitivity enhancement of cross polarization provides effective and informative solid state NMR data. In the present study we have investigated the solid state and solution chemistry of the PdX_2P_2 complexes (X = Cl, I; *P* = PPh_2vinyl) as part of our recent studies of bifunctional phosphine/alkene ligands (7, 8). The reported solution NMR data for these complexes are supplemented here by crystallographic characterization, and by CP/MAS NMR spectroscopy (9). Reactivity initiated by UV irradiation and in the presence of Lewis acids has also been considered.

Results and discussion

Synthesis and characterization of $PdX_2(PPh_2vinyl)_2$ (X = Cl, I)

Synthesis of $PdCl_2P_2$ complexes (*P* = tertiary phosphine) is well established and readily achieved by the reaction of $PdCl_2(PhCN)_2$ with two equivalents of tertiary phosphine. Iodide complexes may be isolated in high yield by metathesis of the respective chloride with excess aqueous NaI (9). The utilization of such synthetic routes and subsequent recrystallization from diethylether–dichloromethane affords crystalline $PdCl_2(PPh_2vinyl)_2$ and $PdI_2(PPh_2vinyl)_2$ in high yield. Crystals of both $PdCl_2(PPh_2vinyl)_2$ and $PdI_2(PPh_2vinyl)_2$ proved suitable for single crystal X-ray diffraction studies, with structure elucidation demonstrating the formation of *trans* square planar $PdCl_2(PPh_2vinyl)_2$ and $PdI_2(PPh_2vinyl)_2$ (Figs. 1 and 2, respectively).

Metal-centred bond lengths and angles for $PdCl_2(PPh_2vinyl)_2$ indicate a centrosymmetric and therefore planar $PdCl_2P_2$ core, with Cl-Pd-Cl and P-Pd-P vectors being almost orthogonal (Table 1). In contrast, no local Pd-centred

symmetry is observed for $PdI_2(PPh_2vinyl)_2$. Moreover, there are significant distortions from planarity for the PdI_2P_2 core and non-equivalence of both iodide and phosphine moieties. The presence and absence of local symmetry between the chloride and iodide complexes may be attributed to the relative ligand field splitting contributions of the respective anions. Solution $^{31}P\{^1H\}$ NMR spectroscopy is not representative of either *trans* solid state structure. For the former complex, this is due to the rapid establishment of *cis-trans* equilibria. Whilst for the latter thermal energy is sufficient to allow rapid exchange on the NMR time-scale between inequivalent phosphines resulting in the observation of a single solution resonance for the two ligands, Table 2. However, CP/MAS $^{31}P\{^1H\}$ NMR spectroscopy does readily characterize the two solid state structures affording a single resonance for the centrosymmetric *trans*-$PdCl_2(PPh_2vinyl)_2$ and two resonances for the asymmetric *trans*-$PdI_2(PPh_2vinyl)_2$. In both cases, the observed chemical shifts are similar to those assigned to the solution resonances of the *trans*-$PdX_2(PPh_2vinyl)_2$ complexes, Table 2. $^{13}C\{^1H\}$ CP/MAS NMR spectroscopy has been successfully employed in the characterization of other palladium(II) phosphines (10). Such spectra were recorded here for both *trans* complexes. However, it is apparent from solution $^{13}C\{^1H\}$ NMR spectroscopy that phenyl and vinyl $^{13}C\{^1H\}$ resonances lie within the same region and display significant ^{13}C–^{31}P coupling. This feature, along with the additional complications of solid state line broadening, plus non-equivalence for the phosphine ligands of $PdI_2(PPh_2vinyl)_2$, results in extensively overlaid resonances for which deconvolution and assignment are unreliable.

UV irradiation of $PdX_2(PPh_2vinyl)_2$ (X = Cl, I)

The solution irradiation of $PdX_2(PPh_2vinyl)_2$ complexes offers three principal routes of reactivity. UV absorbance followed by relaxation to the kinetically favored *cis* isomer may occur to afford *trans-cis* isomerization (11). Alternatively, short wavelength UV activation of alkene moieties

can produce oligomerization or polymerization (1), while homolytic or heterolytic bond cleavage may result in generalized or specific bond cleavage.[3] The significance of these various factors can be elucidated by comparison of pre- and post-irradiation solution and solid state NMR data (Table 2).

Irradiation of ca. 10^{-1} M CH_2Cl_2 solutions of $PdCl_2(PPh_2vinyl)_2$ and $PdI_2(PPh_2vinyl)_2$ using wavelengths of $\lambda \geq 200$nm results in the rapid precipitation of palladium containing materials. Precipitation results from the rapid solvent heating associated with the relaxation of excited states through vibrational processes. Where appropriate the formation of *cis*-$[PdCl_2P_2]$ and *sym*-$[PdI_2P]_2$, which are recognized to be of lower solubility than the corresponding *trans*-$[PdX_2P_2]$, may also be significant (6, 10, 11). Decanting residual solvent after ca. 2 min irradiation followed by drying in vacuo affords a 95% yield (wt/wt) of materials slightly darkened from the respective yellow and red colors of the initial complexes. Consideration of the post-irradiation NMR spectrum of $PdCl_2(PPh_2vinyl)_2$ affords the following observations. Solution ^1H NMR spectroscopy indicates no change in the extensively coupled vinylic protons associated with *cis* and *trans* $PdCl_2(PPh_2vinyl)_2$. Moreover, no upfield resonances are observed which might be assigned to polyvinyl moieties. Solution $^{31}P\{^1H\}$ NMR spectroscopy also displays resonances that can be assigned to *cis* and *trans* $PdCl_2(PPh_2vinyl)_2$, with no additional features (Table 2). Thus, it may be concluded that any new solid state feature observed in the post-irradiation CP/MAS $^{31}P\{^1H\}$ NMR spectrum of $PdCl_2(PPh_2vinyl)_2$ corresponds to *cis* and *trans* isomers of this complex (Fig. 3). Three new peaks are observed in the CP/MAS $^{31}P\{^1H\}$ NMR spectrum at 16.3, 24.0, and 31.5 ppm. The former may be assigned to a crystallization of *trans*-$PdCl_2(PPh_2vinyl)_2$ in an alternative space group to that crystallographically characterized here; a feature which has been observed for other palladium(II) and platinum(II) complexes (12, 13). Consideration of the resonances at 24.0 and 31.5 ppm in isolation is problematic because, in addition to *cis*-$[PdCl_2P_2]$ complexes, other species such as phosphine oxides afford similar chemical shifts. However, because only *cis* and *trans* $PdCl_2(PPh_2vinyl)_2$ are

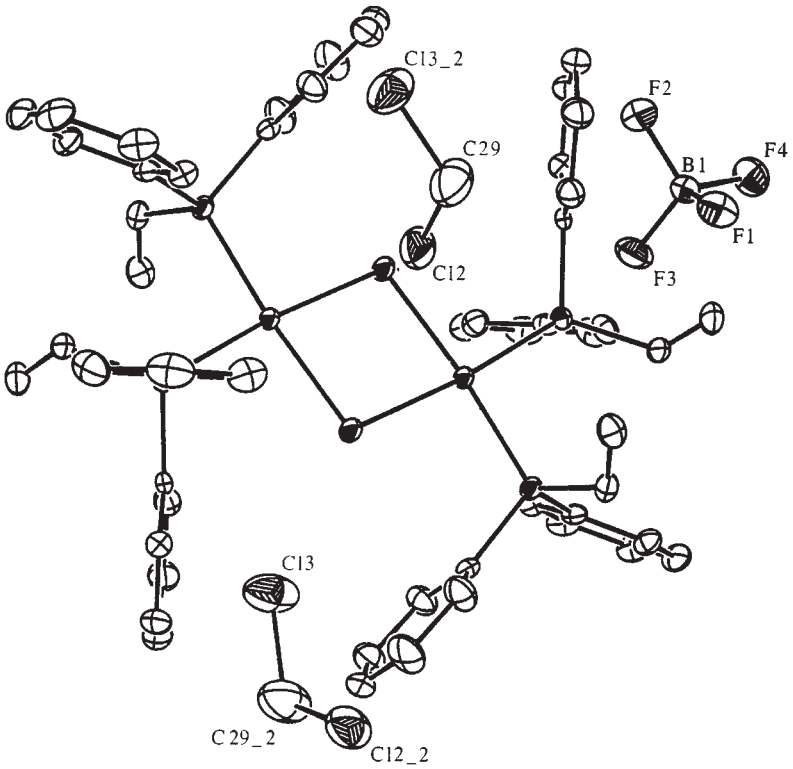
observed on re-dissolution these solid state resonances must be assigned to an unsymmetrical *cis*-$PdCl_2(PPh_2vinyl)_2$ species. While these solid state chemical shifts lie downfield by as much as 10 ppm from solution values, similar movements have been observed in comparable palladium(II) systems (11). Because conventional concentration and crystallization processes yield *trans*-$PdCl_2(PPh_2vinyl)_2$, irradiation may be viewed as enhancing the solid-state concentration of *cis*-$PdCl_2(PPh_2vinyl)_2$.

Irradiation of *trans*-$PdI_2(PPh_2vinyl)_2$ affords a material for which CP/MAS $^{31}P\{^{1}H\}$ resonances at 7.0 and 5.3 ppm are observed which are representative of the original complex. New resonances occur at 23.0, 27.5, and 29.8 ppm (Fig. 4). Unlike the additional post-irradiation resonances of $PdCl_2(PPh_2vinyl)_2$ these new peaks are not lost on re-dissolution. Instead, two peaks of approximately equal intensity are recorded at 22.9 and 26.9 ppm in the solution

Scheme 1. Reactivity of $PdX_2(PPh_2vinyl)_2$ on irradiation and in the presence of $Et_2O{\cdot}BF_3$.



$^{31}P\{^{1}H\}$ NMR spectrum. Formation of *cis*-$PdI_2(PPh_2vinyl)_2$ is unlikely due to the relative instability of this isomer, which does not form by the solution equilibration of *trans*-$PdI_2(PPh_2vinyl)_2$. Moreover, kinetically slow isomerization of such an apparently thermodynamically unstable *cis* species may also be excluded by the static intensities of $^{31}P\{^{1}H\}$ solution NMR resonances over ca. 7 d. Thus, these new resonances may be assigned to reaction, rather than isomerization products. ^{1}H NMR spectroscopy again excludes polymerization products by the absence of upfield resonances. However, extraction of irradiated material with hexane affords identical $^{31}P\{^{1}H\}$ and ^{1}H NMR data to $Ph_2P(O)vinyl$ samples obtained by direct PPh_2vinyl oxidation (Table 3). Thus, it may be suggested that the relaxation of excited species can result in Pd—P cleavage and the subsequent aerobic oxidation of free phosphine (14). Extraction of $Ph_2P(O)vinyl$, followed by recrystallization of the remaining material from Et_2O–CH_2Cl_2 results in the preferential precipitation of deep red *sym*-$[PdI_2(PPh_2vinyl)]_2$. The latter may be manually separated from traces of the paler *trans*-$PdI_2(PPh_2vinyl)_2$. Elemental analysis and comparison with published NMR data confirm the formation of *sym*-$[PdI_2(PPh_2vinyl)]_2$ (15) (Scheme 1).

Reaction of $PdX_2(PPh_2vinyl)_2$ (X = Cl, I) and $Et_2O{\cdot}BF_3$

The addition of $Et_2O{\cdot}BF_3$ to a CH_2Cl_2 solution of $PdCl_2(PPh_2vinyl)_2$ results in an immediate yellow to orange

color change. Removal of solvent in vacuo after 12 h and recrystallization from Et_2O–CH_2Cl_2 yields the crystallographically characterized $[Pd(\mu\text{-}Cl)(PPh_2vinyl)_2]_2[BF_4]_2$, formed by a combination of halide abstraction and exchange (Fig. 5). Solution NMR spectroscopy indicates that this air stable complex is the sole palladium containing product. The complex is stable in CH_2Cl_2, but appears to be reduced to palladium metal in $CHCl_3$. Whilst reports exist of BF_3 extraction in palladium phosphine systems (16), it is notable that the reaction of $PdCl_2(PPh_2vinyl)_2$ with $AgBF_4$ results in palladium reduction to the phosphallyl complex $[Pd(\eta^1\text{-}PPh_2vinyl)(\eta^3\text{-}PPh_2vinyl)]_2[BF_4]_2$ (17) (Scheme 1).

The reactivity of $PdI_2(PPh_2vinyl)_2$ with $Et_2O{\cdot}BF_3$ differs markedly from that of the chloride analogue. Under identical conditions halide abstraction does not occur. The majority of the complex is recovered unchanged, with the remaining material undergoing phosphine abstraction to *sym*-$[PdI_2(PPh_2vinyl)]_2$. Abstraction occurs by virtue of the Lewis acid–base interaction with BF_3; a reaction that is confirmed by the observation of a comparable $^{31}P\{^1H\}$ NMR resonance from binary phosphine–BF_3 mixtures. The latter adduct is air sensitive, being hydrolyzed and oxidized in air to $Ph_2P(O)$vinyl. Separation and characterization of $PdI_2(PPh_2vinyl)_2$, $Ph_2P(O)$vinyl, and *sym*-$[PdI_2(PPh_2vinyl)]_2$ are thus accomplished by similar methods to those employed in UV initiated reaction studies.

The respective centrosymmetric and distorted square planar structures that have been crystallographically observed for *trans*-$PdCl_2(PPh_2vinyl)_2$ and *trans*-$PdI_2(PPh_2vinyl)_2$ have been confirmed using CP/MAS NMR spectroscopy. The latter technique, in conjunction with solution NMR spectroscopy, indicates that UV irradiation of $PdCl_2(PPh_2vinyl)_2$ affords *cis* and *trans*- $PdCl_2(PPh_2vinyl)_2$. Similar treatment of $PdI_2(PPh_2vinyl)_2$ results in phosphine dissociation and the formation of *sym*-$[PdI_2(PPh_2vinyl)]_2$. $PdCl_2(PPh_2vinyl)_2$ reacts in the presence of the Lewis acid $Et_2O{\cdot}BF_3$ to yield $[Pd(\mu\text{-}Cl)(PPh_2vinyl)_2]_2[BF_4]_2$, whilst the corresponding iodide again undergoes phosphine dissociation forming *sym*-$[PdI_2(PPh_2vinyl)]_2$. Although UV irradiation and Lewis acids have been reported to initiate vinyl phosphine polymerization, no evidence suggesting such reactivity is recorded in the present study.

Experimental

Crystallographic characterization

Data collection and structure solution for *trans*-$PdCl_2(PPh_2vinyl)_2$, *trans*-$PdI_2(PPh_2vinyl)_2$, and $[Pd(\mu\text{-}Cl)(PPh_2vinyl)_2]_2[BF_4]_2$ were performed using published methods (18), Table 4.[4]

[4] Complete X-ray data have been deposited as supplementary material and may be purchased from the Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, ON K1A 0S2. Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre (CCDC Nos. 134114, 134115, and 136137, respectively). Copies of the data can be obtained, free of charge, on application to the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. (Fax: 44-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk).

Synthesis and spectroscopy

Solvents were dried and distilled under nitrogen by conventional methods (19). Palladium chloride, diphenylvinylphosphine, and Oxone® (potassium peroxymonosulfate, $2KHSO_5{\cdot}KHSO_4{\cdot}K_2SO_4$) were obtained from Aldrich and used as received. $Pd(PhCN)_2Cl_2$ was prepared by published methods (20). Solution NMR were recorded in $CDCl_3$ at 270.1, 67.9, 81.0 MHz for ^1H, $^{13}C\{^1H\}$, and $^{31}P\{^1H\}$, respectively, using a JEOL GSX-270 spectrometer. CP/MAS $^{31}P\{^1H\}$ NMR was recorded using a 7mm bore Varian UNITYplus spectrometer at 121 MHz. Acquisition parameters were; spectral width 100 kHz, relaxation delay 20.0 s, spin-rate 4500 Hz.

$PdCl_2(PPh_2vinyl)_2$: The complex was prepared on a 5 g scale using published methods; typical yields of 79–88% being obtained. Elemental analysis for $C_{28}H_{26}Cl_2P_2Pd$, expected: C 55.9, H 4.4; found: C 56.1, H 4.4. ^1H and $^{31}P\{^1H\}$ NMR spectra were recorded and found to correspond to published data (9).

$PdI_2(PPh_2vinyl)_2$: The complex was prepared by halide metathesis of $PdCl_2(PPh_2vinyl)_2$. Thus, $PdCl_2(PPh_2vinyl)_2$ (4.05 g; 6.8 mmol) was dissolved in CH_2Cl_2 (25 cm^3) and stirred with 10 cm^3 aqueous saturated NaI. After 0.5 h the aqueous solution was separated. The process was repeated with two further portions of aq. NaI. Finally the organic layer was separated and $PdI_2(PPh_2vinyl)_2$ precipitated by the addition of Et_2O. Yield (4.85 g, 91%). Elemental analysis for $C_{28}H_{26}I_2P_2Pd$, expected: C 42.8, H 3.3; found: C 42.8, H 3.3. ^1H and $^{31}P\{^1H\}$ NMR spectra were recorded and correspond to published data (9).

UV irradiation

The following is typical of the treatment of chloro- and iodo- complexes. $PdCl_2(PPh_2vinyl)_2$ (0.70 g; 1.16 mmol) was dissolved in 10 cm^3 of dry CH_2Cl_2. The solution was placed in a ca. 5 cm diameter petri dish, and exposed to UV radiation (λ ≥ 200 nm, 200 W) for 2 min. Remaining solvent was decanted from the precipitated material and the solid dried in vacuo. Yield 0.65 g (93% wt/wt).

BF_3 reactivity

The following is typical of the treatment of chloro- and iodo- complexes. $PdCl_2(PPh_2vinyl)_2$ (0.087 g; 0.14 mmol) was dissolved in 10cm^3 of dry CH_2Cl_2 under nitrogen. The addition of 100 μL $Et_2O{\cdot}BF_3$ (0.79 mmol) produced no visual change. The solution was stirred for ca. 12 h and concentrated to dryness before further study. Yield 0.67 g (96% wt/wt).

$Ph_2P(O)vinyl$: PPh_2vinyl (1.08 g; 5.1 mmol) was dissolved in CH_2Cl_2 (25 cm^3) and slurried with Oxone® for 1 d, after which the solution was filtered and concentrated to dryness affording $Ph_2P(O)vinyl$ in quantitative yield. Elemental analysis for $C_{14}H_{13}OP$, expected: C 64.5, H 5.7; found: C 64.7, H 6.0. NMR (see Table 3). IR (KBr); ν(O=P) 1148 cm^{-1}; MS (EI) *m*/*e* = 228 (100%).

© 2000 NRC Canada

[$PdI_2(PPh_2vinyl)]_2$: Complex was formed in ca. 5% yield along with $Ph_2P(O)$vinyl by the irradiation of $PdI_2(PPh_2vinyl)_2$. A ca. 12% yield, along with $F_3B{\cdot}PPh_2$vinyl, was observed from the reaction of $PdI_2(PPh_2vinyl)_2$ and $Et_2O{\cdot}BF_3$. In the latter reaction $F_3B{\cdot}PPh_2$vinyl was identified by comparison with $^{31}P\{^1H\}$ NMR data obtained from binary $Et_2O{\cdot}BF_3$ and PPh_2vinyl solutions (δ = 1.7 ppm, $CDCl_3$), and undergoes hydrolysis and oxidation in air to $Ph_2P(O)$vinyl. *sym*-$[PdI_2(PPh_2vinyl)]_2$ was readily separated from $Ph_2P(O)$vinyl by hexane extraction of the latter. The complex was then recrystallized from CH_2Cl_2–Et_2O from which this comparatively insoluble complex preferentially precipitates. Manual separation from traces of the visually distinct $PdI_2(PPh_2vinyl)_2$ affords spectroscopically and analytically pure *sym*-$[PdI_2(PPh_2vinyl)]_2{\cdot}Et_2O$. Elemental analysis for $C_{28}H_{26}I_4P_2Pd_2{\cdot}Et_2O$, expected: C 31.5, H 3.0; found: C 31.4, H 2.7. ^1H (for proton notation see Table 3) δ = 5.58 (H_b dd $^3J(PH)$ = 20.7 Hz, $^3J(H_aH_c)$ = 18.2 Hz, 2H, H_c), 6.10 (H_c dd $^3J(PH)$ = 42.4 Hz, $^3J(H_aH_b)$ = 12.0 Hz, 2H, H_b), 7.10 (H_a ddd $^2J(PH)$ = 24.1 Hz, $^3J(H_aH_c)$ = 18.2 Hz, $^3J(H_aH_b)$ = 12.0 Hz, 2H, H_a), 7.36–7.75 (m, 20H, Ph). $^{31}P\{^1H\}$ δ = 26.9.

[Pd(μ-Cl)($PPh_2vinyl)_2]_2[BF_4]_2$: Product formed by the method outlined above was crystallized from dichloromethane–diethylether to afford an orange microcrystalline solid. There is evidence of decomposition in air and over several hours in chloroform to afford palladium metal. However, the complex is sufficiently stable in $CDCl_3$ to obtain NMR spectra. Elemental analysis for $C_{28}H_{26}BClF_4PPd{\cdot}CH_2Cl_2$, expected: C 47.1, H 3.8; found: C 47.3, H 3.6. ^1H (for proton notation see Table 3) δ = 5.70 (H_b t, br), 6.06 (H_c t, br), 6.22 (H_a m, br), 7.38–7.58 (m, 20H, Ph). $^{31}P\{^1H\}$–$^{31}P\{^1H\}$ δ = 28.6.

Syntheses of 4-[1-(2-deoxy-β-D-ribofuranosyl)]-derivatives of 2-substituted-5-fluoroaniline: "cytosine replacement" analogs of deoxycytidine for evaluation as anticancer and antihuman immunodeficiency virus (anti-HIV) agents

Zhi-Xian Wang, Leonard I. Wiebe, Erik De Clercq, Jan Balzarini, and Edward E. Knaus

Abstract: A group of 4-[1-(2-deoxy-β-D-ribofuranosyl)]-derivatives of 5-fluoroaniline possessing a variety of aryl C-2 substituents (**6a** R = H, **6b** R = F, **6c** R = Me) were synthesized. Accordingly, a Heck-type coupling reaction of the 4-iodoaniline derivatives (**13a**–**c**) with the bis(*tert*-butyldimethylsilyl)glycal (**11**) in the presence of $Pd(OAc)_2$ and Ph_3As, followed by removal of the *tert*-butyldimethylsilyl protection groups using *n*-$Bu_4N^+F^-$, yielded the corresponding 4-(β-D-glycero-pentofuran-3-ulos-1-yl)aniline derivatives (**14a**–**c**) having a C-3 C=O in the sugar ring. Reduction of the C-3 C=O compounds (**14a**–**c**) using $NaB(OAc)_3H$ afforded the target 4-[1-(2-deoxy-β-D-ribofuranosyl)]-derivatives of the respective 2-substituted-5-fluoroaniline (**6a**–**c**). The deoxycytidine mimic, 3-fluoro-4-[1-(2-deoxy-β-D-ribofuranosyl)]aniline (**6a**), in which the cytosine ring of deoxycytidine is replaced by a 4-(3-fluoroaniline) ring system, was inactive as an anticancer agent against a variety of tumor cell lines, and as an antihuman immunodeficiency virus (HIV-1, HIV-2) agent. The failure of this unnatural deoxycytidine mimic (**6a**) to exhibit anticancer–antiviral activity may be due to its inability to undergo phosphorylation by host cell- and virus-induced kinases.

Key words: fluoroanilines, deoxycytidine mimics, anticancer–antihuman immunodeficiency virus (HIV) evaluation.

Résumé : On a synthétisé une série de dérivés 4-[1-(2-désoxy-β-D-ribofuranosyl)]- de la 5-fluoroaniline portant divers substituants en position C-2 du groupe aryle (**6a** R = H, **6b** R = F, **6c** R = Me). À cette fin, on a effectué une réaction de couplage de type Heck des dérivés 4-iodoaniline (**13a**–**c**) avec le bis(*tert*-butyldiméthylsilyl)glycal (**11**) en présence de $Pd(OAc)_2$ et de Ph_3As, suivie de l'élimination des groupes protecteurs *tert*-butyldiméthylsilyle à l'aide de $Bu_4N^+F^-$, conduit aux dérivés 4-(β-D-glycéro-pentofuran-3-ulos-1-yl)anilines correspondants (**14a**–**c**) comportant un C=O en position C-3. La réduction de ces composés carbonylés en C-3 (**14a**–**c**) à l'aide de $NaB(OAc)_3H$ conduit aux dérivés 4-[1-(2-désoxy-β-D-ribofuranosyl)]- recherchés des 5-fluoroanilines substituées en position C-2 (**6a**–**c**). La 3-fluoro-4-[1-(2-désoxy-β-D-ribofuranosyl)]aniline (**6a**) qui est une imitation de la désoxycytidine dans laquelle le cycle cytosine de la désoxycytidine a été remplacé par un système cyclique 4-(3-fluoroaniline) est inactive comme agent anticancéreux contre un grand nombre de familles de cellules tumorales ainsi que contre le virus d'immunodéficience humaine (HIV-1 et HIV-2). Ce manque d'activité anticancéreuse–antivirale de cette imitation non naturelle de la désoxycytidine (**6a**) peut découler de son inaptitude à subir une phosphorylation les kinases de la cellule réceptrice et celles induites par le virus.

Mots clés : fluoroanilines, imitation de la désoxycytidine, évaluation comme anticancéreux–antivirus de l'immunodéficience humaine.

Introduction

Modified nucleosides often exert important biological activities (for a review see ref. (1)), and when incorporated into nucleic acids by normal enzymatic processes, can further alter the structure and (or) function of these biopolymers. In this respect, a number of C-nucleosides have been shown to exhibit anticancer and antiviral activities, presumably due to their structural resemblance to natural *N*-nucleosides (2). Nonpolar hydrophobic isosteres of pyrimidine nucleosides which retain the closest possible structural, steric, and isoelectronic relationships to the natural base that

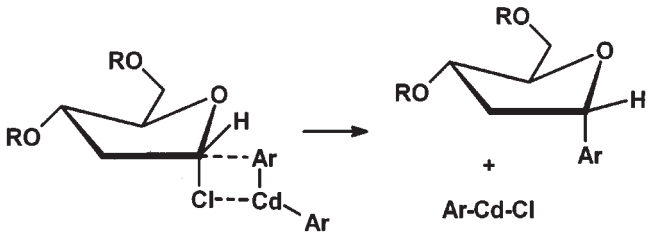
Fig. 1. The structures of the thymidine mimic (**1**), thymidine (**2**), 2′-deoxycytidine (**3**), 5-fluoro-2′-deoxycytidine (**4**), the deletion-modified 2′-deoxycytidine mimic (**5**), and the proposed cytosine replacement 2′-deoxycytidine mimics (**6a**–**c**).



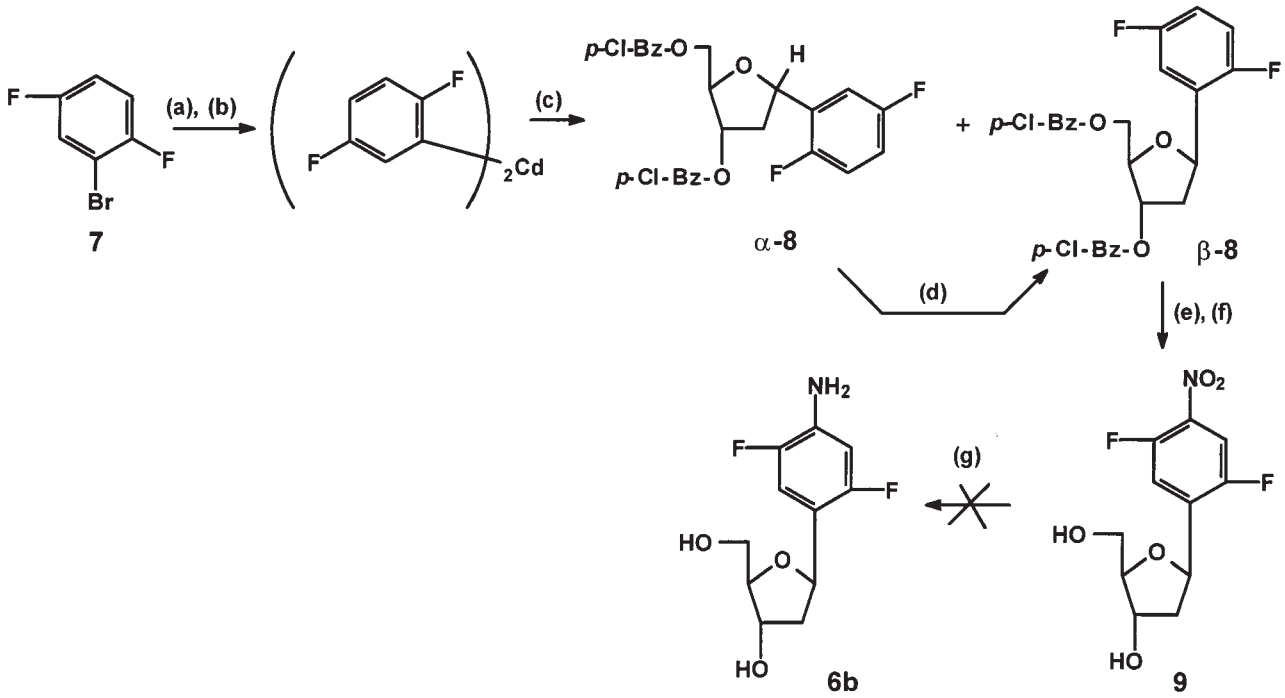
are not likely to form hydrogen bonds were recently designed by Kool and co-worker (3). Thus, the 2,4-difluoro-5-methylphenyl isostere (**1**) was designed as an unnatural mimic of thymidine (**2**). The 5′-triphosphate of **1** (**1**-TP) was inserted into replicating DNA strands by the Klenow fragment (KF, *exo*$^-$ mutant) of *E. coli* DNA polymerase 1 (4). Steady-state measurements indicated that **1**-TP was inserted opposite adenine (A) with an efficacy (V_{max}/K_m) only 40-fold lower than the triphosphate of thymidine (dTTP). Furthermore, it was inserted opposite A, relative to C, G, or T, with a selectivity nearly as high as that for dTTP. Therefore, the 2,4-difluoro-5-methylphenyl moiety of **1** is a shape mimic handled by KF polymerase similar to the natural thymine base which it replaces (5–7).

2′-Deoxycytidine (**3**) and 5-fluoro-2′-deoxycytidine (**4**) have been the subject of numerous chemical and pharmacological studies due to the inherent anticancer and antiviral activities exhibited by 5-fluoro-2′-deoxycytidine (8). Hsieh and McLaughlin (9) reported that the 5-(2-aminopyridyl) "deletion-modified" analog **5** of deoxycytidine (dC) may function as a dC mimic which would provide information regarding the role of the O^2-carbonyl in a variety of recognition and enzymatic processes. Although **5** has the potential to exhibit anticancer or antiviral properties, no biological activities were reported. It was therefore anticipated that structurally related 4-(2-substituted-5-fluoroaniline) nucleoside mimics (**6a**–**c**), which are hybrids of the C-aryl (**1**), C-pyridyl (**5**), and deoxycytidine (**3**–**4**) nucleosides, may be cytotoxic to rapidly multiplying cancer cells (inhibit tumor cell growth) and (or) act as antiviral agents due to their selective phosphorylation in virus-infected cells (10). We now report the synthesis, antiviral and anticancer activities for a group of 4-[1-(2-deoxy-β-D-ribofuranosyl)]- derivatives of 2-substituted-5-fluoroanilines (**6a**–**c**) that were designed as unnatural C-aryl deoxycytidine mimics.

Chemistry

A number of methodologies have been reported for the synthesis of 2′-deoxy-ribo-C-nucleosides (11). Synthesis of the thymidine mimic (**1**), and some related analogs, have been performed by reaction of an arylcadmium reagent with the well known Hoffer (12) α-chlorosugar synthon [2-deoxy-3,5-di-*O*-(*p*-toluoyl)-α-D-ribofuranosyl chloride] by Kool and co-workers (13–15). The resulting α-nucleoside mimic 3′,5′-di-*O*-toluoyl ester was then epimerized (α-epimer → β-epimer) using benzenesulfonic acid in xylene at reflux temperature to afford the desired β-anomeric product.

Fig. 2. Four-center transition state leading to the formation of the α-**8** anomer.



Hoffer's (12) original procedure for the preparation of 2-deoxy-3,5-di-*O*-(*p*-toluoyl)-α-D-ribofuranosyl chloride requires delicate and tedious handling of anhydrous HCl gas. We, and others (a 35% yield was obtained, see ref. (16*a*); for a modified method to prepare the Hoffer α-chlorosugar synthon see ref. (16*b*)), have experienced difficulties in obtaining acceptable yields using this method. Accordingly, 2-deoxy-3,5-di-*O*-(*p*-chlorobenzoyl)-α-D-ribofuranosyl chloride was used in place of the Hoffer α-chlorosugar synthon since it is more stable and readily crystallizes from the solvent. The coupling of 2-deoxy-3,5-di-*O*-(*p*-chlorobenzoyl)-α-D-ribofuranosyl chloride with the organocadmium reagent, generated by reaction of the Grignard reagent with $CdCl_2$, afforded a mixture of α-**8** and β-**8** anomers with an α:β ratio of 7.3 that could be separated by silica gel flash chromatography. The major isomer was formed with retention of configuration to produce the α-anomeric C-nucleoside (α-**8**) (Scheme 1). The predominant formation of the α-**8** anomer may be the result of a four-center transition state at C-1 of the chlorosugar (Fig. 2), as proposed by Hurd and Miles (17) for reactions involving related pyranose systems with Grignard reagents, or by a dissociative mechanism involving predominant α-face attack (18). The configuration at the C-1′carbon of α-**8** and β-**8** was determined from ^{1}H NMR analysis of the $H_{1'}$—$H_{2'}$ coupling constants and comparison to ^{1}H NMR spectral data reported by Kool and co-workers (13–15).

Based on the premise that α-anomer → β-anomer epimerization reactions may involve an acid-catalyzed reversible ring opening at the C-1 position of the sugar ring, we found that α-**8** could be epimerized in the presence of

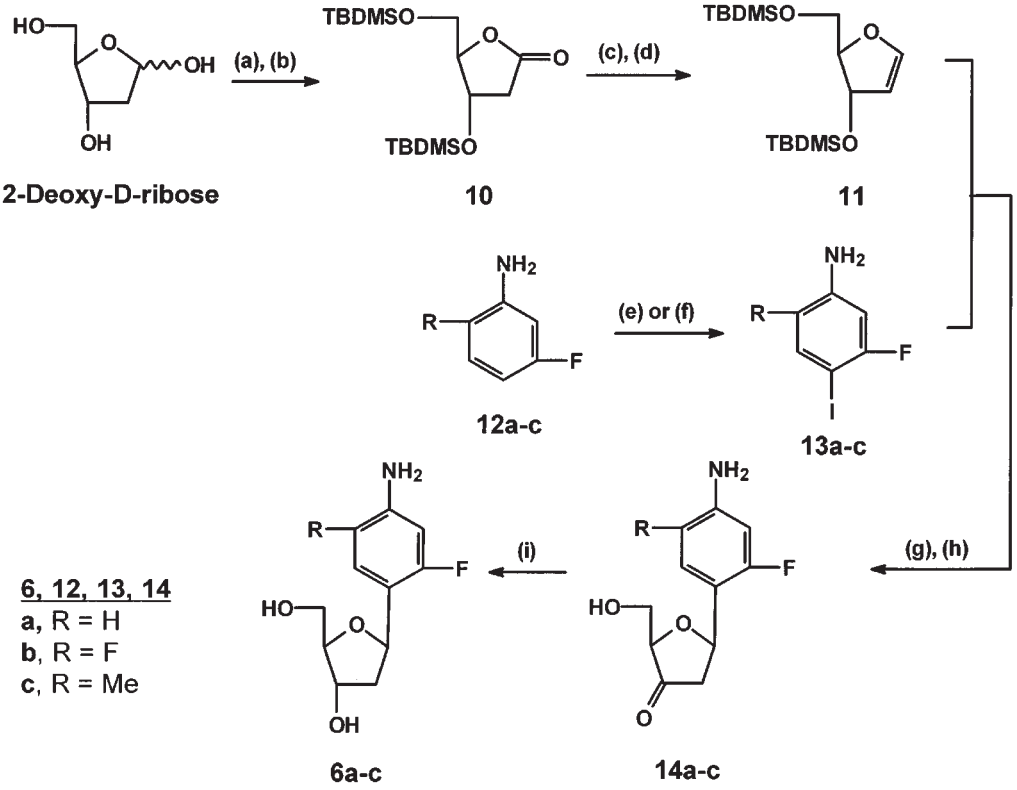
Scheme 1. Reagents and conditions: (*a*) THF, Mg, I_2 catalyst, 40°C, 1 h; (*b*) $CdCl_2$, reflux, 1 h; (*c*) 2-deoxy-3,5-di-*O*-(*p*-chlorobenzoyl)-α-D-ribofuranosyl chloride, 25°C, 12 h; (*d*) $EtNO_2$, BF_3–Et_2O, 110–120°C, 2 h; (*e*) NH_4NO_3, $(CF_3CO)_2O$, 25°C, 30 min; (*f*) 2 N NaOH, THF, 25°C, 6 h; (*g*) 10% Pd-C, EtOH, H_2 gas.

$BF_3 \cdot Et_2O$ in nitroethane at 110–120°C during 2 h to afford a mixture of the α-**8** and β-**8** anomers with an α:β ratio of 3.3. Nitration of the β-anomer (β-**8**) with NH_4NO_3 in $(CF_3CO)_2O$ afforded the 4-nitro derivative (65%), which, on deprotection with NaOH in THF, yielded β-**9** (91%). However, hydrogenation of the 4-nitro compound (β-**9**), using 10% Pd-C and hydrogen gas, produced a complex mixture of products containing only a trace amount of the desired amino derivative (**6b**). Therefore, an alternative method for the synthesis of the deoxycytidine mimics (**6a**–**c**) was developed.

The Heck-type coupling reaction is a simple, but direct, method to form the C—C bond between a suitably protected glycal and an activated iodo- or trifluoromethanesulfonate-substituted heterocycle, to prepare the β-anomer of C-nucleosides in reasonable yields (9, 19). It was expected that the highly activated *p*-iodoanilines (**13a**–**c**) used in this study would undergo efficient coupling using the sequence of reactions illustrated in Scheme 2. The protected bis(*tert*-butyldimethylsilyl)ether ribofuranoid glycal **11** was readily prepared by known procedures (20). Accordingly, oxidation of 2-deoxy-D-ribose using bromine water followed by lactonization afforded 2-deoxy-D-ribonolactone (21). The crude lactone was treated immediately with *tert*-butyldimethylsilyl chloride in the presence of imidazole to give **10** in 80% yield from 2-deoxy-D-ribose. Reduction of the lactone **10** using diisobutylaluminum hydride (DIBAL-H) at –78°C gave the requisite 2-deoxy-D-pentofuranose derivative, which was sufficiently pure for direct mesylation in the presence of triethylamine in CH_2Cl_2 at –78°C. The intermediate mesylate was not isolated since the elimination reaction occurred readily at reflux temperature during 15 h to afford the glycal **11** in 82% yield after flash chromatography purification.



The *p*-iodoaniline derivatives (**13a**–**c**) were synthesized using two different methods. *m*-Fluoroaniline (**12a**) was treated with iodine and sodium periodate in the presence of H_2SO_4 in acetic acid to afford **13a** (Method A) (9). Compounds **13b**–**c** were prepared in good yield via treatment of **12b**–**c** with *N*-iodosuccinimide in trifluoroacetic acid using a method developed by Olah and co-workers (22) (Method B). Direct coupling of *p*-iodoanilines (**13a**–**c**) with the glycal (**11**) was carried out using palladium (II) acetate, triphenylarsine, and triethylamine in dry acetonitrile at 60–70°C (6 h). It was observed that the initially formed 3-silyl enol ether adduct was unstable under these weakly basic reaction conditions, and that a prolonged reaction time resulted in the formation of the 3-keto derivative. Therefore, the reaction mixture was treated with an excess of tetra-*n*-butylammonium fluoride (TBAF) to perform complete desilylation, which afforded the hydroxy ketone derivatives (**14a**–**c**) in 31–39% isolated yields. This procedure provided compounds **14a**–**c** having the β-configuration, since the α-product was produced in only trace amounts allowing its facile removal via simple recrystallization. Reduction of the hydroxy ketones (**14a**–**c**) with $NaB(OAc)_3H$ (6h) in CH_3CN selectively produced the target deoxycytidine C-nucleoside mimics (**6a**–**c**) in 52–75% isolated yields.

Biological evaluation of 4-[1-(2-deoxy-β-D-ribofuranosyl)]- derivatives of 2-substituted-5-fluoroaniline as anticancer and antihuman immunodeficiency virus (anti-HIV) agents

Replacement of the natural cytosine base moiety in deoxycytidine (**3**), or 5-fluorodeoxycytidine (**4**), by an unnatural aryl isostere such as a 2-substituted-5-fluoroaniline ring system attracted our attention since it could confer new

properties that may be useful in the design of a novel class of third generation C-aryl deoxycytidine mimics (**6**) for use as anticancer and (or) antiviral agents. C-aryl nucleoside mimics offer a number of potential advantages relative to classical 5-substituted-2′-deoxyuridines. In this respect, increased stability to pyrimidine phosphorylases (no glycosidic bond) would not require the presence of a 2′-ribo-F (23), or 2′-arabino-OH (24), substituent to provide in vivo stability. Compounds of this type may elicit decreased host cell toxicity due to their inability to inhibit thymidylate synthase, and they maybe resistant to deamination by deoxycytidine deaminase (10). Finally, their greater lipophilicity may alter tissue biodistribution, particularly to treat brain viral infections and brain tumors due to an enhanced ability to cross the blood-brain-barrier (BBB). This latter advantage offers an attractive alternative to making lipophilic prodrugs of nucleosides (25).

The ability of the 2-fluoro-4-aminophenyl compound having a C-3 C=O group in the sugar ring (**14a**), and the 2-fluoro-4-aminophenyl deoxycytidine mimic (**6a**), to inhibit the proliferation of murine leukemia cells (L1210/0), murine mammary carcinoma cells (FM3A/0), and human T-lymphocytes cells (Molt4/C8, CEM/O) in cell cultures by 50% (IC_{50} ± SEM) were evaluated using a previously reported procedure (26). In these assays, **6a** and **14a** provided negligible inhibition of L1210/0 proliferation (IC_{50} = 222 ± 219 μM (**6a**), IC_{50} = 478 ± 31 μM (**14a**)). Both **6a** and **14a** were inactive (IC_{50} > 500 μM) inhibitors of FM3A/0, Molt4/C8, and CEM/0 cell proliferation. In addition, **6a** and **14a** did not protect (IC_{50} > 250 μM) human T-lymphocytes (CEM cells) against the cytopathogenicity induced by human immunodeficiency viruses (HIV-1, HIV-2) (27).

The reason(s) why this novel class of deoxycytidine mimics (**6**) lack anticancer and (or) antiviral activity has not been elucidated. In the event that the failure of these compounds to undergo phosphorylation to the 5′-monophosphate is responsible for the lack of anticancer and (or) anti-HIV activities observed, it is possible that 5′-cycloSal-pronucleotide derivatives of **6** and **14** according to the kinase-bypass concept (28, 29) may result in the transformation of these inactive unnatural deoxycytidine mimics to a class of effective anticancer and (or) antiviral agents.

Experimental

Melting points were determined with a Thomas Hoover capillary apparatus and are uncorrected. Nuclear magnetic resonance spectra (^1H NMR, ^{13}C NMR, ^{19}F NMR) were measured on a Bruker AM-300 spectrometer. The assignment of exchangeable protons (O*H*) was confirmed by the addition of D_2O. Proton chemical shifts (δ) are given relative to internal TMS (δ 0). ^{13}C NMR spectra were acquired using the *J* modulated spin echo technique where methyl and methine carbon resonances appear as positive peaks and

© 2000 NRC Canada

methylene and quaternary carbons appear as negative peaks, and carbon chemical shifts (δ) are given relative to $CDCl_3$ (δ 77), or DMSO-d_6 (δ 39.5). Fluorine chemical shifts (δ) are given relative to external C_6F_6 (δ 0). The "prime numbers" in the ^{1}H NMR spectral data refer to the protons in the sugar ring system. Infrared spectra were recorded on a Nicolet Magna 550 IR spectrometer using air as the reference. Elemental analyses were performed by the MicroAnalysis Service Laboratory, Department of Chemistry, University of Alberta. Silica gel 60 (E. Merck Co.) was employed for all silica gel column flash chromatography separations. All reagents were purchased from the Aldrich Chemical Co.

2,5-Difluoro-1-[1-[2-deoxy-3,5-di-*O*-(*p*-chlorobenzoyl)-α-D-ribofuranosyl]]benzene (α-8) and 2,5-Difluoro-1-[1-[2-deoxy-3,5-di-*O*-(*p*-chlorobenzoyl)-β-D-ribofuranosyl]]benzene (β-8)

1-Bromo-2,5-difluorobenzene (**7**, 3.9 g, 20 mmol) was added drop wise with stirring to a mixture of Mg turnings (0.48 g, 20 mmol) and one crystal of iodine in dry THF (30 mL) under argon. This mixture was stirred at 40°C for 1 h, at which time formation of the Grignard reagent was complete, and a pale brown solution was obtained. Powdered $CdCl_2$ (1.84 g, 10 mmol) (dried in vacuo at 130°C for 2 h) was added, and the mixture was stirred at reflux temperature for 1 h. After cooling to 25°C, 2-deoxy-3,5-di-*O*-(*p*-chlorobenzoyl)-α-D-ribofuranosyl chloride (4.29 g, 10 mmol) was added in aliquots during 1 h, and the reaction mixture was stirred at 25°C for 12 h. The reaction was quenched with saturated aqueous NH_4Cl, and extracted with ether (3 × 20 mL). The combined organic extracts were washed with water, and brine, prior to drying (Na_2SO_4). After filtration, and removal of the solvent in vacuo, the residue obtained was purified via flash chromatography (hexane–ethyl acetate, 17.5:1, v/v) to afford β-**8** (0.32 g, 6.1% yield) and α-**8** (2.57 g, 51% yield).

$BF_3{\cdot}Et_2O$ (1.2 mL) was added to a solution of the α-**8** (1.2 g, 2.35 mmol) in nitroethane (12 mL) under argon, and the resulting solution was stirred at 110–120°C under argon for 2 h. After cooling to 25°C, the reaction mixture was poured onto cold water (20 mL), neutralized with saturated aqueous $NaHCO_3$, and extracted with ether (3 × 20 mL). The combined organic extracts were washed with water, and brine, prior to drying (Na_2SO_4). After filtration, and removal of the solvent in vacuo, the residue obtained was purified via flash chromatography (hexane–ethyl acetate, 17.5:1, v/v) to give the β-**8** anomer (0.226 g, 19%) as a colorless syrup, and the α-**8** anomer (0.75 g, 62%) as white crystals.

α-Anomer (α-8)

White crystals (recrystallized from hexane), mp 119–120°C. ^{1}H NMR ($CDCl_3$) δ: 8.06, 7.73, 7.48 and 7.39 (d, *J* = 8.5 Hz, 2H each), 7.37 (m, 1H), 7.1–6.9 (m, 2H), 5.65 (ddd, *J* = 6.4, 3.4, 2.1 Hz, 1H, H-3′), 5.60 (dd, *J* = 7.9, 4.9 Hz, 1H, H-1′), 4.78 (td, *J* = 5.2, 2.1 Hz, 1H, H-4′), 4.64 (dd, *J* = 11.7, 5.2 Hz, 1H, H-5′a), 4.58 (dd, *J* = 11.7, 5.2 Hz, 1H, H-5′b), 3.02 (ddd, *J* = 14.0, 7.9, 6.4 Hz, 1H, H-2′α), 2.35 (br d, *J* = 14.0 Hz, 1H, H-2′β). ^{13}C NMR ($CDCl_3$) δ: 165.72, 165.27, 159.32 (d, *J* = 241.7 Hz), 155.62 (dd, *J* = 241.7, 2.2 Hz), 140.30, 140.16, 132.42 (dd, *J* = 15.4, 7.7 Hz), 131.41, 131.28, 129.24, 129.14, 128.55, 128.19, 116.76 (dd, *J* = 24.2, 8.8 Hz), 115.37 (dd, *J* = 25.3, 8.8 Hz), 113.97 (dd, *J* = 25.3, 4.4 Hz), 82.85, 76.87, 75.30, 65.06, 39.58. ^{19}F NMR ($CDCl_3$) δ: 43.21 (m), 37.70 (m).

β-Anomer (β-8)

Colorless syrup. ^{1}H NMR ($CDCl_3$) δ: 8.06, 8.01, 7.50 and 7.43 (d, *J* = 8.5 Hz, 2H each), 7.31 (m, 1H), 7.1–6.9 (m, 2H), 5.64 (br d, *J* = 6.1 Hz, 1H, H-3′), 5.49 (dd, *J* = 10.7, 5.5 Hz, 1H, H-1′), 4.75 (dd, *J* = 11.7, 4.3 Hz, 1H, H-5′a), 4.69 (dd, *J* = 11.7, 3.7 Hz, 1H, H-5′b), 4.58 (ddd, *J* = 4.3, 3.7, 2.1 Hz, 1H, H-4′), 2.73 (br d, *J* = 13.7, 5.5 Hz, 1H, H-2′α), 2.17 (ddd, *J* = 13.7, 10.7, 6.1 Hz, 1H, H-2′β). ^{13}C NMR ($CDCl_3$) δ: 165.26, 165.07, 158.90 (dd, *J* = 241.7, 2.2 Hz), 155.44 (dd, *J* = 241.7, 2.2 Hz), 139.94, 139.34, 131.03, 130.94, 129.97 (dd, *J* = 16.5, 7.7 Hz), 128.83, 128.76, 128.13, 127.96, 116.24 (dd, *J* = 24.2, 8.8 Hz), 115.27 (dd, *J* = 24.2, 8.8 Hz), 113.36 (dd, *J* = 26.4, 4.4 Hz), 82.72, 77.24, 74.67, 64.65, 39.98. ^{19}F NMR ($CDCl_3$) δ: 43.89 (m), 36.96 (m).

2,5-Difluoro-4-nitro-1-[1-(2-deoxy-β-D-ribofuranosyl)]benzene (9)

Powdered NH_4NO_3 (0.32 g, 5 mmol) was added in aliquots to a solution of β-**8** (0.6 g, 1.18 mmol) in dry CH_2Cl_2 (5 mL) and trifluoroacetic anhydride (5 mL), and the reaction mixture was stirred at 25°C for 30 min. The resulting yellow solution was poured onto cold water, neutralized with $NaHCO_3$, and extracted with CH_2Cl_2 (3 × 30 mL). The combined organic extracts were washed with water, and brine, prior to drying (Na_2SO_4). Removal of the solvent in vacuo gave a residue that was purified via flash chromatography (hexane–ethyl acetate, 10:1 v/v) to give a yellow syrup (0.5 g), which was recrystallized from hexane–ether to give yellow crystals (0.42 g, 65%), mp 112–113°C. ^{1}H NMR ($CDCl_3$) δ: 8.04 (d, *J* = 8.8 Hz, 2H), 7.97 (d, *J* = 8.8 Hz, 2H), 7.80 (dd, *J* = 9.2, 5.8 Hz, 1H), 7.56 (dd, *J* = 11.0, 5.8 Hz, 1H), 7.48 (d, *J* = 8.8 Hz, 2H), 7.42 (d, *J* = 8.8 Hz, 2H), 5.64 (d, *J* = 6.1 Hz, 1H, H-3′), 5.47 (dd, *J* = 10.7, 5.2 Hz, 1H, H-1′), 4.79 (dd, *J* = 11.6, 4.0 Hz, 1H, H-5′a), 4.66 (dd, *J* = 11.6, 4.0 Hz, 1H, H-5′b), 4.60 (m, 1H, H-4′), 2.80 (dd, *J* = 14.0, 5.2 Hz, 1H, H-2′α), 2.11 (ddd, *J* = 14.0, 10.7, 6.1 Hz, 1H, H-2′β). ^{13}C NMR ($CDCl_3$) δ: 165.09, 164.93, 153.71 (dd, *J* = 247.2, 2.2 Hz), 151.93 (dd, *J* = 261.5, 2.2 Hz), 140.05, 139.79, 137.39 (dd, *J* = 16.5, 7.1 Hz), 135.99 (t, *J* = 8.8 Hz), 130.95, 130.77, 128.78, 127.88, 127.67, 116.48 (dd, *J* = 25.3, 4.4 Hz), 112.77 (dd, *J* = 28.6, 2.2 Hz), 83.08, 76.82, 74.15, 64.25, 39.69. ^{19}F NMR ($CDCl_3$) δ: 41.85 (m), 41.06 (m). Anal. calcd. for $C_{25}H_{17}Cl_2F_2O_7N$: C 54.37, H 3.10, N 2.54; found: C 54.09, H 3.11, N 2.54.

Aqueous NaOH (2 mL of 2 N, 4 mmol) was added to a solution of the product obtained above (0.33 g, 0.6 mmol) in THF (10 mL). After stirring at 25°C for 6 h, the reaction was quenched with solid NH_4Cl, and the solvent was removed in vacuo. The residue obtained was extracted with acetone (10 mL), filtered, and the solid was washed with acetone. Removal of the solvent from the filtrate gave a residue that was purified via flash chromatography (hexane–ethyl acetate, 1:2 – 1:5 v/v) to give a yellow solid, which was recrystallized from hexane–ether to afford **9** (0.151 g, 91%) as pale yellow crystals, mp 177–179°C. ^{1}H NMR

3,5-Bis(*tert*-butyldimethylsilyl)-2-deoxy-D-ribonolactone (10)

Bromine (20 mL) was added to a solution of 2-deoxy-D-ribose (10 g, 74.4 mmol) in water (60 mL), and the brown solution was stirred at 25°C for five days. The excess bromine was extracted with ether, and treated with a saturated solution of NaOH. The solvent from the aqueous fraction was evaporated to give a pale brown syrup, which was heated at 75°C under reduced pressure (30 mmHg) for 4 h. Toluene (100 mL) was added, and the solvent was repeatedly evaporated after each addition of toluene. Methylene chloride (100 mL), and then imidazole (14 g, 206 mmol), were added at 0°C to the syrup obtained above. After stirring at 0°C for 30 min, the reaction mixture turned to a clear solution, to which *tert*-butyldimethylsilyl chloride (23 g, 153 mmol) was added. After stirring at 25°C overnight, the reaction mixture was diluted with ether (200 mL), and the solid was removed by filtration. Removal of the solvent from the filtrate gave a residue that was purified using a short silica gel column (hexane–ether, 10:1 v/v) to give the lactone **10** (21.5 g, 80%) as white crystals, mp 79–80.5°C. ^1H NMR ($CDCl_3$) δ: 4.50 (ddd, *J* = 6.7, 2.4, 2.1 Hz, 1H, H-3), 4.33 (ddd, *J* = 3.4, 2.7, 2.1 Hz, 1H, H-4), 3.81 (dd, *J* = 11.6, 3.4 Hz, 1H, H-5a), 3.76 (dd, *J* = 11.6, 2.7 Hz, 1H, H-5b), 2.82 (dd, *J* = 17.7, 6.7 Hz, 1H, H-2a), 2.39 (dd, *J* = 17.7, 2.4 Hz, 1H, H-2b), 0.89 (s, 18H), 0.09 (s, 6H), 0.08 (s, 3H), 0.06 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 175.47, 87.99, 69.56, 62.44, 38.97, 25.78, 25.63, 18.22, 17.90, –4.75, –4.82, –5.52, –5.64.

1,4-Anhydro-3,5-*O*-bis(*tert*-butyldimethylsilyl)-2-deoxy-D-erythro-pent-1-enitol (11)

DIBAL-H (1.5 M in toluene, 60 mL, 90 mmol) was added drop wise during 30 min to a cold suspension of the lactone **10** (21.5 g, 59.7 mmol) in dry ether (250 mL) at –78°C under argon. The resulting clear solution was stirred at –78°C for 3.5 h, and the reaction was quenched by slow addition of methanol (60 mL). After warming to 0°C, the reaction solution was washed with 10% aqueous disodium tartrate (2 × 200 mL), and the aqueous fraction was extracted with ether (2 × 100 mL). The combined organic extracts were washed with brine, and the organic fraction was dried (Na_2SO_4). Removal of the solvent gave a colorless oil (21.5 g), which was dissolved in CH_2Cl_2 (300 mL), and the resulting solution was cooled to –78°C under argon. Et_3N (31.5 mL), followed by the drop wise addition of methanesulfonyl chloride (6 mL, 77.5 mmol) were added under argon. The resulting solution was stirred at –78°C for 2 h, and then at –10 – –20°C for an additional 2 h. The reaction mixture was allowed to warm to 25°C prior to heating at reflux under argon for 15 h. After cooling to 25°C, the reaction mixture was diluted with hexane (200 mL), filtered through a silica gel pad, and washed with hexane–ether (1:1 v/v). Removal of the solvent from the filtrate gave a residue that was purified via flash chromatography (hexane–ether, 10:1 v/v) to give **11** (16.8 g, 82%) as a colorless liquid. ^1H NMR ($CDCl_3$) δ: 6.48 (d, *J* = 2.4 Hz, 1H, H-1), 5.02 (dd, *J* = 2.7, 2.4 Hz, 1H, H-2), 4.87 (t, *J* = 2.7 Hz, 1H, H-3), 4.29 (ddd, *J* = 6.4, 5.8, 2.7 Hz, 1H, H-4), 3.70 (dd, *J* = 10.7, 5.8 Hz, 1H, H-5a), 3.52 (dd, *J* = 10.7, 5.8 Hz, 1H, H-5b), 0.90 (s, 9H), 0.90 (s, 9H), 0.10 (s, 6H), 0.08 (s, 3H), 0.07 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 148.88, 103.35, 88.95, 76.01, 62.83, 25.93 (6C), 18.40, 18.09, –4.20, –4.34, –5.29, –5.32.

3-Fluoro-4-iodoaniline (13a) (Method A)

A mixture of *m*-fluoroaniline (**12a**, 2.22 g, 20 mmol), $NaIO_4$ (0.92 g, 4.3 mmol), iodine (2.04 g, 8.0 mmol), concentrated H_2SO_4 (0.4 mL), and water (4.4 mL) in acetic acid (14 mL) was stirred at 80°C for 4 h. After cooling to 25°C, the black reaction mixture was poured onto a cooled solution of sodium hydrosulfite, and extracted with ether (3 × 50 mL). The combined organic extracts were washed with a 10% solution of NaOH in water, and water, prior to drying (K_2CO_3). Removal of the solvent in vacuo gave a residue that was purified via flash chromatography (hexane–ethyl acetate, 4:1 v/v) and recrystallized from hexane–ether to afford **13a** (2.1 g, 50%) as brown crystals, mp 67–68.5°C. ^1H NMR ($CDCl_3$) δ: 7.42 (dd, *J* = 8.2, 7.6 Hz, 1H), 6.43 (dd, *J* = 10.1, 2.5 Hz, 1H), 6.28 (dd, *J* = 8.2, 2.5 Hz, 1H), 3.82 (br s, 2H, NH_2). ^{13}C NMR ($CDCl_3$) δ: 162.14 (d, *J* = 242.8 Hz), 148.52 (d, *J* = 9.9 Hz), 139.0 (d, *J* = 3.3 Hz), 112.86 (d, *J* = 2.2 Hz), 102.4 (d, *J* = 27.5 Hz), 65.39 (d, *J* = 25.3 Hz).

2,5-Difluoro-4-iodoaniline (13b) (Method B)

N-Iodosuccinimide (7.9 g, 35 mmol) was added in aliquots to an ice-cold solution of 2,5-difluoroaniline (**12b**, 3.9 g, 30 mmol) in trifluoroacetic acid (10 mL), and the resulting solution was stirred at 25°C for 3 h. The reaction mixture was poured onto ice water and neutralized with sodium hydroxide. Extraction with ether (2 × 50 mL), washing the combined organic extracts with a saturated solution of sodium hydrosulfite, and brine, prior to drying (Na_2SO_4). Removal of the solvent gave a residue that was purified via flash chromatography (hexane–ethyl acetate, 5:1 v/v) and recrystallization from hexane–ether to give **13b** (6.8 g, 89%) as pale brown crystals, mp 61–62°C. ^1H NMR ($CDCl_3$) δ: 7.27 (dd, *J* = 9.8, 5.6 Hz, 1H), 6.51 (dd, *J* = 8.5, 7.5 Hz, 1H), 3.87 (br s, 2H, NH_2). ^{13}C NMR ($CDCl_3$) δ: 158.29 (dd, *J* = 238.3, 2.2 Hz), 147.71 (dd, J = 239.5, 2.2 Hz), 136.03 (dd, *J* = 14.3, 9.9 Hz), 124.13 (dd, *J* = 23.1, 3.3 Hz), 103.03 (dd, *J* = 29.7, 3.3 Hz), 63.08 (dd, *J* = 37.3, 2.2 Hz).

2-Methyl-5-fluoro-4-iodoaniline (13c) (Method B)

Yield 65%, pale brown crystals, mp 75–77°C. ^1H NMR ($CDCl_3$) δ: 7.33 (d, *J* = 7.0 Hz, 1H), 6.41 (d, *J* = 9.5 Hz), 3.70 (br s, 2H, NH_2), 2.09 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 160.56 (d, *J* = 240.6 Hz), 146.28 (d, *J* = 9.9 Hz), 139.23 (d, *J* = 3.3 Hz), 120.21 (d, *J* = 2.2 Hz), 101.81 (d, *J* = 27.5 Hz), 64.99 (d, *J* = 26.4 Hz), 16.23.

3-Fluoro-4-(β-D-glycero-pentofuran-3-ulos-1-yl)aniline (14a)

A freshly dried 100 mL round-bottom flask was charged with palladium acetate (0.135 g, 0.6 mmol) and triphenylarsine (0.54 g, 1.8 mmol) under argon. Dry CH_3CN (20 mL) was added and the yellow suspension was stirred at 25°C for 30 min. A solution of the glycal (**11**, 1.38 g, 4 mmol), 3-fluoro-4-iodoaniline (**13a**, 0.95 g, 4 mmol) and triethylamine (1.2 mL) in CH_3CN (30 mL) was added to this suspension, and the resulting solution was stirred at 60°C for 20 h. After cooling to 25°C, *n*-$Bu_4N^+F^-$ (3.2 g, mmol) was added, and the mixture was stirred at 25°C for 2 h. The reaction was quenched with methanol (4 mL), the solvent was removed in vacuo, and the residue obtained was purified twice in succession via flash chromatography (hexane–ethyl acetate, 1:1 to 1:2 v/v) followed by recrystallization from ether to give **14a** (0.35 g, 39%) as pale yellow crystals, mp 132–133°C. IR (NaCl): 3446, 3364, 3220, 1752, 1635 cm^{-1}. ^1H NMR ($CDCl_3$) δ: 7.20 (dd, *J* = 8.5, 8.2 Hz, 1H), 6.39 (dd, *J* = 8.5, 2.14 Hz, 1H), 6.30 (dd, *J* = 12.5, 2.1 Hz, 1H), 5.22 (dd, *J* = 11.0, 6.0 Hz, 1H), 3.90 (t, *J* = 3.0 Hz, 1H), 3.78 (d, *J* = 3.0 Hz, 2H), 3.62 (br s, 3H, NH_2, OH), 2.70 (dd, *J* = 18.1, 6.0 Hz, 1H), 2.48 (dd, *J* = 18.1, 11.0 Hz, 1H). ^{13}C NMR ($CDCl_3$) δ: 214.2, 161.26 (d, *J* = 243.9 Hz), 148.61 (d, *J* = 9.9 Hz), 128.39 (d, *J* = 6.6 Hz), 115.4 (d, *J* = 14.5 Hz), 110.74 (d, *J* = 2.2 Hz), 101.68 (d, *J* = 25.3 Hz), 82.32, 72.1, 61.05, 43.87. Anal. calcd. for $C_{11}H_{12}FNO_3$: C 58.66, H 5.37, N 6.22; found: C 58.29, H 5.30, N 6.15.

2,5-Difluoro-4-(β-D-glycero-pentofuran-3-ulos-1-yl)aniline (14b)

Compound **14b** was prepared, using a procedure similar to that used for the preparation of **14a**, except that 2,5-difluoro-4-iodoaniline (**13b**) was used in place of 3-fluoro-4-iodoaniline (**13a**). The crude product was purified twice in succession via flash chromatography (hexane–ethyl acetate, 2:1 v/v) followed by recrystallization from ether to give **14b** (31%) as a pale brown syrup. IR (NaCl): 3465, 3368, 3231, 1758, 1649, 1522 cm–1. ^1H NMR ($CDCl_3$) δ: 7.14 (dd, *J* = 11.3, 6.4 Hz, 1H), 6.48 (dd, *J* = 11.3, 7.3 Hz, 1H), 5.29 (dd, *J* = 11.0, 5.8 Hz, 1H), 4.0 (t, *J* = 3.3 Hz, 1H), 3.95 (d, *J* = 3.3 Hz, 2H), 3.92 (br s, 2H, NH_2), 2.84 (dd, *J* = 18.0, 5.8 Hz, 1H), 2.49 (dd, *J* = 18.0, 11.0 Hz, 1H), 2.47 (br s, 1H, OH). ^{13}C NMR ($CDCl_3$) δ: 213.41, 156.45 (dd, *J* = 240.6, 2.2 Hz), 147.47 (dd, *J* = 235.1, 2.2 Hz), 135.83 (dd, *J* = 15.4, 12.1 Hz), 115.41 (dd, *J* = 16.0, 5.5 Hz), 113.5 (dd, *J* = 22.0, 5.5 Hz), 103.3 (dd, *J* = 27.5, 4.4 Hz), 82.0, 71.76, 61.40, 44.10. Anal. calcd. for $C_{11}H_{11}F_2NO_3$: C 54.32, H 4.56, N 5.76; found: C 54.61, H 5.05, N 5.51.

5-Fluoro-4-(β-D-glycero-pentofuran-3-ulos-1-yl)-2-methylaniline (14c)

Compound **14c** was prepared, using a procedure similar to that used for the preparation of **14a**, except that 2-methyl-5-fluoro-4-iodoaniline (**13c**) was used in place of 3-fluoro-4-iodoaniline (**13a**). The crude product was purified twice in succession via flash chromatography (hexane–ethyl acetate, 1:1 – 1:1.2 v/v) followed by recrystallization from ether to give **14c** (38%) as pale yellow crystals, mp 105–107°C. ^1H NMR ($CDCl_3$) δ: 7.11 (d, *J* = 8.2 Hz, 1H), 6.38 (d, *J* = 12.2 Hz, 1H), 5.29 (dd, *J* = 11.0, 6.1 Hz, 1H), 3.99 (t, *J* = 3.4 Hz, 1H), 3.91 (d, *J* = 3.4 Hz, 2H), 2.79 (ddd, *J* = 18.0, 6.1, 0.9 Hz, 1H), 2.60 (dd, *J* = 18.0, 11.0 Hz, 1H), 2.11 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 213.83, 159.81 (d, *J* = 242.9 Hz), 146.25 (d, *J* = 11.0 Hz), 129.01 (d, *J* = 5.5 Hz), 117.81 (d, *J* = 2.2 Hz), 115.14 (d, *J* = 13.2 Hz), 101.67 (d, *J* = 25.3 Hz), 82.04, 72.69 (d, *J* = 2.2 Hz), 61.52, 43.96, 16.52.

3-Fluoro-4-[1-(2-deoxy-β-D-ribofuranosyl)]aniline (6a)

$NaB(OAc)_3H$ was added in one portion to an ice cold solution of **14a** (0.225 g, 1 mmol) in dry CH_3CN (10 mL) with stirring under argon. After stirring at 0°C for 2 h, the reaction was quenched with methanol (10 mL), and the solvents were removed in vacuo. The residue obtained was purified via flash chromatography (hexane–ethyl acetate, 1:2 – 0:1 v/v) to give **6a** (0.17 g, 75%) as a pale yellow solid, which was recrystallized from ethanol to give white crystals (0.13 g, 58%), mp 183–184.5°C. ^1H NMR (DMSO-d_6) δ: 7.10 (dd, *J* = 8.8, 8.5 Hz, 1H), 6.34 (d, *J* = 8.5 Hz, 1H), 6.25 (d, *J* = 13.2 Hz, 1H), 5.31 (s, 2H, NH_2), 5.06 (dd, *J* = 10.4, 5.5 Hz, 1H), 5.0 (d, *J* = 4.0 Hz, 1H, 3′-OH), 4.69 (t, *J* = 5.5 Hz, 1H, 5′-OH), 4.14 (m, 1H), 3.69 (m, 1H), 3.41 (m, 2H), 1.94 (dd, *J* = 12.6, 5.5 Hz, 1H), 1.78 (ddd, *J* = 12.6, 10.4, 5.5 Hz, 1H). ^{13}C NMR (DMSO-d_6) δ: 160.52 (d, *J* = 241.7 Hz), 149.74 (d, *J* = 12.1 Hz), 128.12, 114.91 (d, *J* = 14.3 Hz), 109.73, 99.62 (d, *J* = 27.5 Hz), 87.05, 72.83, 72.30 (d, *J* = 8.8 Hz), 62.41 (d, *J* = 8.8 Hz), 41.76 (d, *J* = 3.3 Hz). ^{19}F NMR (DMSO-d_6) δ: 46.03 (dd, *J* = 12.2, 9.2 Hz). Anal. calcd. for $C_{11}H_{14}FNO_3$: C 58.14, H 6.21, N 6.16; found: C 58.08, H 6.41, N 6.10.

2,5-Difluoro-4-[1-(2-deoxy-β-D-ribofuranosyl)]aniline (6b)

A similar reduction of **14b**, using the procedure described for reduction of **14a** above, and purification of the product afforded **6b** (73%) as a pale yellow solid, which was recrystallized from ether to give pale yellow crystals (65%), mp 163–164.5°C. ^1H NMR (DMSO-d_6) δ: 7.09 (dd, *J* = 12.2, 6.71 Hz, 1H), 6.47 (dd, *J* = 11.9, 7.6 Hz, 1H), 5.35 (s, 2H, NH_2), 5.07 (dd, *J* = 10.4, 5.2 Hz, 1H), 5.02 (d, *J* = 3.7 Hz, 1H, 3′-OH), 4.74 (t, *J* = 5.5 Hz, 1H, 5′-OH), 4.15 (m, 1H), 3.72 (m, 1H), 3.43 (m, 2H), 1.98 (dd, *J* = 12.5, 5.2 Hz, 1H), 1.76 (ddd, *J* = 12.5, 10.4, 5.5 Hz, 1H). ^{13}C NMR (DMSO-d_6) δ: 155.53 (d, *J* = 238.4 Hz), 146.61 (d, *J* = 232.9 Hz), 136.58 (dd, *J* = 15.4, 12.1 Hz), 115.26 (dd, *J* = 16.5, 5.5 Hz), 112.95 (dd, *J* = 20.9, 6.6 Hz), 101.69 (dd, *J* = 27.5, 4.4 Hz), 87.17, 72.22, 72.14, 62.20, 42.02. Anal. calcd. for $C_{11}H_{12}F_2NO_3$: C 53.88, H 5.34, N 5.71; found: C 53.70, H 5.42, N 5.54.

5-Fluoro-4-[1-(2-deoxy-β-D-ribofuranosyl)]-2-methylaniline (6c)

$NaB(OAc)_3H$ (2.54 g, 12 mmol) was added in one aliquot to an ice cold solution of **14c** (0.72 g, 3 mmol) in dry CH_3CN (30 mL) with stirring under argon. After stirring at 0°C for 2 h, the reaction was quenched with methanol (20 mL), and the solvent was removed in vacuo. The residue obtained was purified via flash chromatography (hexane–ethyl acetate, 1:2 – 1:5 v/v) to give **6c** (0.37 g, 52%) as a pale yellow syrup. ^1H NMR (DMSO-d_6) δ: 6.99 (d, *J* = 8.5 Hz, 1H), 6.31 (d, *J* = 12.8 Hz, 1H), 5.05 (s, 2H, NH_2), 5.05 (m, 1H), 4.99 (d, *J* = 3.0 Hz, 1H, 3′-OH), 4.70 (t, *J* = 5.4 Hz, 1H, 5′-OH), 4.14 (m, 1H), 3.69 (m, 1H), 3.42 (m,

Medium-sized cyclophanes. Part 53.[1] Synthesis and conformational studies, and photoinduced cyclization of *syn*-[n.2]metacyclophanenes

Takehiko Yamato, Koji Fujita, Keigo Futatsuki, and Hirohisa Tsuzuki

Abstract: A series of [n.2]metacyclophanenes (**3**) and (**6**) were prepared in good yields by a McMurry cyclization of 1,n-bis(3-acetyl-4-methoxyphenyl)alkanes (**2**) and 1,3-bis(3-formyl-4-methoxyphenyl)propane (**5**), respectively. Compounds **3b**, **3c** exist in the *syn*-conformation due to the steric repulsion between the methyl groups at the ethano bridge and the methoxy groups at the aromatic rings while compound **6** prefers the *anti*-conformation typical of [3.2]metacyclophanes. The assignment of *syn*-conformations has been confirmed by ^{1}H NMR analyses and X-ray diffraction studies. Photoinduced transannular cyclization of [n.2]metacyclophanenes (**3**) and (**6**) in the presence of iodine as an oxidant afforded phenanthrene-anellated polycyclic aromatic hydrocarbons. Apparently, the rate of the photocyclization of *anti*-**6** was found to be much faster than that of *syn*-**3b** and almost completed within 1 h. Thus, the different reactivities for the irradiation of *syn*- and *anti*-conformer were observed. The reason for the present preference for the formation of *trans*-dihydrophenanthrene rather than *cis*-dihydrophenanthrene as the intermediate might be attributable to the more stable chair form transition state than boat one and the conformational fixation to the chair form in the ground and transition state is possible in the *anti*-conformer.

Key words: cyclophanes, strained molecule, McMurry reaction, C—C coupling, conformation analysis, cyclizations, photolysis, transannular reactions, transition states.

Résumé : Faisant appel à une réaction de cyclisation de McMurry des 1,n-bis(3-acétyl-4-méthoxyphényl)alcanes (**2**) et 1,3-bis(3-formyl-4-méthoxyphényl)propane (**5**) respectivement, on a préparé une série de [n,2]métacyclophanènes (**3**) et (**6**). Les composés **3b** et **3c** existent dans la conformation syn en raison de la répulsion stérique entre les groupes méthyles du pont éthano et les groupes méthoxy des noyaux aromatiques alors que le composé **6** adopte la conformation anti des [3,2]métacyclophanes. L'attribution des conformations *syn* a été confirmée par des analyses de RMN du ^{1}H et des études de diffraction des rayons X. La cyclisation transannulaire photoinduite des [n,2]métacyclophanènes (**3**) et (**6**) en présence d'iode, utilisé comme antioxydant, conduit à des hydrocarbures aromatiques polycycliques du type phénanthrène avec annellation. Apparemment, la vitesse de photocyclisation du produit *anti*-**6** est beaucoup plus rapide que celle du *syn*-**3b** et elle est pratiquement complète en une heure. Ainsi, on a pu observer des réactivités différentes pour l'irradiation des conformères *syn* et *anti*. La raison de la formation observée d'une préférence pour la formation comme intermédiaire du *trans*-dihydrophénanthrène plutôt que du *cis*-dihydrophénanthrène pourrait être attribuée à l'état de transition en forme chaise qui est plus stable que celui en forme bateau ainsi que le fait que la conformation des états tant fondamental que de transition du conformère *anti* peut être fixée à la forme chaise.

Mots clés : cyclophanes, molécule tendue, réaction de McMurry, couplage C—C, analyse conformationnelle, photolyse, réactions transannulaires, états de transition.

[Traduit par la Rédaction]

Introduction

Although the parent [2.2]metacyclophane (MCP = metacyclophane) was first reported as early as 1899 by Pelligrin (2), the synthesis of *syn*-[2.2]MCP was not realized until 85 years later. Mitchell et al. (3) have successfully prepared *syn*-[2.2]MCP at low temperature by using (arene)chromiumcarbonyl complexation to control the stereochemistry. Later, Itô and co-workers (4) also isolated and characterized *syn*-[2.2]MCP without complexation. However, *syn*-[2.2]MCP isomerizes readily to the *anti*-isomer above 0°C. On the other hand, Mitchell and Boekelheide (5) and Staab

et al. (6) succeeded in synthesizing intraannularly substituted *syn*-[2.2]MCPs, respectively. However, reports on synthesis and reactions of *syn*-[n.2]MCP-ene have not been published so far.

In cyclophane chemistry, the reductive coupling of carbonyl compounds by low-valent titanium, the McMurry reaction (7), has been used before by Mitchell and Weerawana (8) to synthesize cyclophanes with glycol units as bridges, by Tanner and Wennerström (9), and recently by Hopf and Mlynek (10) and Grützmacher et al. (11) for a cyclization of suitable dialdehydes to yield unsaturated cyclophanes.

In this paper, we report on the syntheses of *syn*- and *anti*-[n.2]MCP-enes using the low-valent titanium induced McMurry reaction and photoinduced transannular cyclization reaction to afford phenanthrene-anellated polycyclic aromatic hydrocarbons.

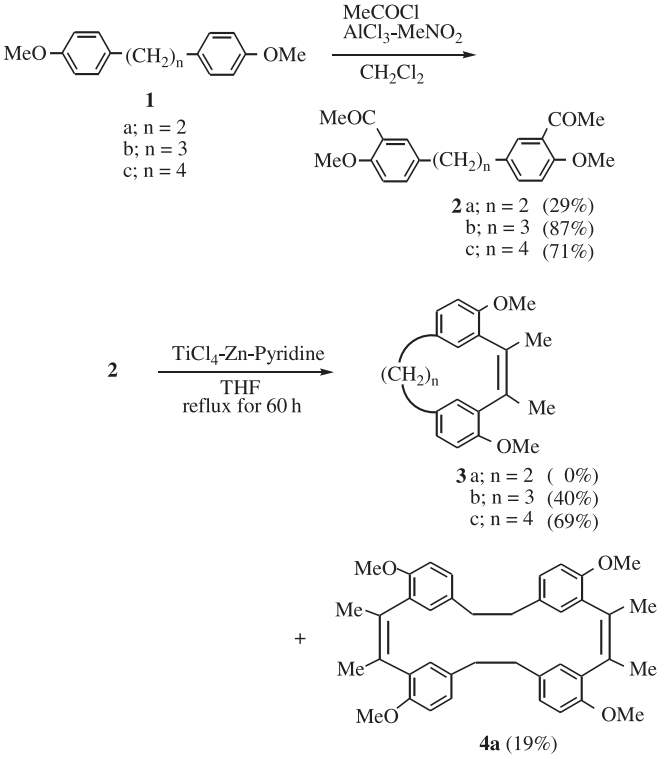
Results and discussion

1,2-Bis(4-methoxyphenyl)ethane (**1a**) has been prepared according our previous paper (12). The cross coupling reactions (13) of 4-methoxyphenylmagnesium bromide with 1,3-dibromopropane and 1,4-dibromobutane have been carried out in the presence of cuprous bromide as a catalyst in a mixture of hexamethylphosphoric triamide (HMPA) and tetrahydrofuran at reflux temperature to give the desired 1,3-bis(4-methoxyphenyl)propane (**1b**) and 1,4-bis(4-methoxyphenyl)butane (**1c)** in satisfactory yields. Although the $AlCl_3$–$MeNO_2$-catalyzed acetylation of compound **1a** with acetyl chloride at 20°C led to complete diacylation, a mixture of the desired 1,2-bis(3-acetyl-4-methoxyphenyl)ethane (**2a)** and other isomers was obtained. The desired product **2a** was isolated in pure by the fractional recrystallization from hexane–benzene (1:1) in 29% yield. In contrast, the $AlCl_3$–$MeNO_2$-catalyzed acetylation of compounds **1b** and **1c** with acetic anhydride or acetyl chloride at 20°C led to regioselective acylation at the meta positions of the 1,n-diphenylalkanes affording the desired 1,n-bis(3-acetyl-4-methoxyphenyl)alkanes (**2b**) and (**2c**) in good yields.

1,2-Bis(3-acetyl-4-methoxyphenyl)ethane **(2a**) was subjected to reductive coupling by the McMurry reaction (7) following the Grützmacher's procedure (11) (Scheme 1). Although none of the desired [2.2]MCP-1-ene (**3a**) was observed, the dimer **4a** was obtained in 19% yield. This finding seems to be due to the much more strained structure of **3a** than dimer **4a** during the formation of the unsaturated C=C linkage. Although several cyclizations of **2a** were attempted under the various reaction conditions, no formation of the desired **3a** was observed, with only dimer **4a** being obtained. Thus, during the McMurry reaction the intramolecular cyclization to afford **3a** might be quite difficult.

The structure of product dimer **4a** was determined on the basis of its elemental analysis and spectral data. The mass spectral data for dimer **4a** (M^+ m/z = 588) strongly supports cyclic dimeric structure. In the ^1H NMR spectrum of tetramethoxyMCP **4a**, methyl protons, methoxy protons, ArCH_2CH_2Ar methylene protons, and the ArC*H*=C*H*Ar olefinic protons each appear as a singlet at 27°C. This behavior indicates that the rate of conformational ring flipping of macrocycle **4a** is faster than the NMR time scale above this temperature. However, in dimer **4a** even at –60°C in

Scheme 1.



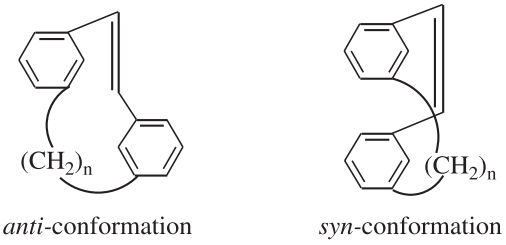


Fig. 1. Possible conformations of [n.2]metacyclophan-1-enes.

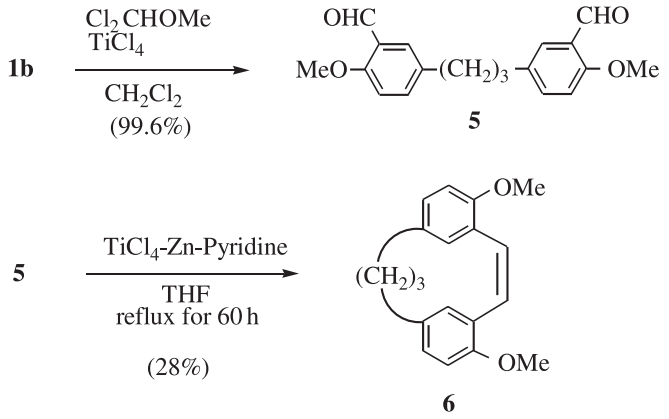

$CDCl_3$–CS_2 (1:3) the singlet signal of the ArCH_2CH_2Ar ethylene protons and the ArC*H*=C*H*Ar olefinic protons both remain unsplit. These observations indicate the flexible structure of **4a** similar to that of the saturated [2_4]MCP (14) in spite of the introduction of two additional double bonds of the ethylene bridge.

Similarly, 1,n-bis(3-acetyl-4-methoxyphenyl)alkanes (**2b**) and **2c** were subjected to reductive coupling by the McMurry reaction (Scheme 1). Novel [n.2]MCP-enes (**3b**) and (**3c**) have been prepared in 40% and 69% yields.

[n.2]MCP-enes adopt either a "staircase" *anti*-conformation or a *syn*-conformation with overlaying aromatic rings (15) (Fig. 1). Depending on the size of the bridges (16) and on the presence of intraannular substituents (17), the interconversion between the *syn*- and *anti*-conformers occur by ring flipping. ^1H NMR spectrum of **3b** showed the doublet of the intraannular proton H_i at δ = 6.95 (J = 2.0 Hz) apart from at δ = 6.33 and 6.60 of the other two protons at the aromatic rings. The methyl protons at the bridged double bond and methoxy protons were observed as a singlet at δ = 2.18 and 3.59, and the protons of the trimethylene bridge generate a complicated signal pattern as expected for a rigid

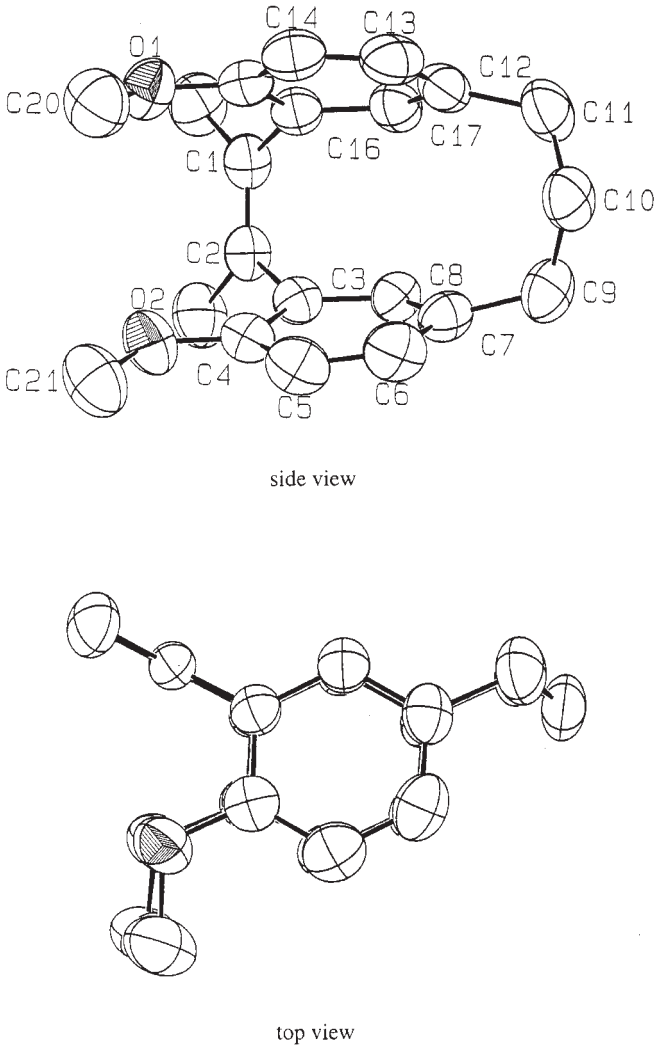
Scheme 2.



syn-[3.2]MCP-10-ene. The protons of the benzylic CH_2 group were observed as two multiplets centered at $\delta = 2.58$ and 2.91 which are further split by coupling with the protons of the central CH_2 group. This central CH_2 group was also observed as two multiplets centered at $\delta = 1.28$ and 2.18. This peak pattern ascribed to six chemically distinct protons of the propano bridge proves the absence of a *syn–syn* interconversion which would exchange H_A and H_B of each CH_2 group. Interestingly, similar findings were also observed in *syn*-[4.2]MCP-11-ene (*syn*-**3c**) in spite of being expected to be more flexible structure attributable to the larger cyclophane ring size. These observations suggest that the introduction of a double dond of the ethylene bridge as well as the substituents such as methyl groups and methoxy groups might control the *syn*- and *anti*-conformation of [n.2]MCP-enes (**3**).

To study the conformation of [n.2]MCP-enes **3** in more detail, we have investigated the conformation of the corresponding [3.2]MCP-10-ene **6**, which was prepared in 28% yield by the McMurry cyclization of 1,3-bis(3-formyl-4-methoxyphenyl)propane (**5**) under the same reaction conditions like *syn*-**3b** (Scheme 2).

Interestingly, in contrast to **3**, the doublet of H_i at $\delta = 6.05$ ($J = 2.4$ Hz) in the ^{1}H NMR spectrum of **6** shows clearly that **6** adopts a staircase *anti*-conformation as known for other [3.2]MCP-10-enes (11*a*, 11*b*) and [3.2]MCPs (13*c*, 15, 16). In addition, the protons of the trimethylene bridge give rise to two multiplets centered at $\delta = 2.35$ and 1.84, respectively, providing a fast interconversion of the two anti conformations of **6** by ring flipping. However, as the temperature of the solution in $CDCl_3$–CS_2 (1:3) is decreased, a single peak of the benzyl protons splits into a pair of doublets below 0°C. The energy barrier to the conformational ring flipping estimated from the coalescence temperature (T_c) is 12.4 kcal mol^{-1}. This finding indicates more flexible structure of **6** than that of *syn*-**3b** in spite of the same ring size.

Usually, the parent [3.2]MCPs in which intraannular substituents are absent, preferably adopt an *anti*-conformation (15, 16). However, in the case of the MCP **3b** the *syn*-conformation is induced by substituents at the ethano bridge. The substituent effect on the preferred conformation (18) and the different molecule flexibility of **3b** and **6** can be attributed to the van der Waals repulsion between the four methyl groups in **3b**. In the *anti*-conformation of [3.2]MCP-10-ene (**6**) the twisted ethano bridge tends to flatten the staircase structure to release the local strain. However, this flattening is especially opposed by the two methoxy groups in the extraannular position 7 and 13 and the two methyl groups in the bridge position 10 and 11 of **3b**. This effect is absent in the *syn*-conformation and, as a consequence, **3b** favors this *syn*-conformation. The conformation of *syn*-**3b** and *syn*-**3c** has also been confirmed by X-ray crystallographic analysis.

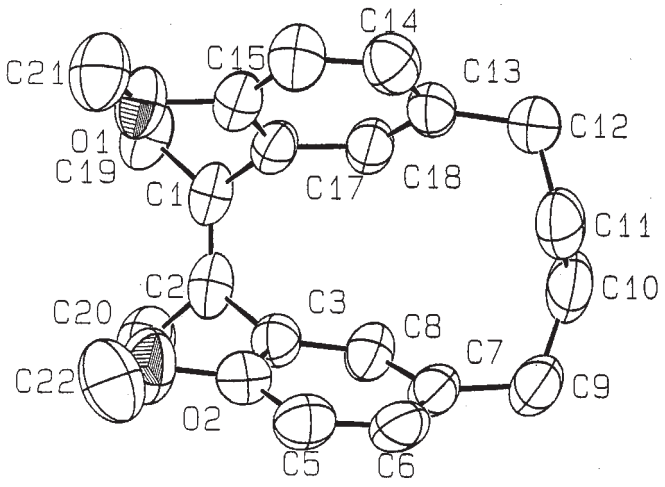


Fig. 2. ORTEP drawing of *syn*-7,13-dimethoxy-10,11-dimethyl-[3.2]MCP-10-ene (*syn*-**3b**). Thermal ellipsoids are drawn at the 50% probability level. All hydrogen atoms are omitted for clarity.

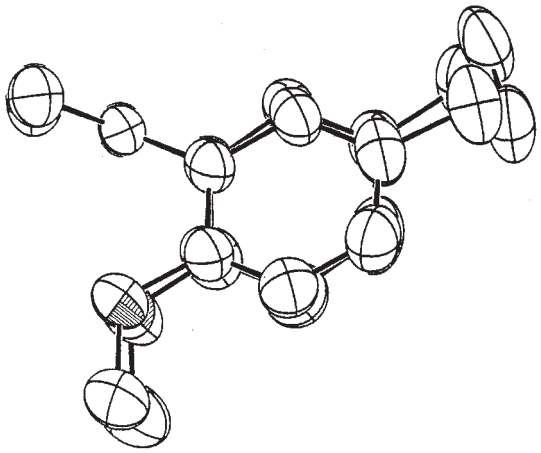

Single colorless crystals of the *syn*-**3b** and *syn*-**3c** suitable for X-ray crystallography were both obtained by recrystallization from methanol–chloroform (1:1). The perspective ORTEP drawings of the *syn*-**3b** and *syn*-**3c** are illustrated in Figs. 2 and 3, with the atom numbering system. Both compounds crystallized in the same monoclinic space group $P2_1/a$. The X-ray crystallography clearly reveals that both conformations of the *syn*-**3b** and *syn*-**3c** adopt the *syn*-form in which two aromatic rings face each other. Two aromatic rings of the *syn*-**3b** and *syn*-**3c**, which deviate from planarity to some extent, locate like an half-open bivalve

Fig. 3. ORTEP drawing of *syn*-8,14-dimethoxy-11,12-dimethyl-[4.2]MCP-11-ene (*syn*-**3c**). Thermal ellipsoids are drawn at the 50% probability level. All hydrogen atoms are omitted for clarity.

side view

top view

using the C(3), C(7), C(12), and C(16) and C(3), C(7), C(13), and C(17) carbons as roots, respectively, to avoid π-electronic repulsion as shown in the side view of the ORTEP drawing. Although the double bond lengths between C(1)-C(2) in the *syn*-**3b** and *syn*-**3c** are reasonable, 1.332 and 1.354 Å, respectively, these compounds have quite different conformations of the two aromatic rings due to the different methylene chain length.

In the *syn*-**3b**, two aromatic rings distort like a boat shape and deviate from planarity to some extent. The C(4), C(7), C(12), and C(15) carbons are out of the C(3)-C(5)-C(6)-C(8) and C(13)-C(14)-C(16)-C(17) planes. The dihedral angles of the C(3)-C(5)-C(6)-C(8) plane between the C(3)-C(4)-C(5) and C(6)-C(7)-C(8) planes, and those of the C(13)-C(14)-C(16)-C(17) plane between the C(14)-C(15)-C(16) and C(12)-C(13)-C(17) planes are 1.77°, 4.52°, 1.53°, and 5.54°, respectively, showing that the aromatic rings in the *syn*-**3b** adopts unsymmetrically strained structure and the rigid ethylene chain against the flexible methylene chains might loose the strain. Furthermore, the intramolecular distances of C(3)-C(16), C(4)-C(15), C(5)-C(14), C(6)-C(13), C(7)-C(12), C(8)-C(17) are 2.745, 3.688, 4.493, 4.229, 3.318, and 2.764 Å, and the dihedral angle between the C(3)-C(5)-C(6)-C(8) and C(13)-C(14)-C(16)-C(17) planes is 39.88°. These clearly show that two aromatic rings in the *syn*-**3b** do not adopt parallel conformation to avoid an electrostatic interaction.

Two aromatic rings in the *syn*-**3c** also strain like a boat shape as well as those in the *syn*-**3b** and the carbons, C(4), C(7), C(13), and C(16) are remote from the C(3)-C(5)-C(6)-C(8) and C(14)-C(15)-C(17)-C(18) planes. The dihedral angles of the C(3)-C(5)-C(6)-C(8) plane between the C(3)-C(4)-C(5) and C(6)-C(7)-C(8) planes, and those of the C(14)-C(15)-C(17)-C(18) plane between the C(15)-C(16)-C(17) and C(13)-C(14)-C(18) planes are 1.76°, 3.85°, 1.65°, and 3.99°, respectively. The fact that the dihedral angles on the side of the methylene chains are somewhat smaller than the corresponding ones in the *syn*-**3b** might be attributed to the cancel of strain to some extent because of lengthening the methylene chains.

Interestingly, the intramolecular distances of C(3)-C(17), C(4)-C(16), C(5)-C(15), C(6)-C(14), C(7)-C(13), and C(8)-C(18) in the *syn*-**3c** are 2.842, 4.060, 5.336, 5.323, 4.135, and 3.038 Å, which are much longer than those of the corresponding carbons in the *syn*-**3b**. The dihedral angle between the C(3)-C(5)-C(6)-C(8) and C(14)-C(15)-C(17)-C(18) planes is 59.53°, which is ca. 20° larger than the appropriate dihedral angle in the *syn*-**3b**. These indicate that two aromatic rings in the *syn*-**3c** might tilt to a greater extent than those in the *syn*-**3b**, since the methylene chain length of the *syn*-**3c** is longer than that of the *syn*-**3b** and the rings are easy to avoid an electronic repulsion.

The substituents effect on the conformation was observed, for example, in 10,15-dihydro-5*H*-tribenzo[*a*,*d*,*g*]cyclononene and its congeners which adopt their stable crown conformation, evidenced, in ^{1}H NMR spectra, by the characteristic AX quartet of the methylene bridges (19). Destabilization of the crown may arise from steric hindrance created either by geminal substitution of one methylene group (20) or by the presence of bulky substituents (21) such as a bromine atom or an allyl group at the aromatic positions *ortho* to the nine-membered ring except a methoxy group (21*d*, 21*e*).

In the present system, the similar substituents effect like 10,15-dihydro-5*H*-tribenzo[*a*,*d*,*g*]cyclononene might be also observed. To elucidate this, we have converted the methoxy group in *syn*-**3b** to hydroxy group by demethylation of *syn*-**3b** with boron tribromide (22). The desired diol **7b** was obtained in 44% yield. Similarly, dihydroxy[4.2]MCP-11-ene (**7c**) was obtained in 53% yield. Interestingly, the bridged double bond was stable in the acidic media quite differnt from the results obtained from the *anti*-[2.2]MCP-enes, in which the transannular cyclization reactions occur to afford the corresponding 4,5-dihydropyrenes under the acidic conditions (23). Furthermore, no *syn*- to *anti*-ring inversion occurred during the demethylation. The ^{1}H NMR spectra for *syn*-**7b** and *syn*-**7c** (in $CDCl_3$) show signals for the hydroxy groups at δ 5.29 and 5.15, respectively. It is well known that the stretching vibration of the OH groups at low frequency

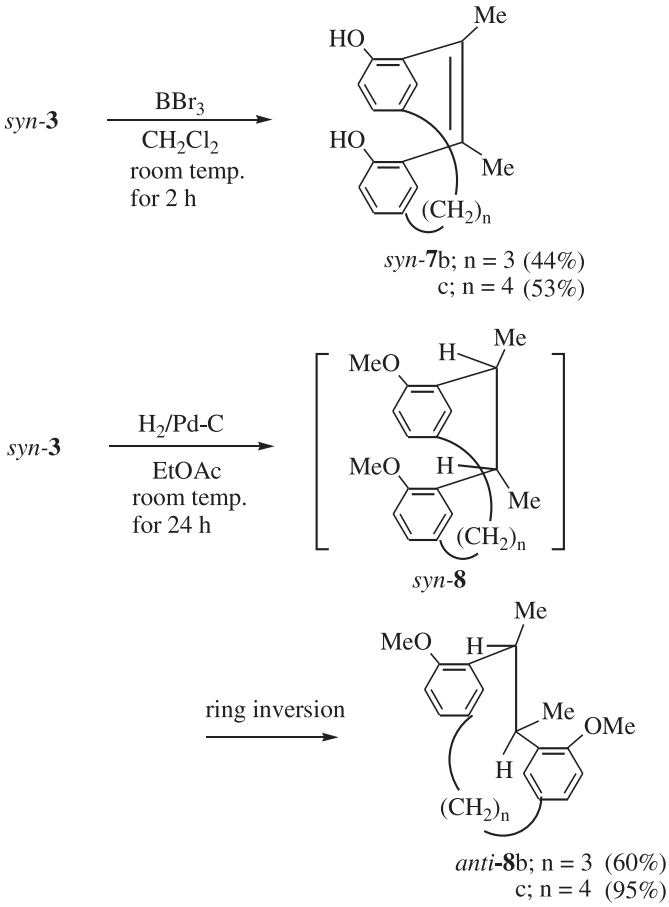
[b]H_i refers to internal protons.

[c]H_o refers to outer protons.



and the resonance for the protons of the OH groups at low field can be attributed to the intramolecular hydrogen bonding (13*c*, 22*d*, 24; for the circular intramolecular hydrogen bonding, see ref. (24*b*–*e*)). The υ_{OH} (3272 cm^{-1} for *syn*-**7b** and 3344 cm^{-1} for *syn*-**7c**) and δ_{OH} values in *syn*-**7b** and *syn*-**7c** in which two hydroxy groups are located in neighbouring positions, show slightly lower frequency IR vibrations and down-field NMR shifts, which imply that a weak hydrogen bond might exist. Therefore, it seems to assume that the *syn*-conformation of **7** might be due to the intramolecular hydrogen bonding. However, in DMSO-d_6 or pyridine-d_5 solution, which can disrupt the intramolecular hydrogen bonding, the ^{1}H NMR spectrum of *syn*-**7b** at room temperature is almost identical with that in $CDCl_3$ and no *anti*-conformer is observed. These findings might be attributable to the similar destabilization of the *anti*-conformation in *syn*-**7b** arising from steric hindrance between the hydroxy groups at the 7,13-positions and the methyl groups on the bridged double bond at 10,11-positions like *syn*-**3b**, but not the intramolecular hydrogen bonding among the two hydroxy groups.

An attempted hydrogenation of *syn*-**3b** in the presence of Pd-C in ethyl acetate at room temperature led to afford *anti*-**8b** in 60% yield. The desired product *syn*-**8b** has not been obtained. Thus, *syn*- to *anti*-ring inversion occurred during the hydrogenation (22). The same result was obtained in the case of the hydrogenation of *syn*-**3c** to afford *anti*-**8c**.

The structures of *anti*-**8b**, **8c** were assigned on the basis of elemental analyses and spectral data. The ^{1}H NMR spectral data of [n.2]MCP-enes **3**, **6** and [n.2]MCPs **8** are summarized in Table 1.

Griffin et al. (25) reported the structure of 1,2-dimethyl[2.2]MCP and assigned the *exo*-*endo*-arrangement (26). We have assigned the ^{1}H NMR signals of **8** in a similar fashion. In the ^{1}H NMR spectrum of *anti*-**8b** in $CDCl_3$ upfield shifts and the different chemical shifts for internal aromatic protons at δ 4.87 and 5.24 due to the ring current of the opposite aromatic ring were observed (27). These data strongly suggest that the structure of **8b** is the *anti*-conformer. Furthermore, the two methyl groups show different chemical shifts at δ 0.95 and 1.68 as a doublet with coupling constant J = 7.3 Hz. The higher field absorption is attributed to the *exo* methyl group and the lower field absorption is attributed to the *endo* methyl group which is in a strongly deshielding region of the oxygen atom of the methoxy group on the aromatic ring. These data strongly support that the two methyl groups are *exo*- and *endo*-arrangement and therefore, *anti*-**8b** is found to be *cis*-hydrogen adduct to the bridged double bond. This assignment is also applied to the hydrogenation product *anti*-**8c**.

Scheme 3.

The conformations of *syn*- and *anti*-[n.2]MCP-enes **3**, **6**, and *anti*-[n.2]MCP **8**, which have been prepared in the present work, in solution are studied by using variable temperature ^{1}H NMR spectroscopy and the results are compiled in Table 2.

The ^{1}H NMR spectrum of *syn*-**3b** and *anti*-**8b** in $CDCl_3$ at room temperature exhibits the split pattern of the protons at the methylene bridge. In spite of an increase of the temperature to 130°C in $CDBr_3$, no change of the spectrum is observed for saturated [3.2]-system *anti*-**8b**. However, in the case of the unsaturated [3.2]-system *syn*-**3b**, as the temperature

Table 2. The coalescence temperatures and energy barriers of *syn*- and *anti*-[n.2]MCP-enes **3**, **6**, and *anti*-[n.2]MCP **8**.[a]

Compd	Number of methylene units (n)	Solvent	T_c (°C)	$\Delta G^{\neq}$ (kcal mol^{-1})
syn-**3b**	3	$CDBr_3$	120	19.0
syn-**3c**	4	$CDCl_3$–CS_2	0	13.0
anti-**6**	3	$CDCl_3$–CS_2	0	12.4
anti-**8b**	3	$CDBr_3$	>130	—
anti-**8c**	4	$CDCl_3$–CS_2	35	14.4

[a]T_c and $\Delta G_c^{\neq}$ were determined in $CDCl_3$–CS_2 (1:3) or $CDBr_3$ using $SiMe_4$ as reference.

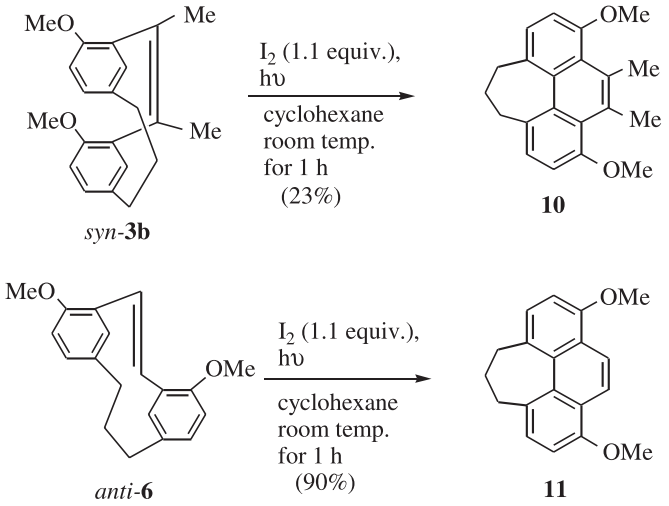
of the solution of the respective compound in $CDBr_3$, is increased, the individual peaks of the benzyl protons merge and eventually a single peak is observed above 120°C. This observation indicates that the rate of conformational ring flipping of *syn*-**3b** is faster than the NMR time scale at this temperature. The energy barrier to the conformational ring flipping estimated from the coalescence temperature (T_c) is 19.0 kcal mol^{-1}. The energy barriers for [4.2]-systems *syn*-**3c** and *anti*-**8c** were also estimated to be 13.0 (T_c = 0°C) and 14.4 (T_c = 35°C) kcal mol^{-1}, respectively. The unsaturated [3.2]-system *syn*-**3b** found to be about 6.0 kcal mol^{-1} larger than that for the corresponding [4.2]-system *syn*-**3c**. Thus, the solution conformation of [n.2]MCP-enes is sensitive to the chain length of the bridges. The ring inversion barriers determined by variable temperature ^{1}H NMR dramatically decrease with increasing length of the bridge by one unit.

Lower ring inversion barriers were observed for the unsaturated systems than those for saturated systems in spite of the smaller ring size due to the introduction of an additional double bond of the ethylene bridge. For example the barrier for ring inversion in the [4.2]-system decreases the rigidity of the system by about 1.4 kcal mol^{-1} in $CDCl_3$. The decreased rigidity of *syn*-[n.2]MCP-enes (**3**) may be attributed to the expanded bond angles of the bridged double bond.

Tetracyanoethylene (TCNE) complexes have often been used in studies on the relative π-base strength of various methyl-substituted benzenes (28). The π-basicity of the donor molecules increases with an increase in the number of substituted methyl groups and (or) stacking benzene rings and an increase in the face-to-face overlapping between aromatic nuclei (29). A solution of *anti*-[3.2]MCP-10-ene (*anti*-**6**) and TCNE in CH_2Cl_2 present a reddish brown colour and the charge-transfer band at 508 nm (log ε = 2.329) was observed in its UV spectrum. This absorption is due to the formation of 1:1 charge-transfer complex among the electron donor, [3.2]MCP, and the electron acceptor, TCNE. The position of absorption maximum and the shape of absorption curve remain unchanged when a 4–12-fold excess of TCNE was added. However, the charge transfer absorption band of the reference compound, 2,4-dimethylanisole (**9**) with TCNE was observed at 414 nm (log ε = 2.073). Such a red shift could be due to the through space electronic interaction of the opposite uncomplexed benzene ring, which tends to work as a π-electron donor.

In contrast to *anti*-[3.2]MCP-10-ene (*anti*-**6**), which exhibits the charge-transfer absorption band with TCNE at 508 nm (log ε = 2.329), a mixture of TCNE and *syn*-[3.2[MCP-10-ene (*syn*-**3b**) exhibits an absorption peak at 525 nm (log ε = 2.334), that of *syn*-[4.2[MCP-11-ene (*syn*-**3c**) is shifted to 466 nm (log ε = 2.001). Introduction of the one methylene to propane bridge of *syn*-**3b** causes a larger blue shift as indicated by the 60 nm shift for the CT-band of *syn*-**3c** due to the decreased transannular π-electron donation from the noncomplexed benzene ring to the complexed benzene ring. This finding is fairly consistent with the fact that the distance between two aromatic rings increased by one methylene bridge increased as previously described in the X-ray structures of *syn*-**3b** and *syn*-**3c**.

In the present [3.2]MCPs there are two possible conformers, *anti*- and *syn*-conformer. The through-space electronic interaction could be performed through the intraannular positions in the former conformer, but through face-to-face overlapping among the two benzene rings in the latter conformer (30). Thus, the charge-transfer complex would be stabilized by two types of the through-space electronic interaction, i.e., face-to-face overlapping and intraannular interaction with the opposing benzene ring, thus shifting the charge-transfer absorption band to the red region. The higher red shift of [3.2]MCP-10-ene (17 nm) are obtained in *syn*-conformer rather than in *anti*-conformer. Therefore, face-to-face overlapping might be much more favorable to stabilize the charge-transfer than the intraannular interaction.



In spite of two routes for the photocyclization of stilbenes such as staircase *anti*-conformation and "face-to-face overlapping" *syn*-conformation are possible (31), the latter reaction pathway has not been established due to the lack of the model compounds. Most investigations of the photoconversion of stilbene derivatives to 9,10-dihydrophenanthrenes have used *anti*-[2.2]MCP-1-enes (32) and *anti*-[2.2]MCP-1,9-dienes (5*a*). Boekelheide et al. (32) reported the photocyclization of *anti*-[2.2]MCP-1-enes in the presence of oxidants to afford the corresponding phenanthrenes, but limited to *anti*-conformation. Later, Mitchell et al. (33) also reported the synthesis of *syn*-[2.2]MCP-1,9-diene, which valence isomerized to *cis*-dihydropyrene, but readily isomerized to *anti*-cyclophane systems. Thus, there is substantial interest in investigating the photocyclization of present *syn*-[n.2]MCP-enes to explore the above reaction pathways.

Actually, when *syn*-**3b** was irradiated in the presence of iodine as an oxidant at room temperature for 1 h, the desired phenanthrene **10** was obtained only in 23% yield along with recovery of the starting compound. In contrast, similar reaction of *anti*-**6** carried out under the same reaction conditions afforded the cyclization product **11** in 90% yield.

The rate of the photocyclization of *anti*-**6** was found to be much faster than that of *syn*-**3b** and almost completed within 1 h. The different reactivities for the irradiation of *syn*-**3b** and *anti*-**6** were observed. In the present photocyclization reaction of *syn*-**3b**, the photoinduced *syn*–*anti*-isomerization might be possible to afford the corresponding *anti*-conformer *anti*-**3b**, which is cyclized to the cyclization product

© 2000 NRC Canada

Scheme 4.

10. In fact, the irradiation of *syn*-**3b** in the absence of iodine as an oxidant at room temperature was attempted, but none of the formation of *anti*-conformer *anti*-**3b** was observed under the present reaction conditions. This result indicates that the cyclization product **10** might be directly formed via the *syn*-**3b**, but not the corresponding *anti*-**3b** as an intermediate.

Examination of molecular models led us to believe that the transformation of *anti*-**6** into phenanthrene **11** should be straightforward, since in the conformationally rigid stilbene moiety of *anti*-**6**, the π orbitals involved in the required photochemically produced disrotatory cyclization leading eventually to the phenanthrene **11** are apparently very close in space. The reason for the present preference for the formation of *trans*-dihydrophenanthrene rather than *cis*-dihydrophenanthrene as the intermediate might be attributable to the more stable chair form transition state than boat one and the conformational fixation to the chair form in the ground and transition state is possible in the *anti*-conformer.

In conclusion, a new synthesis of *syn*- and *anti*-[n.2]MCPenes by a McMurry cyclization has been developed and applied to the synthesis of phenanthrene-anellated polycyclic aromatic hydrocarbons substituted at positions 4 and 5 by the successive photoinduced transannular cyclization reaction. Further studies on the present novel photoinduced transannular cyclization reaction of **3** and **6** are now in progress.

Experimental

All melting points (Yanagimoto MP-S1) were uncorrected. Proton nuclear magnetic resonance (^{1}H NMR) spectra were recorded on a Nippon Denshi JEOL FT-270 spectrometer. Chemical shifts are reported as δ values (ppm) relative to internal Me_4Si. Mass spectra were obtained on a Nippon Denshi JMS-01SG-2 mass spectrometer at an ionization energy of 70 eV (*m*/*z* values reported include the parent ion peak). Infrared (IR) spectra were obtained on a Nippon Denshi JIR-AQ2OM spectrophotometer as KBr disks. Elemental analyses were performed by Yanaco MT-5. GLC analyses were performed by Shimadzu gas chromatograph GC-14A (Silicone OV-1, 2 m, programmed temperature rise, 12°C/min, carrier gas nitrogen, 25 mL/min).

Materials

1,n-Bis(4-methoxyphenyl)alkanes **1** were prepared following previous reports (12, 13).

Preparation of 1,n-bis(3-acetyl-4-methoxyphenyl)alkane (2) — typical procedure

To a solution of 1,3-bis(4-methoxyphenyl)propane (**1b**) (3.84 g, 15 mmol) and acetyl chloride (3.15 mL, 45 mmol) in methylene dichloride (60 mL) was added a solution of aluminum chloride (8.91 g, 67.5 mmol) in nitromethane (15 mL) at 0°C. After the reaction mixture had been stirred at room temperature for 3 h, it was poured into ice water (100 mL). The organic layer was extracted with CH_2Cl_2 (2 × 50 mL). The extract was washed with water (2 × 50 mL), dried (Na_2SO_4), and concentrated. The residue was chromatographed over silica gel (Wako C-300, 300 g) with $CHCl_3$ as eluent to give crude **2b** as a colorless solid. Recrystallization from hexane–benzene (1:1) gave 1,3-bis(3-acetyl-4-methoxyphenyl)propane (**2b**) (4.42 g, 87%) as colorless prisms, mp 46–48°C. IR (KBr) υ_{max}: 1667 (C=O) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 1.85–1.95 (2 H, m), 2.55–2.62 (4 H, m), 2.60 (6 H, s), 3.89 (6 H, s), 6.90 (2 H, d, *J* = 8.0), 7.27 (2 H, dd, *J* = 8.0, 2.0), 7.52 (2 H, d, *J* = 2.0). MS *m*/*z*: M^+ 340. Anal. calcd. for $C_{21}H_{24}O_4$ (340.42): C 74.09, H 7.11; found: C 74.20, H 7.15.

Compounds **2a** and **2c** were similarly prepared in 29 and 71% yields, respectively.

*1,2-Bis(3-acetyl-4-methoxyphenyl)ethane (**2a**)*

Colorless prisms (hexane–benzene (1:1)), mp 114–115°C. IR (KBr) υ_{max}: 1664 (C=O) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 2.60 (6 H, s), 2.84 (4 H, s), 3.89 (6 H, s), 6.87 (2 H, d, *J* = 8.7), 7.23 (2 H, dd, *J* = 8.7, 2.4), 7.54 (2 H, d, *J* = 2.4). MS *m*/*z*: M^+ 326. Anal. calcd. for $C_{20}H_{22}O_4$ (326.4): C 73.6, H 6.79; found: C 73.45, H 6.89.

*1,4-Bis(3-acetyl-4-methoxyphenyl)butane (**2c**)*

Colorless prisms (hexane–benzene (1:1)), mp 74–76°C. IR (KBr) υ_{max}: 1669 (C=O) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 1.60 (4 H, m), 2.57 (4 H, m), 2.60 (6 H, s), 3.88 (6 H, s), 6.87 (2 H, d, *J* = 8.3), 7.25 (2 H, dd, *J* = 8.7, 2.4), 7.52 (2 H, d, *J* = 2.4). MS *m*/*z*: M^+ 354. Anal. calcd. for $C_{22}H_{26}O_4$ (354.5): C 74.55, H 7.39; found: C 74.26, H 7.18.

McMurry coupling reaction of 2 — typical procedure

The McMurry reagent was prepared from $TiCl_4$ [23.8 g (13.8 mL), 125 mmol] and 18 g (275 mmol) of Zn powder in 500 mL of dry THF, under nitrogen. A solution of **2b** (3.06 g, 9 mmol) and pyridine (22.5 mL, 200 mmol) in dry THF (250 mL) was added within 60 h from two Hershberg funnels to the black mixture of the McMurry reagent by using a high-dilution technique (34) with continuous refluxing and stirring. The reaction mixture was refluxed for an additional 8 h, cooled to room temp., and hydrized with aqueous 10% K_2CO_3 (200 mL) at 0°C. The reaction mixture was extracted with CH_2Cl_2 (3 × 200 mL). The combined extracts were washed with water, dried with Na_2SO_4 and concentrated.

© 2000 NRC Canada

The residue was chromatographed over silica gel (Wako C-300, 300 g) with benzene as eluents to give crude **3b** as a colorless solid. Recrystallization from benzene gave *syn*-7,13-dimethoxy-10,11-dimethyl[3.2]metacyclophan-10-ene (*syn*-**3b**) (1.10 g, 40%) as colorless prisms, mp 162–163°C. ^{1}H NMR ($CDCl_3$) δ: 1.20–1.45 (1 H, m), 2.10–2.25 (1 H, m), 2.18 (6 H, s), 2.50–2.65 (2 H, m), 2.85–2.98 (2 H, m), 3.59 (6 H, s), 6.33 (2 H, d, *J* = 8.0), 6.60 (2 H, dd, *J* = 2.0, 8.0), 6.95 (2 H, d, *J* = 2.0). MS *m/z*: M^+ 308. Anal. calcd. for $C_{21}H_{24}O_2$ (308.42): C 81.78, H 7.84; found: C 81.71, H 7.78.

Similarly, the McMurry coupling reaction was carried out for compounds **2a** and **2c** in the same manner as described above.

For **2a** the residue was chromatographed over silica gel (Wako C-300, 300 g) with benzene–$CHCl_3$ (1:1) as eluents to give crude **4a** as a colorless solid. Recrystallization from $CHCl_3$ gave **4a** (500 mg, 19%) as colorless prisms.

For **2c** the residue was chromatographed over silica gel (Wako C-300, 300 g) with hexane–benzene (1:1) as eluents to give crude *syn*-**3c** as a colorless solid. Recrystallization from hexane gave *syn*-**3c** (2.01 g, 69%) as colorless prisms.

*4,14,20,30-Tetramethoxy-1,2,17,18-tetramethyl[2.2.2.2]-metacyclophane-1,17-diene (**4a**)*

Colorless prisms ($CHCl_3$), mp 280–282°C. IR (KBr) υ_{max}: 2930, 1497, 1456, 1262, 1253, 1229, 1133, 1050, 1031, 810 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 2.15 (12 H, s), 2.50 (8 H, broad s), 3.58 (12 H, s), 6.56 (4 H, d, *J* = 8.3), 6.71–6.80 (4 H, broad s), 6.83 (4 H, dd, *J* = 8.3, 2.0). MS *m/z*: M^+ 588. Anal. calcd. for $C_{40}H_{44}O_4$ (588.79): C 81.6, H 7.53; found: C 81.81, H 7.68.

syn-*8,14-Dimethoxy-11,12-dimethyl[4.2]metacyclophan-11-ene (*syn-***3c**)

Colorless prisms (hexane), mp 160–161°C. IR (KBr) υ_{max}: 2923, 1493, 1442, 1252, 1226, 1032, 805, 797 cm^{-1}. ^{1}H NMR ($CDCl_3$) (27°C) δ: 1.55 (4 H, broad s), 2.14 (6 H, s), 2.36 (4 H, broad s), 3.63 (6 H, s), 6.41 (2 H, d, *J* = 8.3), 6.59 (2 H, dd, *J* = 2.4, 8.3), 6.90 (2 H, d, *J* = 2.4). ^{1}H NMR ($CDCl_3$) (–40°C) δ: 1.1–1.4 (2 H, broad s), 1.72–1.92 (2 H, broad s), 2.17 (6 H, s), 2.1–2.3 (2 H, broad s), 2.4–2.6 (2 H, broad s), 3.67 (6 H, s), 6.41 (2 H, d, *J* = 8.3), 6.64 (2 H, dd, *J* = 2.4, 8.3), 6.93 (2 H, d, *J* = 2.4). MS *m/z*: M^+ 322. Anal. calcd. for $C_{22}H_{26}O_2$ (322.45): C 81.95, H 8.13; found: C 82.07, H 8.15.

Preparation of 1,3-bis(3-formyl-4-methoxyphenyl)-propane (5)

To a solution of 1,3-bis(4-methoxyphenyl)propane (**1b**) (2.24 g, 8.75 mmol) and Cl_2CHOCH_3 (2.28 mL, 25.2 mmol) in CH_2Cl_2 (20 mL) was added a solution of $TiCl_4$ (6.0 mL, 54.5 mmol) in CH_2Cl_2 (20 mL) at 0°C. After the reaction mixture was stirred at room temp for 3 h, it was poured into a large amount of ice water (400 mL) and extracted with CH_2Cl_2 (2 × 200 mL). The combined extracts were washed with water, dried with Na_2SO_4, and concentrated. The residue was chromatographed over silica gel (Wako C-300, 500 g) with $CHCl_3$ as eluent to give crude **5**. Recrystallization from hexane gave 2.81 g (99.6%) of 1,3-bis(3-formyl-4-methoxyphenyl)propane (**5**) as colorless prisms, mp 93–94°C. IR (KBr) υ_{max}: 1682 (C=O) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 1.88–2.00 (2 H, m), 2.60–2.67 (4 H, m), 3.95 (6 H, s), 6.95 (2 H, d, *J* = 8.8), 7.39 (2 H, dd, *J* = 8.8, 2.4), 7.66 (2 H, d, *J* = 2.4), 10.48 (2 H, s). MS *m/z*: M^+ 312. Anal. calcd. for $C_{19}H_{20}O_4$ (312.37): C 73.06, H 6.45; found: C 73.19, H 6.32.

McMurry coupling reaction of 5

The McMurry reagent was prepared from $TiCl_4$ [23.8 g (13.8 mL), 125 mmol] and 18 g (275 mmol) of Zn powder in 500 mL of dry THF, under nitrogen. A solution of **5** (3.21 g, 9 mmol) and pyridine (22.5 mL, 200 mmol) in dry THF (250 mL) was added within 60 h to the black mixture of the McMurry reagent by using a high-dilution technique with continuous refluxing and stirring. The reaction mixture was refluxed for additional 8 h, cooled to room temp, and hydrized with aqueous 10% K_2CO_3 (200 mL) at 0°C. The reaction mixture was extracted with CH_2Cl_2 (3 × 200 mL). The combined extracts were washed with water, dried with Na_2SO_4, and concentrated. The residue was chromatographed over silica gel (Wako C-300, 300 g) with hexane–benzene (1:1) as eluents to give crude **6** as a colorless solid. Recrystallization from methanol gave *anti*-7,13-dimethoxy[3.2]metacyclophan-10-ene (*anti*-**6**) (711 mg, 28%) as colorless prisms, mp 94–95°C. IR (KBr) υ_{max}: 1593, 1485, 1461, 1276, 1255, 1242, 1114, 1027, 797, 753 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 1.78–1.89 (2 H, m), 2.20–2.50 (4 H, broad s), 3.85 (6 H, s), 6.05 (2 H, d, *J* = 2.4), 6.77 (2 H, d, *J* = 8.3 Hz), 6.88 (2 H, s), 6.97 (2 H, dd, *J* = 8.3, 2.44). MS *m/z*: M^+ 308. Anal. calcd. for $C_{19}H_{20}O_2$ (280.37): C 81.4, H 7.19; found: C 81.62, H 7.26.

Demethylation of syn-3b

To a solution of *syn*-**3b** (32.2 mg, 0.105 mmol) in CH_2Cl_2 (5 mL) at 0°C was gradually added a solution of BBr_3 (0.03 mL, 0.3 mmol) in CH_2Cl_2 (1 mL) over a period of 15 min. After the reaction mixture has been stirred at room temperature for 2 h, it was poured into ice water (50 mL), extracted with CH_2Cl_2 (3 × 20 mL). The combined extracts were washed with water (2 × 20 mL), dried over Na_2SO_4, and concentrated in vacuo to leave a residue. The residue was recrystallized from hexane–ethyl acetate (1:1) gave *syn*-7,13-dihydroxy-10,11-dimethyl[3.2]metacyclophan-10-ene (*syn*-**7b**) (14.1 mg, 44%) as colorless prisms, mp 189–189.5°C. IR (KBr) υ_{max}: 3272 (OH) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 2.23 (6 H, s), 2.05–2.28 (2 H, broad s), 2.45–2.62 (2 H, broad s), 2.78–2.98 (2 H, broad s), 5.29 (2 H, s, replaced by D_2O), 6.33 (2 H, d, *J* = 8.30), 6.56 (2 H, dd, *J* = 8.30, 2.44), 6.85 (2 H, d, *J* = 2.44). MS *m/z*: M^+ 306. Anal. calcd. for $C_{19}H_{20}O_2$ (280.37): C 81.4, H 7.19; found: C 81.62, H 7.28.

Compound *syn*-**7c** was similarly prepared in 53% yield.

syn-*8,14-Dihydroxy-11,12-dimethyl[4.2]metacyclophan-11-ene (*syn-***7c**)

Colorless prisms (hexane–ethyl acetate (1:1)), mp 194–194.5°C. IR (KBr) υ_{max}: 3344 (OH) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 1.40–1.75 (4 H, broad s), 2.19 (6 H, s), 2.20–2.42 (4 H, broad s), 5.15 (2 H, broad s, replaced by D_2O), 6.38 (2 H, d, *J* = 8.3), 6.52 (2 H, dd, *J* = 2.4, 8.3), 6.80 (2 H, d, *J* = 2.4). MS *m/z*: M^+ 294. Anal. calcd. for $C_{20}H_{22}O_2$ (294.38): C 81.6, H 7.53; found: C 81.91, H 7.50.

Reduction of *syn*-3 with H_2 in the presence of Pd-C — typical procedure

To a solution of *syn*-**3b** (30 mg, 0.097 mmol) in ethyl acetate (40 mL) was added Pd-C (5%, 15 mg) and stirred for 24 h under the hydrogen atomosphere at room temp. The reaction mixture was concentrated. The residue was chromatographed over silica gel (Wako C-300, 100 g) with hexane–benzene (1:1) as eluents to give *anti*-**8b** (18.1 mg, 60%) as a colorless solid. Recrystallization from methanol gave *anti*-10-*exo*,11-*endo*-dimethyl-7,13-dimethoxy[3.2]metacyclophane (*anti*-**8b**) as colorless prisms, mp 84–85°C. ^{1}H NMR ($CDCl_3$) δ: 0.95 (3 H, d, J = 7.3), 1.68 (3 H, d, J = 7.3), 1.80–2.00 (2 H, m), 2.00–2.15 (1 H, m), 2.17–2.34 (1 H, m), 2.33–2.46 (1 H, m), 2.68–2.80 (2 H, m), 3.61–3.76 (1 H, m), 3.78 (3 H, s), 3.85 (3 H, s), 4.87 (1 H, d, J = 2.4), 5.24 (1 H, d, J = 2.4), 6.78 (2 H, d, J = 8.3), 6.93–7.01 (2 H, m). MS m/z: M^+ 310. Anal. calcd. for $C_{21}H_{26}O_2$ (310.44): C 81.25, H 8.44; found: C 81.12, H 8.28.

Compound *anti*-**8c** was similarly prepared in 95% yield.

anti-*11*-exo,*12*-endo-*Dimethyl-8,14-dimethoxy[4.2]metacyclophane (*anti-***8c***)*

Colorless prisms (methanol), mp 93–94°C. ^{1}H NMR ($CDCl_3$) (27°C), δ: 0.70–2.89 (16 H, broad m), 3.81 (6 H, s), 5.52–6.00 (2 H, s), 6.75 (2 H, d, J = 8.3), 6.86 (2 H, dd, J = 8.3, 2.4). ^{1}H NMR ($CDCl_3$–CS_2 (1:3)) (–30°C) δ: 0.82–1.08 (2 H, broad s), 0.98 (3 H, d, J = 7.3), 1.45–1.62 (2 H, broad s), 1.68 (3 H, d, J = 7.3), 2.09–2.28 (2 H, m), 2.55 (1 H, d, J = 7.3), 2.60–2.78 (2 H, m), 3.66 (1 H, d, J = 7.3), 3.80 (3 H, s), 3.87 (3 H, s), 5.61 (1 H, d, J = 2.4), 5.92 (1 H, d, J = 2.4), 6.77 (2 H, d, J = 8.3), 6.86–6.96 (2 H, m). MS m/z: M^+ 306. Anal. calcd. for $C_{22}H_{28}O_2$ (324.47): C 81.44, H 8.7; found: C 81.45, H 8.63.

Photoinduced cyclization of *anti*-6 in the presence of iodine

The mixture of *anti*-**6** (112 mg, 0.4 mmol) and iodine (112.0 mg, 0.44 mmol) was dissolved in cyclohexane (200 mL) in a Pyrex flask and then irradiated by a 400 W high-pressure mercury lamp while being monitored by GLC. Irradiation was continued until the disappearance of the reactant *anti*-**6** (1 h). The reaction mixture was washed with 10% sodium thiosulfate and water, dried with Na_2SO_4, and concentrated. The residue was chromatographed over silica gel (Wako C-300, 100 g) with hexane–benzene (1:1) as eluents to give **11** (100 mg, 90%) as a colorless solid. Recrystallization from hexane gave 1,8-dimethoxy-4,5-propanophenanthrene (**11**) as colorless prisms, mp 86–87°C. IR (KBr) υ_{max}: 2937, 1587, 1498, 1426, 1270, 1241, 1144, 1029, 810 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 2.44–2.55 (2 H, m), 2.76–2.81 (4 H, m), 4.02 (6 H, s), 6.92 (2 H, d, J = 7.8), 7.32 (2 H, d, J = 7.8), 8.11 (2 H, s). MS m/z: M^+ 278. Anal. calcd. for $C_{19}H_{18}O_2$ (278.35): C 81.99, H 6.52; found: C 81.73, H 6.33.

Compound **10** was similarly prepared in 23% yield.

*3,6-Dimethoxy-9,10-dimethyl-4,5-propanophenanthrene (**10**)*

Colorless prisms (methanol), mp 51–53°C. IR (KBr) υ_{max}: 2925, 1577, 1159, 1029, 803, 667 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 2.34–2.47 (2 H, m), 2.6–2.7 (4 H, m), 2.77 (6 H, s), 3.93 (6 H, s), 6.94 (2 H, d, J = 7.82), 7.18 (2 H, d, J = 7.82). MS m/z: M^+ 306. Anal. calcd. for $C_{21}H_{22}O_2$ (306.41): C 82.32, H 7.24; found: C 82.21, H 7.18.

Crystal data and refinement details for *syn*-3b and *syn*-3c

The unit cell constants were derived from least-squares analysis of the settings, on an Enraf–Nonius CAD4 FR 586 diffractometer, for 16 reflections for *syn*-**3b** and 25 reflections for *syn*-**3c** in the range 23.9° < θ < 24.6° for *syn*-**3b** and 22.0° < θ < 32.0° for *syn*-**3c**. The intensities of all independent reflections with 4° < 2θ < 140° for *syn*-**3b** and 4° < 2θ < 144° for *syn*-**3c** were measured with ω-2θ scan (ω scan width = 0.8 + 0.14 tan θ), Ni-filtered Cu–K_α radiation (λ = 1.54184 Å) was used. The structure was solved uneventfully by direct method (SIR88)[3] and difference Fourier syntheses, and refined in full-matrix least-squares method.

Transition state stabilization by micelles: thiolysis of *p*-nitrophenyl alkanoates in cetyltrimethylammonium bromide micelles

Oswald S. Tee and Ogaritte J. Yazbeck

Abstract: Thiolysis of *p*-nitrophenyl esters (acetate to decanoate) by the anion of 2-mercaptoethanol (ME) is catalyzed by micelles of cetyltrimethylammonium bromide (CTAB) in aqueous solution. At fixed [ME], the observed rate constants (k_{obs}) show saturation with respect to added [CTAB], consistent with ester binding in the micelles. Plots of k_{obs} vs. [ME] are linear in the absence and in the presence of the CTAB, and analysis of the slopes of the plots afford rates constants for thiolate ion attack on the esters in the aqueous phase (k_N) and in the micellar phase (k_{cN}). The strengths of substrate binding and transition state binding to the micelles are strongly correlated, with a slope of *unity,* because they have the same dependence on the ester chain. Consequently, the catalytic ratios (k_{cN}/k_N) are independent of the length of the ester. Similar behaviour is found for thiolysis by the dianions of mercaptoacetic acid, 3-mercaptopropionic acid, and cysteine, and also for ester cleavage by the anions of glycine and 2,2,2-trifluoroethanol, as earlier for cleavage by hydroxide ion. The results are consistent with Kirby's dissection of transition state binding into "passive" and "dynamic" components. The passive component involves hydrophobic binding of the ester chain which is more or less the same as in the substrate binding. The dynamic component is associated with reaction in the Stern layer of the micelle, and its magnitude varies with the nucleophiles because of differences in their ease of exchange between the aqueous medium and the Stern layer.

Key words: catalysis, esters, thiolysis, micelles.

Résumé : La thiolyse des esters (acétate à décanoate) de *p*-nitrophényle, par l'anion 2-mercaptoéthanol (ME) en solution aqueuse, est catalysée par les micelles de bromure de cétyltriméthylammonium (« CTAB »). À des valeurs fixes de [ME], les constantes de vitesse observées (k_{obs}) présentent une saturation par rapport à la [CTAB] ajoutée et cette observation est en accord avec une fixation dans les micelles. Les courbes de k_{obs} en fonction de [ME] sont linéaires tant en absence qu'en présence de CTAB et une analyse des pentes de ces courbes permet de déterminer les constantes de vitesse pour l'attaque de l'ion thiolate sur les esters en phase aqueuse (k_N) et en phase micellaire (k_{cN}). Il existe une grande corrélation entre les forces de fixation des micelles avec le substrat ou de l'état de transition; la pente est égale à l'unité en raison du fait qu'elles dépendent toutes les deux de la même chaîne ester. En conséquence, les rapports catalytiques (k_{cN}/k_N) sont indépendants de la longueur de l'ester. On observe un comportement semblable lors de la thiolyse par les anions de l'acide mercaptoacétique, de l'acide 3-mercaptopropionique et de la cystéine ainsi que lors du clivage des esters par les anions de la glycine et du 2,2,2-trifluoroéthanol; antérieurement, on avait observé le même résultat avec l'ion hydroxyde. Les résultats sont en accord avec la dissection de Kirby de la fixation de l'état de transition en des composantes « passive » et « dynamique ». La composante passive implique une fixation hydrophobe de la chaîne de l'ester qui est à peu près semblable à la fixation du substrat; la composante dynamique est associée à la réaction dans la couche de Stern de la micelle et son amplitude varie avec les nucléophiles en raison des différences dans leur facilité d'échange entre le milieu aqueux et la couche de Stern.

Mots clés: catalyse, esters, thiolyse, micelles.

[Traduit par la Rédaction]

Introduction

Over the last forty years, the effects of micelles on organic reactions have been studied extensively (1). One of the first reactions to be studied in detail was the cleavage of aryl esters by hydroxide ion, which is retarded by anionic micelles but catalyzed by cationic ones (for example see ref. (2)). Since the catalytic effects of cationic micelles are more evident for esters with long chains, it was reasonable for authors to conclude that the acceleration is chain length

Fig. 1. Variation of k_{obs} for ester cleavage with [ME] in the presence of 5.00 mM NaBr, but no CTAB, at pH 10.60. The data are for the esters acetate, butanoate, pentanoate, hexanoate, heptanoate, and octanoate, as indicated. The slopes of the plots provide k_N values (Table 1).

dependent, presumably because an ester with a longer acyl chain is more readily incorporated into the micelle.

The origin of the micellar catalysis of ester cleavage was ascribed to concentration of the reactants in the restricted volume of the micelle: hydroxide ion in the Stern layer, and the ester in the hydrophobic core but with its carbonyl group accessible to the aqueous environment of the Stern layer (1, 2). Consistent with this interpretation, Al-Awadi and Williams (3) found that the Hammett ρ value for basic cleavage of substituted phenyl dodecanoate esters in CTAB micelles is the same as the value for reaction in aqueous solution. Subsequently, one of us pointed out (4) that this finding means that the transition state stabilization by CTAB micelles is independent of the aryloxy leaving group of the ester, and so, presumably, it depends on the acyl chain length of the ester.

Recently, we tested this suggestion by studying the basic hydrolysis of *p*-nitrophenyl alkanoates (acetate to octanoate) in CTAB micelles (5). Remarkably, we found that the chain length dependence of the transition state binding, and thus of the transition state stabilization, is exactly the same as that for the substrate binding. As a result, the limiting acceleration is independent of the ester chain length, although it is more evident for longer esters because they bind to the micelles more strongly. The work described below was carried out to see if these features carry over to reactions of aryl esters with thiolate anion nucleophiles. There have been a few previous studies of the effect of cationic surfactants on ester thiolysis (6) but none of them focussed on a series of alkanoates, which is the case here.

Results

We have studied the effect of CTAB micelles on the thiolysis of *p*-nitrophenyl alkanoate esters: acetate, butanoate, pentanoate, hexanoate, heptanoate, octanoate, and in some cases the decanoate. The reaction medium was an aqueous 0.10 M carbonate buffer of pH 10.60. To be consistent with previous work (3, 5), and to avoid the complications arising from variable bromide ion exchange into the micelles (2*c*, 2*d*, 2*h*, 3, 7), the total bromide ion concentration was kept constant at 5.0 mM.

Our first series of experiments involved the anion of 2-mercaptoethanol (ME) as the thiolate nucleophile (Nuc). In the aqueous buffer with no CTAB, the dependence of k_{obs} on added nucleophile is strictly linear (Fig. 1), as expected from previous work (8). For reaction in the presence of a fixed concentration of CTAB, the dependence of k_{obs} on [Nuc] is also linear (Fig. 2), which indicates that even though thiolate ions exchange into the Stern layers of micelles, the effect does not approach saturation. At a fixed concentration of the nucleophile, the variation of k_{obs} with [CTAB] shows saturation behaviour (Fig. 3) due to binding of the ester substrates in the micelles.

Following the approach developed previously for bimolecular reactions mediated by cyclodextrins (8, 9), analysis of the data is based on consideration of four competing processes: (*i*) basic hydrolysis of the ester (Es) in the medium (eq. [1]); (*ii*) basic hydrolysis within the micelles (eq. [2]); (*iii*) nucleophilic attack in the medium (eq. [3]); and (*iv*) nucleophilic attack within the micelles (eq. [4]). Together, these four processes require the variation of the rate constant for ester cleavage with surfactant concentration, [Surf], which is given in eq. [5], assuming that the concentration of ester is low enough not to affect micellization. Note that binding of the ester to the micelle is characterized by a dissociation constant, K_S = [Es][Surf]/[Es/Surf].

[1] $$\mathrm{Es} \xrightarrow{k_u} \text{products}$$

[2] $$\mathrm{Es} + \mathrm{Surf} \underset{K_S}{\rightleftharpoons} \mathrm{Es{\cdot}Surf} \xrightarrow{k_c} \text{products}$$

[3] $$\mathrm{Es} + \mathrm{Nuc} \xrightarrow{k_N} \text{products}$$

[4] $$\mathrm{Es{\cdot}Surf} + \mathrm{Nuc} \xrightarrow{k_{cN}} \text{products}$$

[5] $$k_{obs} = \frac{(k_u K_S + k_c[\mathrm{Surf}]) + (k_N K_S + k_{cN}[\mathrm{Surf}])[\mathrm{Nuc}]}{(K_S + [\mathrm{Surf}])}$$

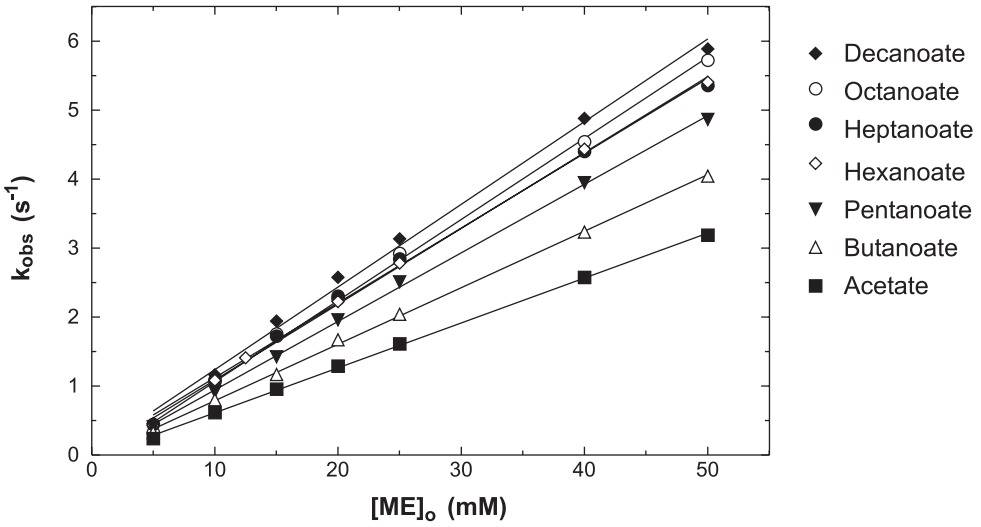
Fig. 2. Variation of k_{obs} for ester cleavage with [ME] in the presence of 5.00 mM of CTAB, but no NaBr, at pH 10.60. The data are for the esters indicated on the graph. Analysis of the slopes (see text) gives values of k_{cN}. Note that, because of micellar catalysis, the vertical scale here is 10 times that in Fig. 1.



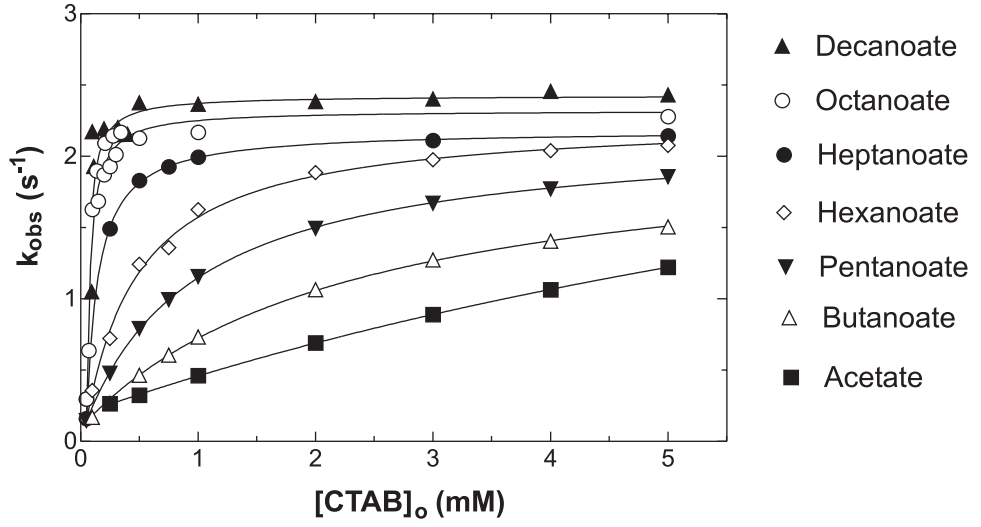


Fig. 3. Variation of k_{obs} for ester cleavage with [CTAB] in the presence of 20 mM mercaptoethanol, and total bromide ion = 5.00 mM, at pH 10.60. The data are for the esters indicated. Fitting eq. [6] to the data, with [Surf] = ([Surf]$_o$- cmc), provide values of K_S for the esters. See Experimental section.

Values of k_N are obtained from the linear plots found for experiments with no added surfactant, when $k_{obs} = k_u + k_N[Nuc]$ (e.g., Fig. 1). With varying [Surf], but constant [Nuc], and assuming that the added nucleophile does not alter K_S or [Surf], eq. [5] simplifies to eq. [6], where $k_u' = (k_u + k_N[Nuc])$ and $k_c' = (k_c + k_{cN}[Nuc])$. Equation [6] corresponds to simple saturation kinetics, as is observed (Fig. 3), and nonlinear regression of the data affords estimates of K_S, as well as of k_u' and k_c'.[2]

$$[6] \qquad k_{obs} = \frac{(k_u' K_S + k_c'[Surf])}{(K_S + [Surf])}$$

For the experiments with constant [Surf], eq. [5] requires a linear dependence of k_{obs} on [Nuc], as observed for ME (Fig. 2), with a slope of $(k_N K_S + k_{cN}[Surf])/(K_S + [Surf])$. Knowing k_N and K_S from the analyses of the other experiments, values of k_{cN} can be estimated from such slopes. Table 1 collects the values of k_N, k_{cN}, and K_S for reaction between the anion of ME and the series of esters, deduced from the kinetic data shown in Figs. 1, 2, and 3.

Analogous experiments with the dianion of mercaptoacetic acid (MAA) gave results similar to those found for the anion of ME. The slopes of the linear plots of k_{obs} vs. [Nuc] in the absence of CTAB provided k_N, and the saturation behaviour of k_{obs} with [CTAB], at fixed [Nuc],

[2] As explained in the Experimental Section, we have taken [Surf] = [Surf]$_o$ – cmc, with the critical micellar concentration (cmc) fixed at 0.05 mM.

[a]At 25°C, in an aqueous carbonate buffer of pH 10.60, with the total bromide concentration ([CTAB] + [NaBr]) kept at 5.00 mM. The actual data for ME are shown in Figs. 1, 2, and 3.

[b]Difficult to determine accurately and so assumed to be the same as for the octanoate.

[c]Obtained by extrapolation of the linear plot of pK_S vs. *N*.

[d]For the experiments with the anions of MPA, CYST, and GLY the values of K_S were to be taken to be the same as those found with the mercaptoacetate dianion.[4]

[e]For the experiments with the anion of TFE, the values of K_S were to be taken to be the same as those found earlier with hydroxide ion (5), under the same conditions.

was analyzed in terms of eq. [6] to find K_S. Plots of k_{obs} vs. [MAA] at fixed [CTAB] show very slight downward curvature[3] at the high end of the range of [MAA] = 0–25.0 mM, and to minimize its effect values of k_{cN} were estimated from the data points in the concentration range 0–15.0 mM, where the variation in k_{obs} is essentially linear.

[3]This curvature may indicate the onset of saturation of the micelles with the thiolate dianions which probably bind stronger than the monoanion of ME — see Discussion. Alternatively, high thiolate concentrations may start to alter the micellization parameters.

[4]The K_S values found with the anions of ME and MAA (Table 1) differ little from those found earlier with hydroxide ion (5), despite differences in pH, buffer, and ionic strength.

© 2000 NRC Canada

Experiments were also carried out with the dianions of 3-mercaptopropionic acid (MPA) and cysteine (CYST), and, for comparison, with the anion of glycine (GLY), an amine nucleophile, and the anion of 2,2,2-trifluoroethanol (TFE), an oxyanion. For the experiments with TFE, the medium was a 0.20 M phosphate buffer of pH 11.60, as used for previous studies of ester cleavage by hydroxide ion (5). Again, the plots of k_{obs} against [Nuc], at constant [CTAB], showed slight curvature at the high [Nuc], and so k_{cN} values were estimated from the linear dependence in the range [Nuc] = 0–15.0 mM. Since the values of K_S do not appear to be significantly sensitive to the nucleophile,[4] the values found from the experiments with MAA were used in the analyses to find k_{cN} values for the anions of MPA, CYST, and GLY. For the anion of TFE, the values of K_S that were found from reaction with hydroxide ion in the same phosphate buffer (5) were used.

Values of k_N and k_{cN} obtained for the anions of MAA, MPA, CYST, GLY, and TFE are also collected in Table 1, along with apparent "equilibrium constants," K_{TS}. Such constants are useful measures of transition state stabilization in catalyzed reactions (4). For the present purposes, K_{TS} is defined in eq. [7] to be the dissociation constant of the transition state for the micelle-catalyzed cleavage (TS·Surf) into the transition state of normal cleavage (TS) and the micellized surfactant (Surf). We have used analogous constants extensively in work on the effects of cyclodextrins on reactions (4, 8, 9, and references therein), as have other authors for various catalysts (10), including enzymes (11), enzyme mimics (12), and micelles (13).

$$[7] \qquad K_{TS} = [TS][Surf]/[TS\cdot Surf] = k_N/k_3 = k_N K_S/k_{cN}$$

Note that in eq. [7], k_3 is the third order rate constant corresponding to the overall process shown below in eq. [8] which is kinetically equivalent to that shown in eq. [4]. Hence, $k_3 = k_{cN}/K_S$.

$$[8] \qquad Es + Surf + Nuc \xrightarrow{k_3} products$$

Discussion

Two features of the rate and equilibrium constants in Table 1 are immediately apparent. First, beyond the acetate, the rate constants k_N and k_{cN} both show almost no variation with ester chain length and so the limiting accelerations, k_{cN}/k_N, are virtually constant for each nucleophile. Second, and in sharp contrast, the equilibrium constants K_S and K_{TS} vary appreciably with chain length. Consequently, the third order rate constants, $k_3 = k_{cN}/K_S$ (eq. [8]), increase substantially: (*i*) 1300-fold for the anion of ME and 1800 for the dianion of MAA (going from the acetate to the decanoate ester); (*ii*) 200-fold for the dianions of MPA and CYST, and (*iii*) 100-fold for the anions of GLY and TFE (going from the acetate to the octanoate). Similar behaviour was found earlier for cleavage of the same series of esters by hydroxide ion (5).

According to eq. [7], the "catalytic" ratio, $k_{cN}/k_N = K_S/K_{TS}$, is determined by the relative strengths of transition state binding and substrate binding (4, 12). Seen from this point of view, the nearly constant k_{cN}/k_N ratios for each nucleophile (Table 1) arise because the substrate binding and transition state binding have exactly the same sensitivity to elongation of the ester chain. This is precisely the case, as shown by the correlations summarised in Table 2, some of which are plotted in Fig. 4. For each thiolate nucleophile, the slopes of the plots of pK_{TS} vs. chain length (N) and pK_S vs. N, are all essentially the same ($\approx 0.43 \pm 0.02$),[5] and they are barely different for the other three nucleophiles: glycinate ion, the TFE anion, and hydroxide ion. Even more to the point, pK_{TS} values (for transition state binding) are very strongly correlated with pK_S values (for substrate binding), and the slopes are very close to *unity* (Table 2), suggesting that transition state binding and substrate binding are governed by the same structural feature(s) of the esters.

Kirby (12) has proposed that transition state binding can be divided into two, conceptually distinct components: (*i*) *passive binding*, which arises from noncovalent interactions, such as those involved in host–guest complexation; (*ii*) *dynamic binding*, which is due to interactions between the catalyst and the substrate(s) at the reaction centre. At first sight, this division may seem artificial or even naive, especially for catalysts as complex as enzymes and catalytic antibodies (12), but it does provide a useful framework for discussion. Moreover, the division seems entirely appropriate for the present results for micelles.

For micellar catalysis of ester cleavage by nucleophiles, transition state binding closely parallels substrate binding (Fig. 4 and Table 2). This behaviour suggests that the passive binding component is more or less totally hydrophobic in origin, since the slopes of the plots of pK_{TS} vs. N, and pK_S vs. N, of 0.4 (Table 2) are perfectly consistent with dominant hydrophobic interactions (5). Conceivably, then, the passive component of the transition state binding is little different from the initial state binding of the esters. The dynamic component, of course, is associated with nucleophilic attack on the micelle-bound ester and it will be greatly influenced by the exchange of nucleophiles into the micelles. The nearly constant ratios, k_{cN}/k_N, for each nucleophile (Table 1 and ref. (5)) are quite understandable if they are determined almost solely by the accessibility of the nucleophile to the micelle-bound ester.

A key feature of current models of the effects of micelles on reactivity is the exchange of ions between the Stern layer of the micelle and the bulk aqueous medium (1, 7). To quote Bunton et al. (1*f*), for cationic micelles, "large, weakly hydrated polarizable anions displace hydrophilic anions." Among other things, this factor explains why added bromide ion depresses the rate of CTAB-catalyzed hydroxide ion attack on esters (and other substrates) and why high concentrations of CTAB are less catalytic than moderate ones (2, 7). Also, it explains why cetyltrimethylammonium chloride micelles are better catalysts for hydroxide ion attack on esters than are CTAB micelles (for example see ref.(2)). With

[5] The cleavage of *p*-nitrophenyl alkanoates by hydroxide ion is strongly retarded by sodium dodecylsulfate (SDS) micelles (1, 2). Analysis of inhibition curves gives K_S values for binding of the esters to SDS micelles, and the slope of the plot of pK_S vs. N is 0.40 ± 0.01 ($r = 0.9986$, 5 points, for acetate to hexanoate) (A.A. Fedortchenko and O.S. Tee. Unpublished work).

	pK_{TS} vs. *N*	0.42 ± 0.02	0.9963	7
	pK_{TS} vs. pK_S	1.00 ± 0.02	0.9994	7

[a]Using the values of K_S and K_{TS} presented in Table 1, except for hydroxide ion where they are taken from ref. (5). "Slope" is the slope of the least squares line, "*r*" is the correlation coefficient, and *n* is the number of data points in the analysis.

[b]The values of K_S were taken to be the same as those found with the mercaptoacetate dianion.[4]

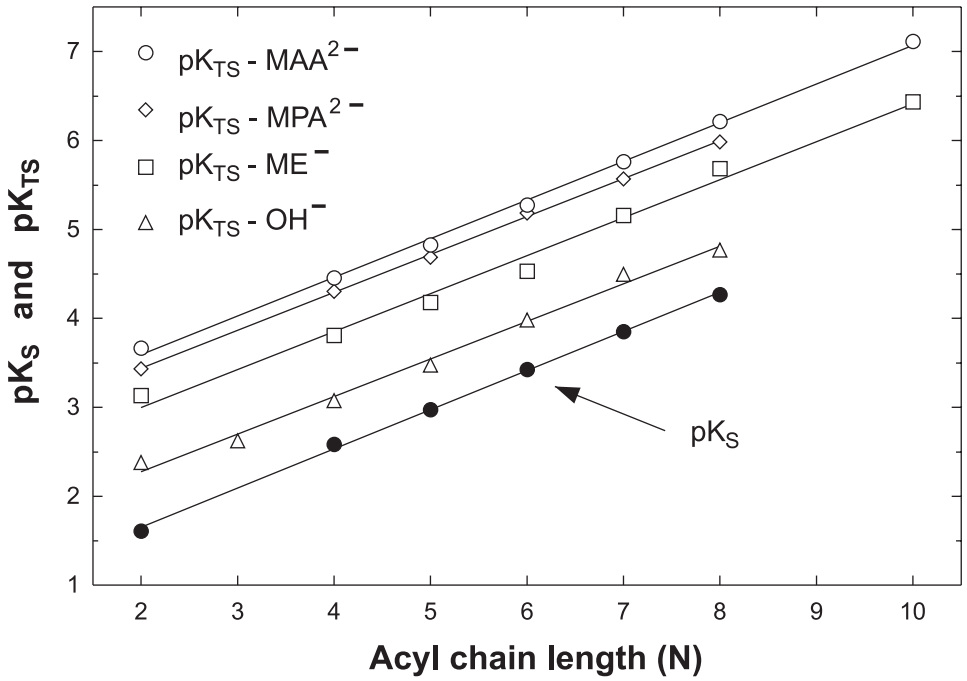
[c]The values of K_S were taken to be the same as those found with hydroxide ion under the same conditions (5).

[d]From previous experiments carried out in an aqueous phosphate buffer of pH 11.60 (5).

respect to the present results, replacement of bromide ions, as well as of hydroxide ion and buffer anions, in the Stern layer by less hydrophilic thiolate anions can explain the catalysis of thiolysis, and also the observation that the catalytic ratios k_{cN}/k_N are independent of the ester.

Hydroxide ion is a small, "hard" anion that is strongly solvated in water, and for its CTAB-catalyzed reaction with *p*-nitrophenyl esters the catalytic ratio k_{cN}/k_N is only 2.4 ± 0.3, when the total bromide ion is kept at 5.0 mM (5). This ratio is low because the heavily hydrated hydroxide ion does not compete well with bromide ion in the Stern layer (7). Thiolate ions, which are "softer," more polarizable, and less strongly solvated, interact more strongly with CTAB micelles, and so they exchange much more readily with bromide ions (6*d*). Consequently, CTAB catalysis of ester thiolysis is appreciably stronger. For the anion of 2-mercaptoethanol, the catalytic ratio is larger than for hydroxide ion and remarkably constant at 15.3 ± 0.6, for esters beyond the acetate (Table 1). For the mercaptoacetate dianion this ratio is larger still, at 79 ± 7, presumably because the double negative charge on the nucleophile enhances its ion exchange. The catalytic ratio is not quite as big for the 3-mercaptopropionate dianion (53 ± 2) or the cysteine dianion (59 ± 4), perhaps because in these larger ions the double negative charge is more spread-out or because they are hydrated slightly more strongly than the dianion of MAA.

By contrast to the high ratios found for the thiolate dianions, for the glycinate anion, which is an amine nucleophile, the catalytic ratio is barely greater than one, at ~1.4 (Table 2). This much lower value is presumably due to a combination of factors: (*i*) the lower overall charge, *(ii)* the harder, nitrogen nucleophile, and (*iii*) stronger hydration in the bulk aqueous medium. Interestingly, the TFE anion has a much higher catalytic ratio (~25) than hydroxide ion (~2.4), even though both are oxyanions. Almost certainly, the TFE anion is appreciably more hydrophobic and less strongly hydrated than hydroxide ion, so that it exchanges into the CTAB micelles more readily.



Catalysis of thiolate attack by cationic micelles has been observed before (6, 14, 15). Moreover, spectral measurements have shown that there are very strong interactions between thiophenoxide ions and CTAB micelles (14). Correspondingly, CTAB micelles catalyze the reaction of thiophenoxide ion with *p*-nitrophenyl acetate by 50-fold (15) and its reaction with 2,4-dinitrofluorobenzene even more so (14). Obviously in this latter case there are additional factors, besides ion exchange, contributing to the dynamic component of transition state stabilization.

Conclusions

On the face of it, Kirby's (12) dissection of transition state binding into passive binding and dynamic binding seems simplistic, and yet it appears to be particularly suitable for the cleavage of *p*-nitrophenyl alkanoates by thiolate ions and other nucleophilic anions in CTAB micelles. From the results discussed above, it is concluded that: (*i*) the passive component of the transition state binding involves hydrophobic binding of the acyl chain of the esters in the micelles that is more or less the same as that involved in the substrate

© 2000 NRC Canada

Fig. 4. The dependence of transition state binding (pK_{TS}) and substrate binding (pK_S) to CTAB micelles on the ester chain length (N) of *p*-nitrophenyl alkanoates. The values of pK_{TS} (open symbols) are for various nucleophiles, as indicated; the values of pK_S (●) are those found with MAA. The pK_{TS} points for CYST and TFE (not shown) are close to those for MPA, and those for GLY are barely different from pK_S because k_{cN}/k_N values are almost one (Table 1). The slopes of the graphs are all about 0.43 (Table 2). The corresponding plots of pK_{TS} against pK_S are linear, with slopes very close to one (Table 2).

binding (Fig. 4); (*ii*) the dynamic component is essentially constant for a given nucleophile because it is primarily determined by the interactions associated with acyl transfer in the Stern layer of the micelle; (*iii*) it varies with the nucleophiles because of differences in their ease of exchange into the Stern Layer, due to their hard and (or) soft character, solvation, and charge.

Support for our first conclusion, (*i*) above, is provided by a recent paper from Buurma et al. (13*c*). These authors probed the nature of the Stern region of micelles (cationic, anionic, and non-ionic) using the kinetics of two pH-independent hydrolysis reactions. From their findings they concluded "…. that the stabilisation by the hydrophobic parts of the micelle is similar for the reactant state and for the activated complex." Obviously, this conclusion is essentially the same as the one we have arrived at from the data in Table 2 and Fig. 4.

Experimental

The *p*-nitrophenyl esters were purchased from Sigma Chemical Co., except for the heptanoate which was synthesized as previously (16). Cetyltrimethylammonium bromide (hexadecyltrimethyl-ammonium bromide, CTAB) was obtained from ICN Biochemicals and purified by extraction with diethyl ether in a Soxhlet apparatus for 4 h to remove any residual amines (17), followed by drying overnight. The other chemicals were the best grades available from the Aldrich Chemical Co.mpany, except for standard NaOH solutions which were obtained from A & C Chemicals (Montreal).

The kinetics of the ester cleavage were followed by monitoring the pseudo-first order appearance of the *p*-nitrophenolate ion at 405 nm, using an Applied Photophysics Ltd. SX17MV Stopped-flow Spectrophotometer, with the cell temperature kept at 25.0 ± 0.1°C. From five to 10 absorbance traces were acquired and computer averaged before estimation of k_{obs} by nonlinear least-squares fitting of an exponential growth curve.

As outlined in the main text, three basic types of kinetics experiments were carried out: (*i*) to find k_N, determine k_{obs} vs. [Nuc], with no CTAB (Fig. 1); (*ii*) to find K_S, determine k_{obs} vs. [CTAB], with fixed [Nuc] (Fig. 2); (*iii*) to find k_{cN}, determine k_{obs} vs. [Nuc], with fixed [CTAB] (Fig. 3). Aliquots of stock ester solutions (0.1 M in spectral grade acetonitrile) were added to solutions of NaBr + requisite amount of CTAB in distilled water to give ester solutions of twice the desired final concentrations. The ester + CTAB solutions were sonicated for 10–20 min to facilitate complete solubilization of the ester and dispersal of the surfactant. The dilute substrate solution was mixed 1:1 with a solution containing carbonate buffer + Nuc, brought to pH 10.60. The final reacting solutions, after mixing in the stopped-flow machine, contained 0.10 M carbonate buffer, CTAB (0–5.00 mM), NaBr (5.00 mM – $[CTAB]_o$), and ester concentrations as follows: (*i*) acetate to pentanoate, 50 μM; (*ii*) hexanoate, 25 μM; (*iii*) heptanoate, 5 μM; (*iv*) octanoate, 2.5 μM; and (*v*) decanoate, 1.5 μM. Note that generally [ester] << $[CTAB]_o$, so the micelles would not be significantly affected by the presence of the esters (1). Experiments with TFE were carried out with a 0.20 M phosphate buffer, at pH 11.60, in place of the carbonate buffer.

© 2000 NRC Canada

Nonlinear fitting of eq. [6] was carried out with GraphPad Prism software. When using eqs. [5] and [6] in data analysis, one has to decide how to handle the concentration of surfactant [Surf] involved in micelles. This quantity is reduced from the total surfactant by the amount of the critical micellar concentration (cmc): [Surf] = ([Surf]$_o$ – cmc) (1). For CTAB, cmc is 0.92 mM at *zero* ionic strength, but it is appreciably lower at high salt concentrations (18) and the lowering effect is greater still for less hydrophilic anions like thiolate ions (19). For example, the addition of only 40 μM thiophenolate ion, in a 0.010 M borate buffer at pH 10, lowers the cmc of CTAB to 0.08 mM (14). In the present work, taking [Surf] = ([Surf]$_o$ – cmc), and treating cmc as a fitting parameter in eq. [6] for the data obtained for each of the seven esters reacting with 20 mM ME in 0.10 M carbonate buffer, gave values of cmc that were close to an average of 0.05 mM. Accordingly, for consistency we have taken the cmc to be equal to this value throughout.

According to the literature, the pK_as of the thiols at zero ionic strength are: (*i*) cysteine, 8.39 (20); (*ii*) 2-mercaptoethanol, 9.72 (21); (*iii*) mercaptoacetic acid, 10.56 (20);[6] (*iv*) 3-mercaptopropionic acid, 10.84 (21), but they are lower at high ionic strength. For example, at μ = 1.0 M, the pK_a of ME is 9.61 (22), and at μ = 0.2 M, the second pK_a of MAA drops from 10.56 to 9.84 (20). Thus, at the working pH of 10.60, in the 0.10 M carbonate buffer, the thiols will exist to a considerable extent as their reactive thiolate anions. The exact fractions of the anions are not important to the discussion above because they are the same for all the esters in the series, and they cancel out in the ratios k_{cN}/k_N and in $K_{TS} = k_N K_S/k_{cN}$ (eq. [7]). The relevant pK_a of glycine is 9.78 (23), and that of TFE is 12.4 (22, 24).

Acknowledgements

We thank the Natural Sciences and Engineering Research Council of Canada for operating grants and an equipment grant, and Mr. A.A Fedortchenko for technical advice. We have also benefited from correspondence with Prof. A. Williams, University of Kent, Canterbury (U.K.). OST is particularly grateful to Dr. Chris Easton and the Research School of Chemistry at the Australian National University for their hospitality during a sabbatical leave spent in Canberra.

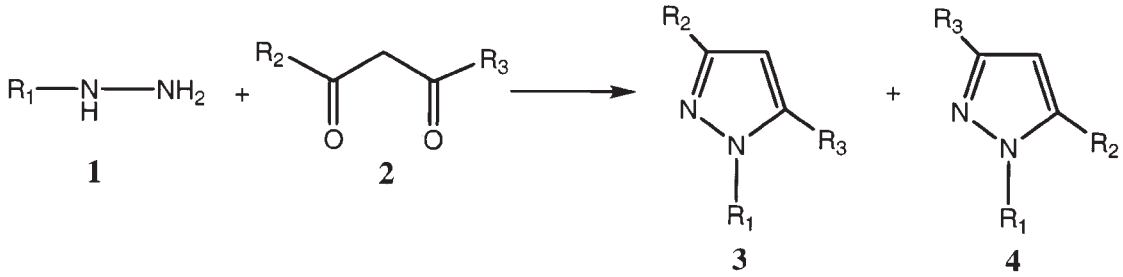
The reaction between hydrazines and β-dicarbonyl compounds: proposal for a mechanism

Shiv P. Singh, Dalip Kumar, Hitesh Batra, Rajesh Naithani, Isabel Rozas, and José Elguero

Abstract: The reaction between aryl or heteroarylhydrazines with fluorinated β-diketones (CF_3COCH_2COR) yields a variety of 3-, 5-, and 3,5-trifluoromethylpyrazoles and 5-trifluoromethyl-5-hydroxy-Δ^2-pyrazolines. Twenty-one of such compounds have been isolated and identified by ^{13}C and ^{19}F NMR. Together with the results from the literature they provide a comprehensive overview of the reaction. Semi-empirical calculations at the PM3 level have been used to rationalize these results. The outcome that emerges seems to be that the dehydration of a pair of 3,5-dihydroxypyrazolidines kinetically controls the isomer formed.



Key words: hydrazines, 1,3-diketones, pyrazolines, pyrazoles, PM3 calculations.

Résumé : La réaction entre des aryl ou hétéroarylhydrazines et des β-dicétones fluorées (CF_3COCH_2COR) donne lieu a une série des 3-, 5- et 3,5-trifluorométhylpyrazoles et 5-trifluorométhyl-5-hydroxy-Δ^2-pyrazolines. Vingt-et-un de ces composés ont été isolés et caractérisés par RMN du ^{13}C et ^{19}F. Avec l'addition des résultats de la littérature, ils donnent une image cohérente de la réaction. Des calculs semi-empiriques PM3 ont été utilisés pour expliquer ces résultats. L'image qui apparaît est celle d'une réaction cinétiquement contrôlée qui correspond à la déshydratation d'une paire de 3,5-dihydroxy-pyrazolidines en équilibre.

Mots clés : hydrazines, 1,3-dicétones, pyrazolines, pyrazoles, calculs PM3.

Introduction

The reaction between a monosubstituted hydrazine (**1**) and a nonsymmetrical β-diketone (**2**) always leads to the formation of a mixture of pyrazole isomers (**3** and **4**) even when one of them is present in a very small amount and the process can be considered regioselective.

This apparently simple reaction, which constitutes the main synthetic approach to pyrazoles (1–5), conceals a complex mechanistic problem. We have summarized in Scheme 1 the different routes that can lead to the two actually isolated compounds making clear where the difficulty of the problem lies. Considering that hydrazine can react initially by the NH (D) or the NH_2 (E) and that a β-diketone has three tautomeric forms (**A**, **B**, and **C**) with two reactive centers, each isomer can be formed by six different routes.

In some cases, it has been possible to isolate the 5-hydroxy-Δ^2-pyrazoline intermediates (**7**) (Scheme 2), but this does not help to solve the mechanistic riddle: which are the route or routes operative in Scheme 1? From low-temperature NMR experiments and from qualitative results, the mechanism represented in Scheme 2 is generally accepted for the synthesis of pyrazoles. The key intermediate is the 3,5-dihydroxypyrazolidine **5** and the formation of both N—C bonds (N2—C3 and N1—C5) of the carbinolamine groups are considered reversible, i.e., when R_2 and R_3 are different, both dihydroxypyrazolidines **5′** and **5″** should be in equilibrium.

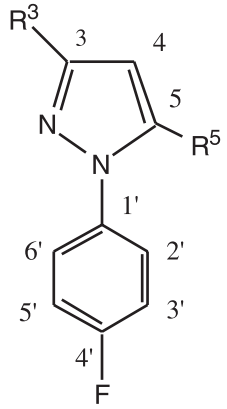
[a]Saccharin stands for 1-(1′,2′-benzisothiazol-3′-yl)-1′,1′-dioxide substituent.

[b]From the pyrrolidino adduct on the $COCF_3$.

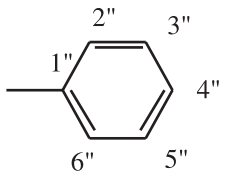
[c]Cycle stands for a medium size carbocycle (tri, tetra, and pentamethylene pyrazoles).

The dehydration steps (**5** → **6** → **7** and **7** → **8** → **9** in Scheme 2) are irreversible, therefore, the kinetic controlling step is the first dehydration (**5** → **7**). All previous publications dealt with the influence of R_2 and R_3, i.e., the structure of the β-dicarbonyl compound, on the relative ratio of the final pyrazoles **3** and **4**, for a given hydrazine. For instance, the consequences over the **3**:**4** ratio of the fact that aldehydes (R_3 = H) are more reactive than ketones ($R_2 \neq$ H), or that trifluoromethylketones ($R_3 = CF_3$) are more reactive than ordinary ketones ($R_2 = CH_3$ or C_6H_5) have been widely studied.

We will discuss, in the present paper, the effect of R_1 on the **3**:**4** ratio in the case of trifluoromethyl β-diketones and, particularly, when $R_2 = CH_3$ and $R_3 = CF_3$. When R_1 = H, **3** ≡ **4** due to the prototropic tautomerism of pyrazoles.



Results and discussion



We have gathered in Table 1 the most relevant experimental results for the present work, that is, the isolation of different 5-hydroxypyrazolines (**7**), the dehydration to the corresponding pyrazoles (**9**) (**3**, $R_2 = CH_3$, Ar or Het, $R_3 = CF_3$; **4**, $R_2 = CF_3$, $R_3 = CH_3$, Ar or Het) and the orientation of the reaction (**3**:**4** ratio).

In the present work, we report complementary experiments (marked "this work" in Table 1). This leads us to describe a series of new Δ^2-pyrazolines and pyrazoles, which have been fully characterized by ^{1}H NMR and mass spectrometry (see experimental part). Particularly important for this purpose have been ^{13}C (Table 2) and ^{19}F NMR (Table 3)

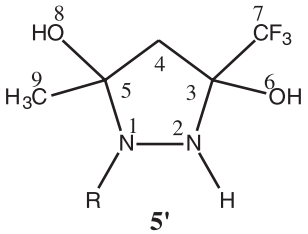
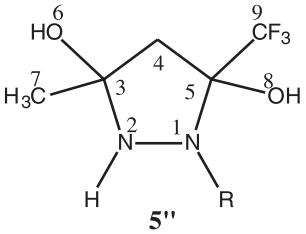
data since they are characteristic of the different structures (5, 7–10, 12–14).



The mechanism of the reaction of β-dicarbonyl compounds and hydrazines has been studied in several occasions, particularly by Selivanov and Ershov and co-workers (15–19), who first used stop-flow NMR techniques to characterize the 3,5-dihydroxypyrazolidines **5** and the 5-hydroxypyrazolines **7** as intermediates and by Elguero and Yranzo (20) who first isolated a 3,5-dihydroxypyrazolidine (**5**, R_1 = H, R_2 = R_2 = CF_3). Russian authors (21, 22) have reported further studies and the reaction has been reviewed (23–25). We have proposed that the dehydration **7** → **9** involves the intermediate **8** to explain why when R_1 is an electron-withdrawing group, the dehydration does not occur or occurs with difficulty (3, 20). Besides, 4-hydroxy-Δ^2-pyrazolines are much more stable than the 5-hydroxy ones and more difficult to aromatize (26).

The results gathered in Table 1 are fully consistent with the role of CF_3 or, more generally, perfluoroalkyl substituents at position 5 and with electron-withdrawing substituents at position 1 to stabilize the 5-hydroxypyrazolines **7**. The role of a 5-trifluoromethyl group is apparent in experiments **b**, **d**, and **z**; that of R_1 in experiment **a** (for brevity's sake, we will use saccharin instead of 1-(1′,2′-benzisothiazol-3′-yl)-1′,1′-dioxide) and that of both in many cases (**e**–**i**, **m**–**o**, s, **t**, **v**, **bb**–**ff**). Note that the CCl_3 group behaves similarly to the CF_3 group (experiments **x** and **y**).



The most difficult point is to rationalize the orientation or **4**:**3** ratio. To advance in this direction, we have carried out a series of semi-empirical calculations, using the PM3 Hamiltonian. We have selected two cases (Scheme 3): the reaction of 1,1,1-trifluoropentane-2,4-dione with phenylhydrazine and 2′,4′-dinitrophenylhydrazine (DNPh). The first yields a mixture of 1-phenyl-3-trifluoro-methyl-5-methyl-

Note: ***u*** = up, ***d*** = down.

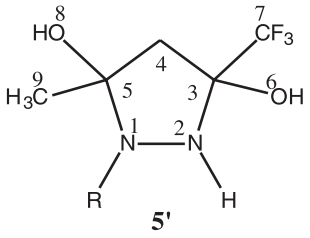
pyrazole **10** and 1-phenyl-3-methyl-5-trifluoromethyl-5-hydroxypyrazoline **11** in a ratio 5:1 (see Table 1, example **b**) (7) (*p*-fluorophenylhydrazine, example **c** behaves similarly). The pyrazoline can be dehydrated with $HCl–CH_2Cl_2$ into pyrazole **12** (7) although other authors failed using H_2SO_4 (8). From DNPh only 1-(2′,4′-dinitrophenyl)-3-methyl-5-trifluoro-methylpyrazole **14** should be formed considering the **3m** or **3s** examples of Table 1.

The first hypothesis we tested was a thermodynamical control related to the equilibrium **5′**–**5′′** between the 3,5-dihydroxypyrazolidines (Scheme 3). The problem is rather complicated because these compounds present three stereogenic centers N1, C3, and C5 (the inversion at the nitrogen atoms has very low barriers and only that bearing the phenyl ring was considered). The equilibrium between **5′** and **5′′** through the β-diketone implies the epimerization of C3 and C5. In addition, in the case of the dinitrophenyl derivatives, two conformations of this substituent, depending on which side the *o*-nitro group lies, have to be considered. Therefore, 16 and 32 conformations were calculated in the cases of Ar = C_6H_5 and Ar = 2′,4′-$(NO_2)_2$-C_6H_4, respectively. The results are given in Tables 4 and 5, which contain heats of formation (in kcal mol^{-1}), dipole moments μ (in D), and charges (q) of N1, N2, O6, and O8 atoms.

In the case of the phenyl derivative, the most stable structure is **5′** (Ar close to the CH_3) with the conformation represented in Fig. 1 (i.e., Ph *up*, 3-OH *down* and 5-OH *down* (**5′*udd***), –207.7 kcal mol^{-1}). The most stable amongst **5′′** structures is **5′′*ddd***, but it lies 2.5 kcal mol^{-1} higher.

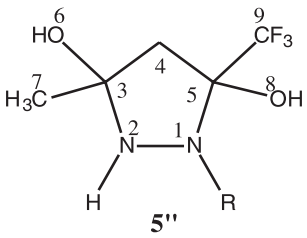
The sixteen values of PM3 heats of formation can be expressed using an additive model with contributions of the different structural features of the compounds. In the **5′** series, a phenyl down is 0 and up is 1 while in the **5** series there is, respectively, 0 and –1. The OH substituents at the 5 position (that close to the phenyl group) is 0 when down and 1 or –1 when up for **5′** and **5′′**. When the Ph and CF_3 substituents are on the same side of the molecule, *cis*, or on opposite sides, *trans*, 1 or 0. The resulting eq. [1] for 16 compounds has an $R^2 = 0.935$

$$[1] \quad \Delta H_f = -(205.2 \pm 0.3) + (3.6 \pm 0.3)\ \text{Ph} - (1.6 \pm 0.3)\ 5\text{OH} + (2.5 \pm 0.4)\ CF_3/\text{Ph}$$



That is, the intercept is close to the average heat of formation for the sixteen compounds. The *N*-phenyl substituent prefers to be down in the **5′** series and up in the **5′′** ones, otherwise it destabilizes the compound by 3.6 kcal mol^{-1}. The contrary happens with the 5-hydroxy substituent, but the effect is lower. Finally, the presence of CF_3 and Ph groups on the same side, *cis*, destabilizes the molecule by an amount of 2.5 kcal mol^{-1}.

Since **5′*udd*** is more stable that **5′′*ddd***, then, if the reaction is thermodynamically controlled, the resulting *N*-phenylpyrazole should have been **10**, which is consistent with the experiment.



A similar analysis of the thirty-two dinitrophenyl derivatives (DNP), show that, here, the additive model is much less satisfactory (eq. [2], $n = 32$, $R^2 = 0.56$), but the effects are

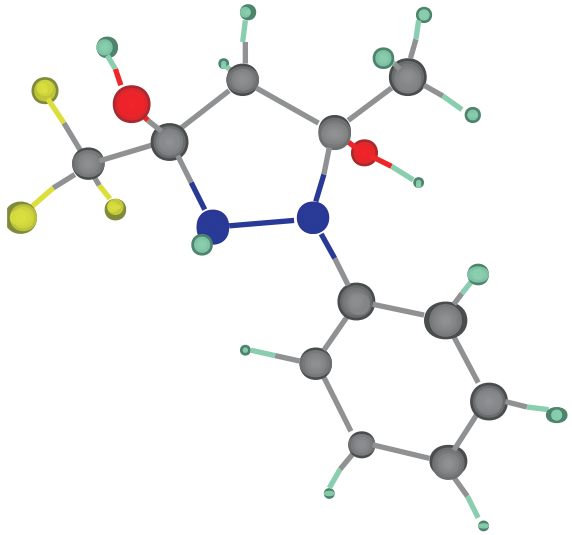
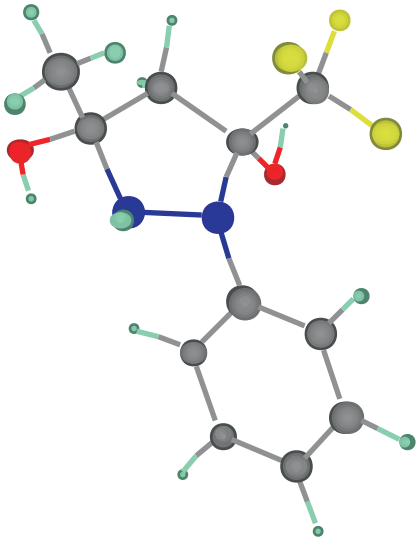
Note: ***u*** = up, ***d*** = down, ***a*** = NO_2 towards N2.

the same including a term defining the position of the nitro group (***a*** towards N2, ***b*** towards the OH).



$$[2]\quad \Delta H_f = -(212.6 \pm 0.8) + (4.3 \pm 0.9)\ \text{DNP} - (1.3 \pm 0.9)\ 5\text{OH} + (1.7 \pm 1.4)\ CF_3/\text{DNP} - (1.7 \pm 1.1)\ NO_2$$

The effects are similar to those in eq. [1]: the structures are more stable when the nitro group is ***b*** in dihydroxypyrazolidines **5**″ and ***a*** in the other isomer **5**′. The two most stable compounds (see Fig. 1) are **5′*udda*** (–220.4 kcal mol^{-1}) and **5″*dudb*** (–217.5 kcal mol^{-1}). Here again, the most stable situation (2.9 kcal mol^{-1}) corresponds to the **5′** series. Consequently, isomer **13** should be formed which is contrary to experiment (formation of **14**, see Scheme 3).



Therefore, this first approach failed. Although the dipole moments are different (Tables 4 and 5), they cannot be used to explain why **14** is preferred over **12**. Since it does not seem to be a thermodynamical control we decided to explore the hypothesis of a kinetic control: the orientation of the pyrazole formation depends on the rate of dehydration of the dihydroxypyrazolidines **5**′ and **5**″. When Ar = Ph, dehydration

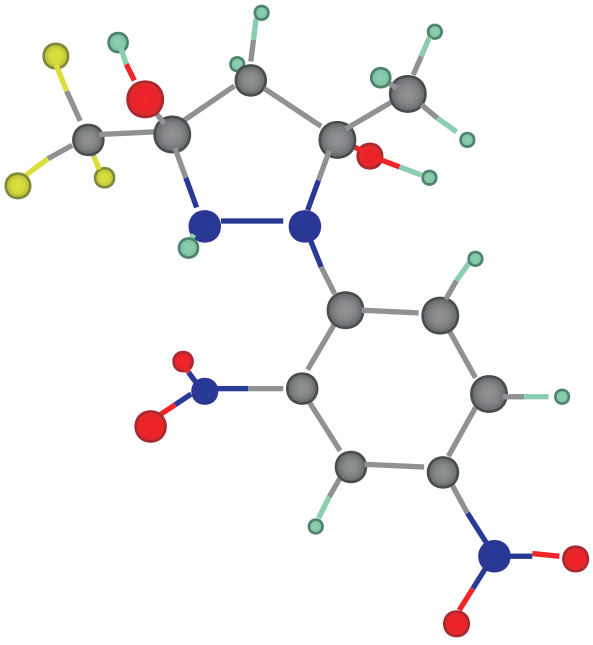

Fig. 1. Optimized PM3 structures of the isomers of minimum energy of derivatives **5′** and **5″** (**5′*udd***, **5″*ddd***, **5′*udda***, and **5″*dudb***).

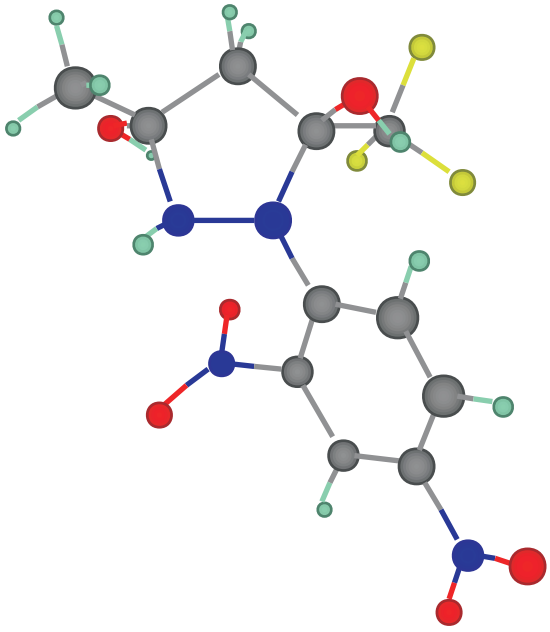
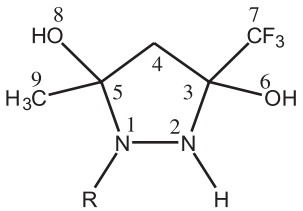


5' *udd*

5'' *ddd*

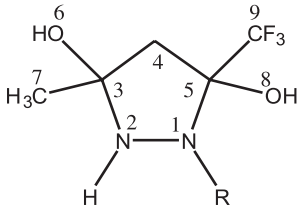
5' *udda*

5'' *dudb*



is faster in **5′** than in **5″**; the contrary should happen when Ar = DNP.

In the second case, the dehydration should involve the N2 lone pair and the OH group at position 3. Although less stable, **5″*dudb*** has more negative charge on N2 (+0.0404) and on O6 (+0.0141) than **5′*udda*** (Table 6). Consequently either neutral or assisted by protonation on O6, the easier loss of water should be that from **5″*dudb***, the less stable dihydroxypyrazolidine, yielding **14** in agreement with experimental results (see Scheme 3).



For Ar = Ph, the results are the same, i.e., the less stable dihydroxypyrazolidine **5″*ddd***, would yield **11**, which is the minor isomer, instead of **10**. Note, however, that the differences of q-N2 and q-O6 although positive are smaller

Fig. 2. Optimized PM3 structures corresponding to the protonation on O6 of **5′*udd*** and **5′′*ddd*** to yield **6′*udd***·H_2O and **6′′*ddd***·H_2O.

6' *ddd* · H_2O 6" *ddd* · H_2O

(+0.0196 and +0.0054) than in the preceding case, pointing out that the preference of **11** over **10** should be smaller than that of **13** over **14**, which is what is found experimentally. It is possible that in this case, the experimental rate of formation of **10** and **11** would include the equilibrium constants between **5′*udd*** and **5′′*ddd***.

We tried to calculate the energies of the four dihydroxypyrazolidines protonated on O6 but the resulting cations are not stable and during the process of optimization, they isomerize to cations **6** (see Scheme 2) solvated by a water molecule, something like **5**$H^+ \rightarrow$ **6**·H_2O. We have represented two of such complexes, those formed from **5′*udd*** and **5″*ddd*** in Fig. 2.

Conclusions

Literature results plus those reported in this work prove that the orientation in the reaction of hydrazines with β-diketones depends on the substituent in the hydrazine. Although the differences in orientation between alkyl and arylhydrazines have been assigned to differences in reactivity of both nitrogen atoms (R_1NH, D, in alkyl- and NH_2, E, in aryl-hydrazines, see Scheme 1), this is certainly not the case of the reactions reported in Table 1, because all of them should start reacting by the NH_2. We propose that the orientation is the result of the difference in the rates of dehydration of the two 3,5-dihydroxy-pyrazolidines in equilibrium.

Experimental

Melting points were determined in open capillaries and are uncorrected. The ^{1}H NMR spectra were obtained at 270, 300, and 400 MHz, ^{13}C NMR spectra at 67.5 and 100 MHz, and ^{19}F NMR spectra at 75 and 376 MHz using Jeol-GX270, Jeol-EX400, Bruker-300, and Bruker-400 instruments. The internal standard for ^{1}H and ^{13}C was TMS and for ^{19}F NMR it was $CFCl_3$ ($\delta = 0.00$). The coupling constants reported for the ^{13}C NMR data correspond to couplings with ^{19}F. Mass spectra were recorded on a Kratos-MS-50 instrument and microanalyses were performed on a Perkin–Elmer 2400 instrument.

Synthesis of 1-(*p*-fluorophenyl)-3(5)-trifluoromethylpyrazoles

*1-p-Fluorophenyl-3-methyl-5-trifluoromethylpyrazole (**3c**) and 1-p-fluorophenyl-3-trifluoro-methyl-5-methylpyrazole (**4c**)*

An ethanolic solution (30 mL) of *p*-fluorophenylhydrazine (1 g, 6 mmol) and sodium acetate (0.5 g, 6 mmol) was refluxed for 15 min. 1,1,1-Trifluoropentane-2,4-dione (0.9 g, 6 mmol) was subsequently added and the solution was refluxed for 2 h. The solvent was evaporated and the residue obtained was extracted with chloroform. The organic phase was dried over anhydrous sodium sulfate and the chloroform was distilled off. The TLC and ^{1}H NMR of the gummy mass showed formation of both isomers in a 4:1 (**4c**:**3c**) ratio. Column chromatographic separation using silica gel (60–120 mesh) and light petroleum (60–80°) as eluent afforded **4c**.

4c: Oil, yield 0.8 g (53%). ^{1}H NMR ($CDCl_3$) δ: 2.32 (s, 3H, C_5-CH_3), 6.45 (s, 1H, C_4-H), 7.17 (unresolved dd, 2H, $C_{3'}$- and $C_{5'}$-H, J = 8.1 and 8.8 Hz), 7.42 (m, 2H, $C_{2'}$- and $C_{6'}$-H). Anal. calcd. for $C_{11}H_8F_4N_2$: C 54.11, H 3.30, N 11.47; found C 53.92, H 3.28, N 11.21.

Further elution of the column with light petroleum afforded the other isomer **3c**.

3c: Oil, yield 0.2 g (13%). ^{1}H NMR ($CDCl_3$) δ: 2.35 (s, 3H, C_3-CH_3), 6.59 (s, 1H, C_4-H), 7.25 (unresolved dd, 2H, $C_{3'}$- and $C_{5'}$-H, J = 8.2 and 8.7 Hz), 7.42 (m, 2H, $C_{2'}$- and $C_{6'}$-H). Anal. calcd. for $C_{11}H_8F_4N_2$: C 54.11, H 3.30, N 11.47; found C 54.05, H 3.13, N 11.34.

Three other pyrazoles **4k**, **4q**, **4u** were prepared and purified similarly.

*1-p-Fluorophenyl-3-trifluoromethyl-5-phenylpyrazole (**4k**)*

Mp 102–103°C, yield 72%. ^{1}H NMR ($CDCl_3$) δ: 6.74 (s, 1H, C_4-H), 7.18–7.22 (m, 2H, $C_{2''}$- and $C_{6''}$-H), 7.30 (m, 5H, Ar-H, $C_{3''}$- $C_{4''}$- $C_{5''}$-, $C_{2'}$-, and $C_{6'}$-H), 7.03 (unresolved dd, 2H, $C_{3'}$- and $C_{5'}$-H, J = 8.1 and 8.8 Hz). Anal. calcd. for $C_{16}H_{10}F_4N_2$: C 62.75, H 3.27, N 9.15; found C 62.67, H 3.41, N 8.84.

*1-p-Fluorophenyl-3-trifluoromethyl-5-(2′-thienyl)pyrazole (**4q**)*

Mp 81–82°C, yield 74%. ^{1}H NMR ($CDCl_3$) δ: 6.70 (s, 1H, C_4-H), 6.78 (dd, 1H, $C_{3''}$-H, J = 1.0 and 3.7 Hz), 6.88 (dd, 1H, $C_{4''}$-H, J = 3.7 and 5.0 Hz), 7.03 (unresolved dd, 2H, $C_{3'}$- and $C_{5'}$-H, J = 8.1 and 8.8 Hz), 7.23 (dd, 1H, $C_{5''}$-H, J = 1.0 and 5.0 Hz), 7.28 (m, 2H, $C_{2'}$- and $C_{6'}$-H). Anal. calcd. for $C_{14}H_8F_4N_2S$: C 53.85, H 2.58, N 8.97; found C 54.02, H 2.46, N 8.63.

*1-p-Fluorophenyl-3-trifluoromethyl-5-(2′-pyridyl) pyrazole (**4u**)*

Mp 72–74°C, yield 73%. ^{1}H NMR ($CDCl_3$) δ: 7.01 (s, 1H, C_4-H), 7.08 (m, 2H, $C_{3'}$- and $C_{5'}$-H, J = 8.1 and 8.8 Hz), 7.22–7.35 (m, 4H, $C_{3''}$-, $C_{5''}$-, $C_{2'}$- and $C_{6'}$-H), 7.64 (unresolved dd, 1H, $C_{4''}$-H, J = 1.8 and 7.8 Hz), 8.58 (dd, 1H, $C_{6''}$-H, J = 3.9 and 7.8 Hz). Anal. calcd. for $C_{15}H_9F_4N_3$: C 58.64, H 2.95, N 13.68; found C 58.39, H 3.00, N 13.54.

Synthesis of 1-phenyl-3-trifluoromethylpyrazoles

*1,5-Diphenyl-3-trifluoromethylpyrazole (**4j**)*

An ethanolic solution (30 mL) of phenylhydrazine (0.64 g, 6 mmol) and sodium acetate (0.5 g, 6 mmol) was refluxed for 15 min. An equimolar amount of benzoyltrifluoroacetone (0.9 g, 6 mmol) was subsequently added and the solution was refluxed for 3 h. On cooling, a solid appeared which was recrystallized from ethanol, mp 80°C (lit. (27) mp 95°C), yield 50%. ^{1}H NMR ($CDCl_3$) δ: 6.80 (s, 1H, C_4-H), 6.85 (d, 2H, $C_{3''}$- and $C_{5''}$-H), 6.36 (dd, 1H, $C_{4''}$-H), 7.31 (dd, 2H, $C_{2''}$- and $C_{6''}$-H), 7.42–7.47 (m, 5H, Ar-H). M^+ 288. Anal. calcd. for $C_{16}H_{11}F_3N_2$: C 66.66, H 3.85, N 9.72; found C 66.47, H 3.81; N 9.70.

*1-Phenyl-3-trifluoromethyl-5-thienylpyrazole (**4p**)*

This compound was prepared similarly from thienoyltrifluoroacetone, mp 92°C, yield 51%. ^{1}H NMR ($CDCl_3$) δ: 6.75 (s, 1H, C_4-H), 7.20–7.37 (m, 8H, Ar-H). M^+ 294. Anal. calcd. for $C_{14}H_9F_3N_2S$: C 57.14, H 3.08, N 9.52; found C 57.33, H 3.17, N 9.36.

Synthesis of 1-*p*-nitrophenyl-3-trifluoromethylpyrazoles

*1-p-Nitrophenyl-3-trifluoromethyl-5-phenylpyrazole (**4l**)*

An ethanolic solution (30 mL) of *p*-nitrophenylhydrazine (0.95 g, 6 mmol) and sodium acetate (0.5 g, 6 mmol) was refluxed for 15 min. An equimolar amount of benzoyltrifluoroacetone was subsequently added and the solution was refluxed for 4 h. After solvent evaporation, the residue obtained was crystallized from ethanol, mp 91°C, yield 62%. ^{1}H NMR ($CDCl_3$) δ: 6.79 (s, 1H, C_4-H), 7.23–7.52 (m, 5H, Ar-H), 7.50 (d, 2H, $C_{2'}$- and $C_{6'}$-H), 8.22 (d, 2H, $C_{3'}$- and $C_{5'}$-H). M^+ 333. Anal. calcd. for $C_{16}H_{10}F_3N_3O_2$: C 57.66, H 3.02, N 12.61; found C 57.81, H 2.88; N 12.71.

*1-p-Nitrophenyl-3-trifluoromethyl-5-(2-thienyl)pyrazole (**4r**)*

This compound was prepared similarly from thienoyltrifluoroacetone, mp 97°C, yield 60%. ^{1}H NMR (CDCl3) δ: 6.84 (s, 1H, C_4-H), 6.93 (dd, 1H, $C_{3''}$-H), 7.04 (dd, 1H, $C_{4''}$-H), 7.44 (dd, 1H, $C_{5''}$-H), 7.69 (dd, 1H, $C_{2'}$- and $C_{6'}$-H), 8.28 (dd, 1H, $C_{3'}$- and $C_{5'}$-H). M^+ 339. Anal. calcd. for $C_{14}H_8F_3N_3O_2S$: C 49.56, H 2.38, N 12.38; found C 49.51, H 2.18, N 12.67.

*1-p-Nitrophenyl-3-methyl-5-trifluoromethyl-5-hydroxypyrazoline (**7e**)*

An ethanolic solution (30 mL) of *p*-nitrophenylhydrazine (0.95 g, 6 mmol) and sodium acetate (0.5 g, 6 mmol) was refluxed for 15 min. An equimolar amount of 1,1,1-trifluoropentane-2,4-dione (0.9 g, 6 mmol) was subsequently added and the solution was refluxed for 2 h. After solvent evaporation, the residue obtained was crystallized from ethanol, mp 102°C, yield 54%. ^{1}H NMR ($CDCl_3$) δ : 2.09 (s, 3H,

© 2000 NRC Canada

CH_3), 3.21 and 3.46 (AB system, 2H, CH_2, J = 18 Hz), 7.42 (d, 2H, $C_{2'}$- and $C_{6'}$-H), 8.04 (d, 2H, $C_{3'}$- and $C_{5'}$-H). M^+ 289. Anal. calcd. for $C_{11}H_{10}F_3N_3O_3$: C 45.68, H 3.48, N 14.53; found C 45.81, H 3.60, N 14.68.

*1-p-Nitrophenyl-3-methyl-5-trifluoromethylpyrazole (**3e**)*

An ethanolic solution of (**7e**) and 2 mL of conc. HCl was refluxed for 10 h. The solvent was evaporated and the residue crystallized from ethanol, mp 80–81°C, yield 56%. ^{1}H NMR ($CDCl_3$) δ: 2.36 (CH_3), 6.54 (s, 1H, C_4-H), 7.72 (d, 2H, $C_{2'}$- and $C_{6'}$-H), 8.33 (d, 2H, $C_{3'}$- and $C_{5'}$-H). M^+ 271. Anal. calcd. for $C_{11}H_8F_3N_3O_2$: C 48.72, H 2.97, N 15.49; found C 49.01, H 3.11, N 15.39.

*1-(1′,2′-Benzisothiazol-3′-yl)-3-methyl-5-trifluoromethyl-5-hydroxypyrazoline 1′,1′-dioxide (**7h**)*

An ethanolic solution (50 mL) of 3-hydrazino-2-benzisothiazole-1′,1′-dioxide (1.2 g, 6 mmol) and sodium acetate (0.5 g, 6 mmol) was refluxed for 15 min. An equimolar amount of 1,1,1-trifluoropentane-2,4-dione (0.9 g, 6 mmol) was subsequently added and the solution was refluxed for 2 h. The solvent was evaporated and the residue extracted with chloroform. The organic phase was dried over anhyd sodium sulfate and the chloroform distilled off, mp 180°C (ethanol), yield 54%. ^{1}H NMR ($CDCl_3$ + DMSO-d_6) δ: 2.14 (CH_3), 3.38 (m, 2H, CH_2), 7.72–7.83 (m, 3H, $C_{5'}$-, $C_{6'}$-, and $C_{7'}$-H), 8.67 (m, 1H, $C_{4'}$-H). M^+ 333. Anal. calcd. for $C_{12}H_{10}F_3N_3O_3S$: C 43.25, H 3.02, N 12.61; found C 43.38, H 2.87, N 12.45.

*1-(2′,4′-Dinitrophenyl)-3-phenyl-5-trifluoromethyl-5-hydroxypyrazoline (**7m**)*

An ethanolic solution (50 mL) of 2,4-dinitrophenylhydrazine (0.95 g, 6 mmol) and sodium acetate (0.5 g, 6 mmol) was refluxed for 15 min. An equimolar amount of benzoyltrifluoroacetone (0.9 g, 6 mmol) was subsequently added and the solution was refluxed for 4 h. The solvent was evaporated and the residue crystallized from ethanol, mp 142°C, yield 54%. ^{1}H NMR ($CDCl_3$) δ: 4.51 (m, 2H, CH_2), 7.38–7.99 (m, 5H, ArH), 8.06 (d, 1H, $C_{6'}$-H), 8.45 (dd, 1H, $C_{5'}$-H), 9.05 (d, 1H, $C_{3'}$-H). M^+ 396. Anal. calcd. for $C_{16}H_{11}F_3N_4O_5$: C 48.49, H 2.80. N 14.14; found C 48.22, H 2.66, N 13.81.

*1-(2′,4′-Dinitrophenyl)-3-phenyl-5-trifluoromethylpyrazole (**3m**)*

To a solution of **7m** (0.2 g, 0.5 mmol) in acetic acid was added 2 mL of pure sulfuric acid. The mixture was refluxed for 24 h. The solvent was evaporated and the residue was extracted with chloroform. The organic phase was dried over anhyd sodium sulfate and the chloroform distilled off, mp 56°C (ethanol), yield 53%. ^{1}H NMR ($CDCl_3$) δ: 6.84 (s, 1H, C_4-H), 7.30 (m, 1H, $C_{6'}$-H), 7.92 (d, 1H, $C_{5'}$-H), 8.06–9.05 (m, 6 H, Ar-H). M^+ 378. Anal. calcd. for $C_{16}H_9F_3N_4O_4$: C 50.80, H 2.40, N 15.07; found C 50.66, H 2.37, N 14.86.

*1-(1′,2′-Benzisothiazole-1′,1′-dioxide)-3-phenyl-5-trifluoromethyl-5-hydroxypyrazoline (**7o**)*

With the same method used in the case of **7i**, compound **7o** was obtained, mp 160°C (ethanol), yield 48%. ^{1}H NMR ($CDCl_3$) δ: 3.35 and 3.69 (AB system, 2H, CH_2, J = 18 Hz), 7.26–7.42 (m, 5H, Ar-H), 7.75–7.82 (m, 3H, $C_{5'}$-, $C_{6'}$-, and $C_{7'}$-H), 8.53 (s, 1H, $C_{4'}$-H). M^+ 395. Anal. calcd. for $C_{17}H_{12}F_3N_3O_3S$: C 51.65, H 3.06, N 10.63; found C 51.42, H 321, N 10.65.

*1-(2′,4′-Dinitrophenyl)-3-(2-thienyl)-5-trifluoromethyl-5-hydroxypyrazoline (**7s**)*

This compound was prepared using the procedure described for **7m**, mp 152°C, yield 58%. ^{1}H NMR ($CDCl_3$) δ: 4.42 (m, 2H, CH_2), 7.28 (m, 1H, $C_{3''}$-H), 7.92 (d, 1H, $C_{4''}$-H), 8.02 (d, 1H, $C_{5''}$-H), 8.04 (d, 1H, $C_{6'}$-H), 8.44 (dd, 1H, $C_{5'}$-H), 9.07 (d, 1H, $C_{3'}$-H). Anal. calcd. for $C_{14}H_9F_3N_4O_5S$: C 41.80, H 2.25, N 13.93; found C 42.03, H 2.41, N 13.71.

*1-(2′,4′-Dinitrophenyl)-3-(2-thienyl)-5-trifluoromethylpyrazole (**3s**)*

Following the same procedure as described for **3m**, compound **3s** was prepared, mp 61°C, yield 53%. ^{1}H NMR ($CDCl_3$) δ: 6.88 (s, 1H, C_4-H), 6.92–7.80 (m, 5H, ArH), 7.90 (d, 1H, $C_{6'}$-H), 8.66 (m, 1H, $C_{5'}$-H), 8.88 (d, 1H, $C_{3'}$-H). M^+ 384. Anal. calcd. for $C_{14}H_7F_3N_4O_4S$: C 43.76, H 1.84, N 14.58; found 43.71, H 1.56, N 14.61.

*1-(1′,2′-Benzisothiazol-3′-yl) 3-(2-thienyl)-5-trifluoromethyl-5-hydroxypyrazoline-1′,1′-dioxide (**7t**)*

With the same method used in the case of **7h**, compound **7t** was obtained, mp 190°C, yield 56%. ^{1}H NMR ($CDCl_3$ + DMSO-d_6) δ: 3.75 (m, 2H, CH_2), 7.5–7.7 (m, 3H, thienyl), 8.0–8.3 (m, 3H, $C_{5'}$-, $C_{6'}$-, and $C_{7'}$-H), 8.71 (m, 1H, $C_{4'}$-H). M^+ 401. Anal. calcd. for $C_{15}H_{10}F_3N_3O_3S_2$: C 44.89, H 2.51, N 10.47; found C 45.00, H 2.69, N 10.30.

*1-(1′,2′-Benzisothiazol-3′-yl)-3-(2-pyridyl)-5-trifluoromethyl-5-hydroxypyrazoline 1′,1′-dioxide (**7v**)*

With the same method used in the case of **7h**, compound **7v** was obtained, mp 224°C, yield 67%. ^{1}H NMR ($CDCl_3$ + DMSO-d_6) δ: 3.70 (AB system, 2H, CH_2, J = 19 Hz), 7.70–7.90 (m, 3H, $C_{5'}$-, $C_{6'}$-, and $C_{7'}$-H), 8.70–8.80 (m, 5H, pyridine and C_4-H of the benzisothiazolyl). M^+ 396. Anal. calcd. for $C_{16}H_{11}F_3N_4O_3S$: C 48.49, H 2.80, N 14.14; found C 48.36, H 2.71, N 13.85.

*1-(1′,2′-Benzisothiazol-3′-yl)-3,5-bis-trifluoromethyl-5-hydroxypyrazoline 1′,1′-dioxide (**7ff**)*

Using the same method as in the case of **7h**, compound **7ff** was obtained, mp 208°C (ethanol), yield 54%. ^{1}H NMR ($CDCl_3$ + DMSO-d_6) δ: 3.27 (m, 2H, CH_2), 7.8–7.9 (m, 3H, $C_{5'}$-, $C_{6'}$-, and $C_{7'}$-H), 8.46 (m, 1H, $C_{4'}$-H). M^+ 387. Anal. calcd. for $C_{12}H_7F_6N_3O_3S$: C 37.22, H 1.82, N 10.85; found C 36.98, H 2.07, N 10.70.

*1-(p-Fluorophenyl)-3,5-bis-trifluoromethylpyrazole (**9aa**)*

This compound was prepared like **3c** and **4c** but using 1,1,1,5,5,5-hexafluoropentane-2,4-dione. Mp 54°C (ethanol), yield 65%. ^{1}H NMR ($CDCl_3$) δ: 6.97 (s, 1H, C_4-H), 7.12 (unresolved dd, 2H, $C_{3'}$- and $C_{5'}$-H, J = 8.0 and 8.9 Hz), 7.38 (m, 2H, $C_{2'}$- and $C_{6'}$-H). Anal. calcd. for $C_{11}H_5F_7N_2$: C 44.31, H 1.69, N 9.40; found C 44.28, H 1.41, N 9.12.

Computational details

All the possible isomers considered for compounds **5′** and **5″** (for both R = C_6H_5 (Ph) and R = 2′,4′-$(NO_2)_2$-C_6H_4 (DNP)), see Fig. 1 for four representative examples, have been studied at semi-empirical level, optimizing all the geometrical parameters. The different configuration of the C3 and C5 atoms of the pyrazolidine ring was considered (relative orientation of both OH groups, and of the CH_3 and CF_3 groups). Besides, considering the rotation between the rings, two different orientations for the NO_2 group in *ortho* in the dinitrophenyl derivatives were taken into account. The protonated species of the most stable of each one of the compounds (**5′** and **5″**, R = Ph and DNP) were also computed. At semi-empirical level, the PM3 Hamiltonian (28), as implemented in the MOPAC 6.0 package (29), was used increasing the precision in a factor of 100 and optimizing until a gradient of 0.01 was reached. This Hamiltonian was chosen since good results had been previously obtained predicting the "stereoselectivity" of certain Michael type reactions (for example ref. (30)). In all the cases, the corresponding heats of formation, dipole moments, and charges of the atoms involved in the possible dehydration (N1, N2, O6, and O8) were calculated and gathered in Tables 4 and 5.

Acknowledgements

We are grateful to Ranbaxy Research Laboratories, Council of Scientific and Industrial Research, and to the University Grants Commission, New Delhi for financial assistance. Thanks are due to RSIC, Chandigarh, for NMR spectra and elemental analysis. We are also thankful to Mass Spectrometry Facility, California University, San Francisco, U.S.A., for mass spectra. Two of us (IR and JE) thank the Spanish DGICYT (Project no. SAF 97-0044-C02).

Densities, refractive indices and excess properties of mixing of the *n*-octanol + 1,4-dioxane + 2-butanol ternary system at 298.15 K[1]

Alberto G. Camacho, Miguel A. Postigo, Graciela C. Pedrosa, Inés L. Acevedo, and Miguel Katz[2]

Abstract: Excess molar volumes and excess refractive indices of the *n*-octanol + 1,4-dioxane + 2-butanol system and the three corresponding binary mixtures have been determined at 298.15 K by measuring densities and refractive indices. Different expressions exist in the literature to predict these excess properties from binary data. An estimation of excess molar volumes is also evaluated using a modified Heller equation which depends on the refractive indices of the mixtures. A comparison of the predictions of different methods with the experimental values of the physical properties has been made.

Key words: excess molar volumes, densities, refractive indices, *n*-octanol, 1,4-dioxane, 2-butanol, ternary system.

Résumé : Opérant à 298,15 K et faisant appel à des mesures de densités et d'indices de réfraction, on a déterminé les volumes molaires en excès ainsi que les indices de réfraction en excès du système octanol + 1,4-dioxane + butan-2-ol et des trois mélanges binaires correspondants. Il existe différentes expressions dans la littérature pour faire des prédictions relatives aux propriétés en excès de systèmes binaires. Une évaluation des volumes molaires en excès peut aussi être faite en utilisant l'équation de Heller modifiée qui dépend des indices de réfraction des mélanges. On a effectué une comparaison des diverses prédictions obtenues à l'aide de ces différentes méthodes avec les valeurs expérimentales des propriétés physiques.

Mots clés : volumes molaires en excès, indices de réfraction, octanol, 1,4-dioxane, butan-2-ol, système ternaire.

[Traduit par la Rédaction]

Introduction

This paper is a continuation of our studies about excess thermodynamic properties (1, 2). Densities, refractive indices, and excess properties on mixing of the *n*-octanol (1-OC) + 1.4-dioxane (D) + 2-butanol (2-BU) system are reported at 298.15 K. Data on physical properties, like refractive indices and densities, for liquid mixtures are important from a theoretical and practical point of view. The thermodynamics of ternary mixtures of non-electrolytes has not received as much attention as the thermodynamics of binary mixtures. It is therefore interesting to estimate excess molar volumes and excess refractive indices with more than two components. If significant changes of refractivity and volumes during mixing are present as a result of physical and or chemical interactions, some mixing rules will be suitable for predictive calculations. A search of the literature for ternary systems suggests that some empirical correlations can be used to calculate the molar excess volumes and excess refractive indices from binary mixtures, and by knowing refractive indices molar volumes can be calculated.

In this paper we report corresponding densities and refractive indices of the ternary system and the respective three binary mixtures. Some of the components studied here are mentioned in the literature (4–8). Molar excess volumes and excess refractive indices were calculated from those experimental data. As computer design of chemical processes requires mathematical models to predict or describe excess properties of mixtures over the entire range of composition, such information is very useful in chemical engineering. The excess properties are analyzed (in this case two alcohols and a cyclic substance) because of their importance for inferring which type of interaction predominates in liquid mixtures.

Experimental

Densities were determined with a digital densimeter DA 310, Mettler, and a thermostatically controlled bath constant to 0.01 K was used (with a Digitec digital thermometer with an error of ±0.01 K). Calibration was carried out with air and doubly distilled water with an uncertainty of ±0.01 kg m^{-3} in the densimeter and ±0.02 kg m^{-3} in densities. Refractive

indices were measured at the sodium D line with a Jena dipping refractometer with an accuracy of $\pm 2 \times 10^{-5}$. In this case a thermostatic controlled bath constant was also used with an error of ±0.01 K.

All the substances used were Merck (puriss.). The alcohols were distilled over calcium oxide and the middle fraction collected. 1,4-Dioxane was distilled over sodium at reduced pressure and the middle fraction was also collected.

Mixtures were prepared by mixing weighed amounts of the pure liquids. Caution was taken to prevent evaporation.

Results and discussion

The experimental results for the pure liquids together with literature values for comparison are reported in Table 1.

The excess function of a binary mixture can be represented by a Redlich–Kister equation of the form

$$[1] \qquad X^E = X_j X_j \sum_{k=0}^{n} a_k (x_i - x_j)^k$$

where X^E represents V^E or n_D^E, x_i and x_j are the mole fractions of the component i and j, and a_k are the polynomial coefficients. The method of least squares has been used to determine the values of the coefficients. In each case, the optimum number of coefficients was ascertained from an examination of the standard deviation of the estimate with n

$$[2] \qquad \sigma = [(X^E_{obs} - X^E_{cal})^2 \,/\, ((n_{obs} - (n+1))]^{1/2}$$

Tables 2, 3, and 4 show the values of densities and refractive indices of the binary systems at different mole fractions.

The values adopted for the coefficients and the standard deviation of estimates associated with the use of eq. [1] are summarized in Table 5.

Figures 1 and 2 show the experimental values of V^E_{ij} and n^E_{Dij} for the three binary systems.

The experimental values of densities and refractive indices of the ternary system were obtained by adding the third component to a constant ratio of the other two.

Tables 6 and 7 show the experimental values for the densities and refractive indices for the ternary 1-OC (1) + D (2) + 2-BU (3) system at 298.15 K at different mole fractions.

Molar excess volumes and changes in refractive indices on mixing were calculated using the following equations

$$[3] \qquad V^E_{123} = \sum x_i M_i (\rho^{-1} - \rho_i^{-1})$$

$$[4] \qquad n^E_{D123} = n_D - \sum x_i n_{Di}$$

where M_i is the molecular weight of component i, ρ_i is the density of the pure component i, ρ is the density of the mixture, n_{Di} the refractive index of the pure component i, and n_D the refractive index of the solution at the sodium D line. These values are shown in Tables 6 and 7.

Figures 3 and 4 show lines of constant V^E_{123} and n^E_{D123}. These lines were obtained by plotting excess molar volumes and excess refractive indices of the binary systems as a function of x_3 and considering mole fractions with the same excess functions.

In Fig. 1 two binary systems with D show positive excess molar volumes. Alcohols are composed of associated molecules and the addition of the other component produces a rupture of the hydrogen bonding and an expansion of volume. The other system with the two alcohols shows a sigmoid curve with small values for excess molar volume. This

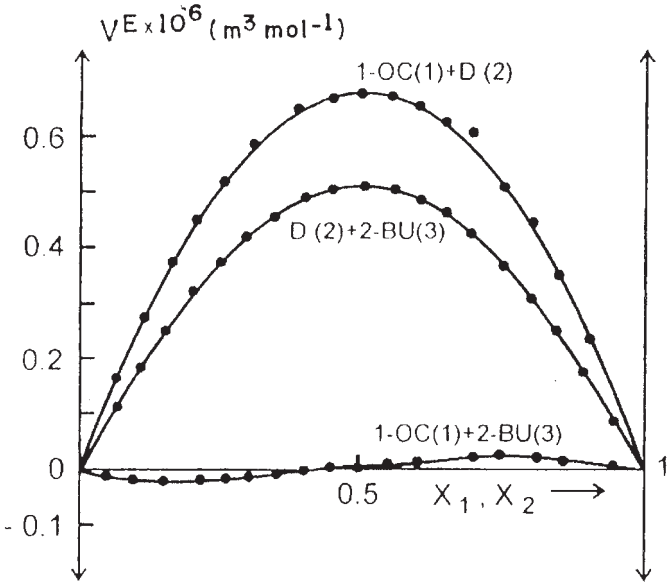
Fig. 1. Excess molar volumes for the three binary systems at 298.15 K. Continuous curves were calculated from eq. [1]. System D(2) + 2-BU(3) in the *x*-axis D, and the other two systems 1-OC(1).



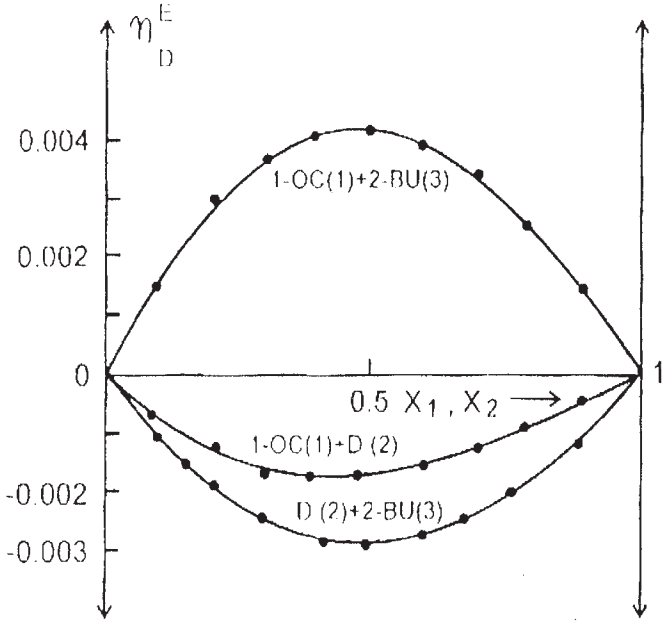


Fig. 2. Excess refractive indices for the three binary systems at 298.15 K. Continuous curves were calculated from eq. [1]. System D(2) + 2-BU(3) in the *x*-axis D, and the other two systems 1-OC(1).

can be explained by the fact that strong interactions between the alcohols is compensated by the broken or formed interactions. Likewise, the differences in molecular sizes between the mixture components must lead to interstitial accommodation of molecules in the mixture and hence to a negative contribution to V^E. A further effect to consider is the difference in free volume between 1,4-dioxane and alcohols. Figure 2 shows positive excess refractive indices for the mixtures of alcohols and negative for the other two systems

Estimation of excess properties

From the different expressions existing in the literature, we applied the equation of Radojkovic et al. (9), which considered an expression proposed by Redlich and Kister. For excess molar volumes for a ternary system,

$$[5] \qquad V^E_{123} = V^E_{12} + V^E_{13} + V^E_{23}$$

where V^E_{12}, V^E_{13}, and V^E_{23} represent the excess molar volumes at x_1, x_2, and x_3 (mole fractions in the ternary system) calculated with eq. [1] using the coefficients of Table 5.

Jacob and Fitzner (10) suggested an equation for estimating the excess properties based on the binary data at the composition nearest the ternary composition, using the following form for the excess molar volume:

$$[6] \qquad V^E_{123} = \frac{x_1 x_2 V^E_{12}}{\left(x_1 + \frac{x_3}{2}\right)\left(x_2 + \frac{x_3}{2}\right)} + \frac{x_1 x_3 V^E_{13}}{\left(x_1 + \frac{x_2}{2}\right)\left(x_3 + \frac{x_2}{2}\right)} + \frac{x_2 x_3 V^E_{23}}{\left(x_2 + \frac{x_1}{2}\right)\left(x_3 + \frac{x_1}{2}\right)}$$

and that, for binary composition x^o_i, x^o_j, is $x_i - x_j = x^o_i - x^o_j$.

Kohler (11) proposed an equation for a ternary system of the following form:

$$[7] \quad V^E_{123} = (x_1 + x_2)^2 V^E_{12} + (x_1 + x_3)^2 V^E_{13} + (x_2 + x_3)^2 V^E_{23}$$

Kohler's equation is symmetrical in that all three binary systems are treated identically. In this equation V^E_{ij} refers to the excess volumes of x_i^o, x_j^o in the binary system using $x_i^o = 1 - x_j^o = x_i/(x_i + x_j)$.

Tsao and Smith (12) proposed an equation for excess enthalpies, which for excess molar volumes is

$$[8] \quad V^E_{123} = \frac{x_2}{1-x_1} V^E_{12} + \frac{x_3}{1-x_1} V^E_{13} + (1-x_1) V^E_{23}$$

Table 8. Standard deviations of excess molar volumes (eq. [9]) for 1-OC (1) + D (2) + 2-BU (3) system at 298.15 K.

Equation	$V^E_{123} \times 10^{-6}$ (m^3 mol^{-1})	n^E_{D123}
[5]	0.027	0.0004
[6]	0.027	0.0004
[7]	option (a) = 0.043	option (a) = 0.0007
	option (b) = 0.027	option (b) = 0.0004
	option (c) = 0.059	option (c) = 0.0007
[9]	0.018	0.001
[10]	0.0202	0.00005

Binary contributions were evaluated at $x_i^o = x_1$ and $x_j^o = 1 - x_i^o$ for 1–2 and 1–3 binaries, and $x_2^o = x_2/(x_2 + x_3)$ and $x_3^o = x_3/(x_2 + x_3)$ for 2–3 binary (option a in Table 8). As this model is asymmetric, we evaluate binary contributions alternatively at $x_i^o = x_2$ and $x_j^o = 1 - x_i^o$ for 2–1 and 2–3 binaries, and $x_3^o = x_3/(x_1 + x_3)$ and $x_1^o = x_1/(x_1 + x_3)$ for the 3–1 binary (option b in Table 8). The third alternative (option c in Table 8), was using $x_i^o = x_3$ and $x_j^o = 1 - x_i^o$ for 3–1 and 3–2 binaries and $x_2^o = x_2/(x_2 + x_1)$ and $x_1^o = x_1/(x_2 + x_1)$ for the 1–3 binary system.

These equations were used to calculate V^E_{123} and n^E_{D123} from binary mixture data and were compared with experimental data. Table 8 shows the deviation defined by

$$[9] \qquad SD = \left[\frac{\sum (X^E_{obs} - X^E_{cal})^2}{n}\right]^{1/2}$$

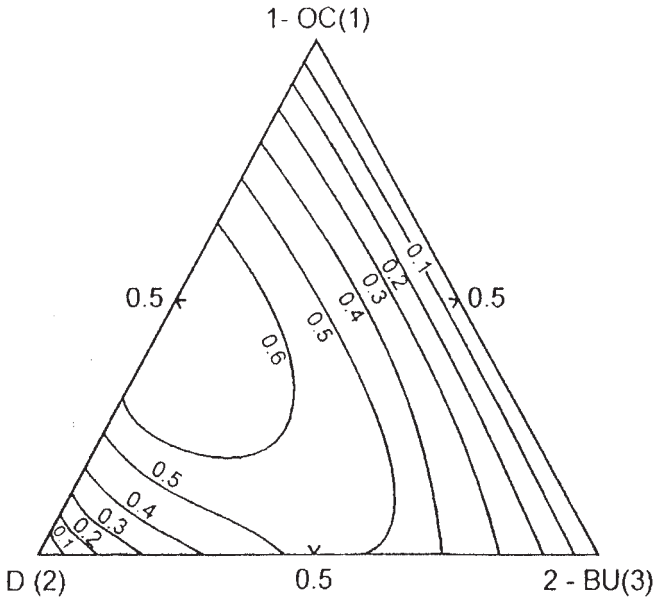
for excess molar volume and excess refraction index using the different expressions in this system.

There exist other equations which introduce fitting parameters like that of Cibulka (13) which propose

$$[10] \qquad V^E_{123} = V^E_{12} + V^E_{13} + V^E_{23} + x_1x_2x_3(A + Bx_1 + Cx_2)$$

where A, B, and C are parameters calculated from experimental data. The parameters obtained for the excess molar volume are A = 1.7391, B = –1.6380, and C = –0.1504. For refraction index, the parameters obtained are A = 0.0786, B = – 0.8660, and C = – 0.1278.

Fig. 3. Lines of constant excess molar volumes for the *n*-octanol (1) + 1,4-dioxane (2) + 2-butanol (3) system at 298.15 K.



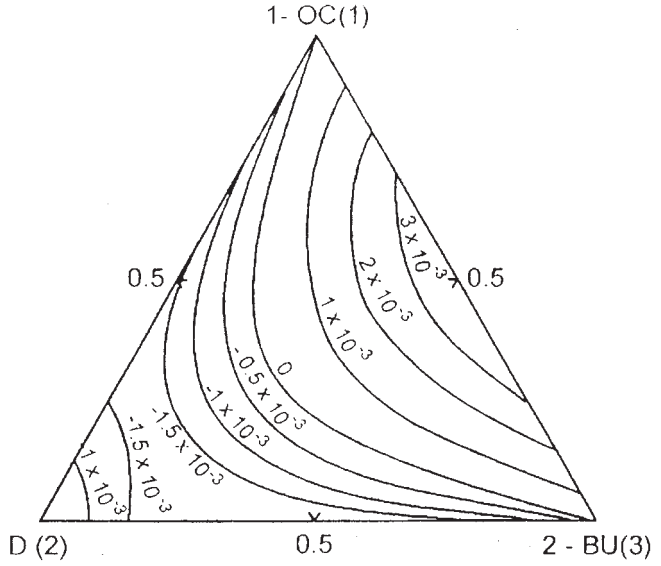


Fig. 4. Lines of constant excess refractive indices for the *n*-octanol (1) + 1,4-dioxane (2) + 2-butanol (3) system at 298.15 K.

Singh et al. (14) proposed an equation of the following form:

$$[11] \qquad V^E_{123} = V^E_{12} + V^E_{13} + V^E_{23} + x_1x_2x_3[A + Bx_1(x_2 - x_3) + Cx_1^2(x_2 - x_3)^2]$$

The parameters obtained for the excess molar volume are A = 1.0378, B = –1.5086, and C = 21.4848. For refraction index, the parameters obtained are A = 0.01517, B = – 0.1889, and C = – 0.9922.

These parameters are also evaluated by the least squares method. These last two equations are modifications of the Radojkovic's equation and the standard deviations are summarized in Table 8.

© 2000 NRC Canada

The models using ternary parameters are superior to the predictive ones (not containing ternary parameters). The fact that so many equations have been developed suggests that no simple equation can describe all types of available systems.

Cibulka's equation shows the best agreement with experimental data for the excess molar volumes and the equation of Singh at al. for the refractive indices of this system.

The prediction of excess molar volumes from refractive index mixing rules has been suggested by some authors (15–17). Following Heller (18)

$$[12] \quad \frac{f(n_D)}{\rho} = \sum_{i=1}^{n} \frac{w_i f(n_{Di})}{\rho_i}$$

where ρ is the density of the mixture, ρ_i is the density of component i in the mixture, w_i is the weight fraction, and f is a mathematical function of the refractive index of the mixture. By substituting $1/\rho$ from eq. [12] and w_i by the mole fraction x_i, we obtain

$$[13] \quad V^E = \frac{\sum_{i=1}^{n} x_i V_i f(n_{Di})}{f(n_D)} - \sum_{i=1}^{n} x_i V_i$$

Expressed in another way, the relation of the excess volumes to the function of the refractive indices would be:

$$[14] \quad V^E = \sum_{i=1}^{n} \left[f(n_{Di}) - f(n_D) \frac{x_i V_i}{f(n_D)} \right]$$

Typical equations for $f(n_D)$ are Lorentz–Lorenz, Dale–Gladstone, Eykman, and Oster. (eq. [15], [16], [17], and [18] respectively). The refractive index mixing rules are:

$$[15] \quad f(n_D) = \frac{(n_D^2 - 1)}{(n_D^2 + 2)}$$

$$[16] \quad f(n_D) = n_D - 1$$

$$[17] \quad f(n_D) = \frac{n_D^2 - 1}{n_D + 0.4}$$

$$[18] \quad f(n_D) = \frac{(n_D^2 + 1)(2n_D^2 + 1)}{n_D^2}$$

Table 9 gives the standard deviation defined by eq. [9] where it could be observed that the Eykman and Oster equations provide the minor deviation for this system to calculate excess molar volumes from refractive indices.

Table 9. Standard deviations of excess molar volumes (eq. [14]) for 1-OC (1) + D (2) + 2-BU (3) system at 298.15 K.

Coefficient d'activité de l'acide sulfurique déterminé par titrage infrarouge

Christophe Ménichelli, Jean-Joseph Max et Camille Chapados

Résumé : Le titrage fait par spectroscopie infrarouge (IR) en utilisant la technique de la réflexion totale atténuée (Attenuated total reflexion, ATR) des solutions aqueuses de l'acide sulfurique H_2SO_4 est effectué pour des pH variant entre 0 et 14 dans la gamme de concentrations 1,89 à 0,01 M. La soustraction du spectre de l'eau dans les spectres des solutions est faite en tenant compte de l'eau acide, neutre et basique qui ont des spectres différents. Les spectres résultants sont les spectres de mélanges des espèces ioniques HSO_4^- et SO_4^{2-}. Pour chaque concentration, l'analyse par facteurs (AF), donne le spectre des espèces ioniques pures et les facteurs multiplicatifs (FM) dont on tire la distribution des espèces en fonction du pH. Cette distribution est semblable à celle qui est obtenue à partir des équations d'équilibre. La mesure IR permet d'obtenir directement le rapport des coefficients d'activité des ions HSO_4^- et SO_4^{2-}. Ce rapport varie essentiellement avec la concentration des ions sans dépendre de leur concentration relative. L'ajustement des courbes de titrage volumétrique expérimental et théorique dans les régions à haut et à bas pH a permis de déterminer les coefficients moyens d'activité des autres espèces présentes en solution. Les valeurs obtenues sont similaires à celles obtenues par mesures électrochimiques. Ceci montre que la spectroscopie IR peut-être utilisée pour étudier des solutions aqueuses d'acides inorganiques allant de concentrations faibles aux concentrations élevées.

Mots clés : spectroscopie IR, ATR, acide sulfurique, solutions aqueuses, analyse par facteurs, spectres principaux, solvatation, coefficients d'activité, titrage IR.

Abstract: The titration of sulphuric acid by infrared spectroscopy using the attenuated total reflection (ATR) technique was made in the 0 to 14 pH range for solutions ranging from 1.89 to 0.01 M. The subtraction of the water spectrum was made using acidic, neutral, and basic waters which exhibit different spectra. The results gave the spectra of mixtures of the HSO_4^- and SO_4^{2-} ionic species in solutions. For each concentration, factor analysis (FA) sorted the spectra of the pure ionic species and gave through the multiplying factors (MF) the distribution of the species as a function of pH. This distribution is the same as that obtained from the equilibrium equations. The IR measurements gave directly the ratios of the activity coefficients of HSO_4^- and SO_4^{2-} ions. This ratio varies with the total concentration of both ions but is independent of the relative concentration. The fitting of the experimental and theoretical volumetric titration curves in the high and low pH regions gave the mean activity coefficients of the other species present in the solutions. The values obtained are comparable to those obtained by electrochemical measurements. These results show that it is possible to use IR spectroscopy to study aqueous solutions of inorganic acids from low to high concentrations.

Key words : IR spectroscopy, sulfuric acid, aqueous solutions, factor analysis, ATR, principal spectra, solvation, activity coefficients, IR titration.

Introduction

L'acide sulfurique (H_2SO_4) pur et en solution aqueuse est impliqué à tous les niveaux de la chimie, qu'elle soit industrielle ou environnementale. Les propriétés thermodynamiques de ce système ont fait l'objet de nombreuses études au cours des 80 dernières années (1–8). Une de ces propriétés est le coefficient d'activité qui indique l'activité de l'acide différente de sa concentration. Staples (8) a donné une revue complète de la littérature sur le sujet. Les travaux décrits dans cette revue ont été réalisés à l'aide de mesures électrochimiques et thermodynamiques et ils indiquent que ces solutions ont un comportement fortement non idéal. Le désavantage de ces mesures est que les résultats obtenus le sont de façon indirecte et qu'ils donnent peu d'informations sur l'organisation des molécules en solution.

La spectroscopie vibrationnelle est un complément essentiel à ces mesures physico-chimiques car elle permet des mesures directes des espèces en présence tout en fournissant une information de nature structurale sur le système. L'analyse des spectres Raman des solutions aqueuses du H_2SO_4 a fait l'objet de plusieurs études (9–14). Irish et ses collaborateurs ont identifié et quantifié les espèces présentes en solutions (12–14). En spectroscopie

infrarouge (IR), peu de travaux ont été effectués sur ces solutions à cause de la forte absorptivité de l'eau qui rend difficile l'analyse quantitative des espèces en solution (15–17).

Récemment, Chapados et ses collaborateurs ont étudié la modification du spectre IR de l'eau par ATR lors de l'ajout d'un sel binaire (NaCl), d'un acide fort (HCl) ou d'une base forte (NaOH) et ont développé une méthode simple pour soustraire quantitativement le spectre d'eau de ces systèmes afin d'obtenir le spectre des autres espèces dissoutes (18–20). Ces études indiquent que la présence d'ions H_3O^+ (ou $H_5O_2^+$), OH^- (ou $H_3O_2^-$), Cl^- ou Na^+ en solution modifie l'organisation naturelle des molécules d'eau et en modifie le spectre.

Dans l'article précurseur à celui-ci (21) (ci-après **I**), nous avons effectué le titrage par spectroscopie IR (titrage IR) d'une solution aqueuse d'acide sulfurique à 0,50 M par des solutions de titrants HCl et NaOH sur la gamme de pH 0 à 14. Des spectres d'eau acide, neutre et basique ont été soustraits quantitativement des spectres des solutions d'acide sulfurique afin d'obtenir les spectres des mélanges HSO_4^- et SO_4^{2-}. L'analyse par facteurs (AF), qui est un traitement mathématique permettant de séparer les spectres des composantes principales (spectres principaux) et d'en déterminer l'abondance, a été effectuée suivant la méthode décrite dans la référence 20. Les facteurs multiplicatifs (FM) déterminés lors de l'AF sont directement proportionnels à la concentration et permettent de calculer les courbes de distribution des espèces en fonction du pH (20–24). Pour l'acide sulfurique 0,50 M, cette méthode a permis de déduire le rapport des coefficients d'activité de l'ion sulfate et de l'ion bisulfate (21). La comparaison des courbes de titrage volumétrique expérimental avec les courbes théoriques obtenues à partir des équations d'équilibre, a conduit à la détermination du coefficient moyen d'activité des autres espèces présentes dans ces solutions.

Le but de ce travail consiste à étudier, suivant la même méthode, le comportement des espèces ioniques de l'acide sulfurique sur une gamme de concentrations de 1,89 à 0,01 M afin d'obtenir les coefficients moyens d'activité dans une gamme étendue de concentrations pour les comparer aux valeurs de la littérature. L'influence du NaCl, un sel binaire, sur les coefficients d'activité sera étudiée afin de tester par IR l'influence d'ions étrangers sur le système sulfate.

Considérations théoriques[3]

Calcul des courbes de la distribution théorique du titrage volumétrique

Introduction

Le développement des équations est le même que dans (**I**). Seul un résumé des étapes essentielles est présenté ici. Lors du titrage, le produit à titrer est en équilibre thermodynamique avec ses différentes espèces ioniques :

$$[1] \qquad H_2SO_4 \overset{pK_1}{\underset{H^+}{\rightleftharpoons}} HSO_4^- \overset{pK_1}{\underset{H^+}{\rightleftharpoons}} SO_4^{2-}$$

L'entité moléculaire de l'acide sulfurique ne coexiste pas en solution aqueuse avec ses deux espèces ioniques (15, 21). L'équation d'équilibre entre les espèces mises en jeu lors de l'ajout de titrant HCl ou NaOH à la solution aqueuse d'acide sulfurique peut s'écrire comme suit :

$$[2] \qquad \begin{array}{c} H_2SO_4 + H_2O + NaOH + HCl \\ A \qquad D \qquad C_1 \qquad C_{-1} \end{array}$$
$$\rightarrow \begin{array}{c} HSO_4^- + SO_4^{2-} + H^+ + OH^- + Na^+ + Cl^- + H_2O \\ y_1 \qquad y_2 \qquad x \qquad x' \qquad c \qquad c' \qquad d \end{array}$$

Pour simplifier, l'équation est écrite comme si HCl et NaOH étaient ajoutés en même temps mais séparés à la fin du traitement. Le côté gauche de l'équation [2] représente l'état de départ et la partie droite l'état d'équilibre du mélange. La seconde ligne représente les quantités (en mol) impliquées dans le titrage. À gauche, A, C_1, C_{-1} et D sont les quantités originales et connues tandis que les quantités à droite (y_1 à d) doivent être déterminées.

Équations d'équilibre de dissociation

L'équilibre de dissociation entre HSO_4^- et SO_4^{2-} dans l'eau est donné par l'équation [3] en utilisant pour simplifier $[H^+]$ au lieu de $[H_3O^+]$ (ou $[H_5O_2^+]$).

$$[3] \qquad \frac{[SO_4^{2-}][H^+]}{[HSO_4^-]} \frac{\gamma_{SO_4^{2-}}\gamma_{H^+}}{\gamma_{HSO_4^-}} = K_2$$

avec

$$[4] \qquad \frac{\gamma_{HSO_4^-}}{\gamma_{SO_4^{2-}}} = \Gamma_2$$

De même pour l'eau :

$$[5] \qquad \frac{[H^+][OH^-]}{[H_2O]} \frac{\gamma_{H^+}\gamma_{OH^-}}{\gamma_{H_2O}} = K_0$$

avec

$$[6] \qquad \frac{\gamma_{H_2O}}{\gamma_{OH^-}} = \Gamma_0$$

Les coefficients d'activité des espèces en solution (γ_i) diffèrent de l'unité dans la gamme de concentrations étudiées et sont exprimés en terme de coefficient moyen d'activité $\gamma_\pm$. (1, 8) :

$$[7] \qquad \gamma_\pm = \frac{\gamma_{H^+}}{\Gamma_2}$$

Distribution des espèces

La mesure obtenue par le pH-mètre conduit à la relation suivante :

$$[8] \qquad X = \frac{V}{\gamma_{H^+}x} = \frac{1}{\gamma_{H^+}[H^+]} = 10^{pH}$$

La quantité (en mol) des espèces est déterminée suivant les équations d'électroneutralité, de conservation des espèces et des constantes d'équilibre (**I**) :

[3] Pour la signification des symboles, voir la liste en annexe.

© 2000 CNRC Canada

$$[9] \qquad y_1 = \frac{A}{1 + K_2 \Gamma_2 X}$$

$$[10] \qquad y_2 = \frac{A}{\frac{1}{K_2 \Gamma_2 X} + 1}$$

L'abondance relative des espèces ioniques HSO_4^- et SO_4^{2-} en fonction du pH est obtenue en divisant les équations [9] et [10] par A et en remplaçant X par 10^{pH}. Les courbes de distribution des espèces en fonction de l'équivalent titrant (P) sont obtenues en transformant la masse de titrant (m_δ) en P par l'équation :

$$[11] \qquad P = \delta \frac{\frac{m_\delta \varepsilon_\delta}{M_\delta}}{\frac{(m - m_\delta)\varepsilon_2}{M_2}}$$

où $\delta = 1$ pour l'ajout de titrant NaOH et $\delta = -1$ pour l'ajout de titrant HCl.

Variation théorique du pH en fonction de la masse de titrant

Le développement des équations (**I**) pour obtenir la variation théorique de la masse de titrant m_δ en fonction du pH conduit à :

$$[12] \qquad m_\delta = \frac{\rho_0 V \left[\frac{\varepsilon_2}{M_2} \frac{1 + 2K_2\Gamma_2 10^{pH}}{1 + 2K_2\Gamma_2 10^{pH}} + \frac{1 - \varepsilon_2}{M_{H_2O}} \frac{K_2\Gamma_2 10^{pH}}{1 + K_2\Gamma_2 10^{pH}} \right] - \frac{V 10^{-pH}}{\gamma_{H^+}}}{\frac{\varepsilon_\delta}{M_\delta} \frac{\delta + \frac{\delta - 1}{2} K_2\Gamma_2 10^{pH}}{1 + K_2\Gamma_2 10^{pH}} + (1 - \rho_\delta) \frac{\varepsilon_\delta}{M_\delta} \frac{1 + 2K_2\Gamma_2 10^{pH}}{1 + K_2\Gamma_2 10^{pH}} - \frac{(1 - \varepsilon_\delta) - (1 - \rho_\delta)(1 - \varepsilon_2)}{M_{H_2O}} \frac{K_2\Gamma_2 10^{pH}}{1 + K_2\Gamma_2 10^{pH}}}$$

où ρ_0 est la densité de la solution aqueuse d'acide sulfurique sans titrant et ρ_δ le coefficient sans dimension de la variation de la densité ρ défini par $\rho_\delta = (\rho - \rho_0)/(m_\delta/V)$. La distribution des espèces et la courbe de titrage volumétrique sont données par les équations [9, 10 et 12]. Les paramètres à déterminer dans ces équations sont les coefficients d'activité Γ_0, Γ_2 et γ_{H^+}. L'étude du comportement aux limites de ces équations permet de déterminer la zone d'influence de chacun de ces paramètres sur les courbes de distribution. Au pH d'équipartition ($[HSO_4^-] = [SO_4^{2-}]$), l'équation [3] est réécrite :

$$[13] \qquad \Gamma_2 = 10^{(pK_2 - pH_{\text{équipartition}})}$$

Cette équation montre que le titrage IR avec une simple mesure de pH permet de déterminer directement le coefficient moyen d'activité (Γ_2) des ions sulfate et bisulfate en équilibre.

À pH élevé, avec ajout de titrant NaOH, ($16 > pH > 13$), où $K_0\Gamma_0 10^{pH} << 1 << K_2\Gamma_2 10^{pH}$, l'équation [12] peut être évaluée par la relation suivante :

$$[14] \qquad m_1 \approx \rho_0 V \frac{2\frac{\varepsilon_2}{M_2} + \frac{1 - \varepsilon_2}{M_{H_2O}} K_0\Gamma_0 10^{pH}}{\frac{\varepsilon_1}{M_1} + 2(1 - \rho_1)\frac{\varepsilon_2}{M_2}} \approx G + \rho_0 V \frac{\frac{1 - \varepsilon_2}{M_{H_2O}} K_0\Gamma_0 10^{pH}}{\frac{\varepsilon_1}{M_1} + 2(1 - \rho_1)\frac{\varepsilon_2}{M_2}}$$

Où G est une constante correspondant à deux équivalents titrants pour la neutralisation totale de l'acide sulfurique. L'équation [14] indique que seul Γ_0 influence la courbe à haut pH. À bas pH, avec ajout de titrant HCl, ($pH < 0{,}5$), où $K_0\Gamma_0 10^{pH} << 1$ et $K_2\Gamma_2 10^{pH} << 1$, l'équation [12] peut être évaluée par la relation suivante :

$$[15] \qquad m_{-1} \approx \frac{\rho_0 V \frac{\varepsilon_2}{M_2} - \frac{V}{\gamma_{H^+}} 10^{-pH}}{\frac{\varepsilon_{-1}}{M_{-1}} + (1 - \rho_{-1})\frac{\varepsilon_2}{M_2}} \approx -H \frac{\frac{V}{\gamma_{H^+}} 10^{-pH}}{\frac{\varepsilon_{-1}}{M_{-1}} + (1 - \rho_{-1})\frac{\varepsilon_2}{M_2}}$$

Où H est une constante correspondant à la première dissociation complète de l'acide en milieu aqueux. L'équation [15] indique que seul γ_{H^+} influence la courbe de titrage à bas pH, tant que la première dissociation de l'acide sulfurique peut-être considérée comme complète.

La spectroscopie IR par réflexion totale atténuée (ATR)

Les spectres IR de solutions aqueuses obtenus par transmission nécessite l'utilisation de films minces afin d'éviter que l'intensité de la bande d'élongation OH de l'eau ne sature. L'ATR permet de surmonter ces difficultés car le spectre obtenu ne dépend que des propriétés optiques (intensives) du film mesuré. Bien que les effets de dispersion anormale (DA) produisent des variations dans le spectre ATR par rapport à une mesure idéale, les travaux antérieurs sur les effets de la DA dans les spectres ATR de solutions salines montrent que les spectres ATR varient directement avec la concentration de la solution. Il en est de même des spectres de *k*. Ces derniers et les spectres ATR de l'eau varient de façon quasi proportionnelle (25). Il n'est donc pas nécessaire de séparer les effets optiques du spectre ATR pour établir une corrélation entre les modifications des spectres et les modifications chimiques des solutions.

Partie expérimentale

Produits chimiques et solutions

L'acide sulfurique (H_2SO_4) (Aldrich Chemical Co., pureté 98 %) est utilisé sans traitement supplémentaire. De l'eau déionisée est utilisée pour obtenir les solutions aqueuses d'acide sulfurique. Des solutions de NaOH à 49,5 % (±0,7 %) (p/p) et de HCl à 37 % (±0,5 %) (p/p) sont utilisées pour le titrage de l'acide sulfurique afin de travailler sur toute la gamme de pH.

Préparation des échantillons

Les solutions de H_2SO_4 aux concentrations de 1,886; 1,02, 0,500; 0,204; 0,102; 0,0509 et 0,0103 M (±1 %) sont préparées selon la méthode décrite dans **I.** La solution acide salée est préparée en ajoutant du NaCl à du H_2SO_4 0,558 M afin que la solution contienne NaCl 1,00 M.

Mesure de pH

Pour chaque échantillon, les mesures de pH sont effectuées à température ambiante (26,5 ± 0,3°C) avec un pH-mètre Omega, modèle PHH-253, couplé à une électrode combinée (Analytical Sensors, Inc., modèle PH10107B-03-B). Une calibration appropriée (pH = 2,00; 7,00 et 10,00) est effectuée avant chaque série de mesures. Un temps de stabilisation de 20 min est alloué pour chaque prise de mesure. La validité des mesures obtenues avec l'appareil a été vérifiée dans la gamme de pH de –0,25 à 13,89 (20).

Mesures infrarouges

Les mesures IR entre 4800 et 650 cm^{-1} sont effectuées sur un spectromètre FTIR Nicolet, modèle 510P, équipé d'un détecteur TGS. Deux fenêtres de KBr isolent la chambre de mesure de l'extérieur. L'échantillon à analyser est placé dans une cellule ATR cylindrique (SpectraTech, Inc.) équipée d'un cristal de ZnSe cylindrique (11 réflexions internes). Les spectres sont pris sous flux continu d'azote. Pour chaque prise de spectre, une accumulation de 200 balayages est faite avec une résolution de 4 cm^{-1}. Toutes les mesures sont effectuées à 26,5°C ± 0,3°C. Un spectre de référence de la cellule vide est pris avant chaque spectre d'échantillon.

Traitement des données

Les données spectrales pour chaque échantillon (2152 points {I ($\tilde{\nu}$) vs. $\tilde{\nu}$ (en cm^{-1})} sont transférées sur micro-ordinateur et traitées avec le chiffrier Microsoft Excel97. Les intensités I sont transformées en absorbance (log(1/I)). Une légère correction (plus petite que 0,03 UA) de la ligne de base est effectuée par ajustement de la région 4600–4450 cm^{-1} au zéro d'absorbance. Pour chaque série de spectres, la soustraction des différents types d'eau est effectuée sans aucune correction des lignes de base; les spectres principaux des espèces ioniques de l'acide sulfurique sont déterminés et l'AF est appliquée sur l'ensemble des spectres en utilisant la minimisation de la différence quadratique (hors des zones de bruit) comme critère de qualité.

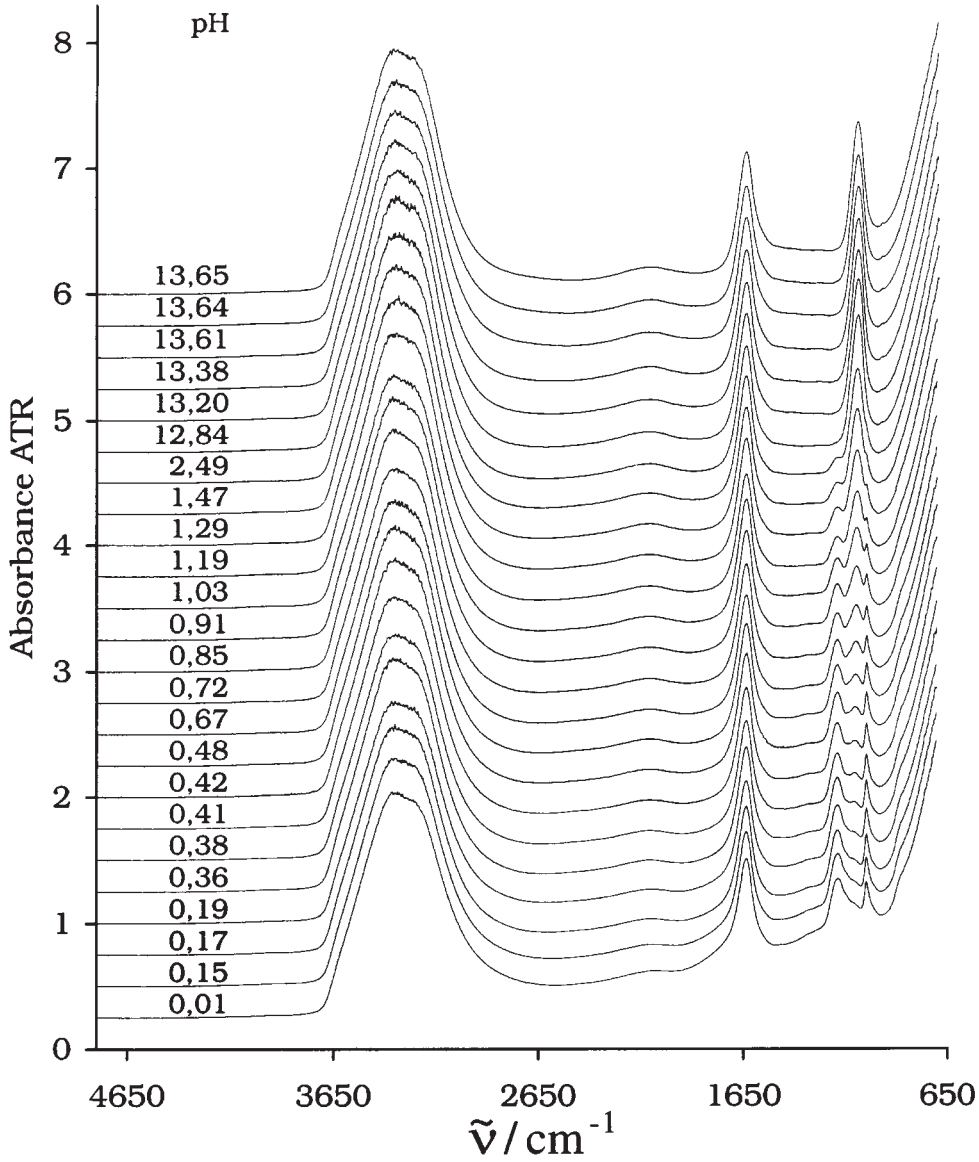
Résultats et discussion

Les spectres et les courbes de distribution relatifs au titrage IR seront présentés suivant l'exemple du titrage de la solution à 1,02 M. Le développement des résultats s'intéressera à l'ensemble des concentrations.

Spectres de mélanges de H_2SO_4 aqueux avec HCl ou NaOH

La figure 1 donne les spectres expérimentaux des solutions aqueuses de H_2SO_4 1,02 M sur la gamme de pH de 0 à 14. La bande large et intense dans la région 3700–2800 cm^{-1} résulte de la vibration d'élongation OH de l'eau (ν_{OH}) et la bande à 1640 cm^{-1} résulte de la vibration de déformation OH de l'eau (δ_{OH}). L'augmentation de l'intensité du spectre dans la région en dessous de 950 cm^{-1} provient de la bande de libration de l'eau. Les bandes relatives aux groupements sulfates sont observées dans la région 1300–800 cm^{-1}. Dans cette région, la variation de l'intensité des bandes en fonction du pH est directement reliée à la variation de la composition ionique des solutions. La modification du spectre d'eau en fonction du pH est due à la présence de l'eau acide, de l'eau neutre et de l'eau basique. La forte absorptivité des spectres des différents types d'eau rend difficile l'analyse quantitative des bandes des espèces ioniques de l'acide sulfurique.

Pour les autres concentrations, les spectres expérimentaux des solutions aqueuses de l'acide sulfurique sur la gamme de pH 0–14 sont obtenus de la même façon. Les intensités des bandes d'eau sont du même ordre de grandeur pour chacune des concentrations alors que les intensités des bandes des espèces ioniques de l'acide sulfurique diminuent avec la concentration. Elles deviennent imperceptibles en dessous de 0,01 M.



La figure 1 pourrait paraître semblable à celle publiée des spectres de solutions aqueuses d'acide sulfurique à 0,50 M (21). C'est une illusion puisque la différence entre les deux séries de spectres est autre qu'un facteur de concentration puisque l'intensité de la bande à 1098 cm^{-1} est supérieure à celle de la bande à 1637 cm^{-1}, tandis que c'est l'inverse dans la référence 21.

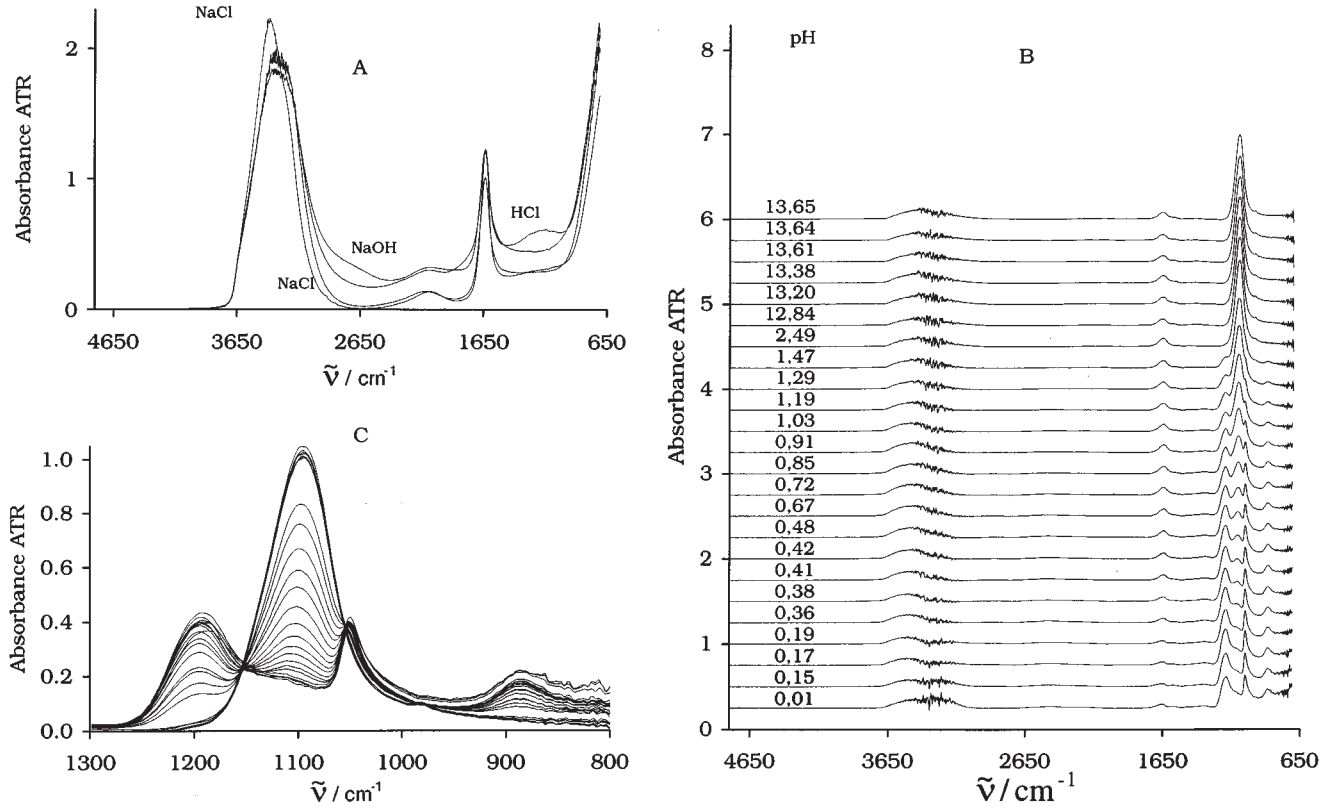
Soustraction des différents types d'eau

La figure 2A présente les spectres d'eau qui sont utilisés comme spectres principaux pour la soustraction des spectres d'eau dans les échantillons titrés : eau acide (HCl 1,54 M);

© 2000 CNRC Canada

Fig. 1. Spectres IR ATR des 24 mélanges de H_2SO_4 1,02 M avec HCl ou NaOH 0 < pH < 14. Chaque spectre est décalé successivement de 0,25 UA.

eau neutre (H_2O); eau basique (NaOH 2,23 M) et eau saline (NaCl 5,00 M). Les spectres de la figure 2A sont superposés afin de mieux souligner leurs différences. La figure 2B donne les spectres des solutions aqueuses de l'acide sulfurique 1,02 M sur la gamme de pH 0–14 après la soustraction des spectres de l'eau acide, de l'eau neutre et de l'eau basique. Pour chaque spectre, la ligne de base est régulière et se situe au 0,00 UA. La figure 2C présente ces spectres d'une façon superposée dans la région des bandes sulfates (1300–800 cm^{-1}). Les points quasi–isobestiques situés à 1147 et 1051 cm^{-1} et la variation de l'intensité des bandes à 1192, 1098, 1050 et 883 cm^{-1} indiquent une transformation unitaire en fonction du pH de HSO_4^- en SO_4^{2-} dans ces solutions. La large bande de faible intensité située dans la région 3700–3050 cm^{-1} et la bande située vers 1640 cm^{-1} (fig. 2B) indiquent que toute l'eau n'a pu être soustraite. Ces bandes résiduelles sont attribuées à l'eau complexée avec les espèces ioniques de l'acide sulfurique et feront l'objet d'un travail subséquent.



Détermination des spectres des espèces ioniques pures

Les spectres des figures 2B et C représentent les spectres de mélanges des espèces ioniques solvatées HSO_4^- et SO_4^{2-} sur la gamme de pH 0–14 après la soustraction des différents types d'eau. Après la seconde équivalence, tous les groupes HSO_4^- ont été neutralisés. Le spectre le plus basique correspond donc au spectre de l'espèce ionique pure SO_4^{2-}. En fait, il représente le spectre de SO_4^{2-} avec ses contre-ions (ici 2 Na^+) et avec l'eau complexée à cette paire d'ions.

Dans la solution aqueuse d'acide sulfurique sans ajout de titrant, les espèces ioniques présentes en solution sont HSO_4^-, SO_4^{2-}, les deux ayant H_3O^+ comme contre-ion (**I**). Comme l'espèce HSO_4^- n'est jamais pure en solution, le spectre de

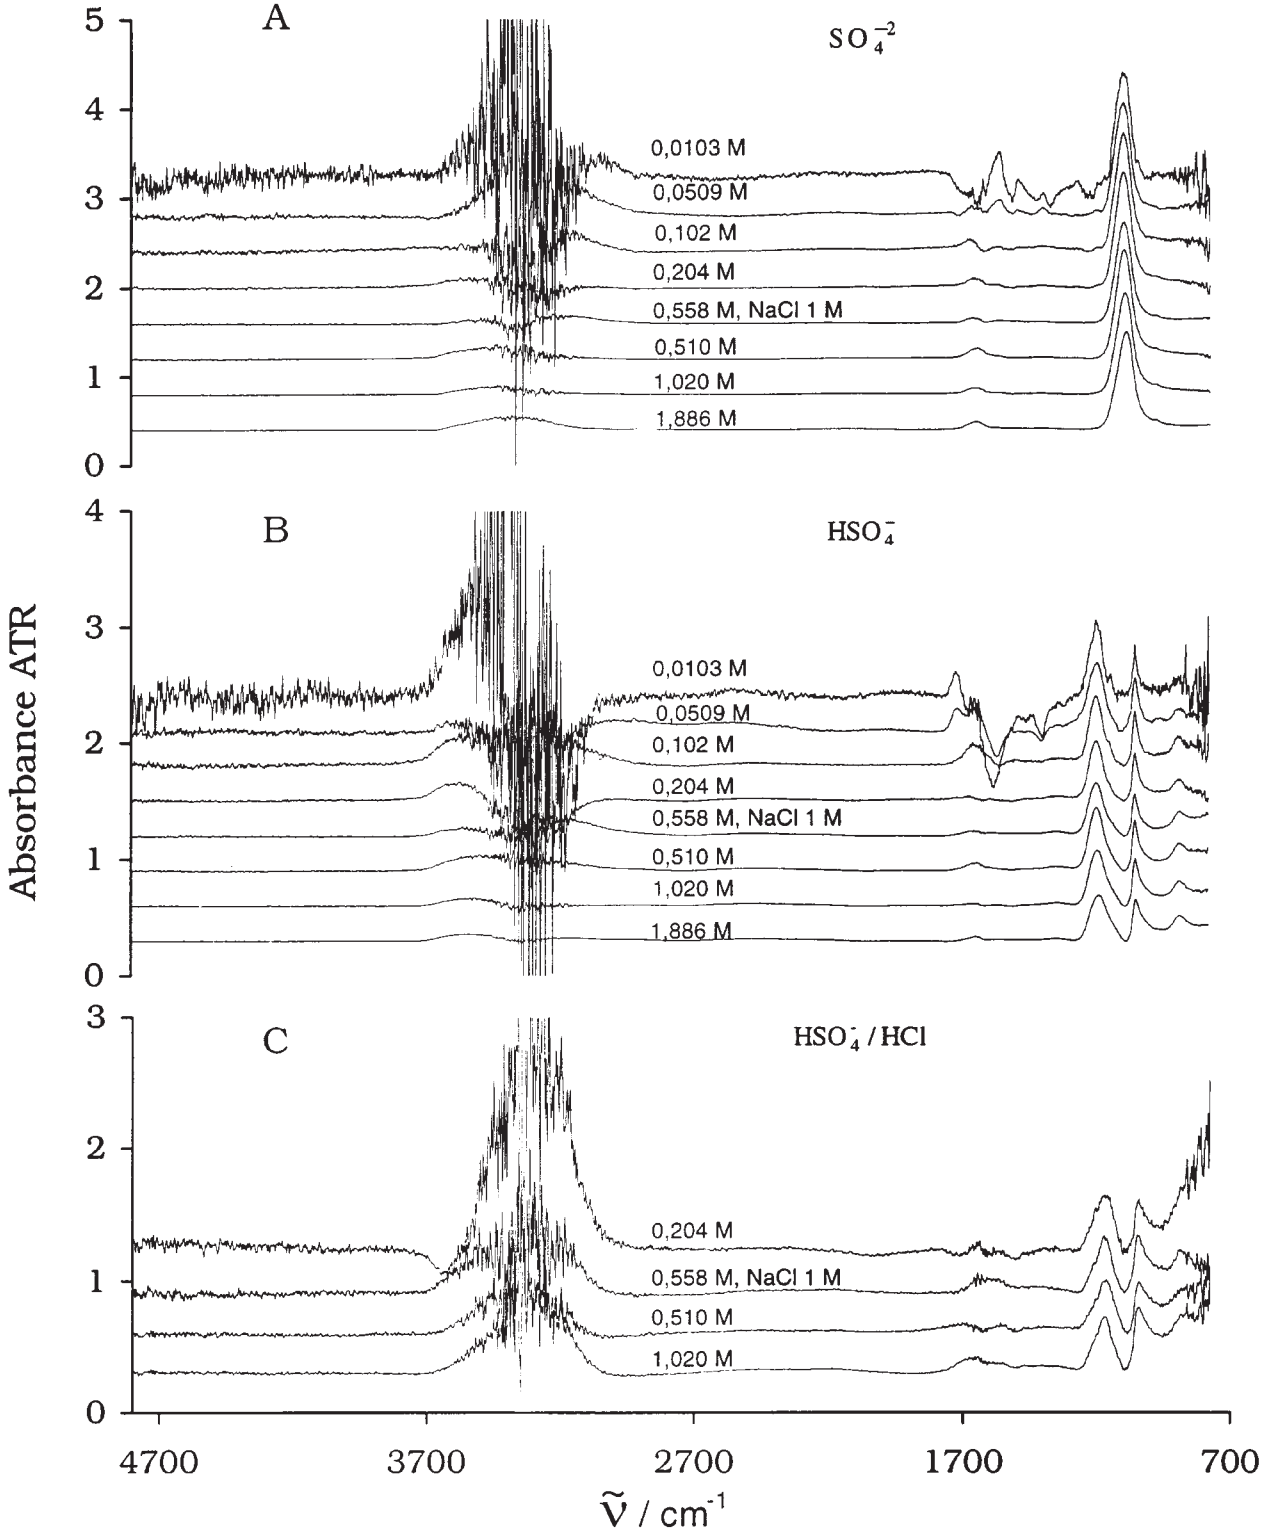
© 2000 CNRC Canada

Fig. 2. A, Spectres principaux des espèces d'eau : eau acide (HCl 1,54 M); eau neutre (H_2O); eau basique (NaOH 2,23 M) et eau saline (NaCl 5,00 M). B, Spectres IR ATR des 24 mélanges de H_2SO_4 1,020 M après soustraction des spectres d'eau. Chaque spectre est décalé successivement de 0,25 UA. C Superposition des spectres de 2B dans la région des bandes sulfates.

l'espèce ionique pure HSO_4^- est obtenu en retranchant la contribution du spectre de l'espèce ionique pure SO_4^{2-} du spectre des solutions à bas pH. Ceci est effectué par la minimisation de l'intensité de la bande ν_4 du SO_4^{2-} qui est située à 1098 cm^{-1}.

Comme première approximation, on considère que les bandes propres à chacun des ions HSO_4^- et SO_4^{2-} sont indépendantes du contre-ion H_3O^+ ou Na^+. Ceci est confirmé par la position des bandes à 1192, 1098, 1050 et 883 cm^{-1} en fonction du pH (figs. 2B et C). Cependant, la solvatation de ces espèces est influencée par le contre-ion (**I**). Ainsi, le spectre déterminé de l'espèce pure HSO_4^- est celui de la paire d'ions solvatée (H_3O^+ et HSO_4^-). Le spectre de la paire d'ions solvatée (Na^+ et HSO_4^-) est obtenu quand tous les H_3O^+ sont remplacés par des Na^+ dans la paire d'ions, par l'ajout de titrant NaOH à la solution aqueuse d'acide sulfurique. De même, le spectre de l'espèce pure SO_4^{2-}, qui fut déterminé précédemment, est celui du groupe d'ions ($2Na^+$ et SO_4^{2-}). Les spectres des groupes d'ions (H_3O^+, SO_4^{2-} et Na^+) et ($2H_3O^+$ et SO_4^{2-}) sont obtenus par ajout de NaOH à la solution aqueuse d'acide avant la seconde équivalence. Pour l'AF des espèces ioniques de l'acide sulfurique, on s'est intéressé à la détermination de la concentration des deux espèces HSO_4^- et SO_4^{2-}. Ainsi, pour obtenir la distribution de ces deux espèces, il n'est pas nécessaire de différencier le spectre des groupes ou paires d'ions.

Pour chaque concentration, les spectres des espèces ioniques HSO_4^- et SO_4^{2-} sont déterminés de la même manière que pour la solution à 1,02 M et sont donnés respectivement sur la figure 3 après leur normalisation à 1,00 M. La normalisation des spectres aux plus faibles concentrations a pour effet d'augmenter l'intensité du bruit, notamment au niveau des bandes d'eau de solvatation dans la région 3700–3050 cm^{-1}. Les bandes de chacune des espèces ont une intensité et une position semblables pour chaque concentration. Ceci indique la validité des critères de sélection des spectres des espèces ioniques pures. Les résultats ainsi obtenus sont concordants sur toute la gamme de concentrations étudiées, même aux très faibles concentrations.



Résultats de l'AF des espèces ioniques de l'acide sulfurique

Pour chaque concentration, les spectres des espèces ioniques pures déterminés précédemment sont soustraits dans tous les spectres auxquels les spectres d'eau ont été retranchés. Les FM impliqués dans la soustraction donnent la proportion de chacune des espèces ioniques.

Dans (**I**), une seconde forme solvatée de l'espèce HSO_4^- a été mise en évidence lors de l'ajout de titrant HCl à la solution aqueuse de l'acide. Ce spectre est observé aux concentrations supérieures à 0,20 M, excepté pour les solutions à 1,89 M dans lesquelles aucun titrant HCl n'a été ajouté. Ce spectre est obtenu en soustrayant les contributions des spectres des espèces ioniques pures HSO_4^- et SO_4^{2-} du spectre sans eau de la solution la plus acide. Ce nouveau spectre de l'espèce que nous appellerons (H_3O^+ et HSO_4^-)$_{\text{-HCl}}$ est ensuite soustrait des spectres des solutions auxquelles du

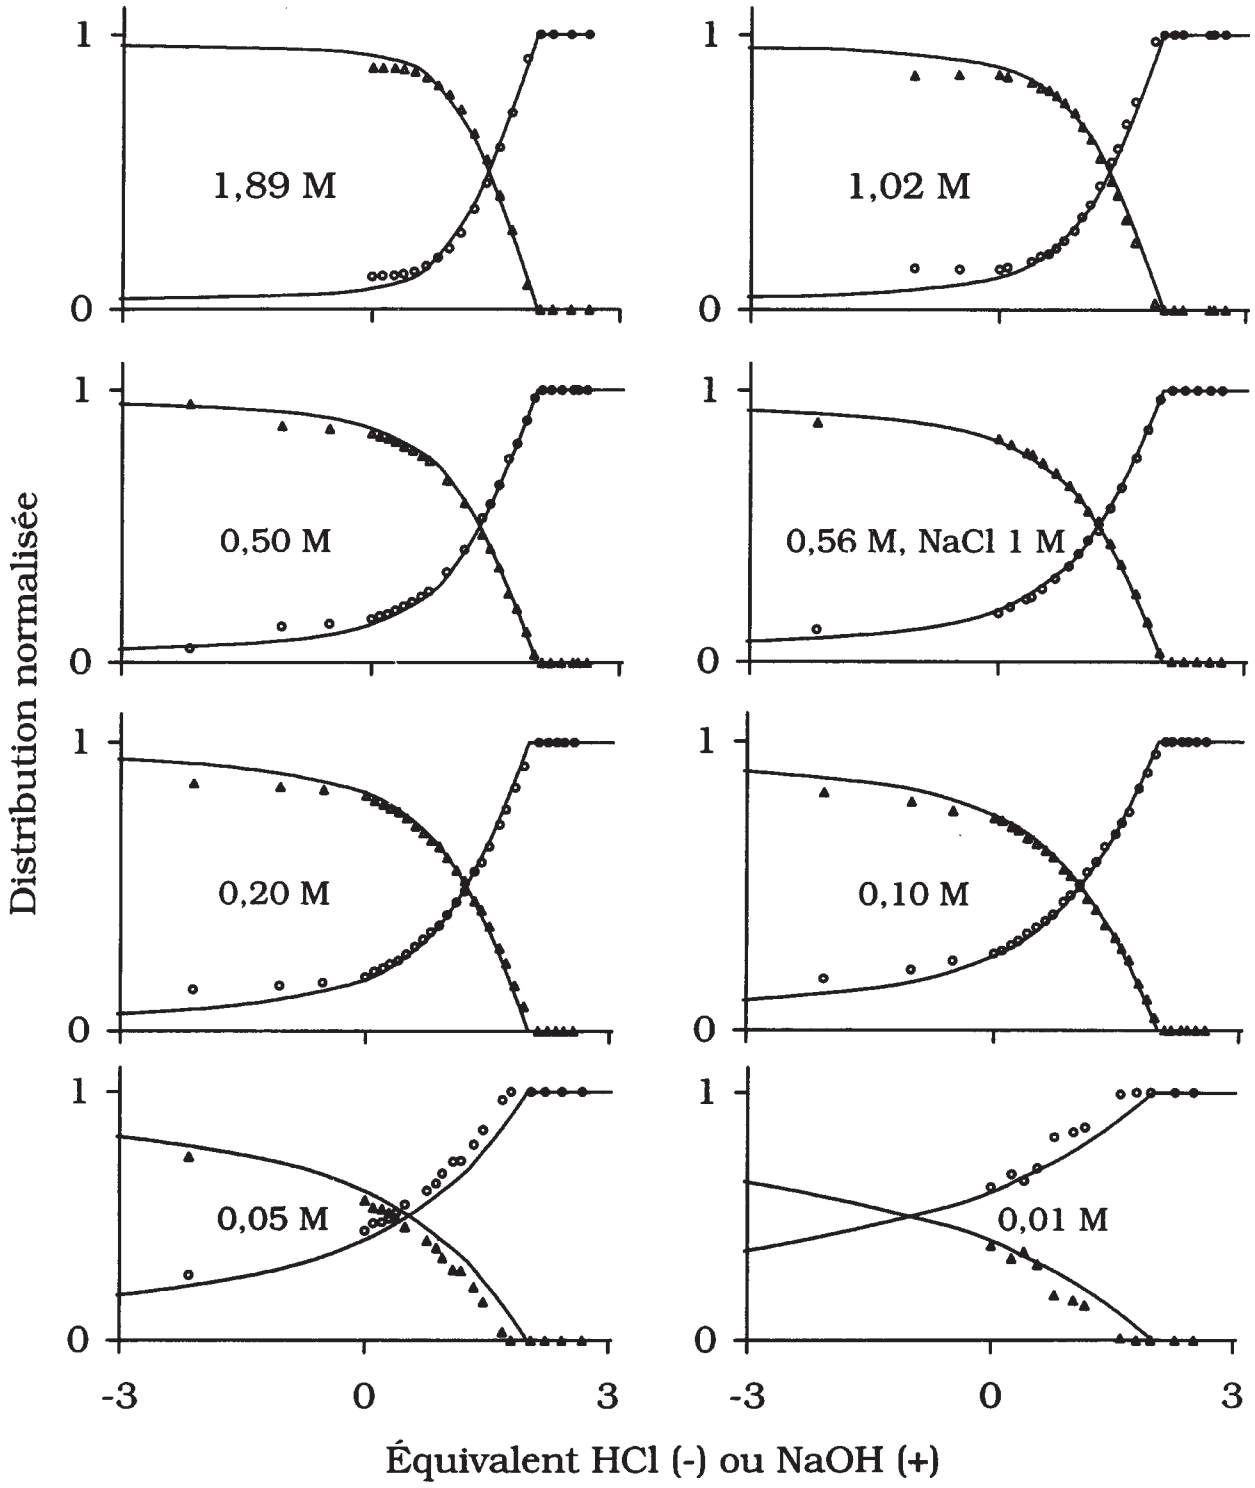

Fig. 3. Spectres IR ATR des espèces ioniques du H_2SO_4 aqueux sur la gamme de concentrations 1,89–0,01 M. Les spectres sont normalisés à 1,00 M de chacune des espèces et sont décalés. À cause de la normalisation, des bandes artifactuelles apparaissent entre 1500 et 1200 cm^{-1} aux concentrations les plus basses (0,0103 et 0,0509 M).

titrant HCl a été ajouté. L'observation de cette espèce à plusieurs concentrations révèle sa présence réelle en solution. Elle résulte de l'influence d'une paire d'ions (H^+ et Cl^-) sur une paire d'ions (H_3O^+ et HSO_4^-). Un élément de preuve supplémentaire est fourni par l'analyse du titrage IR de l'acide sulfurique en présence de NaCl 1,00 M (voir plus loin). Dans les solutions les plus acides, la concentration de cette espèce représente au maximum 20 % de celle de

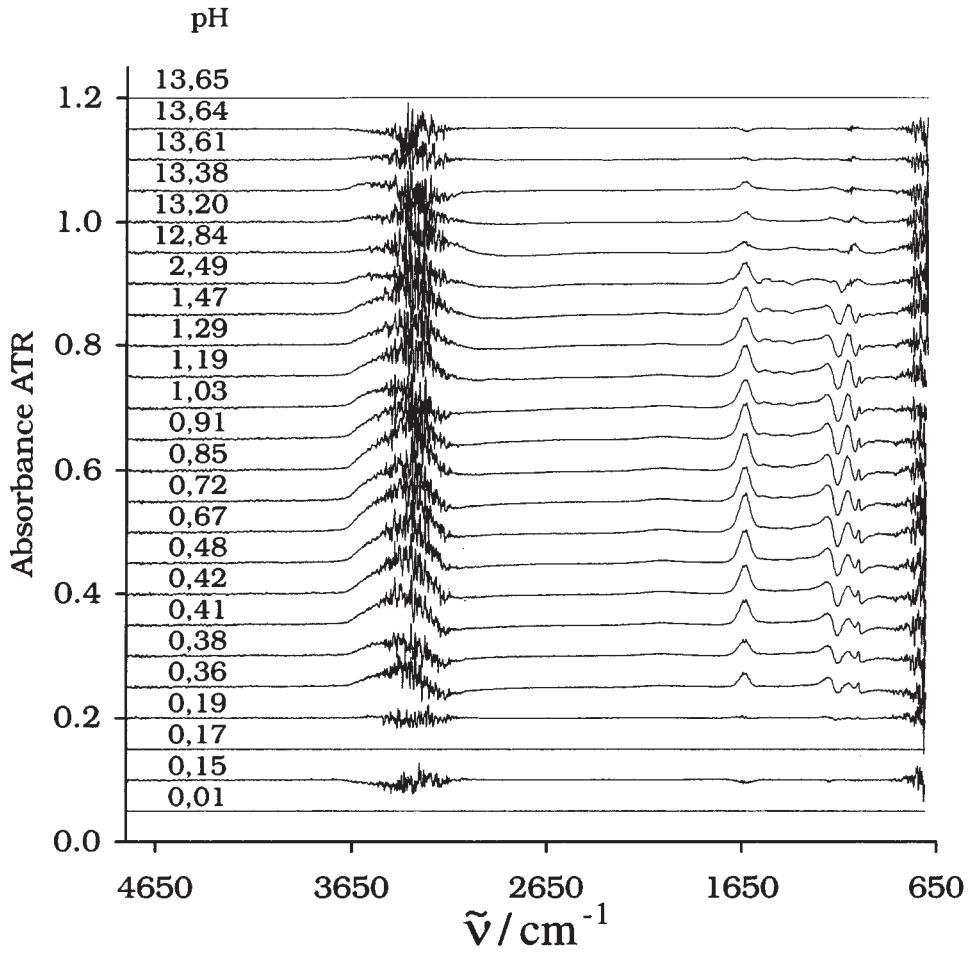
Fig. 4. Distribution relative des espèces ioniques de H_2SO_4 aqueux en fonction de l'équivalent titrant sur la gamme de concentration 1,89–0,01 M. Lignes pleines (——), distribution théorique (obtenues avec les équations 9 et 10); points en triangles vides (△△△), HSO_4^- par IR; points en ronds vides (○○○), SO_4^{2-} par IR.



l'espèce (H_3O^+ et HSO_4^-). L'incertitude sur les FM lors de l'AF rend moins précise la normalisation du spectre de cette espèce pure. Ainsi, la figure 3C donne les spectres principaux de l'espèce (H_3O^+ et HSO_4^-)$_{-HCl}$ pour les concentrations précédemment citées.

La figure 4 donne, pour chaque concentration, les résultats de la décomposition par facteurs à partir des spectres principaux en terme de distribution des espèces ioniques HSO_4^- (Δ) et SO_4^{2-} (O) en fonction de l'équivalent titrant. Comme dans **I**, les 2 espèces (H_3O^+ et HSO_4^-) et (H_3O^+ et

Fig. 5. Résidus résultant de l'AF à partir des spectres principaux pour H_2SO_4 1,02 M pour les pH entre 0 et 14. Les spectres sont décalés successivement de 0,05 UA. Par rapport à la Fig. 2B, l'échelle d'intensité est étalée par un facteur de 5.

$HSO_4^-)_{\text{-HCl}}$ ont été comptabilisées ensemble. Les FM ont été normalisés à 1. Dans la figure 4, les courbes formées de symboles représentent les valeurs réelles de distribution des espèces car elles proviennent de la mesure directe de la concentration des espèces. Les courbes en trait plein représentent les courbes théoriques (équations [9] et [10]) en considérant la contribution des coefficients d'activité du proton, de l'eau et des espèces ioniques de l'acide. Le choix des valeurs des coefficients d'activité dans les courbes de distribution théoriques est expliqué plus loin. Les courbes théoriques et expérimentales montrent une bonne concordance. Aux plus faibles concentrations (0,01 et 0,05 M), l'augmentation du bruit dans les spectres influence l'incertitude des résultats de l'AF. Ces courbes de distribution nous indiquent clairement que l'équilibre se déplace avec la concentration.

Les résidus

La figure 5 donne les résidus de la décomposition par facteurs des solutions aqueuses de l'acide 1,02 M en utilisant trois spectres principaux (Fig. 3). L'AF a été effectuée suivant la minimisation des carrés de la différence entre le spectre expérimental et le spectre calculé. Pour cette raison, les spectres obtenus ont des intensités négatives par endroits. On remarque la présence de bandes résiduelles à 1215, 1116 et 1055 (±3) cm^{-1}. Ces bandes n'ont pas pu être soustraites par l'AF. En effet, la faible intensité des bandes dans la région 1300–800 cm^{-1} ne nous a pas permis de trouver le nombre d'espèces secondaires et leurs spectres. Avec ces résultats, il est évident que plusieurs de ces espèces secondaires existent et qu'elles peuvent s'expliquer par la formation de complexes entre les espèces HSO_4^- et SO_4^{2-}. En **I**, pour l'acide sulfurique 0,50 M, ces bandes résiduelles étaient à peine perceptibles. Dans ce travail, elles ne sont pas visibles aux concentrations inférieures à 0,50 M. Comme ces bandes sont peu intenses, elles peuvent être négligées pour le reste de cette analyse qui porte sur la détermination du coefficient d'activité.

Résultats de la décomposition par facteurs

Les spectres principaux de SO_4^{2-}, de HSO_4^- et de (H_3O^+ et $HSO_4^-)_{\text{-HCl}}$ pour les différentes concentrations sont présentés sur la figure 3. Les spectres sont normalisés à 1,00 M de chacune des espèces. À cause de cette normalisation, les bandes qui apparaissent entre 1500 et 1200 cm^{-1} aux concentrations les plus basses (0,0103 et 0,0509 M) sont artifactuelles. Ces bandes qui sont en dehors de la zone d'absorption des groupes sulfates ne nuisent pas à l'analyse

de ces groupes. L'attribution des bandes qui est donnée dans le tableau 1 est basée sur **I**. La distribution des espèces en fonction des équivalents titrants est donnée sur la figure 4.

Les spectres IR des espèces ioniques de l'acide sulfurique

SO_4^{2-}: Les spectres principaux normalisés (à 1,00 M) de l'espèce ionique SO_4^{2-} sont donnés sur la figure 3A pour chaque concentration. La bande située vers 1098 cm^{-1} est attribuée à la vibration d'élongation SO asymétrique (ν_3). À la concentration de 1,886 M, la bande est située à 1092 cm^{-1} (Tableau 1). Cette position augmente progressivement jusqu'à 1102 cm^{-1} à la concentration de 0,204 M et demeure constante jusqu'à 0,0103 M. L'intensité de la bande tout en ne variant que très peu suit la même tendance : elle est de 100 Abs cm^{-1} à 1,886 M et se stabilise vers 111 Abs cm^{-1} à 0,204 M. Le NaCl 1,00 M ajouté à la solution de 0,558 M n'influence pas la position de la bande et a très peu d'effet sur l'intensité. Ces variations de position et d'intensité sont différentes de la variation du coefficient d'activité avec la concentration (voir ci-après et la figure 7) et ne peuvent par conséquent provenir de la même origine.

Nous apercevons du côté des basses fréquences de la bande ν_3 un épaulement qui devient plus précis au fur et à mesure que la concentration augmente. Cette bande située à 978 cm^{-1} est attribuée à ν_1 de SO_4^{2-}. Avec une symétrie T_d, ce mode, qui n'est pas actif normalement, l'est devenu faiblement à cause des perturbations que subit cet ion en présence de l'eau de solvatation et des contre-ions.

HSO_4^-: Les spectres principaux de l'espèce ionique HSO_4^- sont donnés sur la figure 3B pour chaque concentration. Les spectres de cette espèce obtenus après normalisation à 1,00 M sont semblables mais les positions et les intensités sont un peu modifiées. La bande située vers 1192 cm^{-1} est attribuée à la vibration d'élongation SO_3 dégénérée. À la concentration de 1,886 M, cette bande est située à 1188 cm^{-1}, cette position augmente jusqu'à 1196 cm^{-1} à la concentration de 0,50 M et demeure constante aux plus faibles concentrations. La variation de l'intensité de cette bande est à la limite quand la précision expérimentale mais semble augmenter légèrement si la concentration diminue. Le comportement de cette bande est similaire à celui de ν_3 du SO_4^{2-}. La bande de faible intensité située vers 1150 cm^{-1} est attribuée à une bande harmonique d'une bande fondamentale qui est située en bas de 700 cm^{-1}. Cette bande s'affine lorsque la concentration d'acide diminue.

La bande située vers 1050 cm^{-1} est attribuée à la vibration symétrique du SO_3. La position de cette bande fine ne varie pas avec la concentration de l'acide. Bien que nous ne puissions pas mesurer avec précision l'intensité de cette bande à cause de la ligne de base changeante, elle change peu ou pas.

La faible bande située vers 889 cm^{-1} est attribuée à la vibration d'élongation S—O du groupe SOH. La position et l'intensité de cette bande sont entichées d'une erreur plus grande que les autres bandes parce qu'elle est située à la limite inférieure de nos mesures et que son intensité est faible. Malgré cette limite, la position et l'intensité de cette bande semblent peu varier. L'ajout de sel dans la solution de 0,558 M n'influence ni la position ni l'intensité de la bande.

$(H_3O^+$ et $HSO_4^-)_{\text{-HCl}}$: En interaction avec HCl (Fig. 3C), la bande d'élongation dégénérée du SO_3 passe d'environ 1196 à 1172 cm^{-1}, la bande d'élongation symétrique du SO_3 passe de 1051 à 1044 cm^{-1} pour des déplacement respectifs d'environ 24 et 7 cm^{-1}. La bande d'élongation S—O(H) ne semble pas affectée par l'ajout de sel bien que cette observation soit limitée par la précision de la mesure de cette bande. La bande d'eau située vers 3400 cm^{-1} est plus intense dans les spectres de ces solutions que dans les situations sans HCl.

Le déplacement de la bande principale nous indique que l'ajout de HCl dans une solution aqueuse de H_2SO_4 a pour effet de former un complexe entre les ions H_3O^+, HSO_4^-, Cl^- et les molécules d'eau. Parce que la détermination de ce

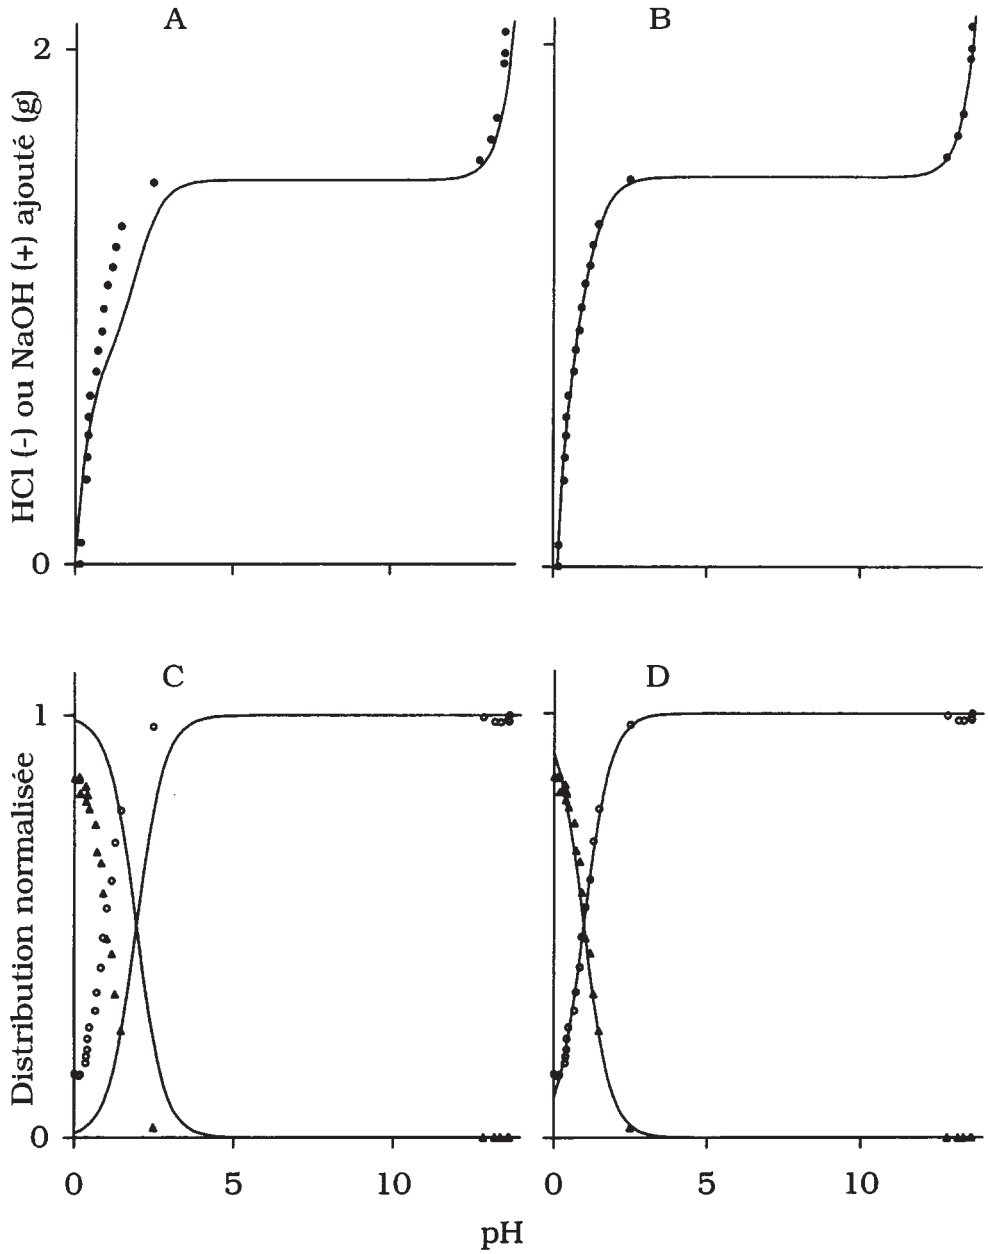
Titrage volumétrique et coefficients d'activité

Analyse des courbes de distribution

Les tracés de la figure 4 montrent que la position du point d'équipartition en fonction de l'équivalent titrant varie fortement au fur et à mesure que la concentration en acide sulfurique diminue (de haut en bas sur la figure). La seconde dissociation de l'acide sulfurique varie donc avec la concentration ce qui signifie que les coefficients d'activité varient. Les valeurs du pH des solutions sans titrant et celles du point d'équipartition sont données dans le tableau 2. L'évolution de ces valeurs est approximativement logarithmique, ce qui est attendu pour les valeurs de pH qui varient logarithmiquement avec la concentration. Le pH d'équipartition et l'équation [13] permettent d'obtenir directement la valeur de Γ_2, le rapport des coefficients d'activité des ions bisulfate et sulfate (Tableau 2). Dans les équations [9], [10] et [12] (Fig. 4) on a fait l'approximation que Γ_2 est indépendant du pH pour calculer les courbes théoriques de distribution des espèces (lignes pleines de la figure 4). Les valeurs expérimentales obtenues par l'AF des spectres IR (symboles sur la figure 4) qui se situent sur les courbes théoriques confirment que Γ_2 est indépendant du pH. Le phénomène relié au coefficient d'activité serait donc davantage lié à la concentration totale en ions sulfate et bisulfate qu'à la concentration de l'une ou l'autre de ces deux espèces. Plus encore, les valeurs du tableau 2 indiquent qu'en fonction de la concentration, Γ_2 augmente. Ceci indique que l'activité de l'ion sulfate diminue beaucoup plus rapidement que celle de l'ion bisulfate lorsque la concentration augmente.

La figure 6A présente les résultats du titrage volumétrique pour les solutions aqueuses de l'acide à une concentration de 1,02 M. Les valeurs expérimentales de pH en fonction de la masse de titrant (●) sont comparées aux valeurs théoriques dans une situation idéale (équation [12] avec des coefficients d'activité égaux à 1). De même, les courbes de distribution expérimentales des espèces ioniques HSO_4^- (△) et SO_4^{2-} (○) sont comparées aux courbes théoriques idéales de distribution (équations [9] et [10]) en figure 6C. Les différences observées entre les valeurs expérimentales et théoriques proviennent de la déviation des coefficients d'activité des espèces en solution par rapport au comportement idéal. Dans les figures 6A et 6C, ces coefficients sont négligés dans les équations théoriques. En accord avec l'étude aux conditions limites des équations de distribution (équations [13] à [15]) et avec **I**, les coefficients d'activité Γ_2, γ_{H^+} et Γ_0 sont déterminés, le premier par IR et les derniers en ajustant leur contribution dans les équations théoriques pour que la courbe de titrage volumétrique corresponde aux valeurs expérimentales. Les figures 6B et 6D donnent les courbes théoriques pour les valeurs suivantes des coefficients d'activité : $\Gamma_0 = 1{,}5$; $\gamma_{H^+} = 0{,}67$; $\Gamma_2 = 9{,}5$. Ces courbes sont en accord avec les résultats expérimentaux. Sauf aux deux plus basses concentrations étudiees, les coefficients moyens d'activité du proton (γ_{H^+}) et de l'eau (Γ_0) ne sont que faiblement influencés par la concentration d'acide sulfurique : $\gamma_{H^+} = 0{,}70 \pm 0{,}05$ et $\Gamma_0 = 1{,}4 \pm 0{,}2$.



Le coefficient moyen d'activité

La figure 7A présente, sous forme graphique, les valeurs des pH sans titrant et celles d'équipartition en fonction de la concentration en acide sulfurique. Les deux courbes sont monotones et le pH d'équipartition varie peu en fonction de la concentration lorsque celle-ci est supérieure à 1 M. La figure 7B donne la distribution en termes de concentrations relatives des ions bisulfate et sulfate dans les solutions sans titrant. Les lignes pleines correspondent aux valeurs Raman de Chen et Irish (13) et ont été obtenues aux concentrations supérieures à 0,25 mol/kg tandis que les lignes pointillées présentent nos résultats obtenus en IR aux concentrations supérieures à 0,01 M. À la concentration de 0,25 mol/kg, les deux méthodes donnent des résultats identiques ce qui indique que les deux systèmes étudiés étaient semblables. Malgré la concordance observée à cette concentration, les résultats obtenus en spectroscopie Raman montrent une inversion de tendance pour les concentrations supérieures, inversion qui n'est pas confirmée par IR. Les résultats obtenus par Chen et Irish l'ont été par l'analyse du contour des bandes tandis que nos résultats le furent par l'analyse de la totalité du spectre IR dans une gamme plus étendue de concentrations. Ceci nous permet de penser que nos résultats ont une fiabilité plus grande que ceux qui ont été obtenus en Raman.

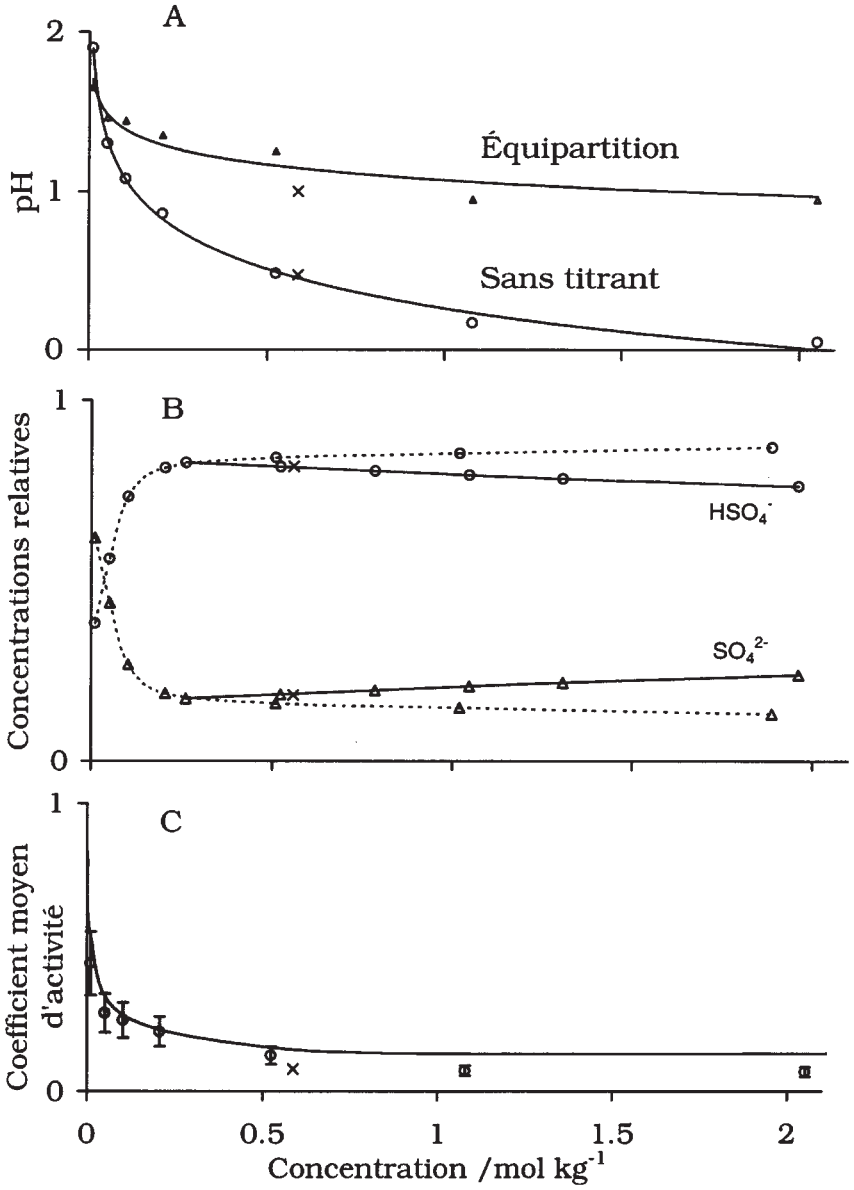
La figure 7C donne les valeurs du coefficient moyen d'activité de l'acide sulfurique γ_{H^+}/Γ_2 en fonction de la concentration. La courbe en trait plein représente les valeurs de la littérature (26, 27). Les résultats du présent travail sont présentés avec le symbole (○). Il y a une bonne concordance

© 2000 CNRC Canada

Fig. 6. Courbes de titrage volumétrique (A et B) et de distribution (C et D) pour les solutions aqueuses du H_2SO_4 1,02 M. Tracé A : ligne pleine (——), titrage volumétrique théorique (éq. 12) avec $\Gamma_0 = \Gamma_2 = \gamma_{H^+} = 1$; points pleins (●●●), résultats expérimentaux. Tracé B : même que A mais $\Gamma_0 = 1{,}5$; $\Gamma_2 = 9{,}5$ et $\gamma_{H^+} = 0{,}68$. Tracé C ligne pleine (——), distribution théorique (éq. 9 et 10) avec $\Gamma_0 = \Gamma_2 = \gamma_{H^+} = 1$; triangles vides (△△△) et ronds vides (○○○), valeurs obtenues par IR respectivement pour HSO_4^- et SO_4^{2-}. Tracé D, même que C avec $\Gamma_0 = 1{,}5$; $\Gamma_2 = 9{,}5$ et $\gamma_{H^+} = 0{,}68$.

entre les deux séries de valeurs, bien que celles-ci aient été obtenues par des méthodes différentes : électrochimie et IR. Comme sur la figure 7B, une légère divergence que nous ne pouvons pas expliquer apparaît pour les concentrations supérieures à 0,5 mol kg^{-1}. Cependant, comme nos résultats en IR viennent de mesures directes de l'abondance des espèces, ils seraient plus fiables que les mesures électrochimiques qui donnent indirectement ces valeurs.

Le spectre des espèces ioniques pures de l'acide sulfurique est indépendant de la concentration et, par conséquent, la variation des coefficients d'activité des espèces impliquées en solution n'a pas de répercussion sur les spectres de ces espèces. Ce résultat concorde avec les résultats obtenus pour les mélanges NaOH–HCl (20).



Titrage IR des solutions aqueuses du H_2SO_4 0,56 M dans NaCl 1,00 M

Analyse des spectres des solutions

Pour évaluer l'influence de sels sur les coefficients d'activité et confirmer que le spectre IR des espèces ioniques en solution n'est pas influencé par la variation du coefficient d'activité,[20] le titrage IR d'une solution aqueuse de H_2SO_4, à une concentration de 0,56 M et NaCl 1,00 M, est effectué de

© 2000 CNRC Canada

la même manière que précédemment. Le spectre d'eau salée a aussi été soustrait. Les FM obtenus dans la soustraction de cette eau indiquent que la solvatation des paires d'ions Na^+ et Cl^- reste inchangée en solution en présence d'acide sulfurique comme cela fut rapporté pour le système (HCl, NaCl) (20). Ceci est en accord avec les travaux sur l'eau salée qui indiquent que NaCl en solution reste en forme complexée avec 5 molécules d'eau (28). Les spectres principaux des espèces ioniques montrent que les bandes de vibration sulfate ne sont pas affectées par la présence de sel (Fig. 3). La seconde forme solvatée de HSO_4^- est aussi observée dans les solutions contenant du HCl. Contrairement à l'action de H_3O^+ et Cl^-, la présence des ions Na^+ et Cl^- dans la solution d'acide sulfurique ne modifie pas le spectre des espèces $H_3O^+ - HSO_4^-$ et $Na^+ - HSO_4^-$. Donc, ce ne sont pas les interactions des ions chlorure (Cl^-) seuls avec l'ion HSO_4^- qui produisent le complexe observé lorsque du HCl est ajouté à la solution d'acide sulfurique. Il s'agit là d'une preuve supplémentaire que c'est l'interaction d'une paire H_3O^+–Cl^- solvatée avec une paire $H_3O^+ - HSO_4^-$ solvatée qui produit le complexe $(H_3O^+ - HSO_4^-)_{\text{-HCl}}$. Ceci confirme le fait que la solvatation des ions par l'eau se fait en conservant le cation et l'anion proches l'un de l'autre (20, 28).

Effet du sel sur le coefficient moyen d'activité de l'acide sulfurique

La présente étude n'est pas une étude exhaustive de l'effet de sels neutres sur l'équilibre de l'acide sulfurique en

© 2000 CNRC Canada

solution aqueuse. Une seule concentration d'un seul sel (NaCl 1,00 M) a été appliquée à une seule concentration d'acide sulfurique : 0,56 M). La figure 7A montre que le pH sans titrant n'a pas été affecté par l'ajout de NaCl (symboles ×). Le pH d'équipartition, lui, a été sensiblement abaissé par la présence de NaCl. La figure 7B montre que la dissociation de l'acide sulfurique a été modifiée par l'ajout du NaCl (symboles ×). Le degré de dissociation de HSO_4^-, de 0,16 en l'absence de sel (SO_4^{2-} = 0,16 et HSO_4^- = 0,84) augmente à 0,18 en présence de NaCl 1,00 M (SO_4^{2-} = 0,18 et HSO_4^- = 0,82). Cette variation est dans le sens opposé de celle observée par Chen et Irish dans une solution aqueuse de NH_4HSO_4 (13). Les deux systèmes étudiés et les méthodes d'analyse étant très différents, il n'est pas possible d'établir la raison de cette différence.

Les valeurs des coefficients d'activité $\Gamma_2 = \gamma_{HSO_4^-}/\gamma_{SO_4^{2-}}$ déterminées par le titrage IR sont données dans le tableau 2. L'ajout de NaCl abaisse le coefficient d'activité de l'ion sulfate relativement à celui de l'ion bisulfate. Cette modification est obtenue avec une bonne précision puisqu'elle provient de la mesure par IR de la répartition des deux espèces ioniques. De plus, cette modification des coefficients d'activité des ions n'est aucunement reliée à des modifications spectrales.

Le coefficient moyen d'activité $\gamma_\pm$ (= γ_{H^+}/Γ_2) de l'acide sulfurique est abaissé en présence de NaCl (symbole ×, fig. 7) contrairement à ce qui a été observé pour HCl (20, 29). Les valeurs du coefficient moyen d'activité de l'acide sulfurique sont obtenues dans la présente étude avec une précision de ±25 %. La majeure partie de cette marge d'erreur provient de l'imprécision sur la valeur du coefficient moyen d'activité γ_{H^+} qui est obtenu par mesures de pH. La figure 7C n'a été présentée que pour permettre une comparaison des résultats obtenus par titrage IR avec les valeurs de la littérature.

Conclusion

Le titrage IR des solutions aqueuses d'acide sulfurique est possible sur une gamme étendue de concentrations et de pH en utilisant la technique ATR. La méthode de soustraction des spectres d'eau permet d'obtenir l'information sur les espèces ioniques présentes en solution même à de très faibles concentrations. L'AF appliquée aux spectres de mélanges des espèces ioniques permet de déterminer la concentration réelle des espèces d'une façon directe, ce que ne peuvent faire les méthodes électrochimiques, et d'une manière plus précise que l'analyse du contour de bandes qui a été faite en Raman. La comparaison des courbes expérimentales de distribution obtenues par IR avec les courbes théoriques donne des valeurs du coefficient moyen d'activité qui sont comparables aux valeurs obtenues par mesures électrochimiques. Le rapport des coefficients d'activité des ions sulfate et bisulfate est constant sur toute la gamme de pH et dépend de la concentration totale des ions mais pas de leur concentration relative.

La spectroscopie IR se révèle être un outil performant dans l'étude des solutions aqueuses qui n'est limité que par la qualité des spectres et des traitements numériques. Nous travaillons sur ces aspects qui nous permettront de saisir des informations précises sur la formation des complexes dont nous avons révélé la présence dans ce travail et le précédent (**I**).

Synthesis of nanocrystalline $Cu_{2-x}Se$ at room temperature by γ-irradiation

Zhengping Qiao, Yi Xie, Jianguang Xu, Xianming Liu, Yingjie Zhu, and Yitai Qian

Abstract: Ten nm nonstoichiometric compound $Cu_{2-x}Se$ was firstly synthesized at room temperature by γ-irradiation, using sodium selenosulfate as the selenium source. The influence of the coordination of copper ions and the pH value of the solutions on the formation of $Cu_{2-x}Se$ has been studied. The $Cu_{2-x}Se$ was prepared here for $x = 0.13$.

Key words: copper selenide, nanocrystalline, γ-irradiation.

Résumé : Opérant à la température ambiante, faisant appel à une irradiation γ et utilisant du sélénosulfate de sodium comme source de sélénium, on a réalisé la première synthèse d'un composé non stoechiométrique de $Cu_{2-x}Se$ de 10 nm. On a étudié l'influence de la coordination des ions cuivre et de la valeur du pH des solutions sur la formation de $Cu_{2-x}Se$. Pour le $Cu_{2-x}Se$ préparé, $x = 0{,}13$.

Mots clés : séléniure de cuivre, nanocristallin, irradiation γ.

[Traduit par la Rédaction]

Introduction

Extensive attention has been paid to the preparation and characterization of selenides owing to their interesting properties and potential applications. Among these materials, copper selenide has recently aroused much interest and attention since it has been widely used in solar cells (1, 2), as an optical filter (3), and as a superionic material (4). For example, $Cu_{2-x}Se$ is a p-type extrinsic semiconductor with an energy gap of 1.1–1.29 eV (5), which is near the optimum value for solar cell applications (6).

Considerable progress has been made in the synthesis of copper selenides in the last few years, such as elemental reactions (7–9) and metathesis reactions (3). However, most of these methods need high temperature (470°C), or dangerous liquid ammonia, or toxic H_2Se, or complex metal precursors. Recently, Wang et al. (10) successfully obtained nanocrystalline $Cu_{2-x}Se$ by heating CuI and Se in an autoclave at 90°C for 4 h. To obtain nanoscale $Cu_{2-x}Se$ under mild conditions, organic ethylenediamine must be used. Thus, it is desirable to find a good selenium source in aqueous solution and appropriate methods to prepare nanocrystalline $Cu_{2-x}Se$ under mild conditions.

In the past twenty years, sodium selenosulfate has been used to prepare bulk selenide materials (5, 11). Padam (12) reported the preparation of chemically deposited polycrystalline $Cu_{2-x}Se$ thin films in a hot water bath maintained at a temperature of 90–95°C, which was proved to be homogeneous with an average grain size of the order of 0.7 μm. Under such conditions it is difficult to grow nanocrystalline materials. To obtain nanocrystalline $Cu_{2-x}Se$, a synthesis method, which can be more easily controlled, is important. Recently, γ-irradiation technique has become an important room temperature, ambient pressure method to prepare nanoscale materials since it can provide high-energy and an evenly distributed irradiation field. We have successfully expanded this method to prepare nanoscale metal sulfide (13). However, it is much easier to get a suitable sulfur source in aqueous solution under γ-irradiation and meanwhile, it is much more difficult but meaningful to find an appropriate selenium source for preparation of nanoscale metal selenides. Here, we firstly report the synthesis of nanocrystalline $Cu_{2-x}Se$ in aqueous solution using sodium selenosulfate as selenium source under γ-irradiation at room temperature and ambient pressure.

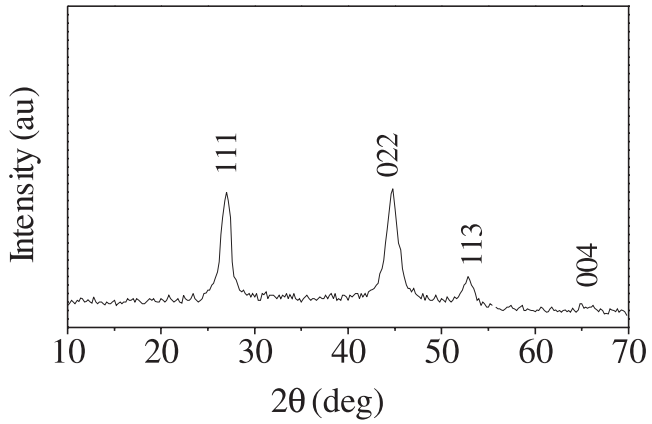
Experimental



The solutions were prepared by dissolving analytically pure copper acetate (0.001 mol) and freshly prepared sodium selenosulfate (0.5 mol dm^{-3}, 10 dm^{-3}) in 100 dm^{-3} distilled water. Appropriate electrolytes (analytically pure sulfuric acid and sodium hydroxide) were used to adjust the pH value of the solution. Isopropyl alcohol was added as a scavenger for hydroxyl radicals at concentration of 3 mol dm^{-3}. To study the influence of coordination of copper ions on the formation of $Cu_{2-x}Se$, 0.05 mol dm^{-3} sodium chloride and 0.02 mol dm^{-3} $NH_3 \cdot H_2O$–NH_4Cl buffer was used to provide Cl^- and NH_3, respectively, in some solutions (experimental conditions given in Table 1). After the solutions were irradiated in the field of a 2.59×10^{15} Bq ^{60}Co γ-ray source with absorbed dose rate of 1×10^2 Gy min^{-1} for several hours, the black precipitates were collected and washed with dilute acetic acid, distilled water, and absolute alcohol in sequence

to remove the by-products. The final products were dried in vacuum at room temperature for 4 h.

The samples were characterized by powder X-ray diffraction (PXRD) patterns employing a scanning rate of 0.05° s^{-1} in 2θ range from 10° to 70° using a Japan Rigaku Dmax γ_A X-ray diffractometer equipped with a graphite monochromatized CuK_α radiation (λ = 1.54178 Å). The morphology and particle size were determined by transmission electron microscopy (TEM). The TEM images were taken with a Hitachi Model H-800 transmission electron microscope with an accelerating voltage of 200 kV. The purity and composition of the products were examined by X-ray photoelectron spectra (XPS) on an ESCALab MKII instrument with MgKα radiation as the exciting source. The ratio of Cu to Se was determined using an atomic absorption spectrometer (Model WYX-40).

Results and discussion

All the products were examined by XRD. Figure 1 shows the XRD pattern of the as-prepared $Cu_{2-x}Se$ (sample 8 in Table 1) from a solution, which consists of 0.01 mol dm^{-3} copper acetate, 0.05 mol dm^{-3} sodium selenosulfate, 0.02 mol dm^{-3} $NH_3 \cdot H_2O$–NH_4Cl, and 3 mol dm^{-3} isopropyl alcohol. All of the peaks could be indexed as the cubic $Cu_{2-x}Se$ (JCPDS Card File no. 6–680) with cell constant a = 5.741 Å. The broadening of the peaks indicates the product is nanocrystalline. The crystalline size of the product, as calculated from the half-width of diffraction peaks using the Scherrer formula[2] is 9 nm.

The purity and composition of sample 8 were examined by XPS. The survey, the Cu_{2P} region and Se_{3d} region, are shown in Fig. 2. The results indicate that the product was relatively pure. Since $Cu_{2-x}Se$ is stable over a wide range of departures from stoichiometry (the composition parameter x varying from 0 to 0.15) (14, 15), quantification of peaks was done roughly and gave a ratio of Cu to Se as 1.85:1. In addition, the ratio of Cu to Se measured accurately by Atomic Absorption Spectrometer is 1.87:1. So the $Cu_{2-x}Se$ was here prepared for x = 0.13.

Figure 3 is the TEM image of sample 8. From the image, one can see that the product consists of nearly spherical grains with the average size of about 10 nm, which is consistent with the XRD result. This also proved that the broadening of the peaks is caused by the small particle and not the lattice distortion in the crystallite, which is a common phenomenon in nonstoichiometric compounds.

In these γ-irradiation processes, the mechanism of the formation of nanocrystalline selenide is presently not very clear up to now. Few reports have been given on the transformation of the sodium selenosulfate under γ-irradiation. However, it is clear that S^{2-} can be homogeneously released from the decomposition of sodium thiosulfate upon γ-irradiation (16, 17). It is reasonable that Se^{2-} can be released from sodium selenosulfate upon γ-irradiation due to the similarity in the structures of $S_2O_3^{2-}$ and $SeSO_3^{2-}$, shown in Fig. 4.

Meanwhile, hydrated electrons, which are reducers with strong reducibility, were produced from H_2O under γ-irradiation. Isopropyl alcohol was added to scavenge the oxidative free radical OH.

$$H_2O \xrightarrow{\text{radiation}} e^-_{aq},\ H_3O^+,\ H,\ H_2,\ OH,\ H_2O_2$$

$$(CH_3)CHOH + OH \rightarrow (CH_3)COH + H_2O$$

The existence of ligand NH_3 led to the slow release of copper ions and controlled the following nucleation and growth of $Cu_{2-x}Se$ nanocrystalline. Under this condition, the total reaction of the formation of nanocrystalline $Cu_{2-x}Se$ can be formulated as follows

$$(2-x)[Cu(NH_3)_4]^{2+} + Se^{2-} + (2-2x)e^-_{aq} + H_2O \rightarrow Cu_{2-x}Se + (8-4x)NH_3 \cdot H_2O$$

In our experiments, the pH value of the solutions and some coordination of copper ions (Cl^- and NH_3) were studied in detail. The results, as listed in Table 1, showed: (*i*) the existence of ligands (Cl^- and NH_3) takes advantage of the formation of $Cu_{2-x}Se$ in aqueous solution; and (*ii*) without the presence of ligands, the pH value of the solutions is the most important factor for the formation of product. Specifically, when the pH value is 1–2, the products are also pure $Cu_{2-x}Se$ (sample 1). However, the particle size of

Fig. 2. XPS spectra of the sample 8. (*a*) Survey (• ___ Cu, * ___ Se, # ___ O,◦ ___ C); (*b*) Cu_{2p} region; (*c*) Se_{3d} region.

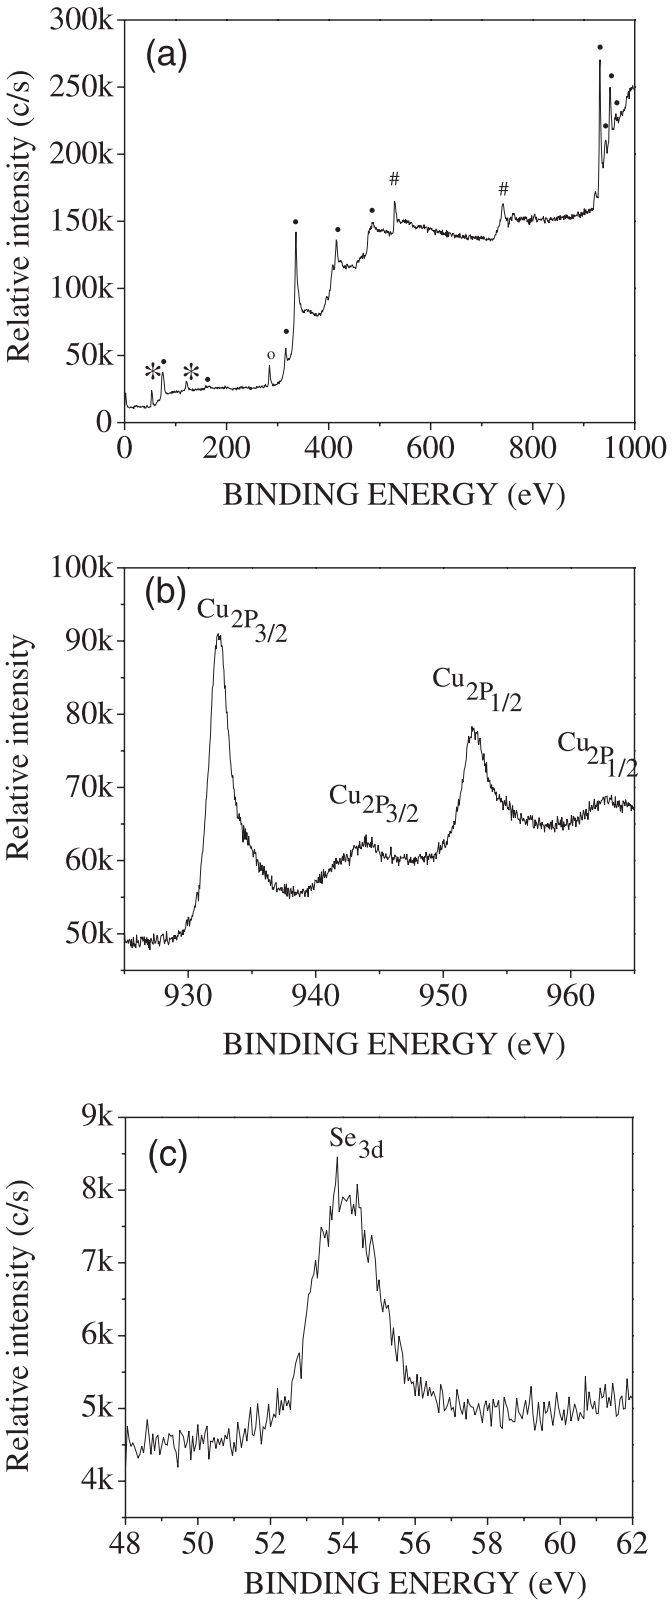

Fig. 3. TEM image of the sample 8.

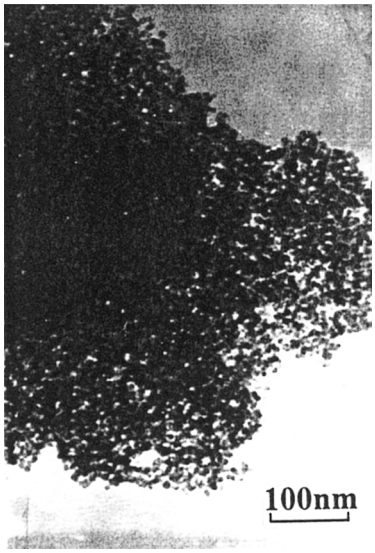

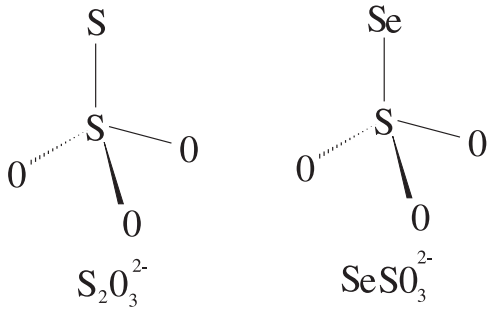

Fig. 4. Schematic structure of $S_2O_3^{2-}$ and $SeSO_3^{2-}$.

$Cu_{2-x}Se$ prepared from acidic solutions (pH = 1, 2, sample 1) — 27 nm, as calculated from the half-width of diffraction peaks using the Scherrer formula[2], is much larger than that of the product from solution with the existence of ligand NH_3 — 9 nm.

As well known, many kinds of metal ions can be slowly reduced by hydrated electrons or solvented electrons produced in water or other organic solvent under γ-irradiation and produced metastable ions by controlling appropriate conditions (18). It is reasonable to expect that the γ-irradiation method can be widely used to prepare other nanocrystalline nonstoichiometric compounds.

Conclusions

In summary, the γ-irradiation method was firstly used to prepare 10 nm $Cu_{2-x}Se$ at room temperature in aqueous solution, using sodium selenosulfate as the selenium source. The influence of the coordination of copper ions and the pH value of solutions were studied in detail. Without the presence of ligand the suitable pH range for the formation of $Cu_{2-x}Se$ is 1–2. Ligand (NH_3) is helpful in the formation and the size control of $Cu_{2-x}Se$. XPS and atomic absorption spectrometer examined the purity of products. The γ-irradiation method is likely to be useful in the preparation of other

nonstoichiometric nanocrystalline selenides at room temperature and ambient pressure.

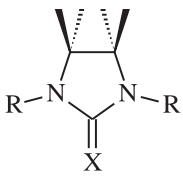
An experimental and theoretical approach to the study of the properties of parabanic acid and related compounds: synthesis and crystal structure of diethylimidazolidine-2-selone-4,5-dione

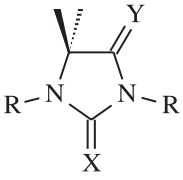
Massimiliano Arca, Francesco Demartin, Francesco A. Devillanova, Francesco Isaia, Francesco Lelj, Vito Lippolis, and Gaetano Verani

Abstract: The syntheses of the first examples of selenoparabanic acid derivatives (dialkylimidazolidine-2-selone-4,5-dione, $\mathbf{3e^R}$, R = Me, Et, Bu) are presented along with the X-ray crystal structure determination of $\mathbf{3e^{Et}}$. To gain an insight in the properties of parabanic acid derivatives on the basis of their electronic structures, we report the results of comparative hybrid-DFT calculations performed on parabanic, thioparabanic, and selenoparabanic acids ($\mathbf{3a^H}$, $\mathbf{3b^H}$, and $\mathbf{3e^H}$) and on their *N*,*N*′-dimethyl derivatives ($\mathbf{3a^{Me}}$, $\mathbf{3b^{Me}}$, and $\mathbf{3e^{Me}}$). Calculations show that the different nature of the frontier orbitals of $\mathbf{3a^R}$ compared to those of $\mathbf{3b^R}$ and $\mathbf{3e^R}$, might account for the different reactivities of these compounds. Moreover, the weak donor character of $\mathbf{3b^R}$ and $\mathbf{3e^R}$ towards molecular di-iodine, estimated by FT-Raman measurements is in agreement with the calculated NBO-charge distribution.



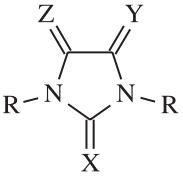
Key words: selenation, selenoparabanic derivatives, crystal structure, DFT calculations.

Résumé : Les synthèses des premiers exemples des dérivés de l'acide sélénoparabanique sont présentés avec la structure des rayons X du composé $\mathbf{3e^{Et}}$. Pour mieux comprendre les propriètés des dérivés de l'acide parabanique sur la base de leurs structures électroniques, nous reportons les résultats des calculs comparatifs hybride-DFT effectués sur les acides parabanique, thioparabanique et sélénoparabanique ($\mathbf{3a^H}$, $\mathbf{3b^H}$ et $\mathbf{3e^H}$) et sur les leurs dérivés *N*,*N*′-dimethyliques ($\mathbf{3a^{Me}}$, $\mathbf{3b^{Me}}$ et $\mathbf{3^{Me}}$). Les calculs montrent que la différente nature des orbitals de frontière de $\mathbf{3a^R}$ comparés avec ceux de $\mathbf{3b^R}$ et $\mathbf{3e^R}$ pourrait expliquer les différentes réactivités de ces composés. De plus, le faible caractère de donneur de $\mathbf{3b^R}$ et $\mathbf{3e^R}$ vers le iode moléculaire, évalué au moyen des mesures FT-Raman, est en accord avec la distribution des charges NBO.



Mots clés : Sélénation, dérivés de l'acide sélénoparabanique, structure cristalline, calculs DFT.

Introduction



For more than twenty years, our research group has dealt with the synthesis, characterization, and study of the coordination properties of imidazolidine derivatives containing one or two *exo*-chalcogen atoms (**1** and **2** respectively) (1, 2).

1

2

3

As a natural evolution of this research, we have turned our attention to trichalcogen-substituted imidazolidine derivatives **3**, with the aim of synthesizing dischotic metal complexes having a highly delocalized π-system for the preparation of unidimensional conducting materials. Among all the possible compounds (X, Y, Z = O, S, Se; R = H, alkyl, or aryl groups), only the syntheses of $\mathbf{3a^R}$ (X = Y = Z = O, R = H (parabanic acid), alkyl, or aryl groups), (3, 4) $\mathbf{3b^R}$ (X = S, Y = Z = O, R = H (thioparabanic acid), alkyl or aryl groups) (3) and $\mathbf{3c^R}$ (Z = O, X = Y = S, R = Me, dithioparabanic acid derivatives) (5, 6) were reported in the literature. No other member of the possible compounds in this class has

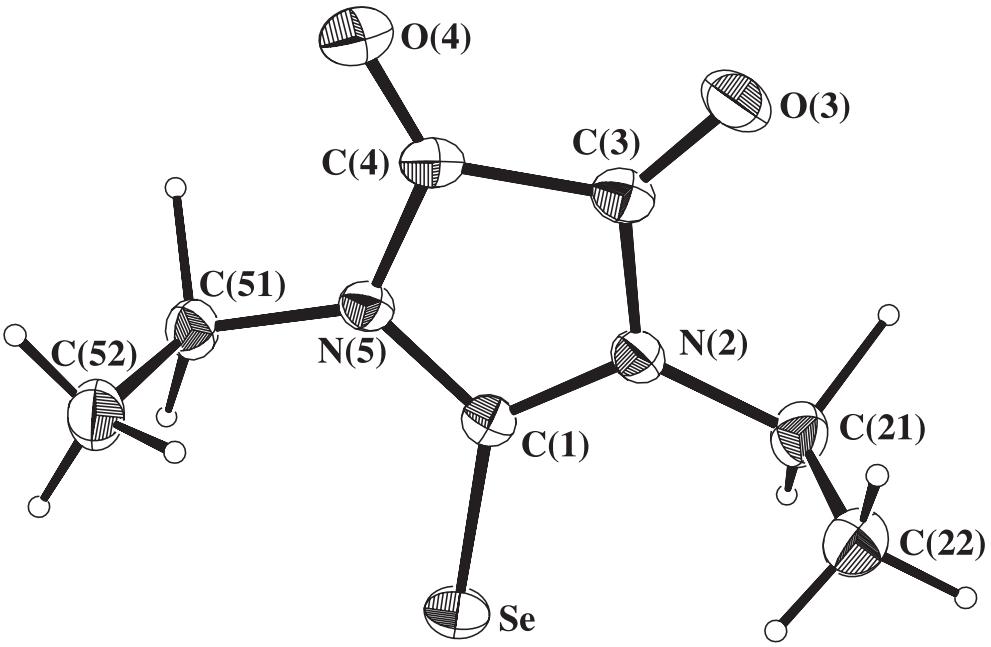
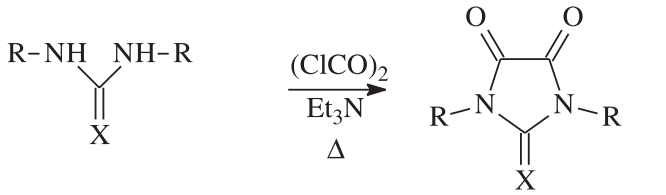
Scheme 1. Reactivity of **3b^R** towards Lawesson's reagent (LR) and P_4S_{10} in refluxing toluene.



been synthesized and isolated so far. This seems to be in agreement with the alleged instability reported in the literature for five-membered cyclic dithioxamides, (7) which is probably also valid for diselenooxamides. However, the coordination chemistry of these compounds is completely unexplored, with the only exception of **3a^R** (R = $C_6H_5NHCH_2$), for which at any rate just the NH groups seem to be responsible for the coordination to Co(II), Ni(II), and Cu(II) (8). This poverty of data seems to be due to the poor coordination abilities of the chalcogen donor atoms in **3**, rather than to a lack of interest for these compounds by the scientific community.

Many studies (5, 9, 10, 11) have been carried out on the sulphuration reaction of **3a^R** and **3b^R** with P_4S_{10} and Lawesson's reagent (LR) (12) because this reaction represents a possible direct method for synthesizing trithione derivatives **3d^R** (X = Y = Z = S). In particular, while the reaction of **3b^R** with LR in a 1:0.5 ratio leads to **3c^R** (Scheme 1, R = Me) (5) and in a 1:1 ratio to both 4,5,6,7- and 4,5,9,10-tetrathiocino compounds (**5** and **6**, respectively), (9, 10) the reaction with P_4S_{10} leads to bis(1,3-dialkyl-2-thioxoimidazolin-4-yl)disulfide (**7**, alkyl = *i*-Pr, see Scheme 1) (10). When the sulphuration of **3b^R** with LR is carried out in presence of metal powder or salts, (13) the corresponding [M(R_2timdt)$_2$] neutral complexes (**8**) can be obtained (M = Ni, Pd, Pt), where R_2timdt is the monoreduced anion of **3d^R** (11, 14). Complexes **8** represent a brand new class of metal dithiolenes characterized by a very large π-delocalization.



So far, no type **3** compounds containing a Se atom have been reported. In the present paper the synthesis and characterization of imidazolidine-2-selone-4,5-diones having methyl (**3e^{Me}**), ethyl (**3e^{Et}**), and butyl (**3e^{Bu}**) substituents is reported along with the single crystal X-ray structure of **3e^{Et}**. Analogously to **3b^R**, the sulphuration reaction of **3e^R** (synthesized by us according to the method reported here and donated to the authors to study the reactivity of these compounds towards LR) leads again to tetrathiocino analogues (15). By carrying out the sulphuration reaction for longer times, the exocyclic selenium atoms can be replaced by sulphur atoms and move into the octa-membered ring (15).

Fig. 1. View of the molecular structure of compound $\mathbf{3e^{Et}}$ with the numbering scheme adopted. Displacement ellipsoids are drawn at the 30% probability.

Scheme 2. Synthesis of parabanic, thioparabanic, and selenoparabanic acid derivatives from the corresponding ureas, thioureas, and selenoureas.

X = O $\mathbf{4a^R}$ X = O $\mathbf{3a^R}$
X = S $\mathbf{4b^R}$ X = S $\mathbf{3b^R}$
X = Se $\mathbf{4e^R}$ X = Se $\mathbf{3e^R}$

To rationalize the different chemical behavior of $\mathbf{3a,b,e^R}$, especially as far as regarding sulphuration and coordinating ability, we performed hybrid-DFT (16, 17) calculations on $\mathbf{3a^H}$, $\mathbf{3b^H}$, and $\mathbf{3e^H}$ and their methylated derivatives ($\mathbf{3a^{Me}}$, $\mathbf{3b^{Me}}$, and $\mathbf{3e^{Me}}$).

Moreover, the donor properties of imidazolidine-2-selone-4,5-diones towards molecular di-iodine have been explored by electronic and FT-Raman spectroscopy, and the weakness of the interaction has been explained on the basis of the NBO-charge distribution.

Results and discussion

Synthetic aspects

The syntheses of $\mathbf{3a^R}$ and $\mathbf{3b^R}$ have long since been reported, (3, 4) and consist of a cyclization reaction between the corresponding ureas $\mathbf{4a^R}$ or thioureas $\mathbf{4b^R}$ and dicyanogen (the resulting 4,5-diiminoimidazolidine-2-one is hydrolyzed with diluted HCl) or oxalyl chloride (Scheme 2) (3). To prepare selenoparabanic acid derivatives ($\mathbf{3e^R}$), the substitution of the exocyclic sulphur atom of $\mathbf{3b^R}$ with selenium was first attempted without encouraging results by the standard method for replacing S with Se in the > C=S bond, i.e., addition of MeI to > C=S to form the corresponding substituted *S,N,N′*-isothiouronium iodide and subsequent attack to the cation with HSe^- (18). More satisfactory results were achieved by reacting oxalyl chloride and disubstituted selenoureas $\mathbf{4e^R}$ (Scheme 2, R = Me, Et, Bu), which can easily be prepared in good yields by the above method.

X-ray crystallography

A view of the crystal structure of $\mathbf{3e^{Et}}$ is shown in Fig. 1. Table 1 shows a comparison of the interatomic distances with those of $\mathbf{3a^H}$, which is the only other type **3** compound structurally characterized so far (19, 20, 21). The imidazolidine ring displays similar features in both cases, with a slight lengthening of the N(2)—C(3) and N(5)—C(4) bonds and a slight shortening of N(2),N(5)—C(1) bonds, due to an increase in the conjugation of the lone pairs of the two nitrogen atoms towards C(1) in the presence of the Se atom. The five-membered ring is rigorously planar and the atoms Se, O(3), O(4), C(21), and C(51) lie essentially in the plane of the ring (maximum deviation observed 0.05 Å for Se).

Theoretical calculations

With the aim of understanding the effect of the nature of the chalcogen atom bound to the C(1) on the electronic and structural features, and possibly on the reactivity of the molecules of type **3**, DFT (16, 17) calculations have been performed on the molecules reported in Scheme 3. According to the good results recently found on $[M(R_2timdt)_2]$ dithiolenes **8**, (11) hybrid BECKE3LYP functional (22, 23) and Schafer, Horn, and Ahlrichs' (24) pVDZ basis set have been used throughout in the calculations. The Khon–Sham frontier orbital energies are reported in Fig. 2 and a perspective

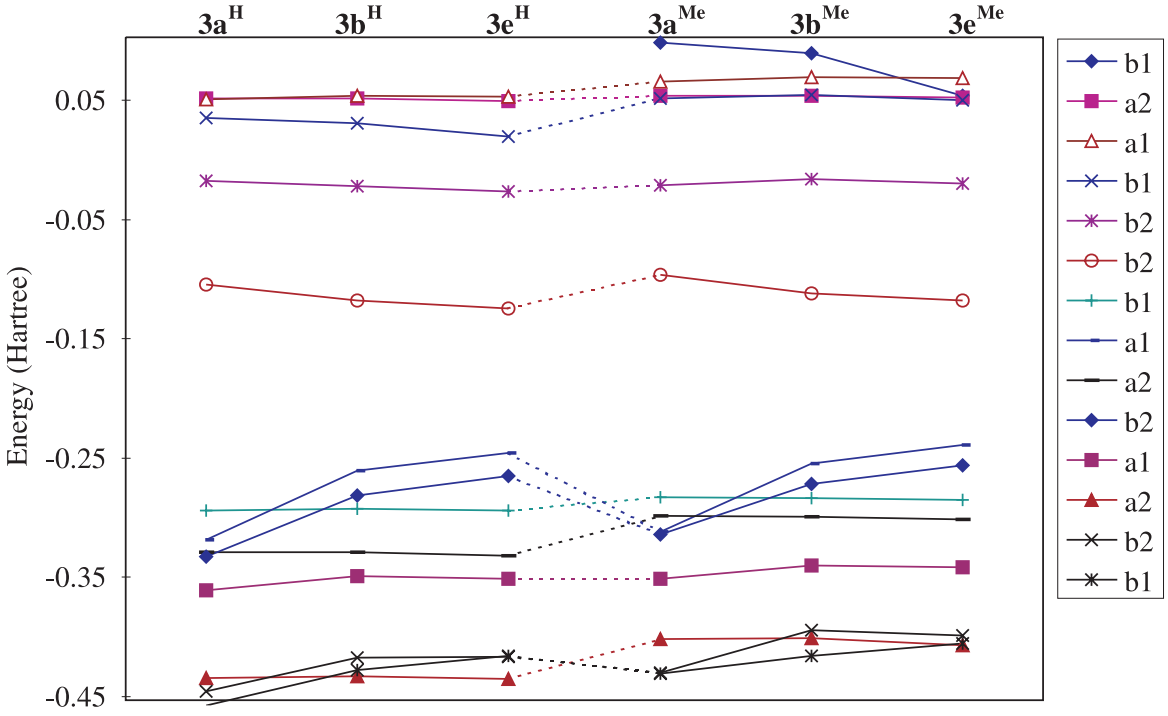
[b]Atom numbering as in Fig. 1. X = O for **3a**^{H}, Se for **3e**^{Et}.

drawing of HOMOs and LUMOs for compounds **3a**, **b**, **e**^{Me} is shown in Fig. 3. The energies of the two highest occupied orbitals (HOMO and HOMO-1) in **3a**^{R} are swapped with respect to those calculated for **3b**^{R} and **3e**^{R} (R = H, Me). As a consequence, while the HOMO in thio- and seleno-



Scheme 3. Naming of the model compounds for DFT-calculations.

		X		
		O	S	Se

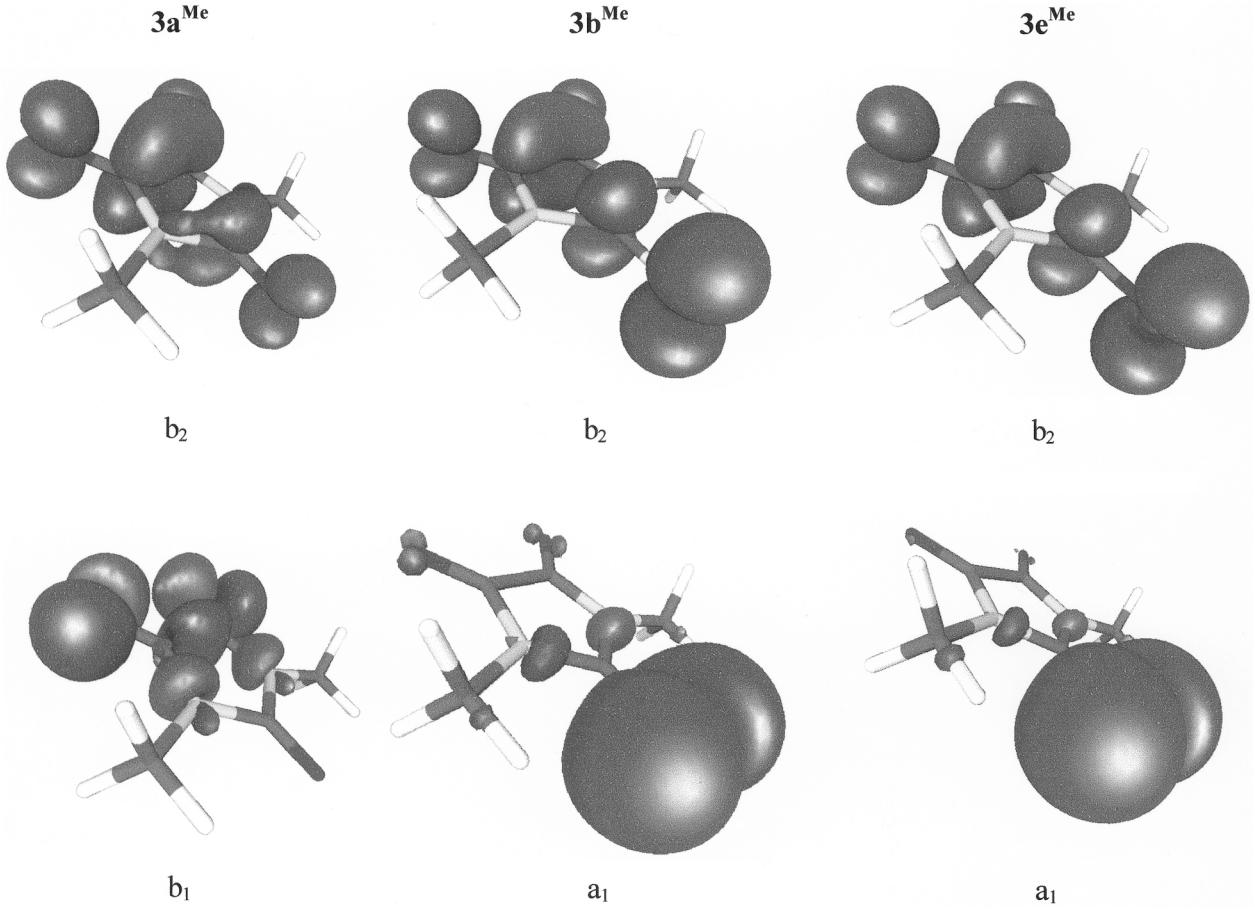
	CH_3	**3a**^{Me}	**3b**^{Me}	**3e**^{Me}



derivatives is an a_1 lone pair centred on the respective chalcogen atom, the HOMO in parabanic acid derivatives is made up of the 2*p* atomic orbitals of O(3) and O(4) lying on the molecular plane, and of the 2*s* and 2*p* atomic orbitals of nitrogen and carbon atoms combining to form a *p*σ bonding molecular orbital extending over the N(2)-C(3)-C(4)-N(5) framework and belonging to the b_1 representation. The different nature of the HOMOs of **3a**^{R} compared to those of **3b**^{R} and **3e**^{R} might be responsible for the different reactivities

Fig. 3. HOMOs (bottom row) and LUMOs (upper row) drawings for compounds **3a**^{Me}, **3b**^{Me}, and **3e**^{Me}.

of these substrates, in particular as far as the sulphuration is concerned.

To ascertain whether the change in the nature of the HOMO only depends upon the nature of the X atom, and is common to all systems containing the -NH-C(X)-NH- moiety, the same type of calculations (BECKE3LYP/Ahlrichs basis set) have been performed on **4a**^{H}, **4b**^{H}, and **4e**^{H} (optimized bond lengths and angles: C—N, 1.375, 1.365, 1.351 Å; C=X: 1.228, 1.669, 1.837 Å; N-C-N: 115.29, 115.01, 116.54°) and on **4a**^{Me}, **4b**^{Me}, and **4e**^{Me} (with the substituents arranged in a *cis-cis* configuration, to preserve the C_{2v} symmetry. Optimized bond lengths and angles: C—N, 1.378, 1.366, 1.358 Å; C=X: 1.232, 1.680, 1.846 Å; N-C-N: 114.64, 113.40, 113.81°). The calculated geometries for **4b**^{Me} can be compared with the experimental bond lengths and angles determined by X-ray diffraction for **4b**^{Et}, **4b**$^{i\text{-}Pr}$, and **4b**^{Ph} (C—N, 1.316(4), 1.332(2), 1.384(5) Å; C=X: 1.707(3), 1.711(2), 1.681(5) Å; N-C-N: 117.3(3), 118.3(1), 113.9(4)°, respectively (25)). The best agreement is found with **4b**^{Ph}, possibly because **4b**^{Et} and **4b**$^{i\text{-}Pr}$ adopt a *cis-trans* configuration in the solid state, which leads to the formation of two-dimensional layers of thiourea derivatives. At any rate, as far as regards the N-C and the > C=S moieties, it should be remarked that bond lengths calculated in **4b**^{Me} correspond well to the unweighted mean values determined in thioureas from diffraction techniques (1.346 and 1.681 Å, respectively) (26). Interestingly, while all compounds with R = H, have the same kind of HOMOs, consisting in the lone pair of the chalcogen atom lying on the molecular plane, as found in **3b**^{R} and **3e**^{R}, those with R = Me show the same level inversion between HOMO and HOMO-1 calculated for **3a**^{R}. The NBO-charges (N: –0.87, –0.80, –0.80, –.69, –0.63, –0.63; C: +0.84, +0.29, +0.25, +0.86, +0.32, +0.27; X: –0.68, –0.25, –0.26, –0.70, –0.28, –0.26 e for **4a**^{H}, **4b**^{H}, **4e**^{H}, **4a**^{Me}, **4b**^{Me}, **4e**^{Me}, respectively) and the analysis of the bond order demonstrate that the nitrogen lone pairs are conjugated with the > C=X system in an order that increases on passing from **4a**^{R} to **4e**^{R} (N lone pair occupancies: 1.80, 1.76, 1.73, 1.77, 1.72, 1.70 e for **4a**^{H}, **4b**^{H}, **4e**^{H}, **4a**^{Me}, **4b**^{Me}, and **4e**^{Me}, respectively). At any rate, the charge distributions in **4b**^{H,Me} and **4e**^{H,Me} are very similar, and sensibly differ from those calculated for **4a**^{H,Me}.

Returning to compounds of type **3**, the b_2 LUMOs are π^* molecular orbitals formed by the 2*p* and 3*p* orbitals of all the endocyclic carbon atoms and of the exocyclic chalcogen atom. Some selected optimized bond lengths and angles are reported in Table 2. The agreement between the calculated parameters and experimental data available for **3a**^{H} (20) and for **3e**^{Et} (Table 1) is quite good, with differences within 2%, probably due to solid state effects. We have recently pointed out (11, 14) that although Koopmans'(27) theorem is not valid in DFT, a linear correlation can be found between the Kohn–Sham orbital energies and electronic properties such as molecular electronic transitions and redox potentials. Analogously, in this case a correlation between experimental photoelectron spectra (reported for **3a**^{H} and **3a**^{Me}) (28) and

calculated Kohn–Sham eigenvalues can be found (Fig. 4 and Table 3). The shifts in the positions of the PES peaks found on passing from **3a^{H}** to **3a^{Me}** due to methylation show the same trend for both experimental and calculated energies (Fig. 5a). Moreover, a new evaluation of the energy values reported for **3a^{Me}**, previously estimated with the help of the results of CNDO/s-CI calculations, (28) leads to a better agreement (Fig. 5*b*). The very good correlation between the shifts in the ionization energies and in the calculated Kohn–Sham orbital energies between methylated and unmethylated parabanic acid indicates that the attribution of π-orbitals perpendicular to the molecular plane (such as HOMO-1 (a_1), HOMO-3 (b_2), and HOMO-5 (a_2) for **3a^{Me}**), in which methyl groups are able to participate sensibly, is correct. As far as

the charge distribution is concerned, NBO (29) charges (which are more reliable (30) than Mulliken charges[2]) are summarized in Table 4. For **3a**^{H,Me} net negative charges are found on all exocyclic O atoms with similar values. In the case of **3b**^{H,Me} and **3e**^{H,Me}, while O(3) and O(4) show very similar NBO-charges, almost identical to those calculated for **3a**^{H,Me}, the S and Se atoms bound to C(1) are almost neutral. Correspondingly, the C(1) atoms in **3a**^{H} and **3a**^{Me} bear a more positive charge than those in **3b**^{H,Me} and **3e**^{H,Me}. While the charge distribution on C(1) and X (X = O, S, and Se for **3a**, **3b**, and **3e**, respectively) strongly depends on the nature of the X atom, in agreement with the trend of the softness of X, the remaining atoms in the molecule show very similar charge distributions. Actually, the almost neutral charges on the sulphur and selenium atoms in **3b**^{H,Me} and **3e**^{H,Me}, respectively suggest a very weak donor character for these compounds towards Lewis acids, such as halogen or interhalogen compounds, compared to that of compounds **1** (31, 32, 33) and **2** (34, 35). This is in accordance with the fact that we have been unable to measure reliable formation

constants of the adduct formed between $\mathbf{3b^R}$ and $\mathbf{3e^R}$ with molecular di-iodine. In fact, when the donor–acceptor interaction is very weak, a spectrophotometric approach (36) is not well-suited, since it is not possible to prepare solutions having a sufficiently high value of the saturation fraction (37, 38). In addition, in this particular class of compounds, an absorption band (λ_{max} = 520 nm, ε = 215 M^{-1} cm^{-1} for $\mathbf{3e^{Me}}$) near to the visible band of molecular di-iodine and a stronger band (λ_{max} = 350 nm, ε = 16 900 M^{-1} cm^{-1} for $\mathbf{3e^{Me}}$) which falls just where the adduct CT-band should appear, make further unreliable simultaneous determinations of the *K* and ε values of the adduct. Nevertheless, it is possible to have a rough estimation of the enthalpy value for the reaction of the 1:1 adduct formation from the lowering of the FT-Raman frequency for the I—I stretching (in methylene chloride solution $\nu_{I\text{-}I}$ falls at 209 cm^{-1} for free I_2 and at 182, 185, and 185 cm^{-1} in the adducts with $\mathbf{3e^{Me}}$, $\mathbf{3e^{Et}}$, and $\mathbf{3e^{Bu}}$, respectively). From the lowering of the $\nu_{I\text{-}I}$ value, a ΔH value of about –15 KJ mol^{-1} can be estimated. This value corresponds to a very weak interaction, and well agrees with the low charges calculated on the S and Se atoms in $\mathbf{3b^R}$ and $\mathbf{3e^R}$. As far as compounds of type **3b** are concerned, an adduct having an elemental analysis indicating a stoichiometry $\mathbf{3b^R}$•I_2 (R = Et) has been isolated in the solid state from $CHCl_3$ solutions. The very low interaction is confirmed by the position of the Raman band (180 cm^{-1}). In fact, their quick decomposition, with ejection of diiodine under the X-ray beam, prevented the crystal structure characterization of this adduct. A low-temperature determination has not been performed because of the scarce diffraction of the crystals.

Vibrational spectroscopy

Finally, DFT calculations can be employed to understand the vibrational spectra of the examined compounds. Calculated harmonic frequencies and experimental values appear to be in fairly good agreement as far as regards the trend in the values of the frequencies and in their intensities. Figure 6 shows a graph reporting the correlation between the experimental FT mid-IR frequencies and the harmonic calculated frequencies for $\mathbf{3b^{Me}}$ and $\mathbf{3e^{Me}}$. For the sake of comparison, the data regarding $\mathbf{3a^H}$ (39) are also reported. A comparison of the data available for all compounds allows to estimate an overall linear average scaling factor of 0.968. Furthermore, the results of our calculations allow to confirm or correct previous attributions based on an exclusively experimental basis. Thus, in Table 5 a comparison between

[b]Scaling factors taken from ref. (40) according to the nature of the vibration.

the experimental (39) and the harmonic calculated mid-IR frequencies for **3a^{H}** is reported. To obtain a better agreement, the calculated spectra can be scaled by the transferable factors recently reported for a series of organic compounds, according to the nature of the vibrational mode (40). The new attributions generally confirm those previously reported (except for modes 1 and 2 in Table 5 and for the order of modes 7 and 8).

Conclusions

Among compounds of type **3**, only **3a^{R}**, **3b^{R}**, and **3c^{R}** were known, (3–6) and only **3a^{H}** was structurally characterized (19). Now, the synthesis of the first examples of selenoparabanic acid derivatives **3e^{R}** (R = Me, Et, Bu) and the single crystal X-ray structure of **3e^{Et}** are reported. The comparison with the structural features (20) of **3a^{H}** supports a higher degree of electron delocalization on the N(2)-C(1)(Se)-N(5) fragment. Hybrid-DFT (16, 17) calculations performed on the molecules **3a**, **b**, **e^{R}** (R = H, Me) confirm an increase in the electron delocalization on this fragment on passing from O to S and Se derivatives, and indicate a different composition of the HOMOs of **3a^{R}** compared to those of **3b**, **e^{R}**. This might explain the similar reactivities of the latter compounds compared to the former, in particular as far as regards sulphuration with Lawesson's reagent (9–11). Because of experimental difficulties, the donor character of the new compounds towards molecular di-iodine cannot be quantitatively explored by UV–vis spectroscopy (36), but FT-Raman spectroscopy allows to estimate a ΔH value of about –15 kJ mol^{-1}. Such a low value corresponds to a very weak donor character of compounds **3b**, **e^{R}** compared to the donor ability of compounds of type **1** and **2**. This is also in good agreement with the NBO-charge distributions.

Experimental section

All solvents and reagents were Aldrich products used as purchased. All reactions were carried out under dry nitrogen atmosphere. Elemental analyses were performed on a FISONS EA-1108 CHNS-O instrument. FT IR spectra were recorded on a Bruker IFS55 spectrometer at room temperature, purging the sample cell with a flow of dried air. Polythene pellets with a mylar beam-splitter and polythene windows (500–100 cm^{-1}, resolution 2 cm^{-1}) and KBr pellets with a KBr beam-splitter and KBr windows (4 000–400 cm^{-1}, resolution 4 cm^{-1}) were used. FT-Raman spectra were recorded with a resolution of 4 cm^{-1} on a Bruker RFS100 FT-Raman spectrometer, fitted with an In-Ga-As detector (room temperature) operating with a Nd-YAG laser (excitation wavelength 1 064 nm), with a 180° scattering geometry. Electronic spectra were recorded with a quartz cell of an optical path of 1 cm or with cells of an optical path of 0.1 cm in the attempt to determine formation constants, on a Varian Cary 5 spectrophotometer in CH_2Cl_2 solution at 20°C in a thermostated compartment. The ^{1}H NMR and ^{13}C NMR spectra were recorded on a Varian Unity Inova 400 operating at 400 and 100.5 MHz, respectively. Chemical shifts of compounds dissolved in $CDCl_3$ were referred to TMS used as an internal reference.

Procedures

Among the examined compounds (Scheme 3), **3a^{H}** is commercially available, while **3b^{H}**, **3a^{Me}**, and **3b^{Me}** have been prepared according to literature methods (3).

Synthesis of 3e^{Me}, $C_5H_6N_2O_2Se$

Iodomethane (2.4 mL, 38.4 mmol) is added dropwise to a methyl alcohol solution (20 mL) of *N*,*N*′-dimethylthiourea (2 g, 19.2 mmol) and the resulting mixture is refluxed for 1 h and then cooled to 0°C. The *S*,*N*,*N*′-trimethylisothiouronium iodide, separated as a white solid (4.3 g, yield 90%), is dissolved in anhydrous methyl alcohol and reacted at room temperature for 15 h with an absolute ethyl alcohol solution of NaHSe freshly prepared from selenium powder (0.834 g, 10.57 mmol) and sodium borohydride (0.492 g, 13.01 mmol). The mixture is neutralized with diluted acetic acid, 25 mL of distilled water are added, and alcohols are removed under reduced pressure. The *N*,*N*′-dimethylselenourea **4e^{Me}** is extracted with methylene chloride and the solution dried over anhydrous sodium sulfate. Trimethylamine (2.26 mL, 16.3 mmol) and oxalyl chloride (0.78 mL, 8.9 mmol) are added dropwise at 0°C to a methylene chloride solution of **4e^{Me}** containing 8.9 mmol and the reaction mixture is stirred at room temperature for 1 h, washed with water, and the organic phase dried under reduced pressure. The product is purified by crystallization from an ethyl

alcohol–hexane solution. Yield 0.917 g, 55%, mp 119°C. UV–vis (CH_2Cl_2 solution) λ (nm) (ε, M^{-1} cm^{-1}): 347 (6800), 518 (200). IR ν (cm^{-1}): 2948vw, 1760vs, 1664w, 1467m, 1446s, 1379vs, 1323vs, 1229m, 1109s, 1027w, 964w, 785m, 711m, 625m, 554m, 484s, 381m, 325m, 249m. ^{1}H NMR (400.0 MHz, $CDCl_3$, TMS) δ: 3.52 (s). ^{13}C NMR (100.5 MHz, $CDCl_3$, TMS) δ: 186.24, 154.91, 30.07. Anal. calcd.(%): C 29.28, H 2.95, N 13.66; found: C 30.08, H 2.81, N 13.94.

Synthesis of $3e^{Et}$, $C_7H_{10}N_2O_2Se$

3e^{Et} was synthesized following the route outlined for **3e^{Me}**. Yield 1.658 g, 65%, mp 111°C. UV–vis (CH_2Cl_2 solution) λ (nm) (ε, M^{-1} cm^{-1}): 350 (6200), 524 (200). IR ν (cm^{-1}): 2971w, 1766vs, 1454m, 1430m, 1396vs, 1242vs, 1117s, 1074m, 1049w, 1010vw, 901w, 875w, 641m, 367m, 488s, 441w, 395w, 325m, 247vw, 225w, 198w, 187w. ^{1}H NMR (400.0 MHz, $CDCl_3$, TMS) δ: 4.12 (q, 2H), 1.30 (t, 3H). ^{13}C NMR (100.5 MHz, $CDCl_3$, TMS) δ: 184.48, 154.81, 38.89, 13.14. Anal. calcd. (%): C 36.06, H 4.32, N 12.28; found: C 36.84, H 4.72, N 12.28.

Synthesis of $3e^{Bu}$, $C_{11}H_{18}N_2O_2Se$

3e^{Et} was synthesized following the route outlined for **3e^{Me}**. Yield 1.227 g, 70%. m p 35°C. UV–vis (CH_2Cl_2 solution) λ (nm) (ε, M^{-1} cm^{-1}): 352 (5600), 525 (200). IR ν (cm^{-1}): 2960m, 2933w, 2874w, 1767vs, 1434m, 1395vs, 1291m, 1209s, 1164w, 1130m, 1089w, 1061w, 957vw, 703vw, 573w, 495m, 397 w, 300w, 249vw. ^{1}H NMR (400.0 MHz, $CDCl_3$, TMS) δ: 4.05 (t, 2H), 1.70 (m, 2H), 1.37 (m, 2H), 0.96 (t, 3H). ^{13}C NMR (100.5 MHz, $CDCl_3$, TMS) δ: 185.20, 154.99 (s), 43.60, 29.81, 19.85 (s), 13.53. Anal. calcd. (%): C 45.68, H 6.27, N 9.69; found: C 46.80, H 7.01, N 9.86.

X-ray crystallography

Crystal data for **3e^{Et}**: $C_7H_{10}N_2O_2Se$, fw 233.13, orthorhombic, space group $P2_12_12_1$ (no. 19), a = 5.249(1), b = 10.406(3), c = 16.647(1) Å, U = 909,3(3) Å^3, Z = 4, μ(Mo-Kα) = 40.48 cm^{-1}, ρ_{calc} = 1.703 g cm^{-3}; 1721 reflections measured, 1580 unique (R_{int} = 0.018). Intensity data were collected at room temperature with an Enraf–Nonius CAD4 diffractometer using graphite-monochromatised Mo-Kα radiation. Lorentz, polarization, and a semiempirical absorption correction (41) were applied to all the data. The structure was solved by direct methods (MULTAN) (42) and refined by full-matrix least-squares with anisotropic displacement parameters for all the non-hydrogen atoms. The final R and R_w indices were 0.030 and 0.044 for 1339 reflections with $I > 3\sigma(I)$. All H atoms were seen in difference Fourier maps, but not refined. Sources of neutral atomic scattering factors for all atoms are given in ref. (43). Anomalous dispersion effects were included in F_c; and the values for δf′ and δf″ were those of ref. (44). All the calculations were performed using Personal SDP software (45, 46). Atomic coordinates, displacement parameters, bond lengths and angles have been deposited as supplementary material and may be purchased from the Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, ON K1A 0S2 (http://www.nrc.ca/cisti/docdel/order_electronic_e.shtml for information on ordering electronically). This material has also been deposited with the Cambridge Crystallographic Data Centre. Copies of the data can be obtained, free of charge, on application to the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. (Fax: 44-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk).

Computations

Quantum chemical calculations were carried out using the commercially available suite of programs Gaussian 94 (47). Density functional calculations (16, 17) (DFT) were performed using the hybrid BECKE3LYP functional (which uses a mixture (22) of Hartree–Fock and DFT exchange along with DFT correlation: the Lee-Yang-Parr correlation functional together with the Becke's gradient correction) (23), Schafer, Horn, and Ahlrichs' (24) pVDZ basis set for C, H, N, O, S, and Se were used for all calculations. Numerical integration was performed using the FineGrid option, which indicates that a total of 7 500 points are used for each atom. After a geometry optimization performed starting from structural data (where available) regularized to satisfy the C_{2v} symmetry, harmonic frequencies were obtained using the second derivatives of the DFT energy, computed by numerical differentiation of the DFT energy gradients. Finally NBO (29) calculations have been performed for each molecule using the converged density matrix corresponding to the equilibrium geometries. All point group representations refer to the model molecules disposed on the *xy* plane with the C(1)=X bond lying on the *y* axis. Calculations have been performed on an IBM Risc 6000 550H, DECServer 4000, and on a VAIER Intel Pentium III 450 MHz Personal Computer running Linux.

Acknowledgments

The project was carried out as a part of the "Progetto Finalizzato Materiali Speciali per Tecnologie Avanzate II" of the "Consiglio Nazionale delle Ricerche." We wish to acknowledge the Advanced Materials Laboratory (LaMI) under the auspices of the European Union and Regione Basilicata for financial support. We also wish to thank Dr. Francesco Usai for help in the synthesis.

Supporting information

Table S1. giving details of the data collection and refinement, atomic coordinates, displacement parameters, bond lengths and angles for **3e^{Et}**. The synthesis of pyrido(2,3,4-*kl*)acridine unit of some marine alkaloids

Turan Ozturk and Alexander McKillop

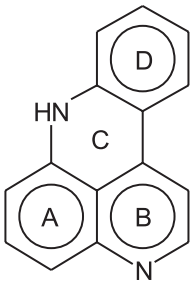
Abstract: A simple and convenient synthesis of pyrido(2,3,4-*kl*)acridine (**1**), the main skeleton of some marine alkaloids, via cyclization and intramolecular nitrene insertion, is described. The importance of the planarity of the molecule during the nitrene insertion is explained.

Key words: pyridoacridine, marine alkaloids, nitrene insertion, quinoline, quinolinone.

Résumé : On décrit une synthèse simple et pratique de la pyrido(2,3,4-*kl*)acridine (**1**), le squelette fondamental de quelques alcaloïdes marins; elle implique une cyclisation et une insertion intramoléculaire de nitrène. On explique l'importance de la planéité de la molécule au cours de l'insertion du nitrène.

Mots clés : pyridoacridine, alcaloïdes marins, insertion de nitrène, quinoléine, quinoléinone.

[Traduit par la Rédaction]



Introduction

Recently, many polycyclic fused-ring alkaloids containing pyrido(2,3,4-*kl*)acridine (**1**) skeleton have been isolated from a variety of marine sources such as sponges, molluscs, and tunicates, most of which have been reported to have cytotoxic, antitumor, and antiviral activities (1). Calliactine (2), 2-bromoleptoclinidinone (3), ascididemin (4), cystodytins A, B, and C (5), petrosamine (6), diplamine (7), varamines (8), dercitin (9), cyclodercitin (10), segolines A (11, 12) and B (12), isosegoline A (11, 12), norsegoline (11, 12), shermilamines A (12), B (13, 14), C (5*b*), D and E (15), styelsamine A, B, C, and D (16), arnoamine A and B (17), kuanoniamine A, B, C, and D (13, 5*b*), eilatin (12), amphimedine (18), neoamphimedine (19), pantherinine (20), lissoclin A and B (21), are among this type of alkaloid. Although elegant synthetic methodologies for most of these alkaloids have been developed and total synthesis of many of these natural products have been achieved, such alkaloids are still continuing to be the focus of many synthetic groups (1, 22). This is due to their interesting biological activities and challenging structures. It seems that any contribution toward the synthesis of pyridoacridine units is worthwhile since most of the strategies involve the synthesis of such units. The route we present here involves two important key steps, cyclization to form the quinolinone moiety and intramolecular nitrene insertion to build a tetracyclic system.

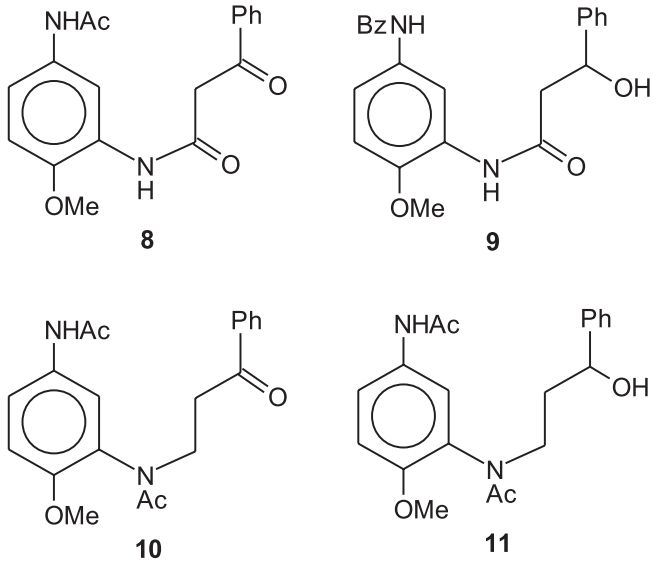
This approach may also be utilized as an easy access for the synthesis of ring B-modified analogues of this type of alkaloid.

Results and discussion



The synthesis of this important pyridoacridine intermediate **21** has been achieved in 10 steps with overall 13.5% yield. Our synthesis started with the condensation of the commercially available reagents 2-methoxy-5-nitroaniline (**2**) and ethyl benzoylacetate (**3**) in toluene, which led to the formation of the amide **4** in 75% yield (Scheme 1) (22*c*). Hydrogenation of the nitro and keto groups of **4**, over palladium on charcoal at room temperature in ethanol, took place at the same time with a 90% yield. Acetylation of the amino group of **5** with acetyl chloride was followed by the cyclization of the corresponding product **6** with 80% H_2SO_4, which smoothly yielded the quinolinone **7** in 92% yield. Unfortunately, our other cyclization attempts with various amides such as **8**, **9**, **10**, and **11** to obtain such an important intermediate were not successful. Although these attempts were carried out in various reagents, conc. H_2SO_4, H_3PO_4, poly.H_3PO_4, $POCl_3$, HCl, and 80% H_2SO_4, in almost all reactions, intractable products or starting materials were obtained, except **8** and **9** which gave hydrolysis of the amide

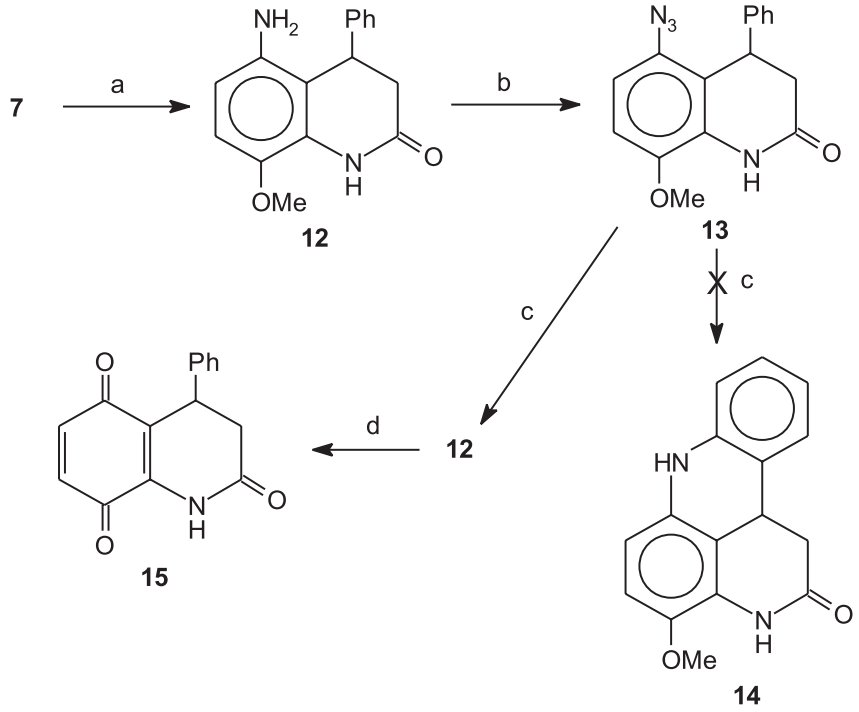
Scheme 1. (a) Toluene, reflux, 75%; (b) Pd/C, H_2, ethanol, rt, 90%; (c) AcCl, pyridine, 75%; (d) H_2SO_4 (80%), 92%.

when treated with HCl or 80% H_2SO_4, and dehydration with 80% H_2SO_4, respectively.



After constructing the quinolinone ring successfully, we concentrated on building the last ring, utilizing the intramolecular nitrene insertion methodology. Initially, deacetylation of **7** was performed, and after some exploratory work, it was found that deacetylation of **7** to **12** best took place in hot 45% sulphuric acid, and **12** was obtained in a very satisfactory, 88% yield (Scheme 2). Conversion of **12** to the corresponding azide **13** was then carried out by the classical nitrous acid followed by sodium azide combination of reactions. With the azide **13** available, conversion to the tetracyclic system **14** was attempted. Thus, **13** was heated in refluxing xylene until no starting material remained in the reaction mixture, as shown by TLC. Examination of the NMR spectrum of the product, however, showed that it was the amine **12**. Further confirmation that **12** had been obtained, was provided by oxidative demethylation with manganese dioxide, which gave the trione **15** in 78% yield, and the analytical and spectroscopic data for **15** were fully consistent with the assigned structure.

In this attempted cyclization of **13** to **14** via the nitrene insertion, which was carried out in xylene, both in the presence and absence of a nitrogen atmosphere, it was assumed that conversion of the nitrene **13** to the aniline **12** was the result of hydrogen abstraction from the solvent. In an attempt to circumvent this, the azide **13** was carefully melted and the liquid azide was stirred under nitrogen in the absence of solvent. After 30 min, NMR and TLC examination of the crude product showed the same result as previously, that is, formation of the amine **12**. Hydrogen abstraction in this case could involve the benzylic hydrogen atom at the 4-position of the dihydroquinolinone ring. Moreover, the stereochemical situation in **13** is probably less than ideal as far as the intended intramolecular cyclisation is concerned. The phenyl group is not on the same plane with the azide, and this is obviously one of the driving forces in such cyclizations (22*g*, *j*, *k*, 23).

To circumvent the problem encountered during intramolecular nitrene insertion, it was decided to introduce a double bond to the system to bring the phenyl group to the same plane with the azide. Then, employment of the one of the most common dehydrogenation reagents DDQ (2,3-dichloro-5,6-dicyanobenzoquinone), unfortunately, did not give any result, only starting material was recovered. This is perhaps not too surprising in view of the large steric bulk of the reagent and the relative steric shielding of the hydrogen atoms at the 3- and 4-positions of the dihydroquinolinone by the 4-phenyl substituent. Then, the conventional method, palladium on charcoal in diphenyl ether, yielded the quinolinone **16** in 65% yield together with 20% of the starting material (Scheme 3). Hydrolysis of the amide group using 45% sulphuric acid proceeded smoothly to give the aminoquinolinone **17** in 96% yield, and conversion of the

Scheme 2. (a) H_2SO_4 (45%), reflux, 2 h, 88%; (b) (*i*) $NaNO_2$, 0–5°C; (*ii*) NaN_3, 0–5°C, 86%; (c) xylene, reflux; (d) MnO_2, H_2SO_4 (35%), 78%.

amino to the azide group, as usual, presented no difficulties. The crude azide **18**, which showed only one spot on TLC, was obtained in 93% yield. It proved to be sensitive to both heat and light and hence no attempt to obtain an analytical sample was made.

The next step in the synthesis was the key intramolecular nitrene insertion reaction. Azide **18** was heated under reflux in xylene for 1.5 h. In contrast to the complete failure to achieve cyclization with the dihydro derivative **13**, the azide **18** reacted quite smoothly to give the required tetracyclic material **19** in 78% yield. Use of the azidoquinolinone rather than the dihydroquinolinone had proved successful, therefore, and would seem to imply that the controlling feature in the reaction as far as nitrene insertion is concerned is sterochemistry.

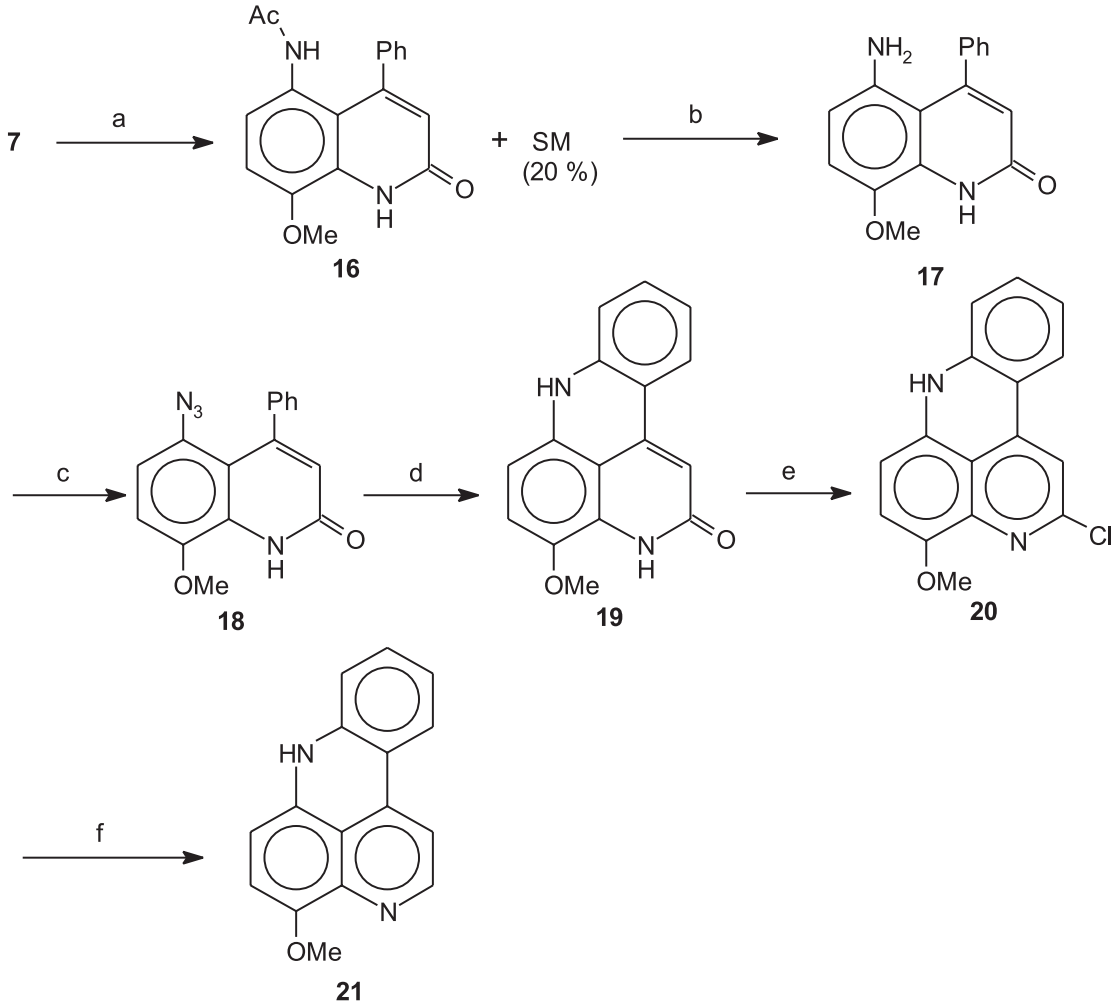
The synthesis of the tetracyclic compound **19** constitutes achievement of one of the major objectives, namely the synthesis of an advanced tetracyclic intermediate in which the B ring is functionalized. Analogues of natural products containing pyridoacridine units could be available from it by manipulation of the quinolinone ring.

The key compound **21** was then easily prepared from **19** by conversion to the chloroquinoline **20** in 83% yield by reaction with hot phosphorus oxychloride, followed by reductive removal of the chlorine on charcoal in triethylamine in 79% yield.

Experimental

Melting points were determined on a Kofler hotstage microscope melting point apparatus and are uncorrected. Microanalysis were performed with a Carlo Erba 1106 elemental analyzer. Infrared spectra were recorded on Perkin–Elmer 257, 297 grating infrared spectrophotometers using the standard Nujol mull or liquid film techniques between sodium chloride plates. Proton NMR spectra were recorded on JEOL PMX 60 MHz and JEOL GX-400 MHz spectrometers. The ^{13}C NMR spectra were recorded on a JEOL EX-90Q 24 MHz spectrometer. Tetramethylsilane (TMS) was used as the internal standard in all NMR spectra run in $CDCl_3$, DMSO-d_6. Mass spectra were recorded on a Kratos MS-25 mass spectrometer with an ionization potential of 70 eV at 200°C. All column chromatography was performed on silica gel (Merck, Kieselgel 60H, Art 7736) and Merck aluminum oxide 60 PF_{24k}.

N-(2-Methoxy-5-nitrophenyl)-3-oxo-3-phenylpropanamide (4)



2-Methoxy-5-nitroaniline (**2**) (15 g, 90 mmol) and ethyl benzoylacetate (**3**) (17.29 g, 90 mmol) were condensed in toluene (400 mL) using a Dean and Stark's apparatus for 6 h, and the mixture was then left overnight at room temperature. The solid, which separated, was collected by filtration and recrystallized from ethanol. Yield: 21.9 g, 75%. Light yellow crystals, mp 183–185°C. MS: *m*/*z* 314 (M^+). ^1H NMR ($CDCl_3$) δ: 4.02 (s, 3H), 4.08 (s, 2H), 6.86 (d, J = 8.4 Hz, 1H), 7.60 (s, 5H), 8.0 (m, 2H). Anal. calcd. for $C_{16}H_{14}N_2O_5$: C 61.14, H 4.46, N 8.91; found: C 61.12, H 4.15, N 8.91.

N-(5-Amino-2-methoxyphenyl)-3-hydroxy-3-phenylpropanamide (5)

Compound **4** (6 g, 19 mmol) and C/Pd (0.21 g, 5%) were hydrogenated in ethanol (100 mL) at room temperature until the disappearance of the starting material (TLC). The

Scheme 3. (a) Pd/C, diphenyl ether, reflux, 65%, 20% (starting material); (b) H_2SO_4 (45%), reflux, 96%; (c) (*i*) $NaNO_2$; (*ii*) NaN_3, 93%; (d) xylene, reflux, 78%; (e) $POCl_3$, reflux, 83%; (f) Pd/C, H_2, Et_3N, 79%.

catalyst was filtered off through kieselguhr under suction and the kieselguhr was washed with acetone. After evaporation of the solvent, the crude solid was recrystallized from toluene. Yield: 4.89 g, 90%. Light yellow needles, mp 155–158°C. MS: *m*/*z* 286 (M^+). IR (Nujol) (cm^{-1}): 3420, 3360, 3100–3480, 1654. ^1H NMR ($CDCl_3$) δ: 2.68 (d, *J* = 2.9 Hz, 2H), 3.28 (s, 2H), 3.68 (s, 3H), 5.08 (t, *J* = 2.9 Hz, 1H), 6.26 (dd, *J* = 10.1, 1.2 Hz, 1H), 6.64 (d, *J* = 9.7 Hz, 1H), 7.26 (s, 5H), 7.82 (d, *J* = 1.2 Hz, 1H), 8.06 (s, 1H). Anal. calcd. for $C_{16}H_{18}N_2O_3$: C 67.43, H 6.29, N 9.79; found: C 67.43, H 6.40, N 9.58.

N-(5-Acetamido-2-methoxyphenyl)-3-hydroxy-3-phenylpropanamide (6)

To compound **5** (3 g, 10 mmol), dissolved in pyridine (25 mL) and cooled in an ice bath, was added dropwise freshly distilled acetyl chloride (0.80 mL, 110 mmol). The mixture was stirred for 2 h at room temperature and then poured into water (50 mL). The resulting mixture was extracted with CH_2Cl_2 (3 × 40 mL), dried over Mg_2SO_4. The solvent was evaporated under reduced pressure. Yield: 2.46 g, 75%. Colorless crystalline solid, mp 79–82°C. MS: *m*/*z* 328 (M^+). IR (Nujol) (cm^{-1}): 3110–3400, 1630–1680. ^1H NMR ($CDCl_3$) δ: 2.04 (s, 3H), 2.68 (d, *J* = 3.0 Hz, 2H), 3.00 (s, 3H), 4.04 (s, 1H), 5.08 (t, *J* = 3.0 Hz, 1H), 6.66 (d, *J* = 10.0 Hz, 1H), 7.24 (s, 5H), 7.44 (dd, *J* = 10.0, 1.1 Hz, 1H), 8.20 (d, *J* = 1.0 Hz, 1H), 8.25 (s, 1H). Anal. calcd. for $C_{18}H_{20}N_2O_4$: C 65.85, H 6.09, N 8.53; found: C 65.24, H 6.18, N 8.21.

5-Acetamido-3,4-dihydro-8-methoxy-4-phenylquinolin-2(1*H*)-one (7)

Compound **6** (0.50 g) was stirred in H_2SO_4 (80%, 100 mL) at 80°C for 1 h. The reaction mixture was cooled to room temperature and poured into ice water. The resulting solution was then neutralized with Na_2CO_3 and the Na_2SO_4 which separated was removed by filtration and washed with CH_2Cl_2 (3 × 40 mL) and the combined extracts were dried (Mg_2SO_4) and the solvent was evaporated under reduced pressure. The crude product was recrystallized from toluene. Yield: 0.42 g, 92%. Colorless crystalline solid, mp 218–220°C. MS: *m*/*z* 310 (M^+), 311. IR (Nujol) (cm^{-1}): 3200–3440, 1656, 1650. ^1H NMR ($CDCl_3$) δ: 1.91 (s, 3H), 2.63 (d, *J* = 15.7 Hz, 1H), 2.89 (dd, *J* = 16.1, 6.9 Hz, 1H), 3.80

© 2000 NRC Canada

(s, 3H), 4.53 (d, J = 5.9 Hz, 1H), 6.93 (d, J = 8.8 Hz, 1H), 6.98 (d, J = 8.8 Hz, 1H), 7.02–7.29 (m, 5H), 9.21 (s, 1H), 9.25 (s,1H). Anal. calcd. for $C_{18}H_{18}N_2O_3$: C 69.67, H 5.80, N 9.03; found: C 69.73, H 5.92, N 8.93.

5-Amino-3,4-dihydro-8-methoxy-4-phenylquinolin-2(1*H*)-one (12)

Compound **7** (0.5 g, 1.6 mmol) was refluxed in H_2SO_4 (25 mL, 45%) for 2 h. The mixture was cooled down to room temperature and poured into water (50 mL). The resulting solution was then neutralized with Na_2CO_3, and the aqueous mixture was extracted with CH_2Cl_2 (3 × 40 mL). The organic extracts were dried over Mg_2SO_4, filtered, and the solvent was evaporated under reduced pressure. The crude solid was recrystallized from ethanol. Yield: 0.41 g, 88%. Colorless crystalline solid, mp 225–228°C. MS: m/z 268 (M^+). IR (Nujol) (cm^{-1}): 3460, 3380, 1700. ^{1}H NMR (DMSO-d_6) δ: 2.49 (d, J = 15.7 Hz, 1H), 2.87 (dd, J = 16.1, 6.9 Hz, 1H), 3.71 (s, 3H), 4.40 (d, J = 6.2 Hz, 1H), 4.57 (s, 2H), 6.21 (d, J = 8.4 Hz, 1H), 6.70 (d, J = 8.4 Hz, 1H), 7.09–7.25 (m, 5H), 9.85 (s, 1H). ^{13}C NMR (DMSO-d_6) δ: 35.7, 38.4, 55.7, 102.8, 109.7, 109.8, 126.4, 127.0, 128.3, 132.1, 134.7, 142.1, 142.4, 168.0. Anal. calcd. for $C_{16}H_{16}N_2O_2$: C 71.64, H 5.97, N 10.44; found: C 71.45, H 6.05, N 10.15.

5-Azido-3,4-dihydro-8-methoxy-4-phenylquinolin-2(1*H*)-one (13)

To concentrated H_2SO_4 (1.72 mL) dissolved in water (5.7 mL) was added **12** (1.90 g, 7 mmol). The mixture was stirred for 10 min at room temperature, then more water (3 mL) was added and the mixture was cooled to 0–5°C in an ice water bath. A solution of sodium nitrite (0.63 g, 10 mmol) in water (5 mL) was carefully added dropwise and the mixture was stirred for 45 min. With strong stirring, a solution of sodium azide (0.7 g, 10 mmol) in water (5 mL) was then added dropwise and stirring was continued for a further 40 min. The light yellow solid, which separated, was collected by filtration and washed with plenty of water. The crystalline solid was dried under vacuum, mp 134–137°C. Yield: 1.80 g, 86%. MS: m/z 294 (M^+). IR (Nujol) (cm^{-1}): 2120, 1656. ^{1}H NMR (DMSO-d_6) δ: 2.60 (d, J = 16.2 Hz, 1H), 2.96 (dd, J = 16.2, 7.3 Hz, 1H), 3.82 (s, 3H), 4.43 (d, J = 6.4 Hz, 1H), 6.91 (d, J = 8.8 Hz, 1H), 7.05 (d, J = 8.5 Hz, 1H), 7.08–7.26 (m, 5H), 9.44 (s, 1H). ^{13}C NMR (DMSO-d_6) δ: 36.2, 36.8, 56.0, 111.4, 112.3, 117.7, 126.7, 128.4, 128.6, 129.5, 141.6, 143.0, 143.8, 168.1. Anal. calcd. for $C_{16}H_{14}N_4O_2$: C 65.30, H 4.76, N 19.04; found: C 65.07, H 4.72, N 18.76.

Compound **13** was dissolved in xylene (750 mL) and refluxed for 4 h until the disappearance of the starting material (TLC). Then the reaction mixture was left in the refrigerator for overnight and the formed deep brown solid was filtered and washed with petroleum ether (bp 49–60°C). The crude material was chromatographed using ethyl acetate as an eluent and a brown crystalline solid was then obtained. Its TLC, NMR, and mass analysis showed that the product was indeed 5-amino-3,4-dihydro-8-methoxy-4-phenylquinolin-2(1*H*)-one (**12**).

Compound **13** (1 g) was melted and kept stirring at 150°C under nitrogen atmosphere for 30 min. Examination of the NMR and TLC of the crude product showed that the product is **12**.

3,4-Dihydro-4-phenylquinolin-2(1*H*),5,8-trione (15)

To a stirred solution of the product obtained from attempted insertion reaction of **13** (0.38 g, 1.4 mmol) dissolved in H_2SO_4 (59 mL, 35%) was added activated MnO_2 (0.46 g) portionwise at 0°C. Stirring was carried out 1 h longer, then the mixture was diluted with CH_2Cl_2 (30 mL), neutralized with Na_2CO_3, and filtered. The filtrate was washed with water and the CH_2Cl_2 phase was separated, dried over Mg_2SO_4, filtered, and the solvent was evaporated under reduced pressure. The crude product was crystallized from toluene. Yield: 0.27 g, 78%. Red needles, mp 154–156°C. MS: m/z 253 (M^+). IR (Nujol) (cm^{-1}): 3340, 1740, 1654, 1640. ^{1}H NMR ($CDCl_3$) δ: 2.88 (m, 2H), 4.44 (m, 1H), 6.66 (s, 2H), 7.22 (s, 5H), 8.22 (s, 1H). Anal. calcd. for $C_{15}H_{11}NO_3$: C 71.14, H 4.34, N 5.53; found: C 70.90, H 4.04, N 5.30.

5-Acetamido-8-methoxy-4-phenylquinolin-2(1*H*)-one (16)

A mixture of compound **7** (0.30 g, 1 mmol) and Pd/C (10%, 53 mg) in diphenyl ether (30 mL) was refluxed for 48 h. The reaction mixture was cooled to room temperature, filtered through kiselguhr under suction, and the kiselguhr washed with CH_2Cl_2 (50 mL). The dichloromethane solution was evaporated under reduced pressure and the resulting diphenyl ether solution was poured into petroleum ether (bp 40–60°C, 100 mL). The solid, which separated, was collected by filtration and washed with petroleum ether (25 mL). The crude solid was chromatographed on silica, using ethyl acetate as the first eluent to remove starting material (20%) and then ethanol–ethyl acetate (1:6) to obtain the product. Yield: 0.2 g, 65%. Colorless crystalline solid, mp 193–196°C. MS: m/z 308 (M^+). IR (Nujol) (cm^{-1}): 1615–1654. ^{1}H NMR (DMSO-d_6) δ: 1.12 (s, 3H), 3.93 (s, 3H), 6.22 (s, 1H), 6.84 (d, 1H, J = 8.2 Hz, 1H), 7.18 (d, J = 8.2 Hz, 1H), 7.21–7.41 (m, 5H), 8.81 (s, 1H), 10.88 (s, 1H). ^{13}C NMR (DMSO-d_6) δ: 21.8, 56.4, 110.9, 115.1, 121.6, 124.3, 127.1, 127.3, 127.5, 127.7, 129.9, 139.4, 144.2, 151.1, 159.9, 168.1. Anal. calcd. for $C_{18}H_{16}N_2O_3$: C 70.12, H 5.19, N 9.09; found: C 70.50, H 5.41, N 8.96.

5-Amino-8-methoxy-4-phenylquinolin-2(1*H*)-one (17)

The same reaction conditions and work-up were applied as in the preparation of **12** for the deacetylation of **16** to obtain **17**. The crude product was recrystallized from toluene. Yield: 96%. Yellow needles, mp 216–218°C. MS: m/z 266 (M^+). IR (nujol) (cm^{-1}): 3480, 3440,1650. ^{1}H NMR (DMSO-d_6) δ: 3.80 (s, 3H), 4.12 (s, 2H), 6.05 (s, 1H), 6.30 (d, J = 8.4 Hz, 1H), 7.03 (d, J = 8.8 Hz, 1H), 7.38–7.51 (m, 5H), 10.39 (s, 1H). ^{13}C NMR DMSO-d_6 δ: 56.9, 105.4, 107.1, 114.7, 121.0, 127.5, 128.4, 128.6, 130.1, 137.0,139.4, 139.7, 151.2, 159.9. Anal. calcd. for $C_{16}H_{14}N_2O_2$: C 72.14, H 5.26, N 10.52; found: C 72.14, H 5.19, N 10.29.

5-Azido-8-methoxy-4-phenylquinolin-2(1*H*)-one (18)

Using the same reaction conditions as in the preparation of **13**, compound **17** was converted to the azide **18**. Instead of filtering the precipitate, which formed after the addition of NaN_3, the reaction mixture was poured into water (30 mL), and the resulting solution neutralized with Na_2CO_3

© 2000 NRC Canada

and extracted with CH_2Cl_2 (3 × 40 mL). The organic extracts were dried (Mg_2SO_4), filtered, and the solvent was evaporated under reduced pressure. The yellow crystalline solid, which was obtained in 93% yield, was used directly for the next insertion step. IR (Nujol) (cm^{-1}): 2120, 1640. ^1H NMR ($CDCl_3$) δ: 4.0 (s, 3H), 6.44 (s, 1H), 6.84 (s, 1H), 6.86 (s, 1H), 7.12–7.24 (m, 5H), 9.16 (s, 1H).

3,7-Dihydro-4-methoxy-2-oxo-pyrido(2,3,4-*kl*)acridine (19)

Compound **18** (0.60 g, 2 mmol) was refluxed in xylene (750 mL) for 1.5 h. The reaction mixture was cooled to room temperature and left overnight. The solid, which separated, was collected by filtration and washed with petroleum ether (bp 40–60°C, 25 mL). This crude product was chromatographed on silica using ethyl acetate–ethanol (4:2) as eluent. Yield: 0.41 g, 78%. Brown crystalline solid, mp 270°C (decomp.). MS: *m*/*z* 264 (M^+). IR (Nujol) (cm^{-1}): 1610–1650. ^1H NMR (DMSO-d_6) δ: 3.83 (s, 3H), 6.44 (s, 1H), 6.56 (d, *J* = 8.7 Hz, 1H), 6.97 (t, *J* = 7.1 Hz, 1H), 7.07 (d, *J* = 8.2 Hz, 1H), 7.18 (d, *J* = 8.7 Hz, 1H), 7.41 (t, *J* = 7.3 Hz, 1H), 7.93 (d, *J* = 7.8 Hz, 1H), 10.01 (s, 1H), 10.42 (s, 1H). ^{13}C NMR (DMSO-d_6) δ: 56.7, 101.8, 102.6, 108.2, 114.1, 115.8, 115.9, 120.1, 124.4, 129.6, 131.6, 131.7, 137.5, 139.2, 142.3, 162.4. Anal. calcd. for $C_{16}H_{12}N_2O_2$: C 72.72, H 4.54, N 10.60; found: C 72.39, H 4.56, N 10.34.

2-Chloro-4-methoxy-7*H*-pyrido(2,3,4-*kl*)acridine (20)

Compound **19** (0.20 g, 0.75 mmol) was refluxed in $POCl_3$ (30 mL) for 1 h. The reaction mixture was cooled to room temperature and poured into water (50 mL). The resulting solution was neutralized with Na_2CO_3 and the solid, which separated, was collected by filtration. This gave 0.17 g (83%) of crude red crystalline solid which showed one spot on the TLC and was used directly for the next step. A sample was crystallized from toluene for the analysis, mp 202°C (decomp.). MS: *m*/*z* 282 (M^+). ^1H NMR (DMSO-d_6) δ: 3.85 (s, 3H), 6.69 (d, *J* = 8.4 Hz, 1H), 6.92–7.41 (m, 5H), 7.99 (d, *J* = 8.0 Hz, 1H), 10.57 (s, 1H). ^{13}C NMR (DMSO-d_6) δ: 56.1, 113.6, 114.3, 115.6, 117.9, 120.2, 124.6, 128.1, 128.8, 131.9, 132.4, 139.8, 140.1, 143.7, 144.8, 151.8, 1H. Anal. calcd. for $C_{16}H_{11}ClN_2O$: C 67.97, H 3.92, N 9.91, Cl 12.54; found: C 67.84, H 4.05, N 9.66, Cl 12.20.

4-Methoxy-7*H*-pyrido(2,3,4-*kl*)acridine (21)

Compound **20** (0.50 g, 2 mmol) was catalytically hydrogenated with 10% Pd/C (50 mg) in ethyl alcohol (40 mL) in the presence of triethylamine (0.25 g, 2.7 mmol) for 6 h at room temperature. The catalyst was filtered off through kieselguhr under suction, and then the solvent was evaporated under reduced pressure. This gave 0.34 g (79%) of red crystalline product, which showed one spot on TLC, mp 224°C (decomp.). MS: *m*/*z* 248 (M^+). ^1H NMR (DMSO-d_6) δ: 3.84 (s, 3H), 6.58 (d, *J* = 8.9 Hz, 1H), 6.90 (t, *J* = 8.3 Hz, 1H), 6.95 (d, *J* = 8.3 Hz, 1H), 7.1 (d, *J* = 8.3 Hz, 1H), 7.33 (t, *J* = 7.6 Hz, 1H), 7.41 (d, *J* = 4.9 Hz, 1H), 7.93 (d, *J* = 7.3 Hz, 1H), 8.48 (d, *J* = 4.9 Hz, 1H), 10.30 (s, 1H). ^{13}C NMR (DMSO-d_6) δ: 56.2, 101.5, 107.1, 112.3, 115.1, 119.2, 119.8, 124.0, 130.8, 131.7, 132.1, 139.6, 140.2, 141.1, 145.7, 150.7. Anal. calcd. for $C_{16}H_{12}N_2O$: C 77.42, H 4.48, N 11.29; found: C 77.21, H 4.84, N 11.24.

A tosyliminium ion-based total synthesis of (±)-schefferine

Darío A. Bianchi and Teodoro S. Kaufman

Abstract: The synthesis of the phenolic tetrahydroprotoberberine alkaloid (±)-schefferine is reported, featuring as key steps a tosyliminium ion-mediated Friedel–Crafts alkylation of eugenol dimethyl ether and an intramolecular Mitsunobu-type amination.

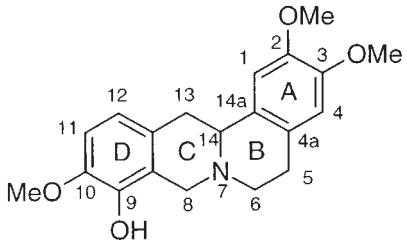
Key words: total synthesis, (±)-schefferine, natural product, tosyliminium ion, Mitsunobu amination.

Résumé : On a réalisé la synthèse de la (±)-schefférine, un alcaloïde phénolique dérivé de la tétrahyroprotoberbérine. Les étapes clés de cette synthèse sont une alkylation de Friedel–Crafts l'éther diméthylique de l'eugénol assistée par l'ion tosyliminium et un amination intramoléculaire du type Mitsunobu.

Mots clés : synthèse totale, (±)-schefférine, produit naturel, ion tosyliminium, amination de Mitsunobu.

[Traduit par la Rédaction]

In 1972, Gellert and Rudzats (1) reported the isolation of schefferine from the bark of *Schefferomitra subaequalis* Diels (Anonaceae), a New Guinea liana found as a climber on rain forest trees. The structure of this phenolic tetrahydroprotoberberine alkaloid, also known as tetrahydropalmatrubine (2), was formulated as **1** on the basis of its ^{1}H NMR and mass spectral data.



Several syntheses of (±)-schefferine have been previously reported, including reduction of protoberberines as well as Mannich cyclization and photolysis of 1-substituted tetrahydroisoquinolines. Späth and Burger (3) prepared (±)-**1** long before its isolation from a natural source by reduction of palmatrubine, a monodemethylation product of the widely known alkaloid palmatine. A similar approach, involving the synthesis and reduction of a palmatrubine derivative, was followed by Dutta and Bradsher (2*b*).

More recently, Kametani and co-workers informed that the Mannich cyclization of a conveniently substituted 1-benzyltetrahydroisoquinoline under careful pH control, furnished moderate yields of (±)-schefferine (4*a*). The same group also reported the synthesis of this natural product employing the Mannich reaction of a brominated 1-benzyl tetrahydroisoquinoline, produced by a Bischler–Napieralski reaction (4*b*). Noteworthy, they were unable to obtain (±)**–1** by phenolic cyclization of a related substrate (4*c*).

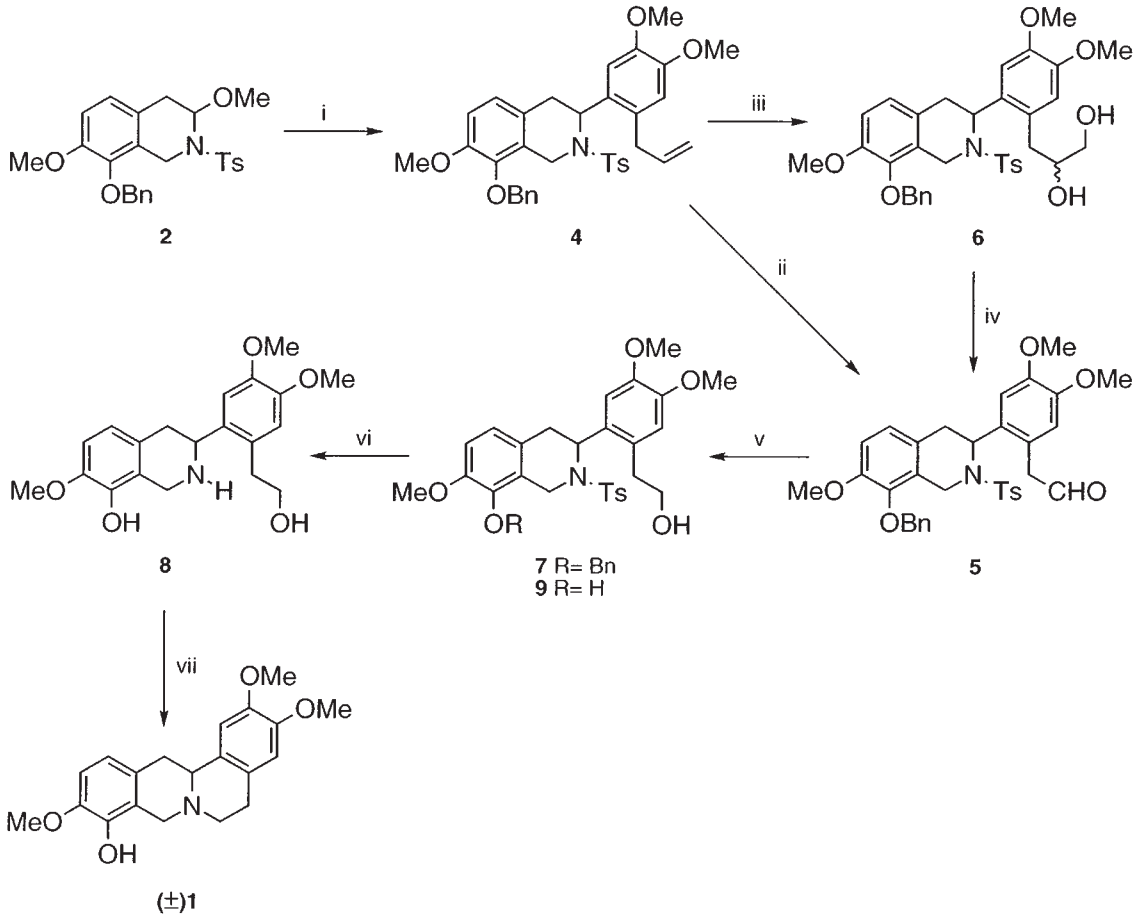
(±)-Schefferine, (±)-1

In addition, (±)-schefferine was isolated as a minor product resulting from the Mannich reaction of a 1-benzyltetrahydroisoquinoline with formaldehyde generated in situ during the photolysis of the starting heterocycle (5). Interestingly, better yields of (±)**–1** were realized when photolysis of bromoenamides was employed as synthetic strategy (6).



Tracer experiments on *Stephania glabra* Miers (Menispermaceae) evidenced high incorporation of (±)-[aryl-^{3}H]-schefferine into corydalmine but not into stepholidine, indicating that **1** might be a possible intermediate of the biosynthesis of corydalmine from reticuline (7*a*). Likewise, schefferine has been postulated as an intermediate in the biosynthesis of sinactine from reticuline (2*a*) and as a precursor of tetrahydropalmatine (7*b*).

We have reported a convenient entry to 3-substituted tetrahydroisoquinolines featuring the reaction of silicon-based nucleophiles with tosyliminium ions, generated upon addition of Lewis acids to tosylamidals (8). By capturing the tosyliminium ions with electron rich aromatics, such as phenols and their ethers, we recently extended the scope of this transformation to the elaboration of the very useful 3-aryl tetrahydroisoquinolines (9).

Herein, we disclose the details of a new and efficient total synthesis of (±)-schefferine via a new approach, consisting in the tosyliminium ion mediated preparation of a 3-aryl

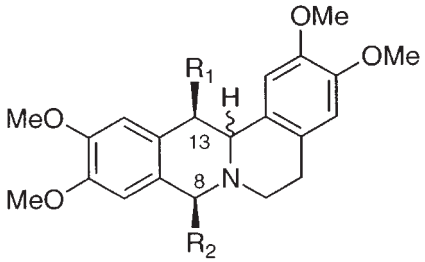
Scheme 1. Reagents and conditions: (*i*) 4-allyl-1,2-dimethoxybenzene (**3**), $BF_3{\cdot}Et_2O$, CH_2Cl_2, –78°C, 15 min, –30°C, 30 min; (*ii*) OsO_4 (cat.), $NaIO_4$, THF–H_2O (3:1); (*iii*) OsO_4 (cat.), NMO, Me_2CO–H_2O–$_t$BuOH (4:2:1); (*iv*) $NaIO_4$, THF–H_2O (3:1); (*v*) $NaBH_4$, MeOH–Et_2O (4:1); (*vi*) (1) Na, NH_3, –33°C; (2) NH_4Cl, –33°C→ rt; and (*vii*) PPh_3, DEAD, HBF_4, THF, reflux.

tetrahydroisoquinoline intermediate and a Mitsunobu-type intramolecular amination (10).

Although syntheses of alkaloids have made extensive use of acyliminium ion chemistry (11), the reactivity of the related tosyliminium ions has been comparatively less explored.

The known amidal **2** (8) was treated at –78°C with the commercially available 4-allyl-1,2-dimethoxybenzene (3) and $BF_3{\cdot}Et_2O$ to give the 3-aryl tetrahydroisoquinoline derivative **4** in 88% yield. β-Phenethyl alcohol **7** was then synthesized from **4** in two steps. First, sodium periodate-assisted oxidative olefin cleavage with osmium tetraoxide as catalyst in THF–water (12) gave aldehyde **5** in 77% yield; then, reduction of aldehyde **5** with sodium borohydride in dry methanol furnished alcohol **7** in 92% yield.



Because phenylacetaldehyde **5** tended to overoxidize, probably through its enol form, the dihydroxylation and oxidative fission steps were carried out separately, employing NMO as cooxidant during the dihydroxylation step, which resulted in an increased overall yield of 89%.

Debenzylation, desulfonylation, and formation of ring B were required to complete the synthesis. Our previous work suggested converting **7** into **8** by a stepwise process, consisting of catalytic debenzylation to yield phenol **9**, followed by sodium-mediated cleavage of the sulfonamide moiety. Although this approach allowed a better control of the delivery of the alkaline metal to the reaction medium to avoid formation of undesirable over-reduced side-products and furnish optimum yields of tetrahydroisoquinolines (13), reaction of **7** with sodium in liquid ammonia was found to cleanly effect simultaneous cleavage of both protective groups (14), providing amino alcohol **8** in 83% yield.

Finally, intramolecular Mitsunobu amination of **8** with the DEAD–PPh_3 couple in dry THF containing 1 equiv of HBF_4 gave 82% of (±)-schefferine [(±)–**1**], exhibiting a melting point and ^{1}H NMR spectrum identical with reported data (4*b*, 5*b*). The use of HBF_4 as additive was key for the success of this transformation to cyclized product in good yields. Protonation of the DEAD-derived hydrazide anion intermediate, is presumed to avoid its involvement as a competing nucleophile in the amination process (10*b*).

Dean and Rapoport (15) reported the syntheses of 8- and 13-methylberbines **10** and **11** by intramolecular cyclizations involving iminium ions formed by α-aminoacid decarbonylation. More recently, Padwa and Waterson (16) described a protoberberine synthesis which furnished **12**, employing a thionium–*N*-acyliminium ion cyclization of amido sulfoxides for the assembly of rings B and C. Unlike the above presented sequence leading to (±)-schefferine, these iminium ion-based synthetic strategies involved construction of ring B by formation of the C_6—N bond prior to the elaboration of the C_{14}—C_{14a} bond between rings A and C. The scope and limitations of this alternative protocol are currently

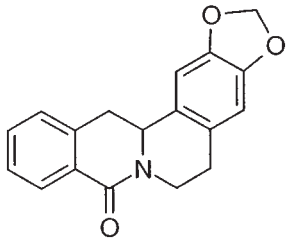
being evaluated for the synthesis of protoberberine-type natural products.



Experimental section

Melting points were measured on an Ernst Leitz hot-stage microscope apparatus and are uncorrected. IR spectra were taken on a Beckman Acculab 8 spectrophotometer with solid samples as KBr pellets and liquid samples as films. ^{1}H and ^{13}C NMR spectra were recorded in $CDCl_3$, on a Bruker AC-200E instrument at 200.13 and 50.33 MHz respectively, with TMS as the internal standard. ^{13}C NMR resonances corresponding to two carbon atoms are designated with an asterisk while those assigned to three carbons are marked with "#." High resolution mass spectra were obtained from UMYMFOR (FCEN, Buenos Aires).

4-Allyl-1,2-dimethoxybenzene was purchased from Aldrich Chemical Co. and used without further purification. All reactions were carried out in a dry oxygen-free nitrogen atmosphere, monitored by thin layer chromatography on Merck's precoated silica gel 60 F_{254} TLC plates developed in hexane–EtOAc (7:3) or $CHCl_3$–EtOH (8:2) and detected by examination under UV light followed by spraying with 2% *p*-anisaldehyde–sulfuric acid reagent in EtOH or 0.2% ninhydrin in EtOH. Careful heating improved the sensitivity of the detection. All new compounds gave a single spot by TLC. Flash chromatography was carried out on Merck Kieselgel 60 (0.04–0.063 mm), packed in hexane; elution was with mixtures of hexane–EtOAc, using gradient techniques. Compounds were preadsorbed from Et_2O or CH_2Cl_2 solutions onto the adsorbent before column chromatography.

3-(2-Allyl-4,5-dimethoxyphenyl)-8-benzyloxy-7-methoxy-2-(toluene-4-sulfonyl)-1,2,3,4-tetrahydroisoquinoline (4)

A CH_2Cl_2 solution of 4-allyl-1,2-dimethoxybenzene (0.88 mL, 0.49 mmol) was added to amidal **2** (110 mg, 0.243 mmol) in anhydrous CH_2Cl_2 (3 mL) and the resulting solution was cooled to –78°C. Then, a solution of $BF_3{\cdot}Et_2O$ in CH_2Cl_2 (0.51 mL, 0.29 mmol) was added dropwise. Stirring continued for 15 min at –78°C and 30 min at –30°C. Then the reaction mixture was rapidly poured over brine (10 mL) and the products were extracted with EtOAc (4 × 25 mL). Drying (Na_2SO_4), concentration, and chromatography of the combined ethereal extracts afforded the 3-aryltetrahydroisoquinoline derivative **4** (128 mg, 88%) as a colourless oil which crystallized on standing, mp 120–121.5°C (hexane–EtOAc). IR (neat) (cm^{-1}): 2920, 2850, 1600, 1500, 1440, 1350, 1280, 1160, 1070, 910, 820, 730, and 660. ^{1}H NMR δ: 2.41 (s, 3H), 2.79 (dd, *J* = 9.0, 11.8 Hz, 1H), 3.36 (brd, 2H), 3.60 (s, 3H), 3.68 (dd, *J* = 5.4, 11.8 Hz, 1H), 3.85 (s, 3H), 3.87 (s, 3H), 3.89 (d, *J* = 15.9 Hz, 1H), 4.38 (dd, *J* = 5.4, 9.0 Hz, 1H), 4.55 (d, *J* = 15.9 Hz, 1H), 4.93–5.10 (m, 2H), 5.03 (d, *J* = 11.1 Hz, 1H), 5.12 (d, *J* = 11.1 Hz, 1H), 5.85–6.06 (m, 1H), 6.23 (s, 1H), 6.48 (d, *J* = 8.7 Hz, 1H), 6.68 (s, 1H), 6.71 (d, *J* = 8.7 Hz, 1H), 7.25 (d, *J* = 8.2 Hz, 2H), 7.30–7.50 (m, 5H) and 7.57 (d, *J* = 8.2 Hz, 2H). ^{13}C NMR δ: 21.37, 36.91, 39.77, 44.31, 49.89, 55.69,* 55.81, 74.22, 111.20, 112.42, 112.71, 115.79, 124.39, 126.77, 127.49,* 127.97,# 128.25,* 129.47,* 130.11, 130.22, 132.34, 133.57, 137.32, 137.42, 143.28,* 147.24, 147.62, and 150.25. 12

2-{2-[8-Benzyloxy-7-methoxy-2-(toluene-4-sulfonyl)-1,2,3,4-tetrahydroisoquinolin-3-yl]-4,5-dimethoxyphenyl}-ethanol (7)

A 2% w/v solution of OsO_4 in *tert*-butanol (0.051 mL) was added to a mixture of allyl tetrahydroisoquinoline **4** (125 mg, 0.21 mmol) and potassium periodate (144 mg, 0.63 mmol) in 3:1 THF–water (4 mL). The mixture was stirred overnight at room temperature and quenched with 10% sodium hydrogensulfite (5 mL); Celite (1 g) was added and stirring continued for an additional 1 h, then the suspension was filtered under reduced pressure through Celite contained in a Büchner funnel and the crude reaction product was exhaustively extracted with EtOAc (5 × 20 mL). The organic portion was dried (Na_2SO_4), concentrated, and chromatographed to furnish aldehyde **5** (96 mg, 77%) as an oil. IR (neat) (cm^{-1}): 2960, 2870, 1750, 1630, 1510, 1480, 1380, 1300, 1190, 1090, 970, 840, 760, and 680. ^{1}H NMR δ: 2.42 (s, 3H), 2.83 (dd, *J* = 8.5, 11.9 Hz, 1H), 3.55–375 (m, 3H), 3.60 (s, 3H), 3.85 (s, 3H), 3.86 (s, 3H), 3.93 (d, *J* = 16.5 Hz, 1H), 4.22 (dd, *J* = 5.0, 8.5 Hz, 1H), 4.47 (d, *J* = 16.5 Hz, 1H), 5.03 (d, *J* = 11.2 Hz, 1H), 5.13 (d, *J* = 11.2 Hz, 1H), 6.34 (s, 1H), 6.52 (d, *J* = 8.6 Hz, 1H), 6.63 (s, 1H), 6.72 (d, *J* = 8.6 Hz, 1H), 7.25 (d, *J* = 8.3 Hz, 2H), 7.35–7.52 (m, 5H), 7.58 (d, *J* = 8.3 Hz, 2H) and 9,70 (s, 1H). ^{13}C NMR δ: 21.32, 40.46, 44.22, 47.64, 49.72, 55.62, 55.72,* 74.16, 111.28, 112.80, 113.41, 122.17, 124.36, 126.61, 127.38,* 127.96, 128.24 (4 carbons), 129.33, 129.49,* 133.41, 133.56, 137.28, 143.18, 143.39, 147.86, 148.19, 150.39, and 198.74. HREIMS calcd. for $C_{34}H_{35}NO_7S$: 601.2134; found: 601.2132.

Without further purification, aldehyde **5** (66 mg, 0.11 mmol) was dissolved in a 4:1 MeOH–Et_2O mixture (10 mL) kept at 0°C in an ice water bath. Sodium

© 2000 NRC Canada

borohydride (10 mg, 0.26 mmol) was added, stirring continued during 15 min and the reaction was quenched with 10% w/v citric acid solution (10 mL). The organic solvent was evaporated under reduced pressure and the reaction product was extracted with EtOAc (4 × 15 mL). The organic extract was dried (Na_2SO_4), concentrated under reduced pressure, and the glassy residue was chromatographed, yielding alcohol **7** (61 mg, 92%), as a solid, mp 148–149.5°C. IR (KBr) (cm^{-1}): 3520, 2960, 2860, 1620, 1530, 1480, 1370, 1310, 1190, 1090, 980, 830, 760, and 680. ^{1}H NMR δ: 1.90 (brs, $w_{1/2}$ = 13 Hz,1H), 2.40 (s, 3H), 2.84 (dd, *J* = 7.4, 10.2 Hz, 1H), 2.88–3.02 (m, 2H), 3.59 (s, 3H), 3.69 (dd, *J* = 4.5, 10.2 Hz, 1H), 3.76–3.90 (m, 2H), 3.84 (s, 3H), 3.87 (s, 3H), 3.91 (d, *J* = 15.9 Hz, 1H), 4.43 (dd, *J* = 4.5, 7.4 Hz, 1H), 4.55 (d, *J* = 15.9 Hz, 1H), 5.03 (d, *J* = 11.2 Hz, 1H), 5.12 (d, *J* = 11.2 Hz, 1H), 6.22 (s, 1H), 6.48 (d, *J* = 8.6 Hz, 1H), 6.70 (d, *J* = 8.6 Hz, 1H), 6.74 (s, 1H), 7.25 (d, *J* = 8.2 Hz, 2H), 7.30–7.51 (m, 5H) and 7.58 (d, *J* = 8.2 Hz, 2H). ^{13}C NMR δ: 21.34, 35.69, 39.60, 44.32, 50.14, 55.64,* 55.77, 63.60, 74.18, 111.16, 112.23, 112.76, 124.35, 126.73, 127.39,* 127.95, 128.20,* 128.25,* 129.04, 129.48,* 130.11, 132.61, 133.54, 137.37, 143.24, 143.33, 147.38, 147.59, and 150.25. HREIMS calcd. for $C_{34}H_{37}NO_7S$: 603.2291; found: 603.2287.

2-{2-[8-Benzyloxy-7-methoxy-2-(toluene-4-sulfonyl)-1,2,3,4-tetrahydroisoquinolin-3-yl]-4,5-dimethoxyphenyl}-acetaldehyde (5)

A 2% w/v solution of OsO_4 in *tert*-butanol (0.100 mL) was added to a mixture of allyl tetrahydroisoquinoline **4** (250 mg, 0.42 mmol) and NMO (103 mg, 0.88 mmol) in 4:2:1 acetone–water–*tert*-butanol (8 mL). The mixture was stirred overnight at room temperature and then quenched with 10% sodium hydrogensulfite (5 mL). Celite (1 g) was added and stirring continued for an additional 1 h, when the suspension was filtered under reduced pressure through Celite contained in a Büchner funnel and the crude reaction product was exhaustively extracted with EtOAc (5 × 20 mL). The organic portion was dried (Na_2SO_4) and concentrated to yield **6**, as an oily 1:1 epimeric mixture (251 mg, 95%). IR (film) (cm^{-1}): 3450, 2950, 2860, 1600, 1500, 1290, 1190, 1070, 920, and 740. Without further purification, the mixture of diols (125 mg) was dissolved in 3:1 THF–water (4 mL) and treated with sodium periodate (101 mg, 0.44 mmol). The reaction was stirred 2 h at room temperature, then it was diluted with brine (5 mL) and extracted with EtOAc (5 × 20 mL). The combined organic extracts were dried (Na_2SO_4), concentrated in vacuum, and chromatographed, providing aldehyde **5** (111 mg, 94%) as an oil.

3-[2-(2-Hydroxyethyl)-4,5-dimethoxyphenyl]-8-hydroxy-7-methoxy-1,2,3,4-tetrahydroisoquinoline (8)

Anhydrous ammonia (10 mL) was condensed in a three-necked flask, fitted with a dry ice – acetone condenser protected with a calcium chloride tube and an ammonia inlet, and containing sulfonamide **7** (50 mg, 0.083 mmol) dissolved in dry THF (3 mL). With rapid stirring, sodium metal contained in a graduated glass tube was added portionwise to the reaction mixture until the characteristic blue colour persisted for 10 min. The reaction was quenched with ammonium chloride (50 mg) and MeOH (2 mL). The ammonia was slowly evaporated and the reaction products were mixed with silica gel. The solvent was removed under reduced pressure and the adsorbed reaction products were chromatographed (CH_2Cl_2–EtOH), furnishing **8** (25 mg, 83%) as an oil. IR (neat) (cm^{-1}): 3550–2500, 2960, 2880, 1630, 1500, 1470, 1280, 1060, 920, and 740. ^{1}H NMR δ: 2.91 (dd, *J* = 8.8, 12.3 Hz, 1H), 2.94 (brd, 2H), 3.31 (dd, *J* = 5.2, 12.3 Hz, 1H), 3.64 (s, 3H), 3.75–3.92 (m, 1H), 3.80 (s, 3H), 3.86 (s, 3H), 4.00–4.30 (m, 6H), 4.35 (dd, *J* = 5.2, 8.8 Hz, 1H), 6.25 (d, *J* = 8.5 Hz, 1H), 6.34 (s, 1H), 6.59 (d, *J* = 8.5 Hz, 1H) and 6.72 (s, 1H). ^{13}C NMR δ: 35.99, 39.31, 43.09, 50.76, 55.72, 55.77, 55.85, 63.62, 106.92, 112.18, 112.84, 119.97, 121.75, 129.17, 131.31, 134.07, 141.37, 144.17, 147.31, and 147.42. HREIMS calcd. for $C_{20}H_{25}NO_5$: 359.1733; found: 359.1736.

(±)-2,3,10-Trimethoxy-9-hydroxy-5,6,13,13a-tetrahydro-8*H*-dibenzo[*a*,*g*]quinolizine ((±)-schefferine, (±)-1)

Diethyl azodicarboxylate (0.022 mL, 0.122 mmol) was added all at once to a stirred solution of **8** (22 mg, 0.061 mmol), triphenylphosphine (32 mg, 0.122 mmol), and ethereal HBF_4 (0.008 mL, 0.067 mmol) in THF (2 mL). The reaction was stirred under reflux until complete conversion of the aminoalcohol was assessed by TLC; then, the volatiles were removed under reduced pressure and the remaining oil was chromatographed, yielding (±)-**1** (17 mg, 82%) as a solid, mp 146.5–148°C (lit. (5*b*) 144–145°C and (4*b*) 147–148°C). Electrochemical studies of Schiff base compounds derived from antipyrine nucleus in ethanolic buffer solutions

Ibrahim S. El-Hallag, Gad B. El-Hefnawy, Youssef. I. Moharram, and Enass. M. Ghoneim

Abstract: The electrochemical behaviour of Schiff base compounds derived from an antipyrine nucleus was investigated in 30% (v/v) ethanolic buffer solutions (pH 3–11) using various electrochemical techniques at mercury electrode. The results showed that, the total limiting current of each of the studied compounds corresponds to 2-electron transfer process. The mechanistic pathway of the electrode reaction of the investigated compounds at mercury electrode, the effect of the medium, and the evaluation of the electrode reaction parameters were illustrated and discussed.

Key words: Schiff base, antipyrine nucleus, electrode reaction, electrochemical parameters, cyclic voltammetry.

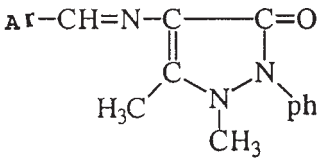
Résumé : Opérant dans des solutions tampons (pH allant de 3 à 11) contenant 30% (v/v) d'éthanol et faisant appel à diverses techniques électrochimiques avec électrode de mercure, on a étudié le comportement électrochimique de diverses bases de Schiff dérivées du noyau antipyrine. Les résultats montrent que, le courant limite total de chacun de composés étudiés correspond à un processus de transfert d'électrons 2-. On illustre et on discute des voies mécanistiques de la réaction à l'électrode, de l'effet du milieu et de l'évaluation des paramètres de la réaction à l'électrode.

Mots clés : base de Schiff, noyau antipyrine, réaction à l'électrode, paramètres électrochimiques, voltampérométrie cyclique.

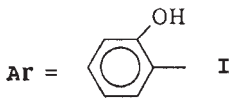
[Traduit par la Rédaction]

Introduction

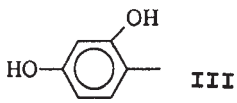
The electroreduction of Schiff base compounds was the subject of several interesting investigations (1–6). Generally, the electroreduction of such compounds at mercury electrode in acidic and alkaline solutions consume two electrons per reactant molecule for saturation of a carbon–nitrogen double bond or four electrons for its reductive splitting.



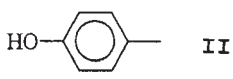
In this paper we report the electrochemical behaviour of some Schiff base compounds derived from an antipyrine nucleus in ethanolic buffer B.R. solutions. The electrochemical parameters of the electrode process were evaluated using dc–polarography, cyclic voltammetry and controlled potential coulometry. Verification of the electrochemical parameters determined experimentally via digital simulation method was also considered. The mechanistic pathway of the electrode reaction was discussed.



Experimental



Chemicals and solutions



The compounds under consideration were prepared by adding a solution of 4-aminoantipyrine (0.01 mol) dissolved in ethanol to an ethanolic solution of 0.01 mol of salicyladehyde, *p*-hydroxybenzaldehyde, 2,4-dihydroxybenzaldehyde, and 2-hydroxy-1-naphthaldehyde. Then, the mixture was heated and refluxed for about 2 h. On cooling the mixture, the solid compounds were separated and filtered off. The crude products were recrystallized several times from hot ethanol, washed with diethyl ether, and finally dried in a vacuum desiccator. The purity of the compounds was ascertained by crystallization until a constancy of the mp was reached. The structure of the prepared compounds were confirmed by elemental and spectral analysis. The prepared compounds have the general structure formula

Fig. 1. Dc–polarograms of **III** in buffer solutions of different pH values, containing 30% (v/v) ethanol.

Stock solutions (2.5×10^{-3} M) of the prepared compounds were obtained by dissolving the accurate mass of the solid compound in appropriate volume of ethanol. Britton–Robinson buffer series (pH 2–12) containing 30% (v/v) ethanol were prepared from analytical grade chemicals and used as supporting electrolyte.

Instrumentation

The dc–polarograms were recorded using a Sargent Welch polarograph model 4001. The capillary characteristics were m = 1.03 mg s^{-1}, t = 3.3 s $drop^{-1}$ at mercury height (h) = 60 cm. The cyclic voltammograms were recorded using a polarographic Analyzer model 264A-PAR (from EG & G) and electrode assembly 303 A with a hanging mercury drop electrode (HMDE) of area = 2.6×10^{-2} cm^2 as a working electrode, Ag–AgCl as a reference electrode, and a Pt-wire as a counter electrode. The number of electrons consumed in the overall electrode reaction was determined using coulometry system model 380-PAR with a mercury pool cathode, saturated calomel electrode as a reference, and a Pt-wire as counter electrode. The electronic spectra were measured using Shimadzu UV–vis spectrophotometer model 160 A. Digital simulation of the extracted parameters for the cyclic voltammetric experiments were run on an PC computer using Condesim software packages (from EG & G) which allows accurate digital simulation for a wide range of mechanisms.

Results and discussion

Dc–polarography

The dc–polarographic behaviour of 2.5×10^{-4} M of Schiff base compounds (**I–IV**) was investigated in Britton–Robinson buffer solutions of pH 3–11 containing 30% (v/v) ethanol. It was found that in strong acidic solutions (pH < 3.0), the polarograms of all compounds under investigation do not show any reduction wave except the hydrogen wave which appears at a potential not more than –1.1 V. However, in solution of 3 ≤ pH ≤ 4.0 the polarograms of the studied compounds show a single reduction wave (A) Fig. 1. At pH > 4.0 a second ill-defined wave (B) appeared. This wave becomes well-defined on increasing the pH up to 7.0, its height increase at the expense of first wave (A) until the two waves merge together and become one wave. This behaviour is characteristic for compounds (**I–III**) while the polarograms of compound (**IV**) exhibit two waves of almost equal height in slightly acidic solutions and the height of the first wave decreases slightly with increasing pH. It is important to note that the total limiting current of the studied compounds corresponds to a two-electron transfer process as evidenced from coulometry studies. Figure 1 gives an example of the recorded dc–polarograms of compound (**III**).

[b](*ii*) Second wave.

The plots of i_l for compounds (**I–III**) as a function of pH of the medium recall a dissociation curve of two steps denoting the presence of an acid–base equilibrium. The height of the reduction waves is proportional to the square root of mercury height (h). The straight lines obtained on plotting log i_l vs. log h have slope values amounting to 0.45–0.53 revealing that the reduction process of the electrode reaction is mainly diffusion controlled (7). Also, the reduction waves of the Schiff base compounds under consideration were analyzed using the fundamental equation of irreversible polarographic waves (8)

$$[1] \qquad E = E_{1/2} - \frac{0.0591}{\alpha n_a} \log \frac{i}{(i_d - i)}$$

The low values (<0.5) of the cathodic symmetry coefficient (α) obtained from the slope S_1 ($S_1 = 0.0591/\alpha n_a$) of the E vs. log ($i/i_d - i$) plots indicate the irreversible nature of the electrode process. The most probable α-values are obtained for n_a = 1.0 (Table 1), where n_a is the number of electrons participating in the rate-determining step.

On increasing the pH of the electrolysis solution, the half-wave potentials ($E_{1/2}$) of the polarographic wave get shifted to more negative values (Table 1), denoting that the

[b](*ii*) Second wave.

hydrogen ions are consumed in the reduction process (9). The $E_{1/2}$–pH plots of the first reduction wave of the studied compounds give a break at pH 4.5–5.5, whereas the $E_{1/2}$–pH plots of the second one exhibit a break at pH 8–9, indicating *the protonation of -CH=N- center and the ionization of OH group of the reactants* at those pH values. From the slope values of logarithmic analysis (S_1) and that of $E_{1/2}$–pH plots (S_2) ($S_2 = (0.0591/\alpha n_a)Z_H^+$), the number of hydrogen ions participating in the rate-determining step is found to equal unity ($Z_H^+ = S_2/S_1$).

Controlled potential coulometry (CPC)

A coulometry measurement is performed by adding 10 mL of Britton–Robinson buffer (slightly acidic or alkaline) to the coulometric cell. The specified potential for each compound was applied to the cell and the electrolysis was continued until the background current attained a constant value. An amount of the reactant solution was then added (1 mL of 10^{-3} M) and the electrolysis was allowed to proceed until completion. The accumulated charge (Q) was read directly from the digital coulometer and the number of electrons (n) consumed for complete reduction of the reactants was calculated using the relation Q = nM/Fw), in which w is the mass (in grams) of the reactant, M is the reactant molecular weight and F is the Faraday's constant. The results obtained denoted that (n) equals two electrons per reactant molecule in both acidic and alkaline media.

Cyclic voltammetry

The voltammograms of the studied compounds in B.R. buffer solution at different scan rates ranging (10–500 mV/s) exhibit one or two well-defined cathodic peaks depending on the pH of the medium and nature of the substituent. In the reverse scan (anodic direction) no oxidation peaks were observed which confirms the irreversible nature of the reduction wave. The extent of the cathodic shift of the peak potential (E_p) as a function of the sweep rate, the difference between the potentials at half-peak ($E_{p/2}$) and at the peak (E_p), confirm the irreversible nature of the electrode process (10). So, the cathodic peak potential (E_p) varies with the logarithm of the potential sweep rate according to the eq. [2] (11)

$$[2]\qquad E_p = -1.14\left(\frac{RT}{\alpha n_a F}\right) + \left(\frac{RT}{\alpha n_a F}\right)\ln\left(\frac{(k_{f,h})}{D^{1/2}}\right) - \left(\frac{RT}{2\alpha n_a F}\right)\ln(\alpha n_a v)$$

On plotting E_p or $E_{p/2}$ for the investigated compounds vs. log v, linear correlations are obtained and the cathodic symmetry coefficient (α) values at selected pH values were calculated from the slopes of these plots. Values of the symmetry coefficient (α) were also determined from the difference of peak and half-peak cathodic potentials by means of the eq. (10)

$$[3]\qquad E_p - E_{p/2} = 1.857(RT/\alpha n_a F)$$

and were found to be less than 0.5 when n_a = 1 (Table 2), confirming the irreversible nature of the reduction process. Good agreement is found between α and n_a values calculated from the cyclic voltammetry data and their values obtained from dc–polarographic measurements.

For the irreversible charge transfer processes (12), the peak current (i_{pirr}) can be expressed by the following equation:

$$[4]\qquad i_{pirr} = 2.99 \times 10^5 n(\alpha n_a)^{1/2} A D^{1/2} C v^{1/2}$$

in which i_{pirr} is the peak current in amp, *and C is the concentration of the reactant species which equals 1.25 × 10^{-4} M in the present study*, and the other terms have their usual meaning.

On plotting the i_{pirr} vs. $v^{1/2}$ at different pH values straight lines with some slight deviation from the origin are obtained revealing the diffusion character of the current (13). Table 2 revealed that the peak width ($E_p - E_{p/2}$) grows larger for the higher molecular weight compounds as well as with increasing pH of the medium, indicating increased irreversibility nature of the electrode process as the molecular weight and (or) the pH are increased (14). The E_p vs. pH plots of the first peak of the investigated compounds give two segments with slope of 60–95 mV/pH which is not much different from the values obtained from dc–polarography experiments and indicates that the species in solution undergoes a fast protonation at the interface, prior to the reduction process (14).

Diffusion coefficient (D) of Schiff base compounds was determined from the following equation (15, 16)

$$[5]\qquad I_{lim} = \frac{i_{pirr}}{3.099(\alpha n_a v)^{1/2}}$$

Also, in the same manner, the ratio $[(dI_1/dt)_f]_{irr}/i_{pirr}$ for irreversible charge transfer can be used for determining the diffusion coefficient of the electroactive species via the following relation (16, 17)

$$[6]\qquad \frac{[dI_l/dt)_f]_{irr}}{i_{pirr}} = 3.73(\alpha/n_a)^{1/2} n v^{1/2}$$

where $[(dI_1/dt)_f]_{irr} = \alpha n^2 F^2 SCD^{1/2} v/3.367RT$ is the height of the forward sweep of the deconvoluted current, and the other terms have their usual meaning. Hence from relation [6], the ratio $[(dI_1/dt)_f]_{irr}$ can be determined which gives another accurate route for determination of the diffusion coefficient.

Values of diffusion coefficient (D) determined via different methods (Table 3), indicate a good agreement between the values of D estimated via these methods. As a result of the disappearing of the anodic peak coupled with the cathodic one of the investigated compounds the heterogeneous rate constant (k_{fh}) of the irreversible electrode reaction can be calculated from cyclic voltammetric data using eq. [2] (11). The plot of E_p vs. log v gives the value of the heterogeneous rate constant (k_{fh}). Also, from the values of $E_p - E_{p/2}$ vs. the dimensionless parameter ψ, the heterogeneous rate constant is estimated. The values of k_{fh} is calculated by performing several simulated cyclic voltammograms with various values of k_{fh}. The true value of k_{fh} is established when the values of i_p, E_p, and $E_p - E_{p/2}$ of the simulated cyclic voltammograms agree well with those values of the experimental one. Values of k_{fh} determined from these methods were reported in Table 4 confirming the agreement and the accuracy of the heterogeneous rate constant estimated via different methods.

Verification of the calculated electrochemical parameters via digital simulation

Digital simulation was used for testing the determined accurate values of the cyclic voltammetry parameters as well as obtaining the true information of the type of electrochemical process of the electrode mechanism. In general the testing of parameters is made by matching the simulated voltammogram on the experimental data, using the average experimentally determined parameters. Also, the accuracy of the electrochemical parameters can be tested via the comparison between the peak characteristics (i_p, E_p, $E_p - E_{p/2}$), of the experimental and theoretical cyclic voltammograms (18, 19). The generated cyclic voltammograms have been carried out using CONDESIM software package (from EG & G).

In this work, the nature of the electrode reaction was determined by running digital simulation for the following types of electrochemical reactions: (*i*) $E_{irr}C_{irr}$; (*ii*) $E_{rev}C_{irr}$; (*iii*) $E_{rev}C_{rev}$; (*iv*) E_qC_{irr}; and (*v*) E_{irr}. The electrochemical parameters used are: (*i*) diffusion coefficient of the electroactive species (D); (*ii*) reduction potential ($E°$); (*iii*) concentration of the electroactive species (C); (*iv*) heterogeneous rate constant (k_{fh}); (*v*) scan rate (v); (*vi*) temperature (T); (*vii*) forward homogeneous chemical rate constant (k_f), (*viii*) backward homogenous chemical rate constant (k_b) ($k_c = k_f + k_b$); and (*ix*) symmetry coefficient (α).

Figure 2 shows the comparison between the experimental and generated cyclic voltammograms of $E_{irr}C_{irr}$ model with its convolution and deconvolution voltammetry of the first peak of compound **I** at pH 6.2 and scan rate 0.2 V/s. The value of reduction potential ($E°$) and the values of k_c for chemical steps which following the slow charge transfer were determined using theoretical treatment and their values at the selected pH values are given in Table 5. The values of the measured peak characteristics and the electrochemical parameters used for generating the voltammograms are listed in Table 5 and confirm the accuracy of calculated parameters from experimental cyclic voltammograms. *The slight deviation between the shape of experimental and simulated cyclic*

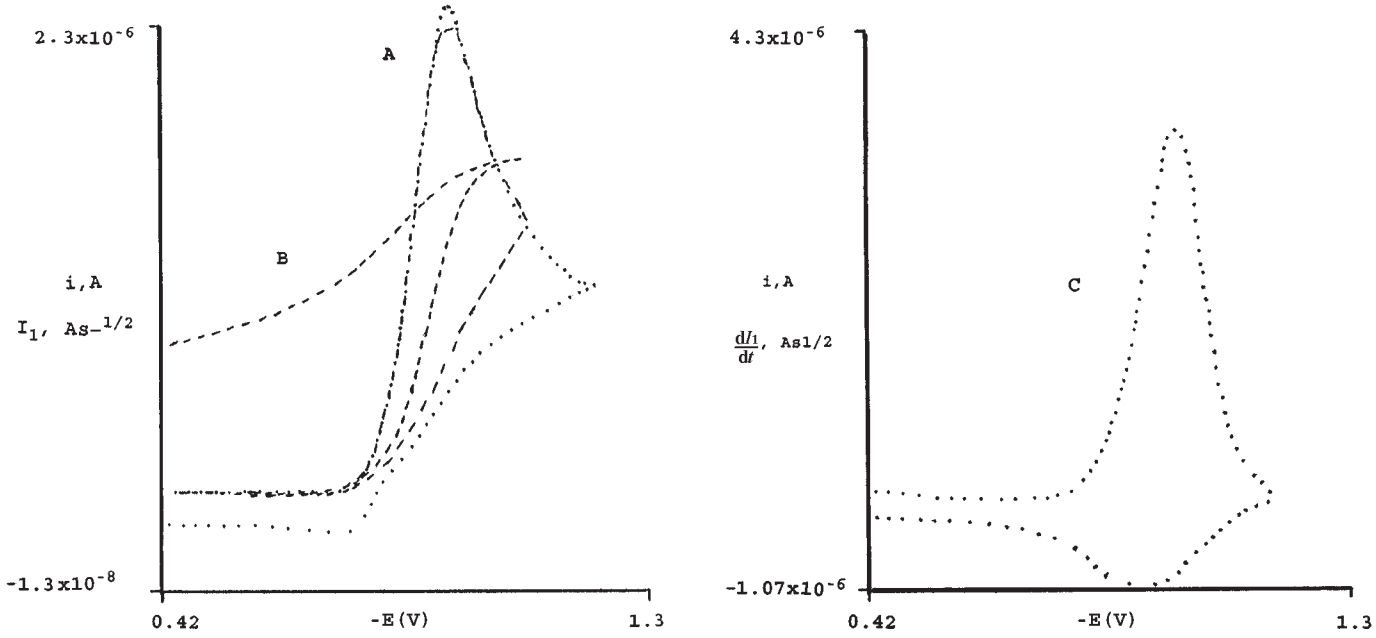
Fig. 2. Matching between experimental (….) and generating (—) voltammograms of I (A), its convolution (B) and deconvolution voltammetry of experimental voltammogram (C) at T = 298 K, sweep rate 0.2 V/s, pH 6.2.



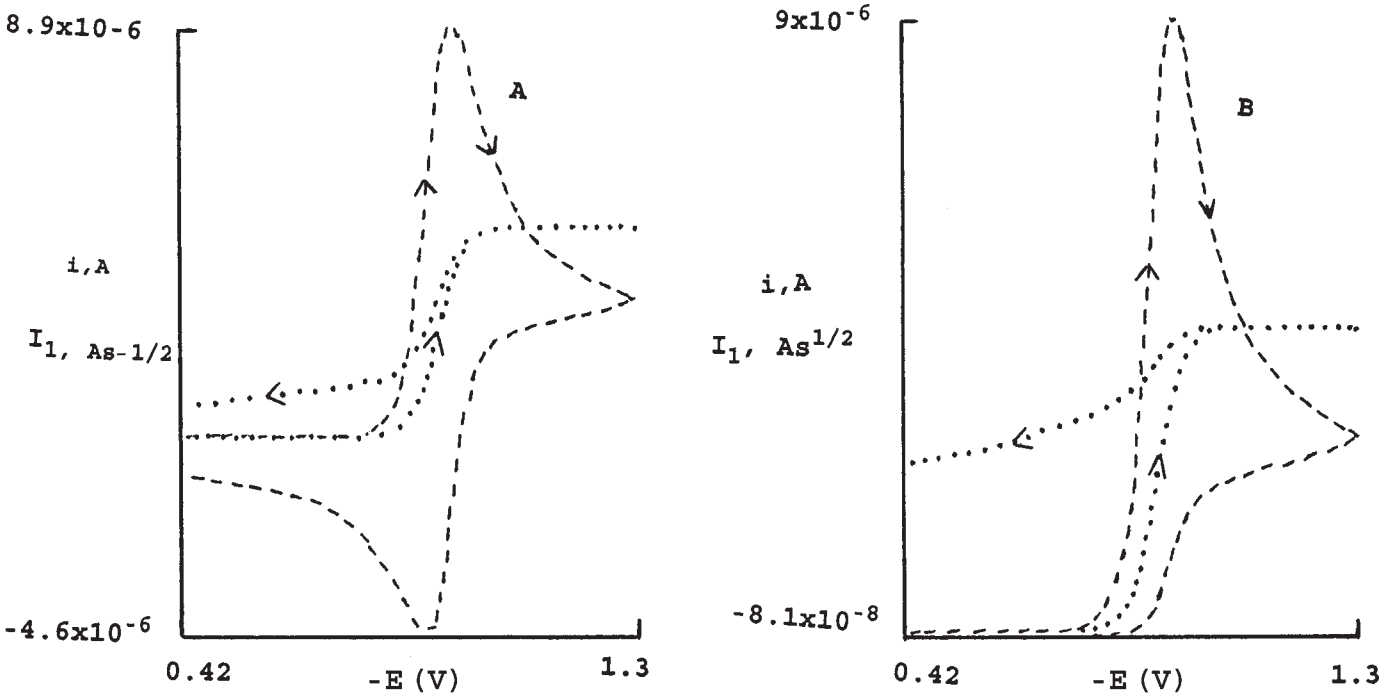


Fig. 3. Generating voltammograms of the models $E_{rev}C_{rev}$ (A) and $E_{rev}C_{irr}$ (B) with their convolution voltammetry at sweep rate 0.5 V/s, T = 298 K.

voltammograms (Fig. 2) is attributed to the weak adsorption of the reactant at electrode surface (20, 21). Figure 3 gives an example response of the simulated cyclic voltammogram along with its convolution voltammetry for the systems $E_{rev}C_{rev}$ and $E_{rev}C_{irr}$ at v = 0.5 V/s which indicate a discrepancy between captured *CV* with these models confirming the validity of the $E_{irr}C_{irr}$ mechanism.

Spectrophotometric determination of the dissociation constants

The spectra of compounds (**I**, **III**, and **IV**) in universal buffer solutions of varying pH values containing 30% (v/v) ethanol are studied within the wavelength range 250–600 nm.

The changes in the absorption spectra on varying the pH of the buffer solution have been used successfully for the de-

termination of the dissociation constant of azomethine group and OH group for the compounds under investigation applying the following methods:

(*i*) The half-height method (22) for which the p*K* is equal to the pH at half height of the absorbance–pH curve, and can be calculated from the following equation

$$[7] \quad pK = pH \text{ at } A_{1/2} = (A_{max} - A_{min})/2;$$

(*ii*) limiting absorbency method (23) using the relation

$$[8] \quad pH = pK + \log\left(\frac{A}{A_{max} - A}\right)$$

Accordingly, a plot of the log $(A/A_{max} - A)$ vs. pH produces a straight line with intercept at log $(A/A_{max} - A) = 0$ equal to p*K*;

(*iii*) The modified limiting absorbency method (24, 25) in which the pK_a is calculated via the following relation

$$[9] \quad pH = pK_a + \log \gamma + \log\left(\frac{A - A_{min}}{A_{max} - A}\right)$$

where the limiting absorbency A_{min} and A_{max} corresponding to the absorbency of the neutral and ionized species liable to exist in the solution of the measuring wavelength and γ is the activity coefficient of the ions which are present in equilibrium. *Since in very dilute solution, log* γ *= 0.0, then eq. [9] takes the following form*

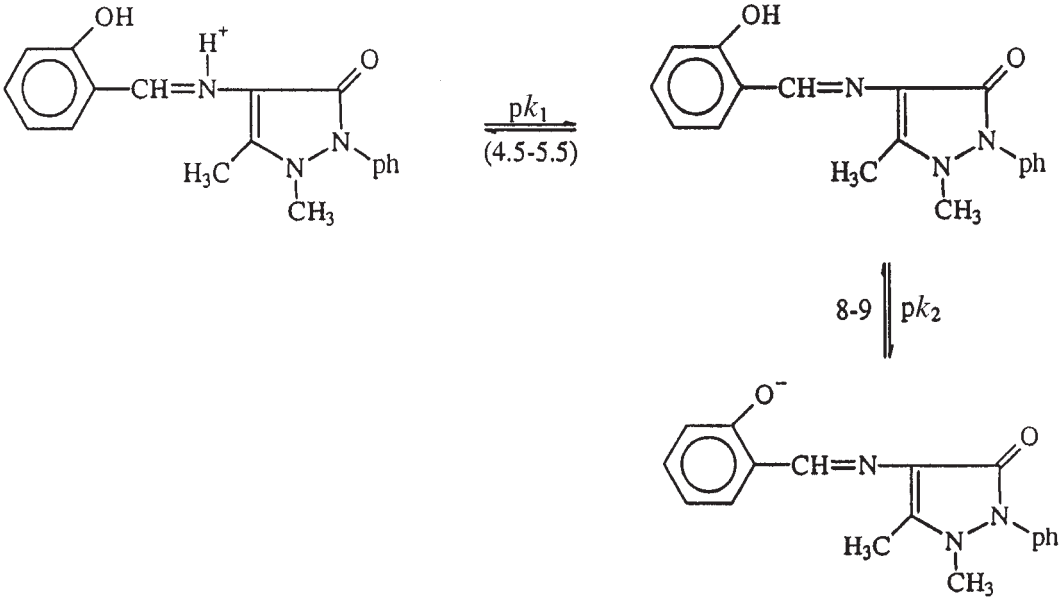
$$[10] \quad pH = pK_a + \log\left(\frac{A - A_{min}}{A_{max} - A}\right)$$

The p*K* value can be evaluated by plotting log $[(A - A_{min})/(A_{max} - A)]$ against pH. Thus, the p*K* value is that corresponding to the value at log $[(A - A_{min})/(A_{max} - A)]$ equals to zero. The values of p*K* obtained from the above three methods are collected in Table 6.

Table 6. pK_a values of the compounds (**I**, **III**, and **IV**) determined from electronic absorption spectra methods.

Comp.	pK_1	pK_2
I	5.2	8.70
III	5.5	9.00
IV	4.5	8.00

Electrode reaction pathway

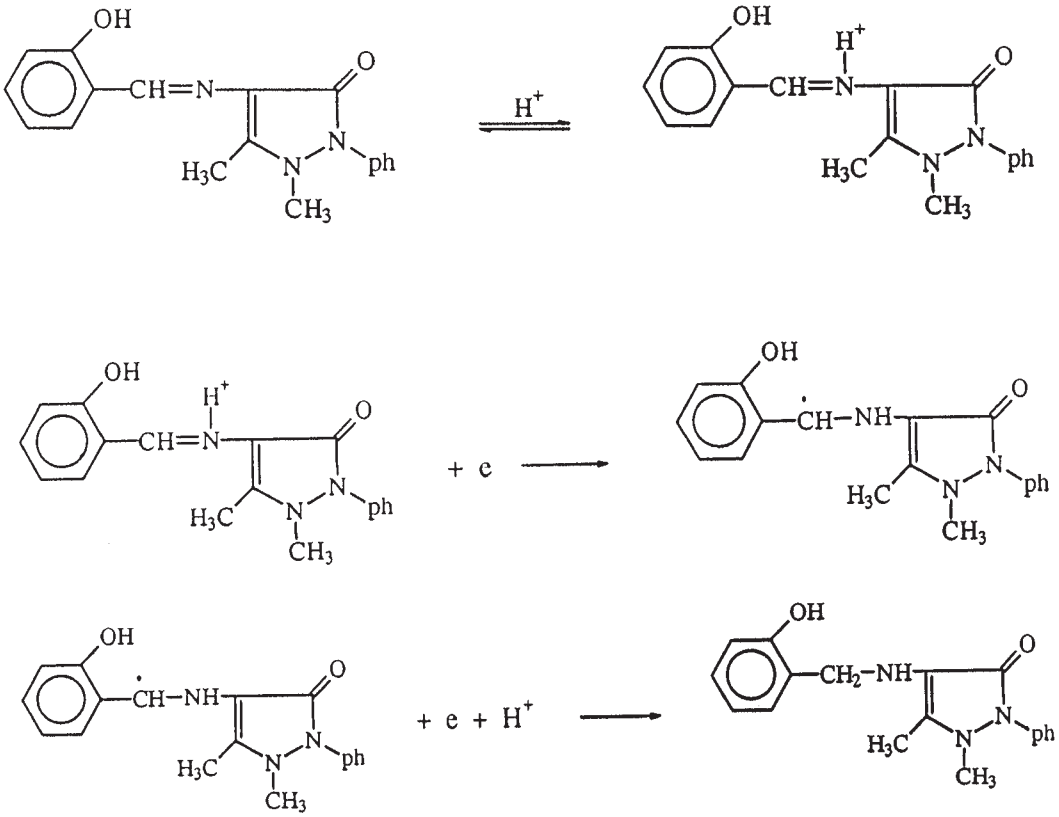


The compounds under consideration are characterized by the presence of azomethine group C=N$^+$H. The number of electrons involved in the reduction is found to be two in acidic as well as in alkaline media as confirmed from a controlled potential coulometry experiments in acidic and alkaline media.

IR (KBr optics) studies of the electrolyzed products gave a broad band at ~3310 cm^{-1} (stretching) which represent the presence of a secondary amine group in the products. Also, it was found that the mp of all the electrolyzed products in the range 338–341°C. All this experimental evidence indicates that the electrode process is irreversible and consumed two-electron reduction transferring the initial electroactive species to an inactive secondary amine (CH_2-NH-).

The $E_{1/2}$–pH plots of the first reduction wave of these compounds give a break at pH 4.5–5.5, whereas the $E_{1/2}$–pH plots of the second one exhibit a break at pH 8–9, indicating the protonation of the azomethine group and dissociation of the OH group of the reactants at these pH values.

On the other hand, calculation of the p*K* values of these compounds using spectrophotometric studies indicated the presence of two p*K* values (Table 6). The equilibria in solution can be represented as follows.



Scheme 2.

Acidity constants and reactivities of the benzidine and *N,N*-dimethylbenzidine dications, the two electron oxidation intermediates of benzidine carcinogens

Robert A. McClelland, Daniel Ren, Raechelle D'Sa, and Abid R. Ahmed

Abstract: This paper describes the behavior in aqueous solutions of the two electron oxidation products of the carcinogens benzidine and *N,N*-dimethylbenzidine. In biological systems there is evidence that these diamines are oxidized by peroxidases, and that a product of this oxidation may be partly responsible for carcinogenicity. Entry into the oxidation products in the present study was provided through the bis-perchlorate salts of dications obtained upon chemical oxidation and through the irradiation of 4′-amino and 4′-*N,N*-dimethylamino-4-azidobiphenyls. The benzidine oxidation product exists in three conjugate acid–base forms, a dication, a monocation and neutral bisimine, with pK_a(1) = 5.0 and pK_a(2) = 9.0. These values stand in marked contrast to ones previously obtained for the two electron oxidation product of *p*-phenylenediamine, pK_a(1) < 1.5 and pK_a(2) = 5.75. The dimethylamino derivative, blocked from forming the neutral form, exists as a dication and monocation, with pK_a = 5.0. Both systems are quite long-lived in aqueous solution, but they do decay on the minutes-to-hours time scale. The kinetics can be explained by reactions of both the dication and the monocation with water, with a reaction of hydroxide and the monocation becoming important around pH 10. One surprising result is that the monocations are two orders of magnitude more reactive than the dications. Thus, at neutral pH the form that exists in both systems is the monocation, and this is the species that is the most reactive towards the solvent. One of the resonance contributors in the monocation is a 4-biphenylylnitrenium ion. Comparison with other 4′-substituted-4-biphenylylnitrenium ions studied by laser flash photolysis shows that the 4′-amino- and 4′-dimethylamino substituents are highly kinetically stabilizing. These cations, for example, are a billion-fold longer-lived in aqueous solution than the parent 4-biphenylylnitrenium ion.

Key words: quinone bisimine, nitrenium, aryl azide.

Résumé : On décrit le comportement de solutions aqueuses de produits provenant de l'oxydation par deux électrons de la benzidine et de la *N,N*-diméthylbenzidine, deux cancérigènes. Il existe des données qui suggèrent que, dans les systèmes biologiques, ces diamines sont oxydées par les peroxydases et qu'un produit de cette oxydation pourrait être partiellement responsable de leur caractère cancérigène. Dans le présent travail, les produits d'oxydation ont été obtenus par le biais des bis(perchlorates) des dications obtenus par une oxydation chimique, suivie d'une irradiation des 4′-amino- et 4′-*N,N*-diméthylamino-4-azidobiphényles. Le produit d'oxydation de la benzidine existe sous trois formes acide-base, un dication, un monocation et une bisamine neutre avec des pK_a(1) = 5,0 et pK_a(2) = 9,0. Ces valeurs diffèrent fortement de celles obtenues antérieurement pour le produit d'oxydation par deux électrons de la *p*-phénylènediamine, pK_a(1) < 5,0 et pK_a(2) = 5,75. Le dérivé diméthylamino qui ne peut conduire à la forme neutre existe comme dication et monocation avec un pK_a = 5,0. En solution aqueuse, les deux systèmes ont une longue durée de vie, mais leur concentration décroît à l'échelle de temps des minutes et des heures. On peut expliquer la cinétique par des réactions du cation ainsi que du monocation avec l'eau, pour lesquelles une réaction de l'hydroxyde et du monocation devient importante à un pH de près de 10. Il est surprenant que les réactions des monocations soient deux ordres de grandeur plus rapides que celles des dications. Ainsi, à un pH neutre, la forme qui existe dans les deux systèmes est le monocation et c'est l'espèce qui est la plus réactive par rapport au solvant. On retrouve l'ion 4-biphénylylnitrénium parmi les formes de résonance du monocation. Une comparaison avec d'autres ions 4-biphénylylnitrénium substitués en 4′ étudiés par photolyse éclair au laser permet de montrer que les substituants 4′-amino et 4′-diméthylamino ont un effet cinétique fortement stabilisant. Par exemple, en solution ces cations ont des temps de vie un million de fois plus élevées que celle de l'ion 4-biphénylylnitrénium parent.

[Traduit par la Rédaction]

Benzidine (**1**) has been recognized as an occupational carcinogen for some time (1) and is now classified as a "proven human" carcinogen (2). Like the majority of carcinogens, the compound is metabolically activated to intermediates that bind covalently to cellular macromolecules, especially DNA. Recent studies have identified the *N*-acetylated guanine adduct **5** (Scheme 1)[2] in peripheral white blood cells (3) and exfoliated urothelial cells (4) obtained from workers exposed to benzidine. This adduct likely arises via an initial acetylation to *N*-acetylbenzidine **2**, a major metabolite (5). Further metabolic activation would lead to an arylnitrenium ion **4**. Such electrophiles are well established as being responsible for the guanine C8 adducts observed with arylamine carcinogens (6–10). Also in parallel with other arylamine carcinogens, *N*-acetylbenzidine is *N*-hydroxylated by cytochrome P-450s (11–13), suggesting that the hydroxylamine **3** is an intermediate between **2** and **4**.

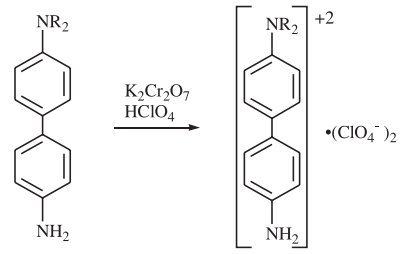
There is also the strong likelihood that non-acetylated intermediates play a role. This appears to be required to explain the formation of urinary bladder tumors in dogs which are deficient in *N*-acetylating enzymes. The parent compound is not a substrate for the P-450s and other enzymes that *N*-hydroxylate other arylamines (11–13). However, it is oxidized by peroxidases (14–21). Although both a cation radical (one electron oxidation) and a dication **6** (two electron oxidation) have been implicated, recent experiments led to the conclusion that it is the two electron product that is responsible for DNA binding (21). The major DNA adducts that are observed are a C8 guanine adduct **8** and a novel cyclic intermediate obtained by further two electron oxidation of this adduct (21). Compound **8** had previously been characterized in nonenzymatic experiments in which DNA was incubated with the bis-perchlorate salt of the dication (22).

It has been suggested that the actual electrophile that reacts with the guanine residue is the monocation **7** (21, 24), an "arylnitrenium ion" when written in the resonance form shown in Scheme 1. We have been interested in substituted biphenylylnitrenium ions of this type (9, 23, 24), and have recently published results pertaining to the *N*-acetyl derivative **4** (25), a cation that can exist as both a more stable tautomer as well as a bisimine conjugate base. In this paper we report a spectroscopic and kinetic investigation of the parent system as well as an *N*,*N*-dimethyl analog. Despite the fact that **6** can be prepared as a stable salt (26), there appears to have been no study of its kinetic behavior in aqueous solutions. Our experiences are that this is not as simple as it seems. Indeed even the acid–base chemistry has not been elucidated, beyond an estimate of a pK_a of ~2 for the dication (20), a number that we show is out by three orders of magnitude. Our results are of additional interest in respect to recent theoretical calculations that suggest that increasing the number of rings separating the ends of benzoquinone bisimines can lead to remarkable enhancements of basicity (27, 28). We indeed find that there is considerable difference between the one ring system (i.e., benzoquinone bisimine) and the two ring benzidine system.

Scheme 1.

Results

Precursors



Experiments were conducted with the two electron oxidation products of both benzidine **1** and *N*,*N*-dimethylbenzidine **9**. The respective dications **6** and **10** obtained in the two electron oxidation could be isolated as bis-perchlorate salts, as shown in eq. [1] (26). These salts proved difficult to use in performing quantitative measurements, since the only solvent in which they were stable was a quite concentrated aq acid (i.e., >2 M $HClO_4$). Accordingly the majority of the spectroscopic and kinetic experiments employed a photochemical entry, as shown in eq. [2]. The is a method that we have used extensively for the generation and study of arylnitrenium ions (23–25, 29–35). The precursors in these experiments are aryl azides, whose irradiation results initially in singlet nitrenes (36). In a number of cases now we have found that the nitrene reacts rapidly as a base with solvent water molecules serving as the proton source. This generates the conjugate acid of the nitrene, a singlet arylnitrenium ion. The azides **11** and **12** are the precursors required in the present study, with the monocations **7** and **15** the conjugate acids of the singlet nitrenes **13** and **14**, respectively. It can be seen that **7** and **15** are also conjugate bases of **6** and **10**. With salts of these dications available, it was possible to establish conclusively that the photochemical route does operate as shown in eq. [2]. This was done by comparing the visible

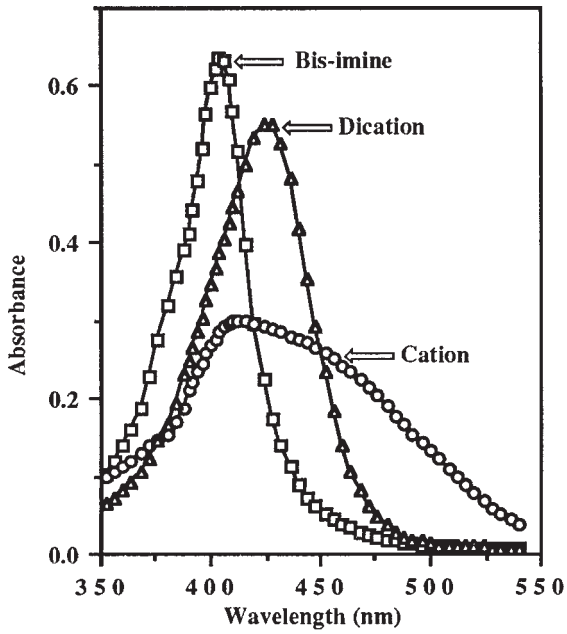
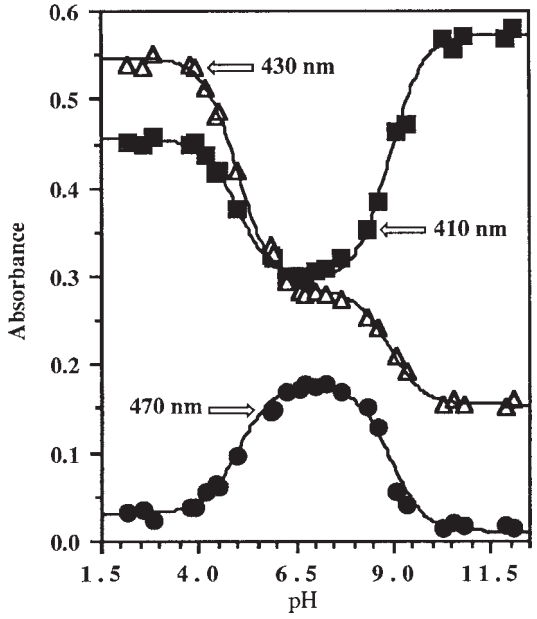
Spectroscopic acidity constants

Solutions of the azides of 10 μM concentration were placed in a UV cuvette and irradiated at 300 nm for 6 s, a time established by HPLC to result in >95% depletion of the azide. The cuvette was then rapidly loaded into a diode array spectrometer, and spectra obtained every 2 s for about 20 s. The data were transported to a spread sheet, and the absorbance at each wavelength extrapolated to zero time, taken as two seconds after the start of the irradiation. In the oxidized benzidine system one expects three forms — a dication, a monocation, and a neutral bisimine. Figure 1 shows the spectra of each of these, obtained at a pH where that particular form dominates. Representative curves plotting absorbance vs. pH are shown in Fig. 2. These take the form of a titration of a diacid with consecutive loss of two protons (eq. [3], where BH_2^{+2}, BH^+, and B are the dication, monocation, and bisimine, respectively). Data at 30 different wavelengths from 380 to 500 nm were fit to eq. [3]. These gave $pK_a(1) = 5.05 \pm 0.08$ and $pK_a(2) = 8.94 \pm 0.07$. As noted above the same spectra were obtained by adding the solid bis-cation salt to the appropriate solutions. It is also worth noting that the dication has been reported to have a λ_{max} of 429 nm, with an extinction coefficient of 6.0×10^4 (37). Our dication spectrum is in good agreement.

[3] $$\text{Abs} = \left(\frac{\text{Abs}(BH_2^{+2})[H^+]^2 + \text{Abs}(BH^+)K_a(1)[H^+] + \text{Abs}(B)K_a(1)K_a(2)}{[H^+]^2 + K_a(1)[H^+] + K_a(1)K_a(2)} \right)$$

Fig. 1. Absorption spectra extrapolated to zero time following irradiation of 4′-amino-4-biphenylyl azide **11** (10 μM) in aq solution at pH 2 (dication spectrum), pH 7 (cation spectrum), and pH 12 (bisimine spectrum).





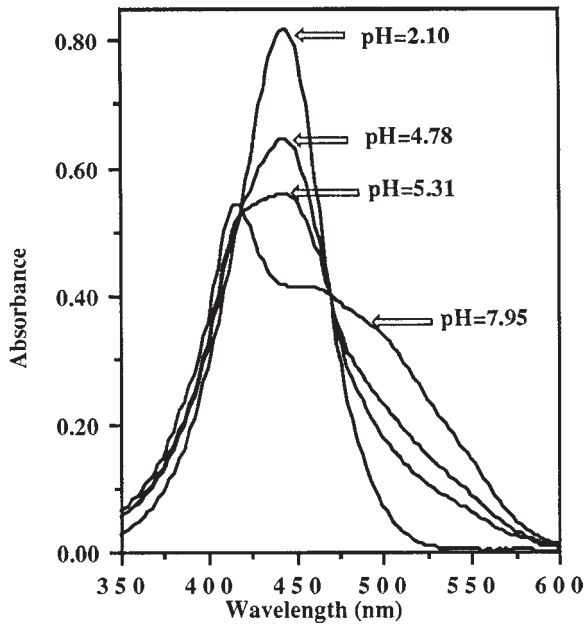


Fig. 2. Absorbance (extrapolate to zero time) vs. pH following irradiation of 4′-amino-4-biphenylyl azide **11** (10 μM) in aq solution. The titration curves drawn through the experimental points are based on a fit of the data to eq. [3] with $pK_a(1)$ and $pK_a(2)$ fixed at 5.05 and 8.94.

Selected spectrum obtained with the dimethylamino derivative are shown in Fig. 3. As expected there is only one spectral change here, from a dication (the spectrum at pH 2.1 in Fig. 3) to a monocation (pH 7.95). The single pK_a obtained in this case is 4.95 ± 0.3. It should be noted that

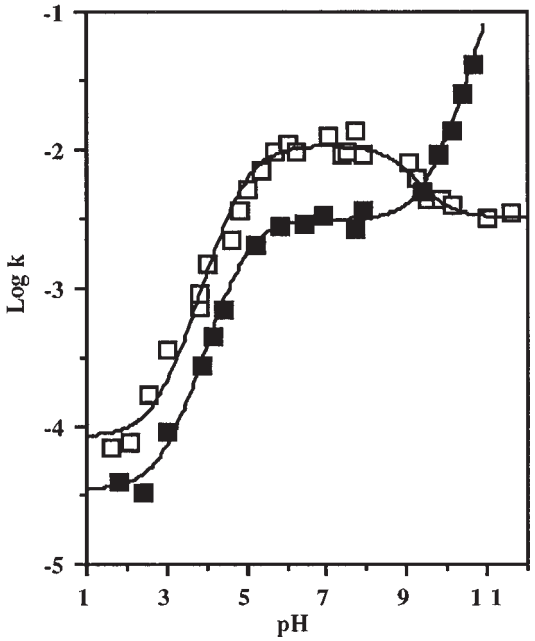
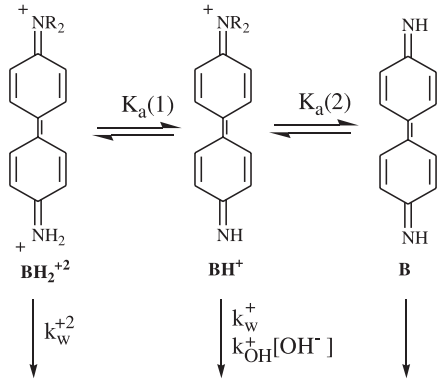
because of solubility limitations, this refers to an aq solution containing 25% acetonitrile.



Kinetics of decay

As is apparent from the previous discussion, both systems are sufficiently stable that it is possible to record spectra of the various forms on a regular UV instrument. There is however a reaction, and ultimately the absorbance in the visible region decays to essentially zero. In our initial kinetic experiments, we found that the rate constants were not reproducible, and more importantly the decay did not follow a good single exponential. In fact the rate increased with time, suggesting that a product of the reaction was reacting with the substrate. We finally realized that we could obtain reasonably reproducible rate constants (±5–10%) with adherence to a single exponential by working at the extremely low concentrations of 0.1–0.2 μM. This is possible because of the very strong absorbance of these highly conjugated systems. Even so, optical density changes were only of the order of 0.01–0.02 OD units.



Rate–pH profiles for the two systems are shown in Fig. 4. The data were obtained in aq perchloric acid and sodium hydroxide solutions, and acetate, phosphate, and carbonate buffers. Low concentrations of the buffers (total concentration ~1 mM) were used; at higher concentrations the buffers were found to accelerate the decay. It can be noted that because of the very low concentration of the precursor azide, it was possible to study the dimethylamino system in 100% aq solutions.

We were unable to identify the nature of the products. The problem, we suspect, is that the products are not stable, and indeed the kinetics suggest that the products react with the precursor. This is particular true at the concentrations (i.e., 100 μM) that are required for HPLC product analysis. We did observe a number of small peaks in the HPLC

Fig. 4. Rate–pH profiles for the decay of the two electron oxidation products of benzidine (□) and *N*,*N*-dimethylbenzidine (■). Rate constants have units of s^{-1} and were obtained at 20°C. The curves are drawn on the basis of eqs. [4] and [5] using the parameters given in Table 1.

Scheme 2.

chromatograms, and this was the case whether the dication salt or the azide was employed. These however could not be identified. In particular any attempt at scaling-up to obtain enough material for NMR resulted in a mess.

Discussion

Kinetic analysis

A mechanistic scheme that accounts for the rate–pH profiles is given in Scheme 2. The dimethyl system is the simpler of the two, since there are just the two forms, $\mathbf{BH}_2^{+2}$ and $\mathbf{BH}^+$. The kinetics are explained by reactions of both with the solvent, with a region above pH 9 due to the monocation reacting with hydroxide. Equation [4] applies to this kinetic system, and parameters obtained by fitting the

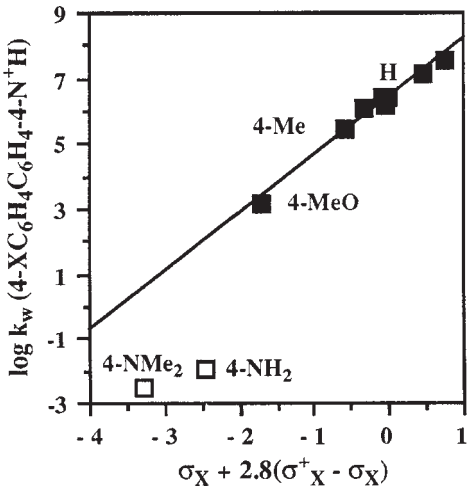
pK_a(2) — kinetic	—	9.01
pK_a(1) — spectr.	4.95[a]	5.05
pK_a(2) — spectr.	—	8.95

[a]25% Acetonitrile.

experimental data are given in Table 1. There is good agreement with the value of pK_a(1) obtained spectroscopically, although this is perhaps accidental since the solvents were slightly different.



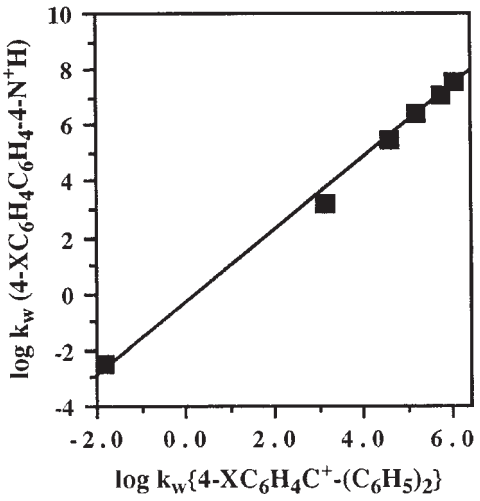
$$[4] \qquad k_{obs} = \left(\frac{k^{+2}_{w}[H^+] + k^{+}_{w}K_a(1) + \frac{k^{+}_{OH}K_a(1)K_w}{[H^+]}}{[H^+] + K_a(1)} \right)$$

There is a third species **B** in the parent system, and therefore a second ionization equilibrium. There is also a kinetic ambiguity in base, where the pH independent region can be explained by either **B** reacting with water, or by $\mathbf{BH}^+$ reacting with hydroxide ion. The analogy with the dimethyl system suggests that it is the latter reaction that is occurring. It is also noteworthy that there is no upswing in rate constant even in 0.01 M NaOH, as would occur if the bisimine were to react with hydroxide ion. The failure to observe such a reaction suggests that the bisimine also does not react with water (or at least does so very slowly). Ignoring the water–bisimine reaction, eq. [5] applies. The five adjustable parameters in this equation obtained by fitting the experimental data are provided in Table 1. There is clearly excellent agreement with the spectroscopic pK_a values. It can also be noted that the ratios k^{+}_{OH}:k^{+}_{w} are essentially the same in the two systems, as is consistent with the parent system reacting in base via the hydroxide–monocation pathway.

$$[5] \qquad k_{obs} = \left(\frac{k^{+2}_{w}[H^+]^2 + k^{+}_{w}K_a(1)[H^+] + k^{+}_{OH}K_a(1)K_w}{[H^+]^2 + K_a(1)[H^+] + K_a(1)K_a(2)} \right)$$

One surprise that emerges from this study is that the dications are less reactive towards water than the monocations. This is counter-intuitive, since one would expect that electrophilicity should increase with protonation. Indeed, in previous studies with the parent 4-biphenylylnitrenium ion (23), the 2-fluorenylnitrenium ion (23) and a series of 4-alkoxyphenylnitrenium ions (32), the dications were the more reactive. All these systems however are inherently many orders of magnitude more reactive than the benzidine derivatives of this study. One possible explanation to explain the differences with the latter is that their dications can localize the two positive charges on the two nitrogens at the end. This is something that cannot be done in, for example, the dication derived from 4-aminobiphenyl, where there is only one amino group. The benzidine monocations on the other hand may have the single positive charge more delocalized throughout the biphenylyl ring system. This would mean that they react more like an arylnitrenium ion, while the dication reacts like an iminium ion.

Fig. 5. Hammett correlation of the water reactivities of 4′-substituted-4-biphenylylnitrenium ions. The substituent constant employed in this plot is calculated as $\sigma + r^{+}(\sigma^{+} - \sigma)$, using $r^{+} = 2.8$ as obtained in a previous study (24) from application of the two parameter Yukawa–Tsuno equation (38). The line drawn in this figure (slope = 1.8) is the least-squares line from that study. Values of σ and σ^{+} are taken from ref. (39).



Whatever the reason it is interesting from a biological point of view that it is the monocation or arylnitrenium ion that is the species that is present at neutral pH when benzidine undergoes two electron oxidation. This ion, in water alone, is remarkably long-lived, with a half-life of the order of a minute or so. On the other hand, this ion is the most reactive of the three acid–base forms, being more reactive than both the conjugate acid dication and the conjugate base bisimine. In fact from pH 3 to pH 12, the species that is reacting is the monocation, whether it be the predominant form that is present or not.

Viewing the monocation as a 4-biphenylylnitrenium ion, the amino groups clearly have a very significant stabilization effect. This can be seen in the correlation shown in Fig. 5. This plot was constructed based on a previous study involving 4′-substituted-4-biphenylylnitrenium ions (24) with substituents ranging from CF_3 to MeO. What was observed was that log k_w values plotted against σ^{+} exhibited a poor correlation. In particular, the points for the *para* π-electron donors deviated from the correlation line based on the other substituents, in a direction requiring a more negative substituent parameter for these substituents. The data were satisfactorily fit to the two parameter Yukawa–Tsuno equation (38), giving a parameter r^{+} of 2.8. This means that for the data of the previous series, the substituent constant that provided the best fit in a Hammett plot was $\sigma + 2.8(\sigma^{+} - \sigma)$. Thus the 4-methoxy substituent constant is –1.7, rather than the –0.8 value of σ^{+} alone. Even with the enhanced effects of the *para* π-donors, the data obtained in this study for

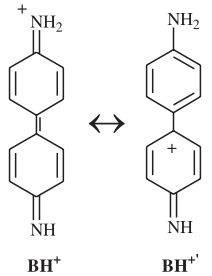
Fig. 6. Linear free energy correlation of rate constants for 4′-substituted-4-biphenylylnitrenium ions with rate constants for 4′-monosubstituted trityl cations. Data for the latter are taken from ref. (40) and ref. therein. The slope of the line is 1.3.



4′-amino- and 4′-dimethylamino- deviate significantly. Again, this deviation is in the direction that says that these substituents are more stabilizing. Thus, for example, the 4-NH_2 system is almost four orders of magnitude less reactive than would be predicted on the basis of the previous correlation line.

Figure 6 shows that this stabilizing effect is not unique to biphenylylnitrenium ions, but it is also seen in arylcarbenium ions. This plot correlates the data for 4-biphenylylnitrenium ions with those of analogously substituted trityl cations. A good correlation with a slope slightly greater than unity is observed, and this includes the point for 4-dimethylamino. Thus, in both the trityl series and the nitrenium series a 4-dimethylamino group makes the cation much less reactive than other substituents, even than 4-methoxy.

A further interesting comparison relates to the pK_a values obtained in the present study for the benzidine dication with values for the dication of *p*-phenylenediamine (or doubly protonated benzoquinone bisimine). The latter pK_as have been obtained in a kinetic study of the hydrolysis of the bisimine and are pK_a(1) < 1.5 and pK_a(2) = 5.75 (41). Thus, the bisimine derived from benzidine is slightly over three orders more basic than benzoquinone bisimine, and there is at least that great a difference in protonating the monocations. The latter is not unexpected, since the positive charges can be more delocalized in the two ring system. Moreover, as noted above, the two positive charges can be placed at the far ends of the two rings, where they would be much further separated than is possible in the one ring dication.

The difference in basicities of the bisimines, on the other hand, seems more surprising, since in both cases protonation is occurring on C=NH. It has been shown theoretically that the greater the number of rings separating the ends of benzoquinonediimines, the greater the proton affinity (27, 28). It was argued that this is associated with increased aromatic character upon protonation of the bisimines with the greater number of rings. Thus, in the present case, one could imagine that the two ring monocation could have a significant contribution from the resonance contributor **$BH^{+'}$**, where the ring bearing the amino group has aromatic character.

Experimental section

4′-Amino-4-azidobiphenyl

N-Acetylbenzidine was obtained by acetylation of hydrazobenzene followed by rearrangement in 80% H_2SO_4 (42). The compound was converted into 4′-(*N*-acetylamino)-4-azidobiphenyl by diazotization and treatment with sodium azide following the procedure given for azidostilbenes in ref. (34). A mixture of *N*-acetylbiphenyl-4-azide in a 1:2 volume ratio of 25% sodium hydroxide solution and ethanol was refluxed for 1 h. The resultant solution was diluted with cold water to give light brown precipitates. These were washed with water and recrystallized with a mixture of ethanol and dichloromethane (5:1). *4′-(N-Acetylamino)-4-azidobiphenyl* (65% yield after column chromatography) had ^{1}H NMR (200 MHz, DMSO-*d*6): 10.10 (s, 1H), 7.67 (m, 6H), 7.20 (d, *J* = 8.4 Hz, 2H), 2.08 (s, 3H). *4′-Amino-4-azidobiphenyl* (90% yield) was obtained as a buff-colored solid that decomposed on heating above 100°C. The solid had ^{1}H NMR (200 MHz, $CDCl_3$): 7.52 (d, *J* = 8.6 Hz, 2H), 7.38 (d, *J* = 8.5 Hz, 2H), 7.05 (d, *J* = 7.6 Hz, 2H), 6.75 (d, *J* = 7.5 Hz, 2H), 5.17 (s, 2H, disappeared upon treatment with D_2O). HRMS (EI, 70 ev): *m*/*z* 210.0911. $C_{12}H_{10}N_4$ requires 210.0905.

N,N-Dimethylbenzidine and 4′-N,N-dimethylamino-4-azidobiphenyl were obtained following procedures previously provided for the preparation of other 4′-substituted-4-amino- and azidobiphenyls (24). *4-(N,N-Dimethylamino)phenylboronic acid,* obtained through the reaction of 4-(*N,N*-dimethylamino)phenyl magnesium bromide and methyl borate, was coupled with 4-bromoaniline to give *N,N*-dimethylbenzidine (24). This was followed by diazotization and treatment with sodium azide to give the azide. *4-(N,N-Dimethylamino)phenylboronic acid* had ^{1}H NMR (DMSO-d_6, 200 MHz): 7.62 (2H, OH), 7.64 (d, *J* = 8.0 Hz, 2H), 6.66 (d, *J* = 8.0 Hz, 2Hz), 2.94 (s, 6H). *N,N-Dimethylbenzidine* had ^{1}H NMR ($CDCl_3$, 200 MHz): 7.42 (d, *J* = 8.6 Hz, 2H), 7.36 (d, *J* = 8.6 Hz, 2H), 6.79 (d, *J* = 8.6 Hz, 2H), 6.73 (d, *J* = 8.6 Hz, 2H), 3.66 (s, 2H), 2.97 (s, 6H). *4′-N,N-Dimethylamino-4-azidobiphenyl* was obtained in 55% after column chromatography. It decomposed on heating above 100°C, and had ^{1}H NMR ($CDCl_3$, 500 MHz): 7.58 (d, *J* = 8.8 Hz, 2H), 7.51 (d, *J* = 8.8 Hz, 2H), 7.10 (d, *J* = 8.8 Hz, 2H), 6.84 (d, *J* = 8.8 Hz, 2H), 3.04 (6H, s). HRMS (EI, 70 ev): *m*/*z* 238.1222. $C_{14}H_{14}N_4$ requires 238.1218.

Benzidine dication bis-perchlorate and *N,N-dimethylbenzidine dication bis-perchlorate* were obtained by

© 2000 NRC Canada

dichromate oxidation in a mixture of acetic acid and aq perchloric acid, as described in the literature (26).

Kinetic experiments were performed by preparing stock solutions of 4′-*N*,*N*-dimethylamino-4-azidobiphenyl and 4′-amino-4-azidobiphenyl in acetonitrile, with a concentration of 0.5 mM. 1–2 μL of this solution were then injected into a UV cuvette containing an aq buffer, and the cuvette irradiated at 300 nm in Rayonet reactor for 6 s. The cuvette was then placed in a Cary 2200 spectrophotometer and the absorbance change followed at 400–440 nm. The exact wavelength was chosen based on the spectrum of the species present at the pH of the experiment (see Figs. 1 and 3). The absorbance–time data were digitized and stored in a computer. Rate constants were obtained by fitting the data to the exponential equation. Kinetic experiments were also performed by adding a very small amount of the solid bisperchlorate salt to an aqueous solution, and transferring this solution to the cuvette. Provided the concentrations were below 0.4 μM there was reasonable agreement (±10%) between experiments in the same solution using the irradiated azide and salt as substrates.

Spectral pK_a determinations were performed in a similar way, except that the stock acetonitrile solutions had concentrations of 10 mM, and the aq solutions concentrations of 10 μM. For a given set of experiments, care was taken to ensure that the final concentration was constant throughout. These experiments were performed by irradiating the cuvette for 6 s in the Rayonet, followed by rapid transfer (2 s) to a Hewlett–Packard 8452A Diode-Array spectrometer. Scans were recorded from 350–600 nm after 2 s for a period of 15–20 s. The diode array apparatus gives an absorbance reading every 2 nm. The data were transferred to an Excel spread sheet, and a linear extrapolation performed at each wavelength to the time 2 s after commencement of the irradiation. The "zero-time" data could be then manipulated into plots of absorbance vs. wavelength (see Figs. 1 and 3) or into plots of absorbance vs. pH (see Fig. 2). The pK_a values were determined from the latter plots by fitting the experimental data to the appropriate titration equation. For each system this was done at a number of wavelengths (where there were significant differences between conjugate acid–base forms), and the average taken.

The tamoxifen cation reacts to give indene products

Cristina Sanchez and Robert A. McClelland

Abstract: The tamoxifen carbocation (Ph(Ar)C=CPh-CH^+-CH_3, Ar = 4-$Me_2NCH_2CH_2OC_6H_4$) is generated from acetate and sulfate precursors by S_N1 ionization in water. The cation exists in (*E*) and (*Z*) forms which equilibrate before reaction. The major products are the α-hydroxytamoxifens Ph(Ar)C=CPh-CHOH-CH_3, both (*E*) 64% and (*Z*) 29%, with the ratio independent of the configuration of the starting ester. Two minor products with a total yield of 7% account for the rest of the products. These have been characterized as indenes derived from intramolecular cyclization, a 4.5% yield of the indene derived from cyclization into the Ar ring with 2.5% due to cyclization into the phenyl ring. Experiments in acid solutions (0.01–0.1 M HCl) starting with pure (*E*)- or (*Z*)-α-hydroxytamoxifen reveal that the two alcohols equilibrate. This occurs by H^+-catalyzed formation of the carbocation followed by water capture. Occurring about 10-fold slower than this isomerization is an irreversible process resulting in the two indenes. This cyclization will result in the destruction of the α-hydroxytamoxifens upon exposure to acidic conditions and also makes the direct observation of the tamoxifen carbocation under super-acid conditions difficult, if not impossible. The indenes do form in low yield whenever the tamoxifen carbocation is generated from an S_N1 precursor. Thus these products could serve as markers for the formation of the tamoxifen carbocation in cellular systems or in in vivo experiments.

Key words: carbocation, indene, allylic cation, isomerization.

Résumé : On a généré le carbocation tamoxifène, [Ph(Ar)C=CPHC$H^+$$CH_3$, Ar = 4-$Me_2NCH_2CH_2OC_6H_4$] à partir de précurseurs acétate et sulfate, par le biais de réactions S_N1, dans l'eau. Le cation existe dans les formes (*E*) et (*Z*) qui se mettent en équilibre avant de réagir. Les produits principaux sont les α-hydroxytamoxifènes Ph(Ar)C=CPH-CHOH-CH_3, *E*, 64 % et *Z*, 29 %, dont le rapport est indépendant de la configuration de l'ester de départ. Deux produits mineurs, qui correspondent à un rendement total de 7 %, forment le reste des produits. Il s'agit d'indènes qui découlent d'une cyclisation intramoléculaire, dont 4,5 % de l'indène dérivé d'une cyclisation dans le noyau aromatique et 2,5 % dû à une cyclisation dans le noyau phényle. Des expériences faites en milieu acide (0,01 à 0,1 M, HCl) faites à partir des (*E*)- ou (*Z*)-α-hydroxytamoxifènes purs révèlent que les deux alcools se mettent en équilibre. Ceci résulte d'une formation acidocatalysée du carbocation, suivie par une fixation d'eau. La vitesse de réaction du processus irréversible conduisant aux deux indènes est dix fois plus faible. Cette cyclisation conduit à la destruction des α-hydroxytamoxifènes lorsqu'ils sont exposés à des conditions acides et elle rend pratiquement impossible toute observation directe du carbocation tamoxifène dans des conditions superacides. Les indènes se forment avec de faibles rendements chaque fois que le carbocation tamoxifène est généré par le biais d'une réaction S_N1. Ces produits pourraient donc servir de marqueurs pour la formation du carbocation tamoxifène dans des systèmes cellulaires ou dans des expériences in vitro.

Mots clés : carbocation, indène, cation allylique, isomérisation.

We have recently reported the direct observation of the tamoxifen carbocation in aqueous solution through the use of the technique of laser flash photolysis (LFP) (1). This cation appears to be responsible for the formation of DNA adducts observed in both animal models (2, 3) and in women treated with the drug tamoxifen (4–7). Such adducts could explain the hepatocarcinogenicity observed in rats (8–10), and the small number of endometrial cancers in women (11–13). The metabolic pathway of Scheme 1 (14–20) accounts for the formation of the cation. The initial metabolic event involves allylic hydroxylation of the parent drug (**Tam**) to form *E*-α-hydroxytamoxifen **E-TOH**, a known metabolite. This is followed by sulfotransferase-mediated conversion to the sulfate **E-TOSO$_3^-$** (21–24). This ester is quite labile in water, undergoing relatively rapid S_N1 ionization, for example, with a half-life around 10 s in water at 20°C (1).

In comparison with other carbocations (25), the tamoxifen intermediate is relatively long-lived. Limiting lifetimes (1/k(decay)) are 160 μs (side-chain amine as free base) and 40 μs (amine protonated).[2] An interesting feature is that the

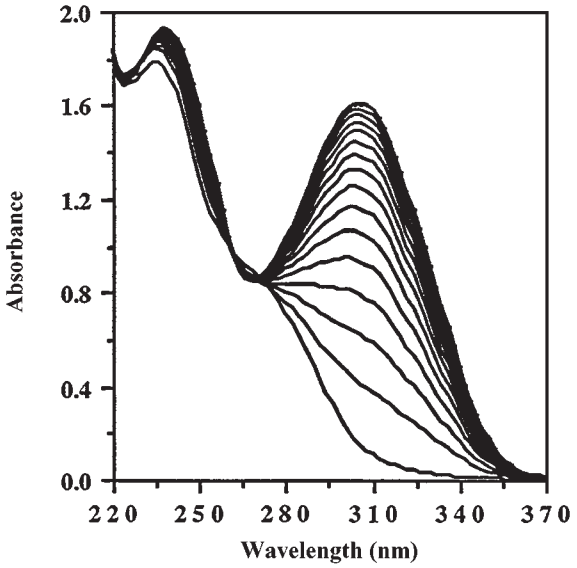
Scheme 1.

intermediate appears to be a rapidly equilibrating mixture of the two isomers **E-T**$^+$ and **Z-T**$^+$. Thus starting from **E-TOSO$_3^-$**, a mixture of the **E-TOH** and **Z-TOH** is observed (1, 18). The same ratio of these two alcohols is obtained with the (*Z*)-sulfate as the starting material (1). Mixtures of (*E*):(*Z*) products are also observed when the cation reacts with azide ion (1) and with the NH_2 group of guanine (18, 19, 26).



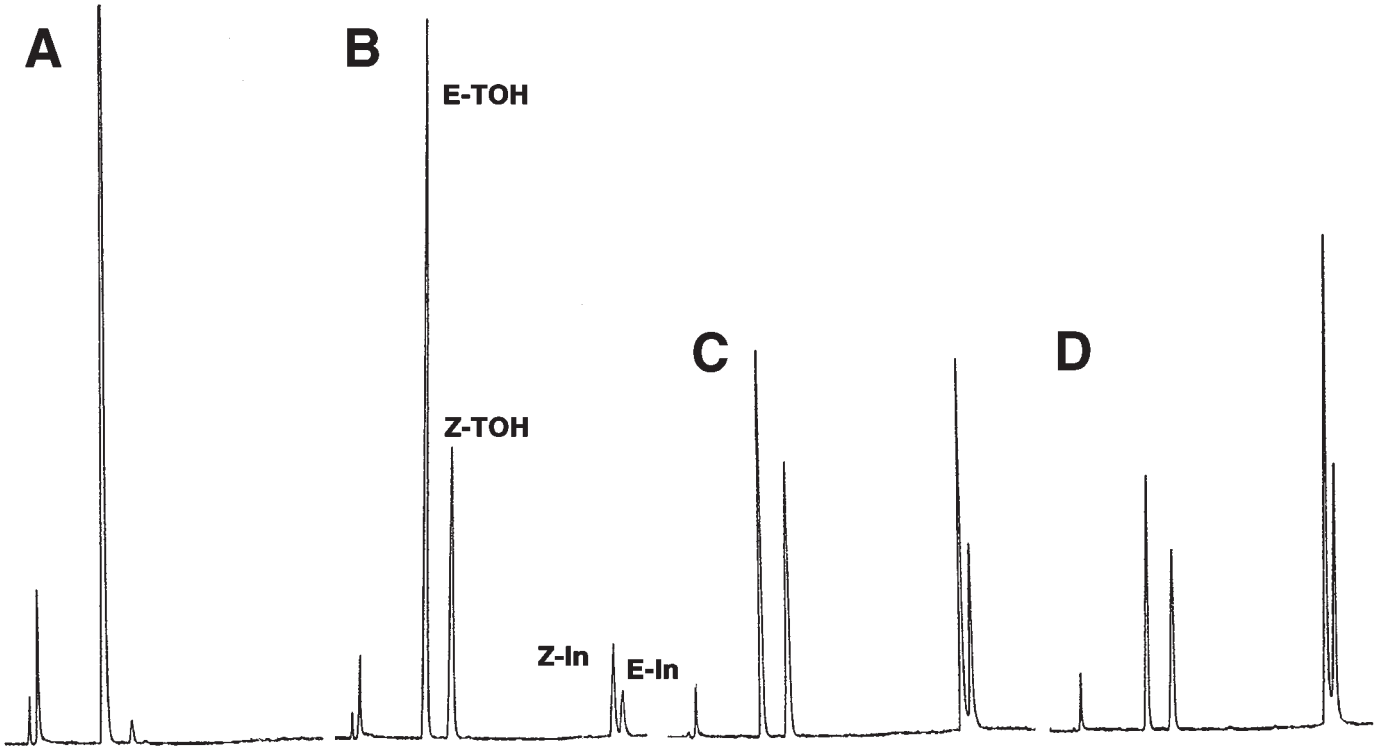
The rapid interconversion can be explained by noting that the cation is better viewed as an α-vinyl substituted diarylmethyl cation such as **E-T**$^{+\prime}$, i.e., where there is little double bond character in the central C—C bond. In fact AM1 calculations show that steric congestion forces the vinyl group to rotate 60–70 degrees out of the plane of the C$^+$-center shown in structure (1). Despite this rotation however we have been unable to detect any products derived from addition of nucleophiles to the C$^+$-center α to the the two aryl groups. In searching for these, we did note two minor peaks in the HPLC chromatogram eluting at considerably longer retention time than the alcohols **E-TOH** and **Z-TOH**. Experiments under acidic conditions where the two alcohols interconvert then revealed that with time an irreversible reaction occurs to produce these same peaks, ultimately as the only peaks in the chromatogram. This provided conditions for isolation of the products responsible. In this paper we provide the details of these experiments, including the characterization of the new products. They turn out to be derived from intramolecular cyclization in the tamoxifen cation. A kinetic analysis shows that the cyclization competes with water addition. Thus, the cyclic products can be taken as an indicator of the formation of the tamoxifen cation.

Results and discussion

Reaction of α-hydroxytamoxifens in acid

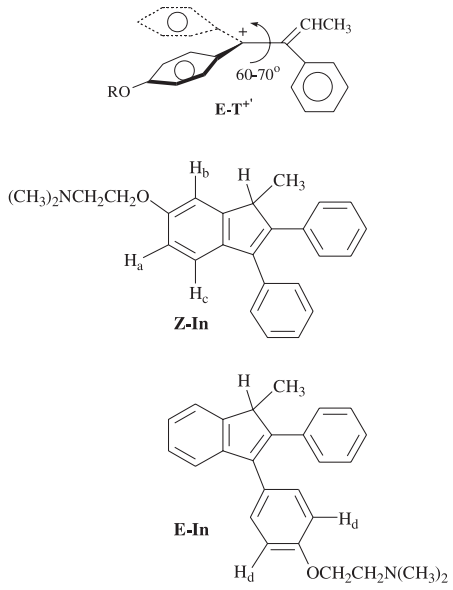
The reactions of **E-TOH** and **Z-TOH** in acidic aqueous solutions were first seen in absorption spectra recorded as a function of time in such solutions. As illustrated by the example in Fig. 1, these show the slow growth of a new peak

Fig. 1. Spectra obtained with 2×10^{-4} M (*E*)-α-hydroxytamoxifen (**E-TOH**) in 0.1 M HCl (20°C). Spectra were recorded every 20 min. The absorbance increase at 310 nm fits to a single exponential with a rate constant of 1.1×10^{-4} s^{-1}.



with λ_{max} at 310 nm. The increase at 310 nm follows good single exponential kinetics and there are reasonable isosbestic points at 260 and 270 nm. This suggests a first-order conversion of the starting alcohol to product (or products). However, HPLC chromatograms recorded on the same solution show that the behavior is more complicated. Starting with **E-TOH** as in Fig. 2, this is found to convert to an approximately 1:1 ratio with its (*Z*)-isomer **Z-TOH**, whose HPLC peak appears at a slightly longer retention time (see labels in Fig. 2B). The same interconversion to an ~1:1 **E**:**Z** ratio is obtained with **Z-TOH** as the starting alcohol. At the same time as the isomerization, two new peaks at longer retention time are appearing. This process is considerably slower, and, as will be apparent later, it accounts for the spectral changes in the UV spectra. Ultimately, the two alcohols completely disappear, and the chromatogram contains only the two peaks for the new products.

Identification of Indenes



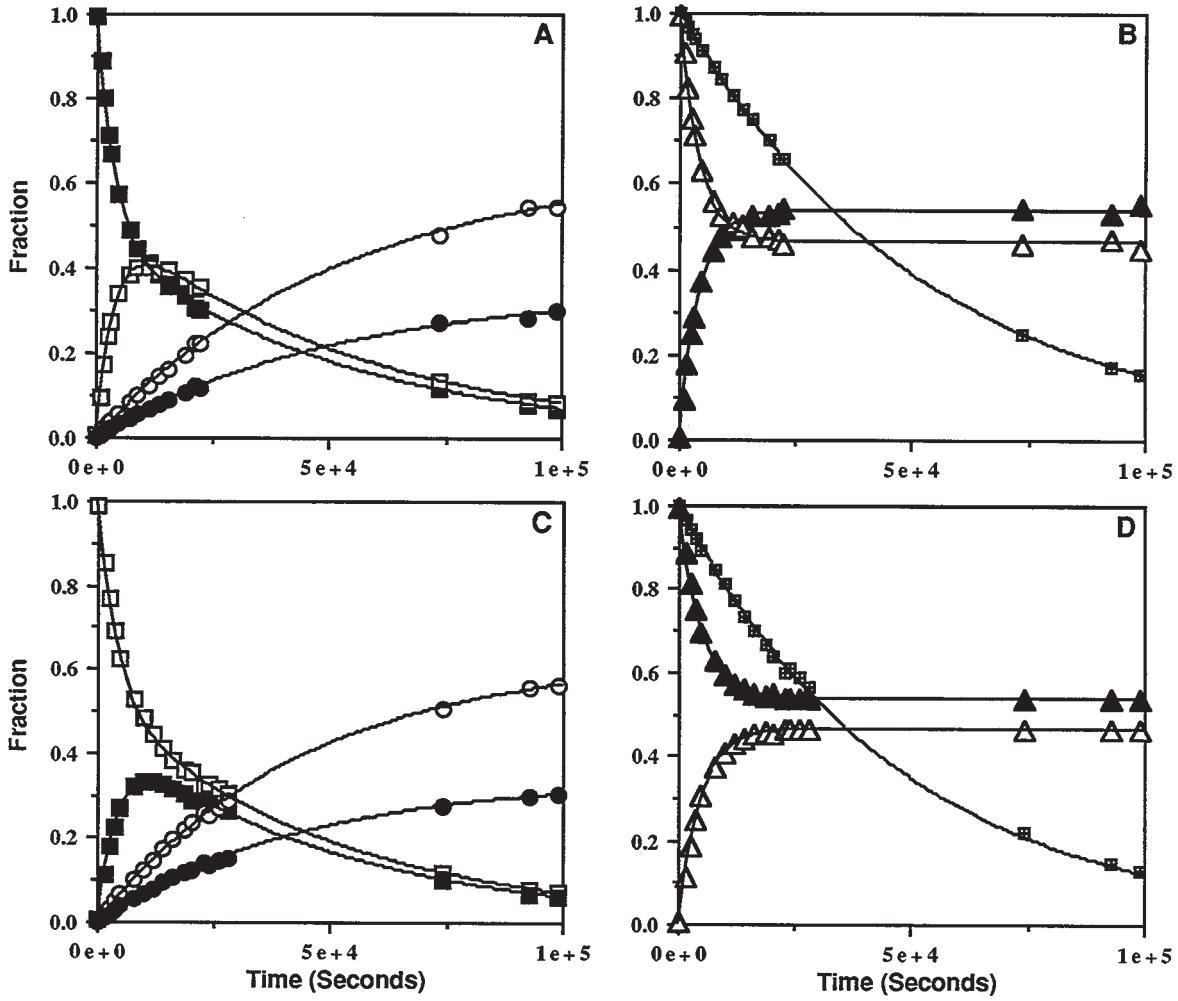
The new products were identified by working on a larger scale in 1 M HCl, and waiting a sufficient time so that there were none of the α-hydroxytamoxifens remaining. An HPLC chromatogram of this mixture was very similar to that obtained at long times on the smaller scales, with the peak at shorter retention time having twice the area of that at the longer retention time. The products were then isolated after neutralization and extraction. Column chromatography unfortunately failed to provide any separation whatsoever, so that identification had to be carried out on the mixture. The mass spectrum showed a molecular ion at *m*/*z* 369 MS, with high resolution MS providing a molecular formula of $C_{26}H_{27}NO$. This indicates that the products are derived from loss of water from the starting material. Considering the chemistry, i.e., that these products arise under acidic conditions where the tamoxifen cations **Z-T**$^+$ and **E-T**$^+$ are being formed, the conclusion is that they are isomeric indenes **Z-In** and **E-In** arising from intramolecular cyclization in the

© 2000 NRC Canada

Fig. 2. HPLC chromatograms (detector at 260 nm) obtained with 2×10^{-4} M (*E*)-α-hydroxytamoxifen (**2**) in 0.1 M HCl (20 ± 1°C). Solutions were injected at 0.8 (**A**), 23.8 (**B**), 95.3 (**C**), and 164.3 (**D**) min after preparation of the solution.

cations. This of course is well established chemistry of phenyl-substituted allylic cations (28–34). The surprising aspect of the present study is that the intramolecular reaction competes with the nucleophilic addition of water. Previous studies of the cyclization have been carried out under strongly acidic conditions where the competing reagents were weakly nucleophilic.

The ^{1}H NMR spectrum of the mixture is consistent with this interpretation. This also shows that the major product at shorter retention time is obtained upon cyclization into the alkoxy-substituted aromatic ring; i.e., the major product is **Z-In**. The indicator here is the aromatic protons next to the alkoxy group, which can be distinguished from the complex multiplet associated with the other aromatic protons. In the indene **Z-In** these protons are nonequivalent. The proton labelled H_a in the representation above appears as a doublet of doublets at 6.87 ppm, with coupling constants of 2.2 and 8.2 Hz representing coupling with H_b and H_c, respectively. The proton H_b is a doublet at 7.18 ppm, with a coupling constant of 2.2 Hz. In **Z-In**, these protons (H_d) are equivalent, and appear as a doublet at 6.95 ppm with a coupling constant of 8.6 ppm. The integration of the doublet of doublets at 6.87 (H_a) vs. the doublet at 6.95 is ~1:1. Since two protons provide the latter doublet, the ratio of **Z**-In**E-In** is ~2:1, so that **Z-In** is the major product eluting at the earlier retention time in the HPLC chromatograms.



Quantitative analysis

The HPLC chromatograms of Fig. 2 show that there are four species present during the reaction that is occurring in acids. The isosbestic point at 260 nm must therefore mean that these four have essentially identical extinction coefficients at this wavelength. This in turn suggests that by operating at 260 nm in the HPLC, the sensitivities of the four peaks are the same, or, in other works, relative peak areas can be converted directly to relative molar amounts. This was verified for **E-TOH** and **Z-TOH** by injecting known amounts of authentic alcohols. It was further observed that the sum of the areas of the four peaks was constant throughout the reaction, within an experimental error of ±3%. This of course means that the products **E-In** and **Z-In** must have the same sensitivity as the alcohols.

Working on the basis of the HPLC sensitivities being the same at 260 nm, Figs. 3A and 3C were constructed. These

Legend for Figs. 3B, 3D: (△) — [**Z-TOH**]/([**E-TOH**] + [**Z-TOH**]), (▲) — [**E-TOH**]/([**E-TOH**] + [**Z-TOH**]), (⊠) — ([**E-TOH**] + [**Z-TOH**]):[**Total**]. The points are experimental. The lines are based upon fitting the data to a double exponential or single exponential equation (see Table 1).

plot the fractions of each of the four species as a function of time for experiments starting with **Z-TOH** (Fig. 3A) and **E-TOH** (Fig. 3C) in the same acid solution. It can be seen that the two alcohols interconvert, reaching what appears to be equilibrium position with the ratio [**E-TOH**]:[**Z-TOH**] slightly greater than unity regardless of the starting alcohol. Superimposed on this is the slower process in which the alcohols convert to the indenes. The ratio [**Z-In**]:[**E-In**] is constant throughout each of the runs, and, moreover is the same whether **E-TOH** or **Z-TOH** is the starting material.

The results of kinetic analyses of the data in Figs. 3A and 3C are provided in Table 1. The data for the two alcohols clearly require fitting to an equation that contains two exponential terms, and indeed satisfactory fits are so obtained. The two rate constants determined in such fits differ by a factor of 10–12. The data for the increases in the two indenes, on the other hand, are satisfied by a single exponential. The rate constants so determined are the same as those associated with the slower process of the double exponential fits. Within experimental uncertainty, the same rate constants are obtained whether **Z-TOH** or **E-TOH** is the starting material. Experiments were also performed in solutions with different HCl concentrations with the ionic strength maintained constant at 0.1 M with NaCl. These show that both the fast process and the slow process are first-order in H^+. A final observation is that the slower rate constant obtained from the HPLC data is, within experimental error, the same as the single rate constant obtained from the exponential rise in the UV spectra (obviously for experiments at the same acid concentration). The explanation for this behavior is that the spectra of the two alcohols **E-TOH** and **Z-TOH** are so similar that their interconversion is invisible in the UV. Thus, the spectral change that is observed represents the irreversible process forming the indene products.

Kinetic analysis

Our proposed kinetic model is shown in Scheme 2. This contains the two intermediate carbocations **E-T**$^+$ and **Z-T**$^+$. Each reacts with water to form the corresponding alcohol, and, in competition, cyclizes to an indene. Associated with these reactions are four first-order rate constants k_w(E), k_{cyc}(E), k_w(Z), and k_{cyc}(Z). The carbocations can also form

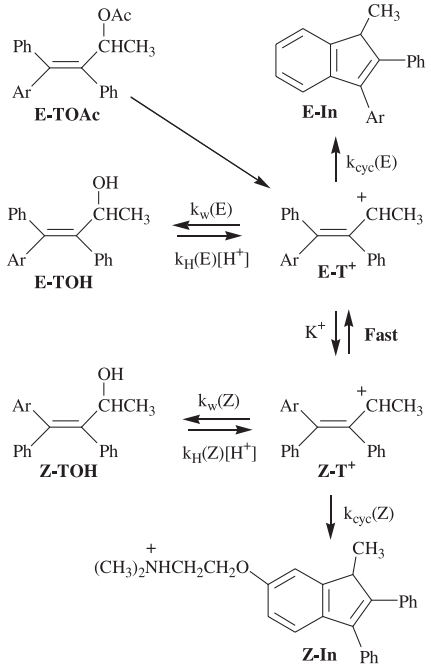
[f](k_2:(k_1 + k_2)) of eq. [12].

[g]Fit to eq. [13]. (Forced to begin at one and end at zero).

from the appropriate alcohols in H^+-catalyzed processes. The second order rate-constants for these pathways are defined as $k_H(E)$ and $k_H(Z)$; in a solution of a particular acid concentration, the cations will form in pseudo-first-order reactions with rate constants $k_H(E)[H^+]$ and $k_Z(E)[H^+]$.



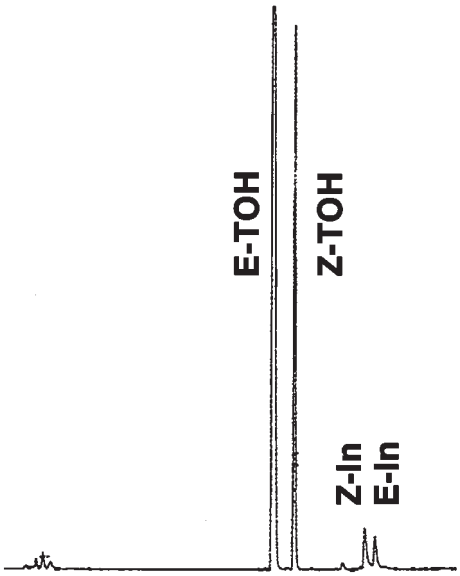
The same carbocations are also the intermediates of the solvolysis of sulfate and acetate precursors. These reactions can be carried out under conditions of kinetic control, i.e., in solutions of very low H^+-concentration such that the alcohol products are stable on the time scale required for complete solvolysis of the ester. An important observation from such experiments is that regardless of whether the ester is (*E*) or (*Z*), **E-TOH** and **Z-TOH** are produced in the same ratio (1), a value of slightly greater than 2:1 in favor of **E-TOH**. The implication is that **E-T**$^+$ and **Z-T**$^+$ achieve equilibrium within their lifetime. These lifetimes (of the equilibrating cations) are known from the LFP experiments, i.e., 40 μs in aq acid. Thus, the (*E*)-(*Z*) interconversion in the cations must be very rapid.[3]

We define the equilibrium constant [**Z-T**$^+$]:[**E-T**$^+$] as K^+. For the solvolysis reactions under conditions of kinetic control, eqs. [1]–[4] can be written for the fraction of each product that is obtained.

[1] $$\mathrm{Fr}(\textbf{E-TOH}) = \left(\frac{k_w(E)}{k_w(E) + k_w(Z)K^+ + k_{cyc}(Z)K^+ + k_{cyc}(E)}\right) = 0.640 \pm 0.005$$

[2] $$\mathrm{Fr}(\textbf{Z-TOH}) = \left(\frac{k_w(Z)K^+}{k_w(E) + k_w(Z)K^+ + k_{cyc}(Z)K^+ + k_{cyc}(E)}\right) = 0.290 \pm 0.003$$

Scheme 2.



Ar = C_6H_4-4-$OCH_2CH_2N^+H(CH_3)_2$

[3] $$\mathrm{Fr}(\textbf{E-In}) = \left(\frac{k_{cyc}(E)}{k_w(E) + k_w(Z)K^+ + k_{cyc}(Z)K^+ + k_{cyc}(E)}\right) = 0.025 \pm 0.002$$

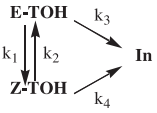
[3] We have recent evidence that the cations can be trapped before rotation at high concentrations of azide ion, a nucleophile which is a very effective quencher (1).

© 2000 NRC Canada

Fig. 4. HPLC chromatogram obtained after solvolysis of 1×10^{-4} M (*E*)-α-acetoxytamoxifen (**E-TOAc**) in 0.0005 M HCl. Note that the gradient employed to obtain this chromatogram is different from that used in Fig. 2 (see Experimental section). The small peak between the peaks for **Z-TOH** and **Z-In** is due to a small amount of unreacted **E-TOAc**.

[4] $$\mathrm{Fr}(\mathbf{Z\text{-}In}) = \left(\frac{k_{cyc}(Z)K^+}{k_w(E) + k_w(Z)K^+ + k_{cyc}(Z)K^+ + k_{cyc}(E)}\right) = 0.045 \pm 0.002$$

Figure 4 shows a chromatogram obtained in such an experiment, the almost complete solvolysis of (*E*)-α-acetoxytamoxifen (**E-TOAc**) in a very dilute acid solution. The acid was added here to ensure that the products reflect reactions of carbocations where the side-chain amine is protonated. The major products are **E-TOH** and **Z-TOH**, but the peaks for the indenes **Z-In** and **E-In** are present in small amounts. These experiments provide numerical values of the fractions in eqs. [1]–[4]; the ones given above are averages of several experiments. It can be noted that the ratio [**Z-In**]:[**E-In**] is 1.75 ± 0.2, within experimental error the same as the value obtained when these two indenes are formed from alcohol starting materials in more acidic solutions.



To analyze the experiments with one of the alcohols as starting material, we calculate the steady state concentration of the two carbocations with the assumption that they are in equilibrium. For further simplification we treat the two indene isomers as one, by setting [**In**] = [**E-In**] + [**Z-In**] and Fr(**In**) = (Fr(**E-In**) + Fr(**Z-In**)). This results in the three differential equations of eqs. [5]–[7].

[5] $$\frac{d[\mathbf{E\text{-}TOH}]}{dt} = k_2[\mathbf{Z\text{-}TOH}] - (k_1 + k_3)[\mathbf{E\text{-}TOH}]$$

[6] $$\frac{d[\mathbf{Z\text{-}TOH}]}{dt} = k_1[\mathbf{E\text{-}TOH}] - (k_2 + k_4)[\mathbf{Z\text{-}TOH}]$$

[7] $$\frac{d[\mathbf{In}]}{dt} = k_3[\mathbf{E\text{-}TOH}] + k_4[\mathbf{Z\text{-}TOH}]$$

Scheme 3.

where

[8] $$k_1 = \mathrm{Fr}(\mathbf{Z\text{-}ROH})\cdot k_H(E)[H^+]$$

[9] $$k_2 = \mathrm{Fr}(\mathbf{E\text{-}ROH})\cdot k_H(Z)[H^+]$$

[10] $$k_3 = \mathrm{Fr}(\mathbf{In})k_H(E)[H^+]$$

[11] $$k_4 = \mathrm{Fr}(\mathbf{In})k_H(Z)[H^+]$$

These equations are identical to ones that pertain to the kinetic system of Scheme 3, a model where **E-TOH** and **Z-TOH** interconvert with rate constants k_1 and k_2, and react irreversibly to form the indenes with rate constants k_3 and k_4. The HPLC data of Fig. 3 show that the alcohols equilibrate about 10 times faster than they cyclize to form the indenes. Thus, we make the approximation that $k_1,k_2 > k_3,k_4$. This is equivalent to treating the kinetics in two distinct phases — a rapid phase where the alcohols achieve equilibrium and a slow phase where they react irreversibly to form the indenes. This approximation results in eq. [12] for the equilibration and eq. [13] for the cyclization.

[12] $$\left(\frac{[\mathbf{E\text{-}TOH}]}{[\mathbf{E\text{-}TOH}] + [\mathbf{Z\text{-}TOH}]}\right) = Ae^{-k(\mathrm{isom})t} + \left(\frac{k_2}{k_1 + k_2}\right)$$

where k(isom) = ($k_1 + k_2$), and $A = k_1$:($k_1 + k_2$) or $-k_2$:($k_1 + k_2$) for the cases where **E-TOH** and **Z-TOH**, respectively are the starting alcohols.

[13] $$\left(\frac{[\mathbf{E\text{-}TOH}] + [\mathbf{Z\text{-}TOH}]}{[\mathbf{E\text{-}TOH}] + [\mathbf{Z\text{-}TOH}] + [\mathbf{In}]}\right) = e^{-k(\mathrm{cyc})t}$$

where k(cyc) = ($k_2k_3 + k_1k_4$)/($k_1 + k_2$).

As shown in Figs. 3B and 3D, [**E-TOH**]/([**E-TOH**] + [**Z-TOH**]) and ([**E-TOH**] + [**Z-TOH**])/([**E-TOH**] + [**Z-TOH**] + [**In**]) satisfy a single exponential, as required by eq. [12] and eq. [13] respectively. As seen in Table 1, the rate constant k(isom) from the fit to eq. [12] is essentially the same as the larger of the rate constants obtained by fitting the data for the individual alcohols to equations with two exponentials. The rate constant k(cyc) is the same as the smaller of the rate constants and is also identical to the value obtained from the appearance of the indene products.

From experiments at different acid concentrations, both k(isom) and k(cyc) were found to be proportional to [H^+]. Average values of the second-order rate constants obtained by dividing by H^+ are given in eqs. [14] and [18] below. In the case of the isomerization process, the following relations apply:

[14] $$\left(\frac{k(\mathrm{isom})}{[H^+]}\right) = \left(\frac{k_1 + k_2}{[H^+]}\right) = (1.16 \pm 0.06) \times 10^{-2}\ M^{-1}\ s^{-1} = \mathrm{Fr}(\mathbf{Z\text{-}TOH})\cdot k_H(E) + \mathrm{Fr}(\mathbf{E\text{-}TOH})\cdot k_H(Z)$$

© 2000 NRC Canada

The fit to eq. [12] also provides the fraction of **E-TOH** that is present when the **E-TOH**: **Z-TOH** equilibrium is established:

$$[15]\quad \left(\frac{k_2}{k_1 + k_2}\right) = 0.535 = \left(\frac{[\mathbf{E\text{-}TOH}]_{eq}}{[\mathbf{E\text{-}TOH}]_{eq} + [\mathbf{Z\text{-}TOH}]_{eq}}\right) = \left(\frac{[\mathbf{E\text{-}TOH}]_{eq}}{\mathrm{Fr}[\mathbf{Z\text{-}TOH}] \cdot k_H(E) + \mathrm{Fr}[\mathbf{E\text{-}TOH}] \cdot k_H(Z)}\right)$$

With some algebraic manipulation, inputting the values of Fr(**Z-TOH**) and Fr(**E-TOH**) from eqs. [1] and [2] gives the second-order rate constants:

$$[16]\quad k_H(E) = 2.14 \times 10^{-2}\ M^{-1}\ s^{-1}$$

$$[17]\quad k_H(Z) = 8.42 \times 10^{-3}\ M^{-1}\ s^{-1}$$

It is interesting to note that **E-TOH** forms from the equilibrating cations with a slightly greater than 2:1 preference over **Z-TOH**, but it also undergoes H^+-catalyzed ionization over two-fold faster. The consequence is that the ratio of the two alcohols at equilibrium is close to unity.

For the cyclization process,

$$[18]\quad \left(\frac{k(cyc)}{[H^+]}\right) = (1.01 \pm 0.04) \times 10^{-3}\ M^{-1}\ s^{-1} = \mathrm{Fr}(\mathbf{In})\left(k_H(E)\left(\frac{k_2}{k_1 + k_2}\right) + k_H(Z)\left(\frac{k_1}{k_1 + k_2}\right)\right)$$

where the last term is obtained by substituting the various relations for k(cyc) from eq. [13], and k_3 and k_4 from eqs. [10] and [11]. Numerical values for all the quantities except Fr(**In**) are known from the isomerization kinetics (see eqs. [15]–[17]). Substitution gives FR(**In**) = 0.066. The overall consistency in the analysis is seen in the excellent agreement with the value of 0.070 obtained as the sum of Fr(**E-In**) and Fr(**Z-In**) obtained from the product analysis in the acetate solvolysis.

Summary

These experiments show that the equilibrating tamoxifen carbocations undergo intramolecular cyclization in competition with their reaction with aqueous solvent. The cyclizations represent 7% of the fate of the cations under conditions of kinetic control. Thus they occur with a rate constant of $1.8 \times 10^3\ s^{-1}$, i.e., 7% of the rate constant of $2.5 \times 10^4\ s^{-1}$ obtained by LFP for cation decay (where these rate constants refer to acidic conditions where the side chain amino group is protonated).

We also show that acid conditions must be avoided when performing quantitative analysis of α-hydroxytamoxifens. The H^+-catalyzed formation of the tamoxifen carbocations will occur under these conditions, and the cyclizations represent irreversible processes that result in removal of the alcohols. We had also hoped that we would be able to generate the tamoxifen carbocations under weakly nucleophilic superacid conditions. The occurrence of the rapid intramolecular cyclization however has made this impossible to date, even working at lower temperatures.

Small amounts of the indenes also form at neutral pH when the carbocations are generated in S_N1 solvolysis reactions of acetate and sulfate precursors. Observation of these indenes could be used as an indicator of the formation of the tamoxifen carbocations in cellular systems and even in vivo. To date such experiments have relied upon the formation of the DNA adducts to indicate the formation of the cation (26). The indenes with their λ_{max} at 310 nm and their relatively long retention time should be easily detected by reversed-phase HPLC. Their formation would be unambiguous proof of the formation of the tamoxifen carbocation (and the S_N1 precursor to this cation).

Experimental section

(*E*)-α-Hydroxytamoxifen and (*Z*)-α-hydroxytamoxifen ((*E*)- and (*Z*)-1-[4-[2-(dimethylamino)ethoxy]phenyl]-1,2-diphenyl-1-buten-3-ol) were prepared as a mixture and separated by column chromatography following a literature procedure (27). (*E*)-Acetoxytamoxifen was prepared from the (*E*)-alcohol by treatment with acetic anhydride in pyridine, followed by chromatography as described previously (26, 35).

Z-In (6-(2-dimethylaminoethoxy)-1-methyl-2,3-diphenyl-*1H*-indene) and **E-In** (3-[4-(2-dimethylaminoethoxy)phenyl]-1-methyl-2-phenyl-*1H*-indene) were obtained as a mixture by adding 50 mg of (*E*)-α-hydroxytamoxifen to 100 mL of 1 M HCl. After stirring at ambient temperature for 14 h, the pH was adjusted to 10–11 by the addition of sodium hydroxide, and the indenes extracted with dichloromethane. After drying ($MgSO_4$) and filtration, the solvent was removed to yield a viscous oil. This was purified by chromatography using 8:11:1 ether:hexanes:triethylamine. This failed to provide any separation of the two isomers, as was also the case of TLC experiments using various other solvent combinations. MS (EI): *m*/*z* 369 (100%), 324 (5%), 298 (50%), 265 (75%), 233 (45%), 202 (30%). HRMS *m*/*z* 369.2097; $C_{26}H_{27}NO$ requires 369.2093. The ^1H NMR (400 MHz, $CDCl_3$) of the mixture exhibited peaks that could be assigned to the major isomer (**Z-In**) and minor isomer (**E-In**): 1.315 (major) and 1.320 (minor) (3H, d, J = 7.5 Hz) (CH_3), 2.384 (major and minor) (6H, s) ($N(CH_3)_2$), 2.790 (major) and 2.780 (minor) (2H, t, J = 5.6 Hz) (NCH_2), 4.025 (major) and 4.044 (minor) (1H, q, J = 7.6 Hz) (CH), 4.152 (major) and 4.118 (minor) (2H, t, J = 5.6 Hz), 6.87 (major) (1H, dd, J = 2.2 Hz and 8.2 Hz) (5-H of indene ring of **Z-In**), 6.95 (minor) (2H, d, J = 8.2 Hz) (protons *ortho* to $OCH_2CH_2N(CH_3)_2$ group in **E-In**), 7.16–7.14 (multiplet) (all the other phenyl protons, H7 of the indene ring of **Z-In** could be seen as a doublet at 7.18 Hz with J = 2.2 Hz).

HPLC experiments were conducted with a Waters 600E system, a Waters 486 Tunable Absorbance Detector set at 260 nm, and Waters 746 Data Module. The column was a Water Symmetry C_{18} μm column of dimensions 4.6 mm × 150 mm. The experiments with the α-hydroxytamoxifens as starting material were performed with a flow of 1 mL/min using a programmed eluting system of 0–2 min — isocratic 60% buffer:40% acetonitrile; 2–8 min — linear gradient ending at 15% buffer:85% acetonitrile; and 8–18 min — isocratic 15% buffer:85% acetonitrile, where buffer = 0.025 M sodium acetate:0.025 M acetic acid. Retention times were 4.6 min (**E-TOH**), 5.9 min (**Z-TOH**), 14.2 min

© 2000 NRC Canada

(**Z-In**), and 15.4 min (**E-In**). Experiments starting with α-acetoxytamoxifen used a program of 0–1 min — isocratic 70% buffer:30% acetonitrile; 1–11 min — linear gradient ending at 15% buffer:85% acetonitrile; and 8–18 min — isocratic 15% buffer:85% acetonitrile, where buffer = as above. Retention times were 11.3 min (**E-TOH**), 12.1 min (**Z-TOH**), 13.7 min (**E-TOAc**), 14.8 min (**Z-In**), and 15.3 min (**E-In**). Solutions contained 1×10^{-4} M of the substrate with 60 μL being directly injected into the HPLC.

Reaction of dimethoxycarbene with strained cyclic carbonyl compounds

Paul C. Venneri and John Warkentin

Abstract: A cyclopropanone, a cyclopropenone, cyclobutanones, a cyclobutane-1,3-dione, and a cyclobutene-1,2-dione reacted with dimethoxycarbene to afford acetals of the next larger ring by formal insertion of the carbene into a C—C bond α to the carbonyl group. When either of two saturated α-ring carbons could be involved in the process, the ring expansion was selective, affording primarily the product of apparent insertion into the more substituted ring bond. With 2,3-dimethoxycyclobutene-1,2-dione, insertion occurred between the carbonyl groups and with β-propiolactone it occurred at the lactone bond. β-Propiolactam, however, reacted by insertion of the carbene into the N—H bond.

Key words: β-propiolactone, cyclobutanone, cyclobutananedione, cyclopropanone, dialkoxycarbene.

Résumé : On a fait réagir du diméthoxycarbène avec unr cyclopropanones, une cyclopropénone, des cyclobutanones, une cyclobuta-1,3-dione et une cyclobutène-1,2-dione pour obtenir les acétals des cycles agrandis par une insertion formelle du carbène dans la liaison C—C en α du groupe carbonyle. Lorsque les deux liaisons C—C en α sont saturées, mais différentes, l'extension de cycle se fait de façon sélective et elle conduit principalement au produit résultant de l'insertion apparente dans la liaison du cycle la plus substituée. Avec la 2,3-diméthoxycyclobutène-1,2-dione, l'insertion se produit entre les groupes carbonyles et avec la β-propiolactone elle se produit au niveau de la liaison lactonique. Toutefois, avec le β-propiolactame, l'insertion du carbène se fait dans la liaison N—H.

Mots clés : β-propiolactone, cyclobutanone, cyclobutanedione, cyclopropanone, dialkoxycarbène.

Introduction

Carbenes with one or more donor groups attached to the carbene carbon atom are well known to have singlet ground states and to be relatively long-lived compared to alkylidenes. For example, the singlet state of dimethoxycarbene lies some 76 kcal mol^{-1} below the triplet (1) and several diaminocarbenes are kinetically stable enough to be isolated (2–8). Reduced reactivity is observed with methoxy(methyl)carbene, which undergoes 1,2-migration of H much more slowly than dimethylcarbene (9). The large singlet–triplet gap and the lowered reactivity of such singlets are attributed to conjugative delocalization of electron density from heteroatom substituents (OR, NR_2) into the virtual *p*-orbital of the carbene (10–13). Such delocalization, and analogous delocalization in transition states for reactions of such carbenes with electrophiles, makes them nucleophilic and potentially useful for Michael additions and additions to carbonyl groups. Dialkoxycarbenes do attack isocyanates (14–16), vinyl isocyanates (17–19), isothiocyanates (14, 15), ketenes (20, 21), perchloroketones (22), and anhydrides (23), for example, but they do not attack simple ketones efficiently. Dimethoxycarbene reacts with fluorenone in low yield (24). We now report that strained cycloalkanones and cycloalkanediones react quite cleanly with dimethoxycarbene to afford products of ring expansion (Scheme 1). The only analogous insertions are those of carbenoids into diphenylcyclopropenone (25) and into 1,2-cyclobutenediones (26) reported by Herndon's group.

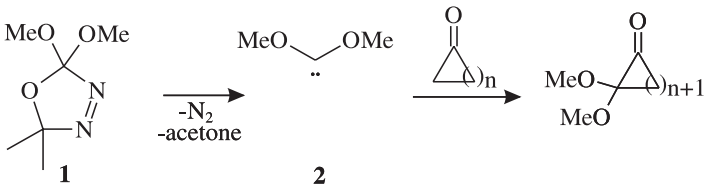
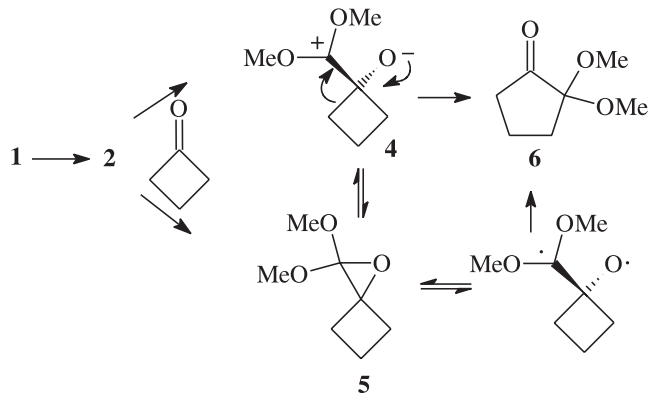
Methods, results, and discussion



A benzene solution of oxadiazoline **1** and the substrate ketone was degassed and sealed into a Pyrex tube which was then heated for 24 h at 110°C with an oil bath. Thermolysis of oxadiazoline **1**, via loss of nitrogen and acetone (27), generates dimethoxycarbene (**2**), which attacks the ketone and (or) dimerises. A sample of the solution was analyzed by GC and GC–MS prior to work-up to estimate the ratios of products. Major products were isolated by means of chromatographic techniques and they were identified by means of spectroscopy.

Reaction of 2 with cyclobutanone (3)



Heating of 2,2-dimethoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline (**1**) with cyclobutanone (**3**) in benzene at 110°C afforded 2,2-dimethoxycyclopentanone (**6**) (Scheme 2) in 75% yield (isolated). The ring expansion is presumably the result of either concerted insertion of dimethoxycarbene (**2**) between the carbonyl group and the α-carbon atom or the result of stepwise reaction in which **2** attacks the electropositive carbon atom of the carbonyl group as a nucleophile, to generate a zwitterionic intermediate (**4**) that is most likely equilibrated with oxirane **5**. Cyclopentanone

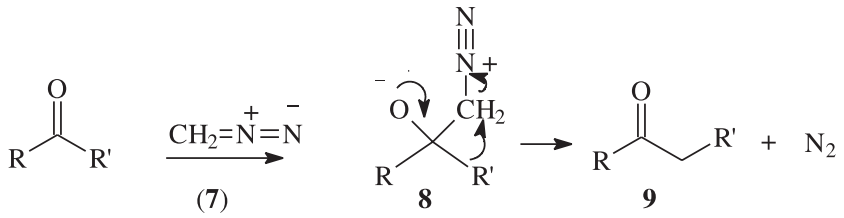
Scheme 2.

(**6**) then arises by α-carbon migration (Scheme 2). These mechanisms differ in that **4** is a transition state in the one case and an intermediate, presumably equilibrated with **5**, in the other. Another mechanism that is not ruled out would involve the diradical analogue of **4**, possibly arising from homolytic ring opening of **5**. The latter could arise from **4** or it could be formed by concerted cycloaddition of **2** to cyclobutanone, Scheme 2.

The reaction can be compared to homologations of alkanones with diazomethane (**7**) (28). The first step is thought to be addition to the carbonyl group to generate intermediate **8** (Scheme 3) that, by alkyl migration with loss of nitrogen, gives the homologous ketone (**9**).

The insertion preference was not clearly predictable on the basis of precedents from ring expansions with diazomethane, in which migration of an α-carbon bearing an electron-withdrawing group, such as methoxy or halogen, is disfavoured (28) and one bearing a donor group is generally favoured. For example, 2-methyl-3-benzyloxycyclobutanone affords 3-methyl-4-benzyloxycyclopentanone with a 3:1 preference over 2-methyl-3-benzyloxycyclopentanone (29). On the other hand, steric effects can dominate as indicated by reports that 2-cyclohexylcyclohexanone gave only ca. 5% of ring expansion products (30) and that 3,3,5-trimethylcyclohexanone afforded more 3,3,5-trimethylcycloheptanone (21%), by migration of the less-hindered primary carbon, than 3,5,5-trimethylcycloheptanone (12%), by migration of the more-hindered primary carbon (31, 32). In 2-phenylcyclohexanone, one might expect electronic and steric effects to operate in the same sense, because phenyl is inductively electron withdrawing, to thwart migration of the CHPh group entirely. The fact that one fourth of the product of ring expansion was 3-phenylcycloheptanone, from migration of CHPh (28, 33), and three fourths was 2-phenylcycloheptanone, probably means that phenyl is partially compensating for its steric and inductive effects with weak conjugative stabilization. An early transition state with some cation character in the migrating group could be appropriate.

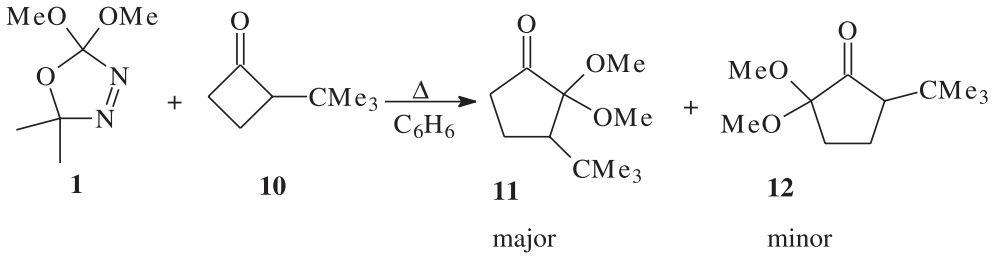


To assess the electronic and steric effects on the insertions of dimethoxycarbene into the cyclobutanone ring, we tested 2-*tert*-butylcyclobutanone (**10**) and 2-methylcyclobutanone (**13**).

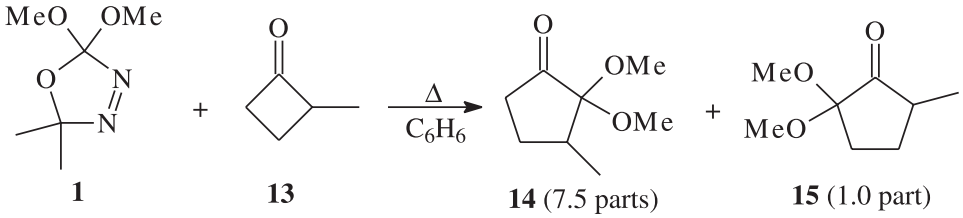
Reaction of 2 with 2-*tert*-butylcyclobutanone (10)

Thermolysis of dimethoxy oxadiazoline (**1**) in the presence of 2-*tert*-butylcyclobutanone (**10**) afforded *tert*-butyl-2,2-dimethoxycyclopentanones (**11** and **12**) in 1.5:1.0 ratio, as determined by NMR spectroscopy (Scheme 4). The major product is that from formal carbene insertion between the carbonyl group and the more substituted α-carbon while insertion into the other α-site led to the minor product.

The isomeric structures were established in two ways. First, irradiation of the *tert*-butyl signal of the major isomer (NOE experiment) enhanced both methoxy group signals in the ^{1}H NMR spectrum, while irradiation of the *tert*-butyl signal in the minor component enhanced only one methoxy signal.[2] Second, the fragmentation patterns in the mass spectra of the major and minor isomers were quite different. That of the major isomer had the base peak at m/z = 129 (144 – $CH_3^{\cdot}$), signifying the connectivity $(CH_3O)_2CCHC(CH_3)_2$ of **11**. On the other hand, the base peak in the mass spectrum



Scheme 3.



[2] AM-1 geometry optimizations show that rotation brings both methoxy groups of **10** into contact with the *tert*-butyl group. In **11** only one methoxy group is close to the *tert*-butyl group.

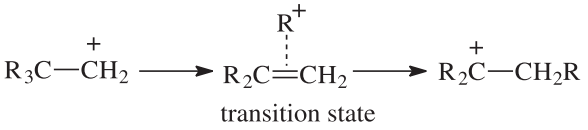


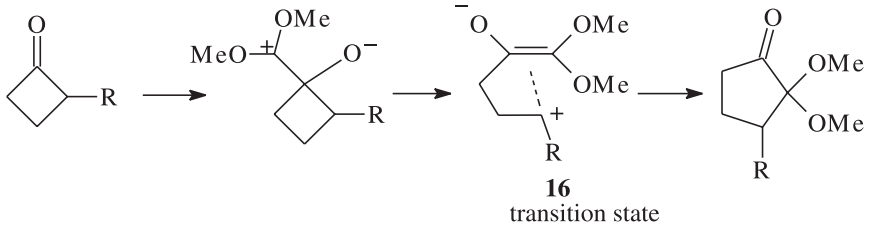
Scheme 4.

Scheme 5.

Scheme 6.

of the minor isomer was at m/z = 88, indicating the connectivity $(CH_3O)_2CCH_2$ of **12**. These results establish the position of the *tert*-butyl group in each isomer.

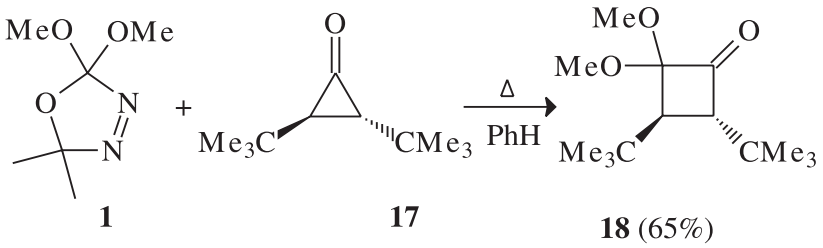
Preferential migration of the $CHC(CH_3)_3$ group during reaction of **2** with 2-*tert*-butylcyclobutanone indicates that electronic effects must outweigh steric effects. The importance of the latter could be assessed qualitatively with cyclobutanone **13**, which afforded **14** and **15** in 7.5:1.0 ratio (Scheme 5).



An alkyl substituent exerts an electronic effect that clearly favours migration while its steric effect operates to moderate the electronic influence. The sense of the migration preference is that observed in carbocation rearrangements, which are often described as resembling a π-complex of an alkene and a cation (Scheme 6) (34–36). To retain this model for the rearrangement of a dipolar intermediate from **10** and **13**, one would draw the transition state (**16**) with enolate character; in other words, the carbonyl group of the product would be only weakly expressed at the transition state and the migrating group would move with cation character, rather than anion character (Scheme 7). This mechanism, if correct, means that migration toward a cationic site involves accumulation of some positive charge on the migrating group, even if the cation is delocalized and an anionic group is "pushing".

Treatment of *trans*-di-*tert*-butylcyclopropanone (17), *cis*-2,4-di-*tert*-butylcyclobutanone (19), 2,2,4,4-tetramethylcyclobutanone (22), 1,2-diphenylcyclopropenone (23), and 3,4-dimethoxycyclobutene-1,2-dione (24) with 2

Generation of **2** in the presence of *trans*-di-*tert*-butylcyclopropanone (**17**) gave cyclobutanone **18** in good yield (Scheme 8). The large relief of strain from quaternization of the CO group of a cyclopropanone is presumably responsible. On the other hand, the corresponding reaction of **2** with *cis*-2,4-di-*tert*-butylcyclobutanone (**19**) was not successful.



The expected **20** was not detected; only unreacted **19** and carbene dimer **21** could be isolated from the thermolysis mixture (Scheme 9). This result was surprising, because one face of the *cis* disubstituted cyclobutanone would appear to be approachable. Thermal isomerization of **19** to the *trans* isomer was not responsible; the ketone left at the end of the experiment was still *cis* by ^{1}H NMR spectroscopy (37). We propose that attack of **2** at the more accessible face of **19** forces the *tert*-butyl groups, which are probably well separated because the ketone is not planar, closer together and introduces steric interactions with the developing alkoxide

Scheme 9.

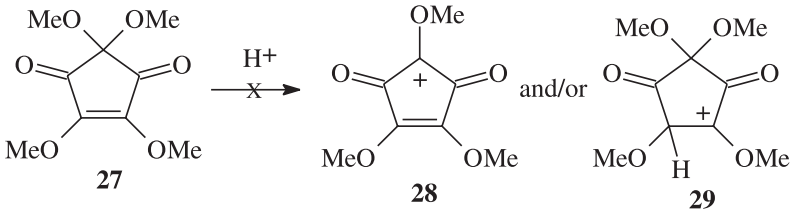
Scheme 10.

function. That hindrance slows attack by dimethoxycarbene enough to make carbene coupling the predominant reaction. *trans*-Di-*tert*-butylcyclopropanone does react with **2**, in spite of steric hindrance, because of its greater ring strain (Scheme 8).

To test for the importance of ring strain, **2** was generated in the presence of cyclopentanone. A small amount of 2,2-dimethoxycyclohexanone (12% yield) was obtained but the major product was the carbene dimer, which is also the major product from the thermolysis of oxadiazoline **1** in the absence of a carbene trap (27). Thus, as expected, the yield of carbene insertion product is dependent on the ring strain of the cyclic ketone.

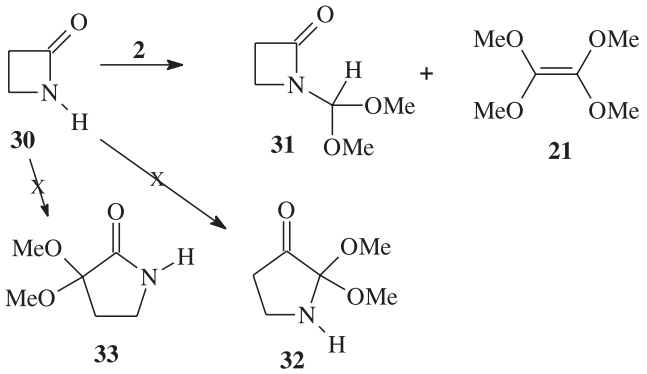
Other cycloalkanones that react with **2** to afford products of ring expansion in acceptable yields are **22**, **23**, and **24** (Scheme 10). It is clear that a tricoordinate carbon atom can migrate, as in diphenylcyclopropenone (**23**) and dimethoxycyclobutendione (**24**), whether the attacking group is a carbenoid (25, 26) or **2**. Products of attack in the Michael sense were not found in either case and, in the case of **24**, the product of insertion between the C—C double bond and the carbonyl group was not found.

Compound **27**, although it is an acetal as well as an enol ether, was easily isolated by chromatography. Its resistance to hydrolysis was demonstrated when it was found to be unaffected when stirred with 10% sulphuric acid at room temperature for 2 h. Some reaction to form a complex mixture did occur during stirring for 24 h with a 50:50 solution of 10% sulphuric acid in methanol, although much of the starting material was left unchanged. The resistance of **27** to acid reflects the destabilization of cations that would need to develop during acetal hydrolysis (**28**) or enol ether hydrolysis (**29**), by one or two neighbouring carbonyl groups (Scheme 11).



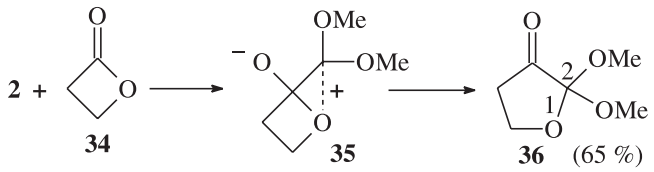
Reaction of 2 with 2-azetidinone (30) and β-propiolactone (34)

The ring-expansion reactions of **2** with small-ring cycloalkanones led us to examine 2-azetidinone (**30**) and β-propiolactone (**34**) also (Scheme 12). With **1** and 2 equiv of 2-azetidinone (**30**), insertion of **2** into the N—H bond (38) was the dominant pathway. Insertion leading to ring expansion products **32** and **33** did not take place. Use of 2 equiv of **1** led to insertion into the N—H bond (76% by GC) but not to subsequent ring expansion of the β-lactam (**31**) via a second carbene insertion. Instead the excess carbene dimerized to **21**. Amide resonance is presumably important enough to reduce the electrophilicity of the carbonyl carbon atom so as to slow ring expansion of **30** and **31**. Whether insertion into the N—H bond is concerted or stepwise is not known.



Reaction of **2** with **34** afforded one major ring expansion product (**36**) in 65% yield (Scheme 13). Insertion between the carbonyl carbon atom and the α-oxygen cannot be accommodated within the mechanism invoked to explain the results from 2-*tert*-butylcyclobutanone (**10**) and 2-methylcyclobutanone (**13**). An enolate-like transition state would

© 2000 NRC Canada

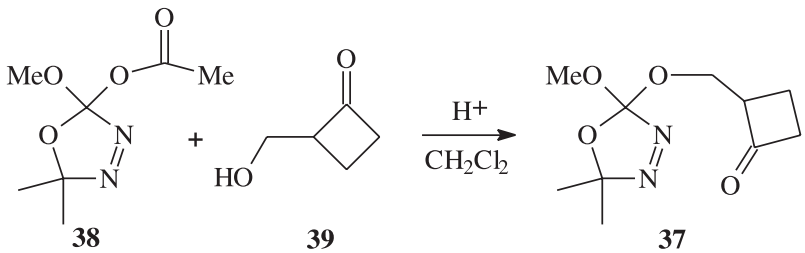


Scheme 11.

Scheme 12.

Scheme 13.

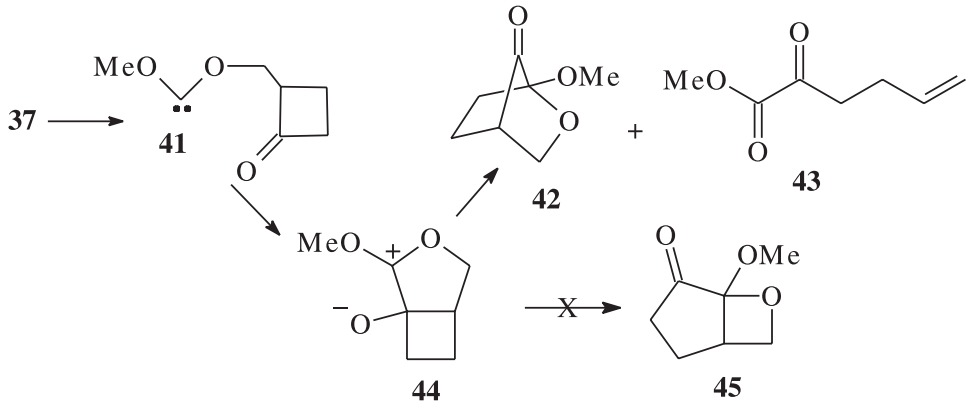
necessarily deplete the migrating ring atom of electron density and lead to migration of the CH_2 group instead of O. We postulate that the ring oxygen interacts with the developing positive site as the carbene begins to bond to the carbonyl carbon. Instead of a zwitterionic intermediate analogous to **4** (Scheme 2) a bicyclic intermediate (or transition state) **35** is reached, with the new bond between O_1 and C_2 partly developed. This picture differs subtly from the previous one in that the migrating atom initially bonds to the migration terminus with an unshared pair rather than with σ-electrons. A similar mechanism fits the insertions of **2** into cyclic anhydrides (23).



Thermolysis of 2-(2-cyclobutanonemethoxy)-2-methoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline (37)

To investigate the potential of ring expansion reactions for the preparation of bicyclic ketones, an intramolecular variant was examined. The cyclobutanone system illustrated in Scheme 14 was chosen because of the high yield of the product of ring expansion in the intermolecular chemistry of dimethoxycarbene and cyclobutanone. A one carbon link between the oxygen of the oxadiazoline and cyclobutanone would lead to a five-membered transition state from attack of the carbene at the carbonyl group of the cyclobutanone ring.

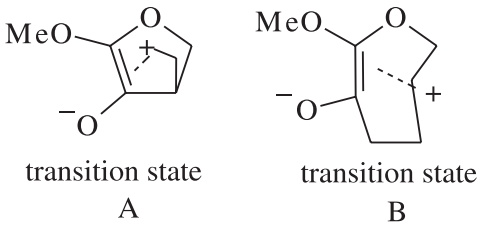
2-(2-Cyclobutanonemethoxy)-2-methoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline (**37**) was prepared by the acetoxy exchange method (27) (Scheme 14). Acetoxymethoxy oxadiazoline (**38**) and 2-hydroxymethylcyclobutanone (**39**), made by literature procedures (27, 39), reacted in dichloromethane containing a catalytic amount of trifluoroacetic acid to yield the desired oxadiazoline (**37**), which was identified by means of ^1H and ^{13}C NMR spectroscopy and mass spectrometry.



Thermolysis of **37** led to the new bicyclic ketone **42** and to compound **43**, (Scheme 15), which are accounted for as follows. Loss of nitrogen and acetone from **37** gives carbene **41**, and intramolecular carbene addition to the tethered carbonyl group affords intermediate **44**. Substituent migration in **44** could proceed in two ways. Ring enlargement by migration of the least substituted α-carbon atom would give rise to **42** and expansion through migration of the most substituted α-carbon would afford **45**. However, instead of **45**, the product of double ring cleavage (**43**) was obtained. The ratio **42**:**43** was 1.2:1.0 and the combined yield was 60% (isolated). These results can be fitted into the proposed mechanism involving an enolate-like transition state (Scheme 7). Geometric constraints in the cyclic transition state (A, Fig. 1) leading to **42**, with five-membered rings only, should be less severe than those in transition state B leading to **45**, which has a new four-membered ring. Moreover, the electron pair required for rearrangement to **45** is roughly orthogonal to the virtual cation orbital to which it

Scheme 14.

© 2000 NRC Canada



Scheme 15.

would need to migrate. Bond cleavages, to relieve strain and to generate a new carbonyl group, occur instead.

The mono acetals of monocyclic β-dicarbonyl compounds (**6**, **11**, **12**, **14**, **15**, **18**, **25**–**27**) are new compounds and the bicyclic system **42** was unknown. The former are readily accessible by reaction of dimethoxycarbene with small-ring carbonyl compounds and the latter was obtained by an intramolecular variant of the other reactions. The fact that dialkoxycarbenes are now available in a wide variety, and that other nucleophilic carbenes (e.g., $RO(R_2N)C$:) may undergo similar reactions, suggests that the type of reactions introduced above could become useful.

Fig. 1.

Experimental

NMR spectra were acquired with a Bruker DRX-500, AC 300, or AC 200 spectrometer. ^{1}H NMR chemical shifts were referenced to internal TMS or $CHCl_3$ (δ = 7.24) in $CDCl_3$, or C_6HD_5 (δ = 7.15) in C_6D_6, while ^{13}C NMR spectra were referenced to the C_6D_6 triplet (δ = 128.0) or the $CDCl_3$ triplet (δ = 77.0). Mass spectra were recorded with a VGH ZAB-E double focusing mass spectrometer or with a Hewlett–Packard MSD GC–MS. IR spectra are from a Bio-Rad FTS-40 instrument. Semipreparative gas chromatography was performed with a Varian Star 3400 CX gas chromatograph with a thermal conductivity detector and a glass column (6′ × 0.25″) packed with 10% OV-17. Analytical GC work involved a Varian Vista 600 gas chromatograph equipped with a flame ionization detector and a DB-1 megabore capillary column (0.53 mm × 30 m). Unless otherwise stated, benzene was dried with activated molecular sieves and other chromatography solvents were distilled before use. Silica gel from Silicycle (230–400 mesh), in a 30 cm × 2.5 cm glass column, was used for flash chromatography.

General procedure

A Pyrex glass tube (25 mL volume) fitted with a Teflon valve was washed, first with acetone (50 mL), then aq sodium bicarbonate (10%, 50 mL), and finally with distilled water (100 mL). The tube (without the valve) was heated in an oven at 100°C for 2 h. Subsequently, the glass tube (with the valve) was flame dried with the exit port attached to a vacuum line (0.1–0.5 mmHg) to remove most of the residual moisture.

*2,2-Dimethoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline **1***

2,2-Dimethoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline (**1**) was prepared by means of reaction between the corresponding 2-acetoxy-2-methoxy oxadiazoline and methanol catalyzed by trifluoroacetic acid. The crude oxadiazoline was purified by flash column chromatography (silica gel – 10% ethyl acetate in hexanes). MS (EI) *m*/*z*: 132, 129, 105, 91, 90,75, 74, 73, 59, 43 (molecular ion not observed). MS (CI–NH_3) *m*/*z*: 178 ($M^{+\cdot}$ + 18). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.53 (s, 6H), 3.45 (s, 6H). ^{13}C NMR (50 MHz, $CDCl_3$) δ: 23.7, 51.5, 118.8, 137.0.

*Thermolysis of **1** in the presence of cyclobutanone **3***

A pyrex glass tube (25 mL) was charged with **1** (0.200 g, 1.25 mmol), cyclobutanone (**3**, Aldrich) (0.175 g, 2.50 mmol), and benzene (5 g). After three freeze–pump–thaw sequences (0.1–0.5 mmHg) with liquid nitrogen as coolant, the glass tube was sealed and immersed for 24 h in an oil bath at 110°C. After the contents had cooled to ambient temperature, the reaction mixture was transferred to a 25 mL round-bottomed flask. The solvent and volatiles were removed with a rotary evaporator and a vacuum pump, yielding 2,2-dimethoxycyclopentanone (**6**) (75% yield). Spectroscopic data were in agreement with those in the literature (40, 41). MS (CI–NH_3) *m*/*z*: 162 ($M^{+\cdot}$ + 18). ^{1}H NMR (500 MHz, C_6D_6) δ: 1.36 (tt, ^3J = 7.0 Hz, ^3J = 7.6 Hz, 2H), 1.61 (t, ^3J = 7.0 Hz, 2H), 1.82 (t, ^3J = 7.6 Hz, 2H), 3.14 (s, 6H). ^{13}C NMR (50 MHz, C_6D_6) δ: 16.9, 33.3, 35.2, 49.9, 100.7, 207.8 (C=O).

*Thermolysis of **1** in the presence of 2-tert-butylcyclobutanone **10***

A 5 mL reaction vessel for thermolysis was charged with **1** (0.078 g, 0.49 mmol), 2-*tert*-butylcyclobutanone (**10**) (38) (0.060 g, 0.48 mmol), and benzene (2.0 g). After three freeze–pump–thaw cycles the tube was sealed and heated at 110°C for 24 h in an oil bath. The contents of the vessel were transferred to a 5 mL round-bottomed flask and the volatiles were removed with a rotary evaporator and then.. a vacuum pump (0.1–0.5 mmHg) leaving a yellow oil. Semipreparatory gas chromatography of the mixture gave two major components in 60% combined yield. 2,2-Dimethoxy-3-*tert*-butylcyclopentanone (**11**) and 2,2-dimethoxy-5-*tert*-butylcyclopentanone (**12**) were obtained in 1.5:1.0 ratio as determined by uncorrected GC analysis and NMR spectroscopy.

11: GC–IR (cm^{-1}): 1762 (C=O). MS (EI) *m*/*z* (rel. intensity): 172 ($M^{+\cdot}$ –28, 5), 153 (3), 144 (13), 129 (100), 113 (10). ^{1}H NMR (500 MHz, C_6D_6) δ: 1.07 (s, 9H), 1.38–1.42 (m, 1H), 1.51–1.65 (m, 3H), 1.95–2.01 (m, 1H), 3.01 (s, 3H, OCH_3), 3.30 (s, 3H, OCH_3). ^{13}C NMR (125 MHz, C_6D_6) δ: 18.9, 29.2, 32.4, 34.7, 48.4, 50.3, 51.5, 103.8, 210.0 (C=O). Irradiation at the frequency of the *tert*-butyl signal (NOE) caused enhancement of both methoxy group signals. In the mass spectrum, the base peak was at *m*/*z* = 129, consistent with loss of a methyl radical from 1,1-dimethoxy-3,3-dimethyl-1-butenyl radical cation (*m*/*z* = 144).

12: IR (CCl_4) (cm^{-1}): 1749 (C=O). MS (EI) *m*/*z* (rel. intensity): 172 ($M^{+\cdot}$ –28, 6), 169 (7), 157 (4), 113 (110), 88 (100). ^{1}H NMR (500 MHz, C_6D_6) δ: 0.95 (s, 9H), 1.30–1.51 (m, 3H), 1.63 (dd, ^3J = 11 Hz, ^3J = 8.8 Hz, 1H), 1.88 (ddd, *J* = 12.7 Hz, *J* = 6.3 Hz, *J*= 1.5 Hz, 1H), 3.13 (s, 3H), 3.16 (s, 3H). ^{13}C NMR (125 MHz, C_6D_6) δ: 20.6, 27.7, 31.5, 33.0, 49.6, 49.9, 56.0, 101.0, 213.3 (C=O). Irradiation at the frequency of the *tert*-butyl signal (NOE) caused enhancement of only one methoxy signal (δ = 3.16). In the mass spectrum the base peak was at *m*/*z* = 88, consistent with 1,1-dimethoxyethene radical cation.

*Thermolysis of **1** in the presence of 2-methylcyclobutanone **13***

A solution of **1** (0.19 g, 1.2 mmol), 2-methylcyclobutanone (**13**, prepared according to the procedure by van Leusen and co-workers ((42, 43), 0.10 g, 1.2 mmol) and benzene (5.0 g) was treated as described above. The residue, a light yellow oil (59%), was a two-component mixture of 2,2-dimethoxy-3-methylcyclopentanone (**14**) and 2,2-dimethoxy-5-methylcyclopentanone (**15**) in 7.5:1.0 ratio, by NMR spectroscopy. The major and minor isomers were distinguished by means of their characteristic mass spectral fragmentation patterns, similar to those observed for **11** and **12**.

14: IR (CCl_4) (cm^{-1}): 1758 (C=O). MS (EI–GC–MS) *m*/*z* (rel. intensity): 158 ($M^{+\cdot}$, 1), 130 ($M^{+\cdot}$–28, 7), 102 ($(CH_3O)_2CCCH_3^{+\cdot}$, 100), 85 (30), 72 (14), 57 (61). MS (CI–NH_3) *m*/*z*: 159 ($M^{+\cdot}$+1), 176 ($M^{+\cdot}$+18). MS (HR) *m*/*z*: calcd. for $(CH_3O)_2CCHCH_3$ (base peak, isomer identification): 102.0703; found: 102.0681. ^{1}H NMR (200 MHz, C_6D_6) δ: 0.79 (d, ^3J = 7.0 Hz, 3H), 1.06–1.24 (m, 1H), 1.60–2.03 (m, 4H), 3.07 (s, 3H), 3.15 (s, 3H). ^{13}C NMR (50 MHz, C_6D_6) δ: 13.9, 25.0, 32.8, 37.3, 49.9 (OCH_3), 50.2 (OCH_3), 102.4 (C_2), 208.3 (C=O).

15: IR (CCl_4) (cm^{-1}): 1758. MS (EI) (GC–MS) *m*/*z* (rel. intensity): 158 ($M^{+\cdot}$, 1), 130 ($M^{+\cdot}$–28, 13), 99 (9), 88 (100), 71(16), 58 (19), 43 (78). ^{1}H NMR (200 MHz, C_6D_6) δ: 0.95 (d, ^3J = 7.0 Hz, 3H), 1.05–1.23 (m, 1H), 1.59–2.02 (m, 4H), 3.13 (s, 3H), 3.16 (s, 3H). ^{13}C NMR (50 MHz, C_6D_6) δ: 15.5, 25.9, 32.0, 41.9, 49.7, 50.2, 101.0, 207.6.

*Thermolysis of **1** in the presence of cyclopentanone*

Thermolysis if **1** (0.100 g, 0.63 mmol) in benzene (5 mL) containing cyclopentanone (0.105 g, 1.25 mmol) as described above for cyclobutanone, gave the known (41) 2,2-dimethoxycyclohexanone in 12% yield.

*Thermolysis of **1** in the presence of cis-2, 4-di-tert-butylcyclobutanone (**19**)*

Thermolysis of **1** (46.1 mg, 0.288 mmol), in benzene (2 g) containing **19** (40.0 mg, 0.219 mmol) did not lead to detectable products of attack by **2** on the ketone. The only species detected were the carbene dimer **21** and unreacted **19**. The latter was still *cis*, as was readily ascertained from the NMR spectrum. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 0.92 (s, 18H), 1.67 (dd, ^3J = 9.4 Hz, ^2J = 19.0 Hz, 1H), 1.96 (dd, ^3J = 10.4 Hz, 1H), 2.86 (dd, ^3J = 9.4 Hz, ^3J = 10.4 Hz, 2H).

*Thermolysis of **1** in the presence of trans-2, 3-di-tert-butylcyclopropanone (**17**)*

A medium-walled NMR tube containing **1** (0.023 g, 0.14 mmol), *trans*-di-*tert*-butylcyclopropanone (**17**) (44–46) (0.020 g, 0.12 mmol) and C_6D_6 (1.0 g) was sealed under vacuum after three cycles of freeze–pump–thaw degassing. The tube was heated for 24 h at 110 °C in an oil bath before it was cut and the contents were transferred to a 3 mL glass vial. Concentration of the sample and semipreparatory gas chromatography gave *trans*-3,4-di-*tert*-butyl-2,2-dimethoxycyclobutanone (**18**) in 65% yield. IR (CCl_4) (cm^{-1}): 1783. MS (EI) *m*/*z* (rel. intensity): 185 ($M^{+\cdot}$ –57, 5), 157 (100), 129 (15), 74 (51), 57 (55). MS (CI–NH_3) *m*/*z*: 260 ($M^{+\cdot}$ + 18), 243 ($M^{+\cdot}$ +1). ^{1}H NMR (300 MHz, C_6D_6) δ: 0.96 (s, 9H), 0.99 (s, 9H), 2.03 (d, ^3J = 7.1 Hz, 1H), 2.62 (d, ^3J = 7.1 Hz, 1H), 2.98 (s, 3H), 3.41 (s, 3H). ^{13}C NMR (75 MHz, C_6D_6) δ: 28.9, 29.0, 30.7, 48.6, 51.0, 51.9, 66.1, 99.6, 111.2, 207.8 (C=O).

*Reaction of **2** with 2,2,4,4-tetramethylcyclobutane-1,3-dione (**22**)*

A 5 mL thermolysis tube was charged with **1** (0.200 g, 1.25 mmol), 2,2,4,4-tetramethylcyclobutane-1,3-dione (**22**, Aldrich, 0.168 g, 1.20 mmol) and benzene (5.0 g). After three freeze–pump–thaw cycles the tube was sealed and heated for 24 h in an oil bath at 110°C. Removal of the volatiles, as described above, left a yellow oil from which the major product (**25**) (70%, estimated by gas chromatography) was isolated, either by semipreparative gas chromatography or by flash column chromatography (silica gel – 10% ethyl acetate in hexanes, R_f = 0.75). IR (CCl_4) (cm^{-1}): 1735. MS (EI) *m*/*z* (rel. intensity): 186 ($M^{+\cdot}$ –28, 12) 149 (8), 116 (32), 101 (16), 84 (28), 43 (100). MS (CI–NH_3) *m*/*z*: 232 ($M^{+\cdot}$ +18). ^{1}H NMR (200 MHz, C_6D_6) δ: 1.06 (s, 6H), 1.09

(s, 6H), 2.91 (s, 6H). ^{13}C NMR (50 MHz, C_6D_6) δ: 18.8, 22.8, 48.6, 50.3, 54.4, 103.9, 208.3 (C=O), 215.5 (C=O).

*Thermolysis of **1** in the presence of 1,2-diphenylcyclopropenone (**23**)*

A solution of **1** (0.200 g, 1.25 mmol) and 1,2-diphenylcyclopropenone (**23**) (Aldrich, 0.450 g, 2.20 mmol) in benzene (5.0 g), in a 25 mL thermolysis tube, was treated as described above. Flash column chromatography (silica gel, 5% ethyl acetate in hexanes, R_f = 0.23) of the residue left after pumping off the volatile components, afforded 4, 4-dimethoxy-2, 3-diphenyl-2-cyclobuten-1-one (**26**) in 60% yield. IR (CCl_4) (cm^{-1}): 1758. MS (EI) *m*/*z* (rel. intensity): 280 ($M^{+\cdot}$, 16), 265 ($M^{+\cdot}$ –15, 6), 249 ($M^{+\cdot}$ –31, 18), 220 (38), 205 (16), 192 (55), 178 (100), 152 (29), 121 (38), 115 (77), 91 (38). MS (HR) *m*/*z*: calcd. for $C_{18}H_{16}O_3$: 280.1090; found: 280.1099. ^{1}H NMR (200 MHz, C_6D_6) δ: 3.47 (s, 6H), 6.98–7.03 (m, 6H), 7.76–7.81 (m, 2H), 7.87–7.92 (m, 2H). ^{13}C NMR (50 MHz, C_6D_6) δ: 53.6, 118.1, 128.3, 128.7, 128.9, 129.0, 129.2, 130.0, 130.9, 131.6, 149.0, 170.7, 193.2.

*Thermolysis of **1** in the presence of 3,4-dimethoxy-3-cyclobutene-1,2-dione (**24**)*

A solution of **1** (0.200 g, 1.25 mmol) and 3,4-dimethoxy-3-cyclobutene-1,2-dione (**24**) (Aldrich, 0.170 g, 1.20 mmol) in benzene (5.0 g) was heated as described above. Flash column chromatography of the residue left after removal of the volatiles (10–30% ethyl acetate in hexanes) gave, from the first yellow band, 2,2,4,5-tetramethoxy-4-cyclopentene-1,3-dione (**27**) in 54% yield as a yellow solid, mp 37.0–38.0°C. IR (CCl_4) (cm^{-1}): 1702. MS (EI) *m*/*z* (rel. intensity): 216 ($M^{+\cdot}$, 100), 185 ($M^{+\cdot}$ –31, 57), 173 (85), 157 (28), 129 (29), 86 (14), 75 (51), 59 (81). MS (CI–NH_3) *m*/*z* : 234($M^{+\cdot}$ +18). MS (HR) *m*/*z*: calcd. for $C_9H_{12}O_6$: 216.0641; found: 216.0634. ^{1}H NMR (200 MHz, C_6D_6) δ: 3.47 (s, 6H), 3.60 (s, 6H). ^{13}C NMR (50 MHz, C_6D_6) δ: 51.8, 59.2, 91.0, 150.8, 188.6 (C=O).

*Thermolysis of **1** in the presence of 2-azetidinone (**30**)*

The procedure described above gave, from **1** (0.200 g, 1.25 mmol) and 2-azetidinone (**30**) (Aldrich, 0.178 g, 2.5 mmol) in benzene (5.0 g), a residue that was worked up by semipreparative gas chromatography. 1-(Dimethoxymethyl)-2-azetidinone (**31**) (76% by GC) was isolated as an oil. IR (CCl_4) (cm^{-1}): 1770. MS (EI) *m*/*z* (rel. intensity): 145 ($M^{+\cdot}$, 1), 130 ($M^{+\cdot}$ –15, 1), 114 (18), 87 (33), 75 ($(MeO)_2CH$, (100), 72 (30), 42 (35). ^{1}H NMR (200 MHz, C_6D_6) δ: 2.24 (t, ^3J = 4.5 Hz, 2H), 2.79 (t, ^3J = 4.5 Hz, 2H), 2.99 (s, 6H), 5.38 (s, 1H). ^{13}C NMR (50 MHz, C_6D_6) δ: 35.5, 36.1, 53.2, 99.5, 166.5.

*Thermolysis of **1** in the presence of β-propiolactone (**34**)*

Heating of a solution of **1** (0.200 g, 1.25 mmol) and β-propiolactone (**34**) (Aldrich, 0.090 g, 1.20 mmol) in benzene (5.0 g), and workup as described above, left a yellow oil. Flash column chromatography (silica gel – 30% ethyl acetate in hexanes, R_f = 0.50) afforded 2,2-dimethoxy-3-oxacyclopentanone (**36**) as an oil in 65% yield. IR (CCl_4) (cm^{-1}): 1741. MS (EI–GC–MS) *m*/*z* (rel. intensity): 118 ($M^{+\cdot}$–28, loss of CO, 29), 115 (40), 91 (90), 59 (100). ^{1}H NMR (500 MHz, C_6D_6) δ: 1.75 (t, ^3J = 7.0 Hz, 2H), 3.25 (s, 6H), 3.50 (t, ^3J = 7.0 Hz, 2H). ^{13}C NMR (125 MHz, C_6D_6) δ: 33.5, 50.2, 60.4, 110.0, 202.8 (C=O).

Synthesis of 1,1-diethoxyethene

1,1-Diethoxyethene was prepared according to the procedure by Thweatt and co-workers (39). A fractional distillation apparatus consisting of a two-necked, round-bottomed flask (50 mL), magnetic stirring bar, addition funnel (20 mL), fractionating column (20 cm), three-way Claisen head with thermometer, condenser (20 cm), and a receiving flask (50 mL) with a vacuum attachment was flame-dried under vacuum. The addition funnel was removed and solid potassium *tert*-butoxide (11.4 g, 102 mmol) was added to the flask. The addition funnel was reattached and 2-bromo-1,1-diethoxyethane (15.3 mL, 20.0 g, 101.5 mmol) was added with a glass syringe to the addition funnel through a rubber septum. The reaction flask was cooled with an ice water mixture (5 min) and 2-bromo-1,1-diethoxyethane was dispensed into the round bottom flask (1 min). A white dense smoke formed immediately. After the reaction appeared to be complete (5 min), the mixture was heated with an oil bath (120–130°C), and *tert*-butyl alcohol (82–83°C/760 mmHg) generated from the reaction was removed by distillation. The system was then attached to a water aspirator and 1,1-diethoxyethene was distilled from the crude reaction mixture (46°C/28 mmHg) (6.70 g, 57%). ^{1}H NMR (200 MHz, C_6D_6) δ: 1.02 (t, ^3J = 7.0 Hz, 6H), 3.17 (s, 2H), 3.55 (q, ^3J = 7.0 Hz, 4H). ^{13}C NMR (25 MHz, C_6D_6) δ: 14.5, 56.6, 63.4, 165.7. The product was used on the same day in the next step.

Synthesis of methyl (2,2-diethoxycyclobutane)carboxylate

A solution of 1,1-diethoxyethene (6.70 g, 58.0 mmol) and methyl acrylate (4.97 g, 58 mmol) was refluxed in dry acetonitrile (40 mL) for eight days. Acetonitrile was distilled out through a Vigreux column, followed by methyl (2,2-diethoxycyclobutane)carboxylate (48°C/0.8 mmHg) (2.0 g, 17%), (lit. (38, 40) 60–63%). ^{1}H NMR (200 MHz, C_6D_6) δ: 0.97–1.24 (m, 1H), 1.01 (t, 3H, 7.0 Hz), 1.11 (t, 3H, 7.0 Hz), 1.58–2.37 (m, 4H), 3.17–3.65 (m, 4H), 3.42 (s, 3H). ^{13}C NMR (125 MHz, C_6D_6) δ: 14.8, 15.3, 15.4, 31.0, 49.6, 51.1, 56.6, 57.1, 102.6, 170.8.

*Synthesis of (2,2-diethoxycyclobutyl)methanol (**47**)*

To a suspension of $LiAlH_4$ (0.25 g, 6.70 mmol) in ether (15 mL) was added, dropwise with stirring, methyl (2,2-diethoxycyclobutane)carboxylate (1.35 g, 6.70 mmol). After the addition the mixture was heated to boiling for 1.5 h before it was cooled with an ice water bath and the excess $LiAlH_4$ was quenched with ethyl acetate (15 mL), followed by water (15 mL, slow addition). The heterogeneous solution left after the fine-grained $Al(OH)_3$ was filtered off with a sintered glass funnel was extracted with diethyl ether (3 × 25 mL) and the combined organic fractions were dried with magnesium sulphate. Filtration through a sintered glass funnel and removal of the volatiles afforded (2,2-diethoxycyclobutyl)methanol in 95% yield. The crude product was used without purification. Purification by distillation (61°C/0.8 mmHg) has been reported (47). ^{1}H NMR (200 MHz, C_6D_6) δ: 0.92 (t, ^3J = 7.1 Hz, 3H), 1.08 (t, ^3J = 7.1 Hz, 3H), 1.35–2.60 (m,

© 2000 NRC Canada

6H), 3.10–3.90 (m, 6H). ^{13}C NMR (25 MHz, C_6D_6) δ: 14.2, 15.3, 15.5, 30.6, 45.9, 56.1, 56.5, 63.1, 103.9.

*Hydrolysis of (2,2-diethoxycyclobutyl)methanol (**48**)*

2,2-(Diethoxycyclobutyl)methanol (0.51 g, 2.93 mmol) was stirred with 3% H_2SO_4 (30 mL) for 20 min in a 50 mL round-bottomed flask. The mixture was extracted with ether (3 × 15 mL) and the combined ether extracts were washed with 5% $NaHCO_3$ (3 × 20 mL). The yellow aq layers were combined in a separatory funnel and CH_2Cl_2 (60 mL) and H_2SO_4 (3%, 30 mL) were added. The yellow aq layer was extracted with CH_2Cl_2 until the yellow colour of the aq layer was completely dissipated. The organic layers were combined and dried with anhyd magnesium sulphate. Filtration through a sintered glass funnel and removal of the solvents yielded the desired 2-hydroxymethylcyclobutanone (**36**) (75%) as an oil. ^{1}H NMR (200 MHz, C_6D_6) δ: 1.45–1.75 (m, 2H), 2.38–2.68 (m, 2H), 2.90–3.10 (m, 2H), 3.37–3.70 (m, 2H). ^{13}C NMR (25 MHz, C_6D_6) δ: 13.5, 45.4, 60.1, 62.8, 210.2.

*Reaction of **38** with 2-hydroxymethylcyclobutanone (**39**)*

Trifluoroacetic acid (4 drops) was added to 2-acetoxy-2-methoxy-Δ^3-1,3,4-oxadiazoline (**38**) (49) (0.700 g, 3.72 mmol), 2-hydroxymethylcyclobutanone (0.220 g, 2.20 mmol), and dichloromethane (35 mL) in a 100 mL round-bottomed flask and the solution was stirred under nitrogen for 48 h at room temperature. Sodium bicarbonate (10%, 20 mL) was added and the contents were stirred for 10 min before the aq layer was separated and discarded. The extraction was repeated before the organic layer was dried with anhyd magnesium sulphate. Filtration and removal of the volatiles afforded a yellow oil. 2-(2-Cyclobutanonemethoxy)-2-methoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline (**37**) was obtained as a 50:50 mixture of diastereomers, in 54% yield, by flash column chromatography on silica gel (20% ethyl acetate in hexanes). IR (CCl_4) (cm^{-1}): 1790 (C=O). MS (EI) *m*/*z* (rel. intensity): (molecular ion not observed) 129 ($M^{+\cdot}$ –99, 14), 117 (7), 83 (35), 73 (31), 55 (100). MS (CI–NH_3): 229 ($M^{+\cdot}$ +1), 246 ($M^{+\cdot}$ +18). ^{1}H NMR (200 MHz, C_6D_6) δ: 1.21 (s, 6H), 1.23 (s, 3H), 1.28 (s, 3H), 1.32–1.71 (m, 4H), 2.34–2.52 (m, 4H), 2.87–2.99 (m, 2H), 3.17 (s, 3H), 3.21 (s, 3H), 3.60–4.00 (m, 4H). ^{13}C NMR (125 MHz, C_6D_6) δ: 14.1, 14.2, 23.7, 23.7, 24.0, 24.1, 45.0, 45.0, 51.6, 51.6, 60.0, 60.0, 62.1, 62.3, 119.3, 119.3, 137.5, 137.5, 206.3, 206.5. The diasteromers could be separated by TLC (20% ethyl acetate in hexanes, R_f = 0.3 and 0.4).

*Thermolysis of 2-(2-cyclobutanonemethoxy)-2-methoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline (**37**)*

2-(2-Cyclobutanonemethoxy)-2-methoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline (**37**, 0.140 g, 0.614 mmol) in benzene (16.5 g) was heated in a 25 mL thermolysis tube as described above. Removal of the volatiles and GC analysis indicated the presence of two major products (**42** and **43**), in 1.2:1.0 ratio. These were isolated by semipreparative gas chromatography in a combined yield of 60%.

42: IR (CCl_4) (cm^{-1}): 1790. MS (EI) *m*/*z* (rel. intensity): 142($M^{+\cdot}$, 20), 124 (21), 97 (25), 81 (53), 55 (100). MS (CI–NH_3) *m*/*z*: 143 ($M^{+\cdot}$ +1), 160 ($M^{+\cdot}$ +18). Aqueous nonelectrolyte solutions. Part XVII. Formula of hydrogen sulfide hydrate and its dissociation thermodynamic functions

David N. Glew

Abstract: Literature data for the saturation vapor pressure $P(hl_1g)$ of hydrogen sulfide hydrate with water, at 43 temperatures between quadruple points $Q(hs_1l_1g)$ at –0.4°C and $Q(hl_1l_2g)$ at 29.484°C, are properly represented by a six-parameter equation to give a standard error (SE) of 0.13% on a hydrate pressure measurement of unit weight. Equilibrium hydrogen sulfide and water fugacities and the gas and aqueous phase compositions are derived using the Redlich–Kwong equation of state. Literature data for the saturation vapor pressure $P(hs_1g)$ of hydrogen sulfide hydrate with ice, at 15 temperatures between –1.249 and –21.083°C, are properly represented by a two-parameter equation to give a SE of 0.26% on a single hydrate pressure measurement. Quadruple point $Q(hs_1l_1g)$ is evaluated at temperature –0.413° with SE 0.042°C and at pressure 94.7 with SE 0.26 kPa. Using the thermodynamic method, described for deuterium sulfide D-hydrate, the equilibrium fugacities of hydrogen sulfide are used to define 43 equilibrium constants $Kp(h \rightarrow l_1g)$ for hydrate dissociation into water and hydrogen sulfide gas. The temperature dependence of ln $Kp(h \rightarrow l_1g)$ is represented by a three-parameter thermodynamic equation which gives both values and standard errors (*i*) for $Kp(h \rightarrow l_1g)$, and for $\Delta H^{ot}(h \rightarrow l_1g)$ and $\Delta Cp^{ot}(h \rightarrow l_1g)$, the standard enthalpy and heat capacity changes for hydrate dissociation and (*ii*) for $n = r$ the approximate formula number of the hydrate $H_2S \cdot nH_2O$ at each experimental temperature. The formula $H_2S \cdot 6.119H_2O$ with standard error $0.029H_2O$ is found for hydrogen sulfide hydrate with water at lower quadruple point $Q(hs_1l_1g)$ –0.413°C: an approximate formula $H_2S \cdot 5.869H_2O$ with SE $0.026H_2O$ is found at upper quadruple point $Q(hl_1l_2g)$ 29.484°C. These estimates for the formula of hydrogen sulfide hydrate at its quadruple points are not significantly different from those found for the deuterium sulfide D-hydrate.

Key words: clathrate hydrate of hydrogen sulfide, hydrogen sulfide hydrate, formula of hydrogen sulfide hydrate, thermodynamics of clathrate hydrate dissociation, dissociation equilibrium constant of hydrogen sulfide hydrate, standard enthalpy and heat capacity changes for dissociation of hydrogen sulfide hydrate.

Résumé : Les données tirées de la littérature pour la tension de vapeur de saturation (Phl_1g) de l'hydrate du sulfure d'hydrogène avec l'eau, à quarante-trois températures entre les points quadruple $Q(hs_1l_1g)$, à –0,4°C, et $Q(hl_1l_2g)$, à 29,484°C, peuvent être adéquatement représentées par une équation à six paramètres pour laquelle l'erreur standard (ES) est de 0,13 % sur une mesure de tension d'une unité de poids. Les fugacités du sulfure d'hydrogène et de l'eau en équilibre ainsi que les compositions des phases aqueuse et gazeuse sont obtenues à l'aide de l'équation d'état de Redlich-Kwong. Les données de la littérature pour la tension de vapeur de saturation $P(hs_1g)$ de l'hydrate d sulfure d'hydrogène avec la glace, à quinze températures entre –1,249 et –21,083°C peuvent être adéquatement représentées par une équation à deux paramètres pour laquelle l'ES est de 0,26 % pour une seule mesure de la tension de l'hydrate. On a évalué que le point quadruple $Q(hs_1l_1g)$ se situe à –0,413°C avec une ES de 0,042°C et à une pression de 94,7 avec une ES de 0,26 kPa. Faisant appel à la méthode thermodynamique décrite pour l'hydrate deutéré du sulfure de deutérium ainsi que les fugacités à l'équilibre du sulfure d'hydrogène, on a pu définir quarante-trois constantes $Kp(h \rightarrow l_1g)$ pour la dissociation de l'hydrate en eau et en sulfure d'hydrogène gazeux. La relation de ln $Kp(h \rightarrow l_1g)$ avec la température est représentée par une équation thermodynamique à trois paramètres qui conduisent aux valeurs et aux erreurs standards (*i*) pour $Kp(h \rightarrow l_1g)$ ainsi que pour $\Delta H^{ot}(h \rightarrow l_1g)$ et $\Delta Cp^{ot}(h \rightarrow l_1g)$, les changements d'enthalpie et de capacité calorifique standards pour la dissociation de l'hydrate et (*ii*) pour $n = r$, le nombre approximatif de la formule de l'hydrate $H_2S \cdot nH_2O$ à chacune des températures expérimentales. On arrive à une formule de $H_2S \cdot 6{,}119H_2O$ avec une erreur de 0,029 H_2O pour l'hydrate du sulfure d'hydrogène avec l'eau au point quadruple le plus bas, $Q(hs_1l_1g)$, à –0,413°C; pour le point quadruple le plus élevée $Q(hl_1l_1g)$, à 29,484°C, on arrive à une formule approximative de $H_2S \cdot 5{,}869H_2O$ avec une erreur de 0,026 H_2O pour l'hydrate du sulfure d'hydrogène. Ces évaluations de la formule de l'hydrate du sulfure d'hydrogène à ses points quadruples ne diffèrent pas beaucoup de celles trouvées à partir de l'hydrate deutéré du sulfure de deutérium.

Introduction

This report is part of a continuing study (1–7) of the thermodynamic properties of aqueous nonelectrolyte solutions and of their clathrate hydrate solid solutions. In this work we evaluate the formula of hydrogen sulfide hydrate with water from literature data (8–20) using the thermodynamic method (7) described in detail for deuterium sulfide D-hydrate. Here a quantitative evaluation is made with standard errors (*i*) of the standard thermodynamic function changes for the ($h \rightarrow l_1 g$) dissociation of hydrogen sulfide hydrate (h) into water (l_1) plus hydrogen sulfide gas (g), and (*ii*) of the formulae for hydrogen sulfide hydrate. These functions and formulae are similar to those reported (7) for the dissociation of deuterium sulfide D-hydrate between its quadruple points $Q(hs_1l_1g)$ and $Q(hl_1l_2g)$.

The literature containing measurements of the saturation pressure $P(hl_1g)$ of hydrogen sulfide hydrate with water goes back to 1882, with the earliest studies (8, 9) having low accuracy, and with the precise measurements of de Forcrand and Villard (10) having an uncertian bias. We fortunately have additional hydrogen sulfide hydrate measurements and careful thermodynamic analyses by Scheffer and his coworkers (11–15) who remeasured and extended the earlier work.

A valuable modern review of the hydrogen sulfide-water system, including both the older (8–15) and more recent hydrate studies (16–19) has been given by Carroll (19). Our assessment of the less reliable hydrate data sets (8, 9, 16–19) generally agrees with the analysis of Carroll et al. (19, 20).

The present study of hydrogen sulfide hydrate with water necessarily uses the same data sets (8–19), but we make an additional quantitative assessment of the reliability of the best data sets (10, 11, 14), and of the resulting formula for hydrogen sulfide hydrate. We find that the measurements of Scheffer et al. (11–15) are the most reliable, but that all of these measurements are not equally reliable. The precise hydrate pressures reported by de Forcrand et al. (10) are unfortunately uniformly biased about 1% lower than the best measurements of Scheffer and Meyer (14), and indicate a temperature significantly higher than –0.4°C for the quadruple point $Q(hs_1l_1g)$ (14, 15). We describe how we weight and combine these three best data sets (10, 11, 14), which to highest accuracy are mutually inconsistent, to provide (*i*) a best equation for $P(hl_1g)$ the saturation pressure of hydrogen sulfide hydrate with water and (*ii*) a best equation for $Kp(h \rightarrow l_1 g)$ the hydrate dissociation equilibrium constant and the values derived for the hydrate formula.

Experimental temperatures are converted to ITS-90, as described in (7), and three digits are retained after the decimal point to enable accurate reconversion, and not to indicate the accuracy of the measurements. The thermodynamic regression equations (21) are evaluated using the method of weighted least-squares (22) and a predicted estimate is qualified with its standard error, written SE. The weights are chosen to indicate the relative importance of measurements within their own data set, and the relative accuracy of the different data sets.

Results and discussion

H_2S hydrate–liquid H_2O-gas (hl_1g) equilibrium

Table 1 presents 43 equilibrium determinations of $P(hl_1g)$, the saturation vapor pressure of hydrogen sulfide hydrate (h) in contact with water-rich liquid (l_1) between 29.484 and –0.413°C.

The second column denotes the data source and datum number. Data S-11 to S-1 are from Scheffer (11, 12): datum S-5 is an outlier and is not included in the regression. Data SM4–16, SM6–8 to SM5–1 are from Tables 4, 6, and 5, respectively, of Scheffer and Meyer (14): datum SM4–10 is an outlier and is not included in the regression. Data dFV-16 to dFV-1 are from de Forcrand and Villard (10). The data listed as Qsol at –0.369°C and QP at –0.413°C are two estimates of the temperature and pressure at the quadruple point temperature $Q(hs_1l_1g)$, evaluated using the equilibrium pressure $P(hs_1g)$ of hydrogen sulfide hydrate with ice (14).

The third column gives the square root of the weights used to combine these data from the various sources into a properly weighted least-squares regression of the logarithm of $P(hl_1g)$ as a function of temperature. The weights are determined by the fit of the best six-parameter equation, using realistic relative weights for the three major data sets (10, 11, 14). Single measurements, which exhibit acceptable large residuals, are given reduced weight; measurements which show unreasonable large residuals (greater than three SE's from their data set) are considered outliers and are excluded from the regression.

The fourth column lists the observed $P(hl_1g)$ MPa and the fifth gives $P(hl_1g)$ calculated from the best (21) equation of the form

$$[1a] \quad \ln P(hl_1g) = b0 + b1{\cdot}u1 + b2{\cdot}u2 + b3{\cdot}u3 + b4{\cdot}u4 + b5{\cdot}u5$$

which is mathematically equivalent to

$$[1b] \quad \ln P(hl_1g) = A + B/T + C \ln T + DT + ET^2 + FT^3$$

and which requires six parameters for a proper representation of the 43 data. The percentage differences between the observed and calculated pressures, shown in the sixth column, yield an overall SE of 0.13% for a single determination of unit weight with 37 degrees of freedom. The seventh column shows the percentage standard error on the pressure estimated from the weighted regression model.

The nine data of unit weight from Scheffer (11, 12) give residuals which indicate a SE of 0.16%: datum S-4 requires the reduced weight $w^{1/2} = 0.05$ to give the same weighted SE. The four data with unit weight from Table 6 of Scheffer and Meyer (14) were measured using a Beckmann thermometer graduated in 1/50°C and their residuals indicate a SE of 0.095%. Data from Tables 4 and 5 of ref. 14 were measured using thermometers graduated in 1/5°C and the six data with $w^{1/2} = 0.4$ correctly reflect their reduced accuracy. The ten residuals with the highest weights from Tables 6, 5, and 4 of ref. 14 indicate a SE of 0.13%. The remaining five measurements from Table 4 of ref. 14 exhibit residuals with large

positive biases and these data are assigned the very small weight, $w^{1/2} = 0.01$, to reduce their possible bias of the regression equation.

The sixteen data from de Forcrand and Villard (10) require the weight, $w^{1/2} = 0.1$, to make the regression model consistent with a quadruple point temperature $t(hs_1l_1g)$ near to –0.4°C: these residuals indicate an elevated SE of 0.51%, resulting mainly from their bias relative to the more reliable measurements of Scheffer and Meyer (14).

The five temperature variables $u1$–$u5$ in eq. [1*a*] are defined in (21) with $x = (T - 298.15)/298.15$ and the parameters $b0$–$b5$ with their (SEs) are: $b0 = 0.288\,621$ (0.000 75), $b1 = 31.6576$ (0.065), $b2 = 266.610$ (7.0), $b3 = 13915.9$ (680), $b4 = 293\,694$ (19 000), and $b5 = 1\,890\,730$ (150 000). It is seen that the hydrogen sulfide hydrate pressures properly define five temperature parameters, $b1$–$b5$ at 25°C, that all parameters are positive with no alternation of sign, and that the value of the least significant parameter $b5$ could arise by pure chance at a probability level of less than one in 10^{15} times.

Comparison of the fit of the 43 $P(hl_1g)$ data by the four-parameter equation of Carroll (19) and by the six-parameter eq. [1*a*] shows that the residuals are seventeen times smaller and the standard deviations are ten times smaller using eq. [1*a*].

At 25°C the saturation pressure $P(hl_1g)$ of hydrogen sulfide hydrate is 1.3346 with SE 0.0011 MPa and for

deuterium sulfide D-hydrate (6) is 1.1701 with SE 0.00011 MPa, a difference of 14%.

Following the work on deuterium sulfide D-hydrate (6), gas phase imperfections of the hydrogen sulfide–water mixtures have been represented by the Redlich–Kwong equation of state. The a_{22} and b_{22} parameters used for hydrogen sulfide vapor are those derived from the high temperature (h.t.) measurements from –30° to +30°C (4): the a_{11} and b_{11} for water vapor are those derived for the solubility measurements (5). The intensive properties of the gas and aqueous phases in equilibrium with hydrogen sulfide hydrate have been evaluated by the same iterative process described in (6) for the D-hydrate. The required modern values (*i*) for p_1°, the saturation vapor pressure of water, are from Haar et al. (23), (*ii*) for V_1^{l1}, the molar volume of water, are from Kell (24), and (*iii*) for V_2^{l1}, the partial molar volume of aqueous hydrogen sulfide, are from Barbero et al. (25), evaluated with proper allowance for the differences of the temperature scales (ITS-27, IPTS-48, IPTS-68, and ITS-90) (26). All temperatures are quoted with Celsius t°C + 273.15 = T K thermodynamic scale ITS-90.

Table 2 presents derived values for the intensive properties of the gas phase (g) and the water-rich phase (l_1) in equilibrium with hydrogen sulfide hydrate (h) under conditions of Table 1. Values shown in columns three to seven are, respectively, for the fugacities f_2 of hydrogen sulfide and f_1 of

water, for the gas-phase mole fraction y_1 of water, and for the mole fractions x_2^{l1} of undissociated hydrogen sulfide and x_3^{l1} of hydrogen sulfide anion in the water-rich phase l_1.

H_2S hydrate–ice-gas (hs_1g) equilibrium

Table 3 presents 15 equilibrium measurements by Scheffer and Meyer (14) of $P(hs_1g)$, the saturation total pressure of hydrogen sulfide hydrate (h) in contact with ice (s_1), between –1.249 and –21.083°C.

The second column denotes the data source and datum number, data SM2–1, SM3–7, and SM1–12 are from Tables 2, 3, and 1, respectively, of ref. 14. Three outliers, at the low temperatures –19.734, –24.580, and –25.829°C, exhibit biased and systematically high pressures and are excluded from the regression, to reduce possible bias of the regression model.

The third column shows the observed $P(hs_1g)$ MPa and the fourth column the $P(hs_1g)$ calculated from the best equation

$$[2] \qquad \ln P(hs_1g) = 8.9718 - 3090/T$$

with thermodynamic temperature T K, which gives a SE of 0.26% for a single determination of $P(hs_1g)$ and a SE of 7.4 K on the parameter –3090.

In Table 1 the data listed as Qsol and QP are two estimates of temperature and pressure at the quadruple point $Q(hs_1l_1g)$, based on the (hs_1g) equilibrium eq. [2]. The datum Qsol is evaluated using eq. [2] together with its equilibrium aqueous solution of hydrogen sulfide (5) at its ice-freezing temperature. Our depression for $t(hs_1l_1g)$ is –0.369°C with SE 0.030°C and is in good agreement with the –0.365°C given by Korvezee and Scheffer (15): both values are insignificantly higher than the accepted –0.4°C of $t(hs_1l_1g)$ (14, 15). The datum QP is evaluated from the cut of eq. [2] for $P(hs_1g)$ with the $P(hl_1g)$ data from ref. 14 only: this estimate of $t(hs_1l_1g)$ is –0.413°C with SE 0.042°C, in agreement with the –0.4°C by Scheffer et al. (14, 15).

The fifth to seventh columns in Table 3 present the equilibrium intensive properties f_2, f_1, and y_1 for the binary gas phase, evaluated using the Redlich–Kwong equation of state with the observed total pressures $P(hs_1g)$, as described in ref. 6. The required vapor pressure of ice between –0.369° and –21.083°C is from Dorsey (27).

Lower quadruple point $Q(hs_1l_1g)$

The lower quadruple point $Q(hs_1l_1g)$, determined from the intersection of eq. [1*a*] for $P(hl_1g)$ with eq. [2] for $P(hs_1g)$, is found at temperature –0.398° with SE 0.035°C and at 94.75 kPa pressure with SE 0.25 kPa. If the 16 data of de Forcrand and Villard (10) are excluded and only the 25 data from Scheffer et al. (11, 14) are used for $P(hl_1g)$, $Q(hs_1l_1g)$ is found at –0.413° with SE 0.042°C. These two estimates of $t(hs_1l_1g)$ are not significantly different. We prefer the value –0.413°C for $t(hs_1l_1g)$ because this value does not depend on the data of de Forcrand et al. (10) which contain an uncertain temperature bias.

The temperature difference between the triple and quadruple points (0.010 – (–0.413)) = 0.423°C for water and hydrogen sulfide hydrate is near that (3.8125 – 3.3917) = 0.4208°C found for deuterium oxide and deuterium sulfide D-hydrate (6).

Standard enthalpy change for dissociation of hydrogen sulfide hydrate into ice and hydrogen sulfide gas

Thermodynamic equations from ref. 7 are used here without derivation since all have been discussed for determination of the formula of deuterium sulfide D-hydrate.

Consider the standard dissociation of one gram mole (gram-molar mass) of hydrogen sulfide hydrate of formula $H_2S{\cdot}nH_2O$ into n mole of ice plus one mole of hydrogen sulfide gas. The equilibrium constant $Kp(h{\rightarrow}s_1g)$ for this process is defined by the equation

$$[3] \qquad \ln Kp(h{\rightarrow}s_1g) = \ln f_2 + n[P(hs_1g) - 0.10][V_1^{s1} - (V^h/46)]/RT$$

in which f_2 is the fugacity of hydrogen sulfide, n the hydrate formula number, V_1^{s1} the molar volume of ice, and V^h the unit cell molar volume of hydrate, at thermodynamic

© 2000 NRC Canada

temperature T K and equilibrium pressure $P(hs_1g)$. Equilibrium values for f_2 are given in Table 3 and the gaseous standard state is one MPa fugacity. Formula number $n = 6.10$ is assumed, but this value is not critical because of the low (hs_1g) equilibrium pressures. The molar volume of ice is from Dorsey (27) and the hydrate molar volume is from von Stackelberg and Jahns (28): the standard state of the condensed phases is 0.1 MPa pressure.

Values of $\ln Kp(h \rightarrow s_1g)$ MPa are best (21) represented by

$$[4] \quad \ln Kp(h \rightarrow s_1g) = 8.8351 - 3057/T$$

with the same standard errors as those given for eq. [2].

The standard dissociation enthalpy change $\Delta H^{ot}(h \rightarrow s_1g)$ is found to be 25416 with SE 52 J/mole of hydrogen sulfide and is temperature invariant, with $\Delta Cp^{ot}(h \rightarrow s_1g)$ insignificantly different from zero. This value for the standard enthalpy change is less than the 25500 J/mole found by Scheffer and Meyer (14) using partial pressures.

Standard enthalpy change for dissociation of hydrogen sulfide hydrate into water and hydrogen sulfide gas.

Consider the standard dissociation of one gram mole of hydrogen sulfide hydrate of formula $H_2S{\cdot}nH_2O$ into one mole of gaseous hydrogen sulfide plus n mole of water. The equilibrium constant $Kp(h \rightarrow l_1g)$ for this process is defined by the equation

$$[5] \quad \ln Kp(h \rightarrow l_1g) = \ln f_2 + n \ln x_1^{l1} + n[P(hl_1g) - 0.10][V_1^{l1} - (V^h/46)]/RT$$

in which V_1^{l1} is the molar volume of water at thermodynamic temperature T K and equilibrium pressure $P(hl_1g)$. Equilibrium values of f_2 and for $x_1^{l1} = (1 - x_2^{l1} - 2x_3^{l1})$ are given in Table 2. Formula number $n = 6.10$ is assumed initially, but this value will vary with temperature along the (hl_1g) equilibrium line. The molar volume of water is from Kell (24). Other parameters have the sources given for eq. [3].

Values of $\ln Kp(h \rightarrow l_1g)$ MPa are best (21) represented by

$$[6a] \quad \ln Kp(h \rightarrow l_1g) = d0 + d1{\cdot}u1 + d2{\cdot}u2$$

which is mathematically equivalent to

$$[6b] \quad \ln Kp(h \rightarrow l_1g) = A' + B'/T + C' \ln T$$

and which, differing from (7), uses only three parameters to represent the 43 equilibrium constants between –0.413° and 29.484°C.

Formula of hydrogen sulfide hydrate at lower quadruple point $Q(hs_1l_1g)$

The formula of hydrogen sulfide hydrate is evaluated by the method of Scheffer and Meyer (14) who first derived the thermochemical identity eq. [7] for n

$$[7] \quad \Delta H^{oq}(h \rightarrow l_1g) - \Delta H^{oq}(h \rightarrow s_1g) = n\ \Delta H^{oq}(s_1 \rightarrow l_1)$$

which is exact at the quadruple point $Q(hs_1l_1g)$, with the equilibrium standard enthalpy changes denoted by superscript q. Substitution into eq. [7], of 62088 with SE 165 J/mole H_2S for $\Delta H^{oq}(h \rightarrow l_1g)$, of 25416 with SE 52 J/mole H_2S for $\Delta H^{oq}(h \rightarrow s_1g)$, and of 5993 with SE 4 J/mole H_2O for $\Delta H^{oq}(s_1 \rightarrow l_1)$, evaluated from Osborne (30) and from Giauque and Stout (31), yields $n = 6.119$ with SE 0.029 for the hydrogen sulfide hydrate formula at –0.413°C.

Using this method, which they had developed for the purpose, Scheffer and Meyer (14) determined $n = 6.06$ for the formula of hydrogen sulfide hydrate at the quadruple point –0.4°C: later reevaluation (15) of the same data (14), using only the four most accurate (hl_1g) measurements, confirmed $n = 6.06$ with error 0.13.

Making a t-test of the formula difference (6.119 – 6.06)/0.029 gives $t = 2.03$ with 40 degrees of freedom which indicates that this difference could arise by pure chance with probability 2.5%, that is, there is a 97.5% probability that the difference is significant. Using the 0.13 error given by Korvezee and Scheffer (15) our value of n is well within their error range from $n = 5.93$ to $n = 6.19$.

At 0°C we estimate $n = r = 6.114$ with SE 0.028, this value is in good agreement with the $n = 6.119$ derived from direct hydrate synthesis at 0°C and listed in the Table II by Cady (32).

Formula of hydrogen sulfide hydrate at temperatures above the lower quadruple point

We now extend eq. [7], valid at $Q(hs_1l_1g)$, for more general use at temperature t °C to evaluate an approximate formula number, defined as r, using the thermochemical identity [8]

$$[8] \quad \Delta H^{ot}(h \rightarrow l_1g) - \Delta H^{ot}(h \rightarrow s_1g) = r\ \Delta H^{ot}(s_1 \rightarrow l_1)$$

in which superscript q in [7] is replaced by t in [8]. Values of $\Delta H^{ot}(h \rightarrow s_1g)$ and $\Delta H^{ot}(s_1 \rightarrow l_1)$ at temperature t are equal to their values at the quadruple point plus the integral of their heat capacities from the quadruple point.

The first term in eq. [8] is from the (hl_1g) data (10, 11, 14) of this work. The second term $\Delta H^{ot}(h \rightarrow s_1g)$ is temperature invariant and is 25416 with SE 52 J/mole H_2S, the same as $\Delta H^{oq}(h \rightarrow s_1g)$ in eq. [7]. The final term in eq. [8] is the standard molar enthalpy change for fusion of metastable ice H_2O (s_1) into liquid H_2O (l_1) at t°C. This is evaluated using the Taylor's series expansion

$$[9] \quad \Delta H^{ot}(s_1 \rightarrow l_1) = \Delta H^{oo}(s_1 \rightarrow l_1) + \Delta Cp^{oo}(s_1 \rightarrow l_1)t + d\Delta Cp^{oo}(s_1 \rightarrow l_1)/dt(1/2)t^2 + d^2\Delta Cp^{oo}(s_1 \rightarrow l_1)/dt^2(1/6)t^3$$

about the normal freezing point 0°C, with $\Delta H^{oo}(s_1 \rightarrow l_1) = 6009$ with SE 4 J/mole (30). The standard molar heat capacity change and its temperature derivatives for fusion are evaluated at 0°C using (*i*) the heat capacities of ice between –74° and –2.6°C by Giauque and Stout (31) and (*ii*) the tabulated heat capacities of liquid water between 0° and 100°C (23).

Method for evaluation of dissociation equilibrium constant of hydrogen sulfide hydrate and its formula number *r*

The phase rule requires that the equilibrium water-hydrogen sulfide, two-component, three-phase, (hl_1g) system is univariant and that the intensive properties of the three equilibrium phases are continuous functions of temperature. In particular, the equilibrium hydrate composition and its

© 2000 NRC Canada

component H_2O/H_2S mole ratio $n = r$ are continuous functions of temperature only.

A method is now presented to evaluate the approximate formula number r for the hydrate $H_2S{\cdot}rH_2O$ and its dissociation equilibrium constant $Kp(h{\rightarrow}l_1g)$ at each experimental temperature on the univariant (hl_1g) equilibrium line, from –0.413°C the lower quadruple point $Q(hs_1l_1g)$ up to 29.484°C the upper quadruple point $Q(hl_1l_2g)$.

The method of convergence to a stable solution depends on the temperature continuity of r the approximate hydrate formula number. Initially we assume that $n = r = 6.1$ in eq. [5] for all measurements, giving a first approximation for the logarithm of the equilibrium constant, abbreviated to ln Kp(1st). The ln Kp(1st) values are fitted as a proper function of temperature (21) by the method of least squares (22) to yield the best thermodynamic equation of the form of eq. [6*a*]. These measurements use two temperature variables ($u1$ $u2$) with $x = (T - 298.16)/298.15$, and define (21) three thermodynamic function parameters ($d0$ $d1$ $d2$) and their standard errors at 298.15 K.

Derived from ($d1$ $d2$) of eq. [6*a*], the first approximation standard enthalpy changes $\Delta H^{ot}(h{\rightarrow}l_1g)$, abbreviated to ΔH(1st), for each measurement at its temperature t are substituted into eq. [8], to give a first approximation formula number r(1st).

Values of r(1st) are substituted for n in eq. [5] for each measurement to provide a second approximation for the logarithm of the equilibrium constant ln Kp(2nd); the ln Kp(2nd) values are refitted by eq. [6*a*], thence to obtain second approximation ΔH(2nd) values; these are substituted for $\Delta H^{ot}(h{\rightarrow}l_1g)$ in eq. [8] to give r(2nd) values which are recycled for n in eq. [5], and so on. Iterations for 124 cycles give the converged values of $Kp(h{\rightarrow}l_1g)$ and of r which are presented in Tables 4 and 5.

Equilibrium constant for dissociation of hydrogen sulfide hydrate into water and hydrogen sulfide gas

Table 4 lists 43 determinations between 29.484° and –0.413°C of the equilibrium constant, $Kp(h{\rightarrow}l_1g)$, for dissociation of hydrogen sulfide hydrate to liquid water and hydrogen sulfide gas with $n = r$. Standard thermodynamic function changes refer to dissociation of one mole of $H_2S{\cdot}rH_2O$ (h) at 0.10 MPa pressure to form one mole of H_2S (g) at 1.0 MPa fugacity together with r mole of pure H_2O (l_1) at 0.10 MPa pressure.

The third column of Table 4 gives the square root of the weights used to combine the measurements from the three sources (10, 11, 14) into a properly weighted least-squares regression of the logarithm of $Kp(h{\rightarrow}l_1g)$ as a function of temperature.

The fourth column lists $Kp(h{\rightarrow}l_1g)$ MPa observed, the fifth gives $Kp(h{\rightarrow}l_1g)$ calculated from the best converged eq. [6*a*]. The percentage differences between observed and calculated equilibrium constants, shown in the sixth column, yield an overall SE of 0.11% for a single $Kp(h{\rightarrow}l_1g)$ determination of unit weight with 40 degrees of freedom. The seventh column shows the percentage error on the estimated equilibrium constant defined by the regression eq. [6*a*].

In defining the best values for ($d1$ $d2$) in eq. [6*a*] for the hydrogen sulfide hydrate it is considered that these enthalpy change parameters at 25°C should be of the same sign and numerically smaller than those found in ref. 7 for the deuterium sulfide D-hydrate. Preliminary investigation shows that the hydrogen sulfide hydrate measurements (10, 11, 14) are sufficiently accurate to evaluate only ($d0$ $d1$ $d2$) in eq. [6*a*], but are insufficiently accurate to define any value for $d3$.

The three parameters of the best converged eq. [6*a*] with their (SEs) are: $d0 = 0.019\,008$ (0.000 73), $d1 = 26.6871$ (0.040), $d2 = 19.2499$ (1.2). We note that the equilibrium constants of hydrogen sulfide hydrate properly define only the two enthalpy parameters ($d1$ $d2$) at 25°C, that these two parameters are both positive, and that the value of the least significant parameter $d2$ could arise by pure chance at a probability level of less than one in 10^{15} times.

The SE estimate of 0.11% for a single $Kp(h{\rightarrow}l_1g)$ datum of unit weight given by the three-parameter eq. [6*a*] is seen to be near in value to the SE estimate of 0.13% for a single $P(hl_1g)$ measurement of unit weight given by the six-parameter eq. [1*a*].

The 10 weighted residuals of data by Scheffer (11) show a SE of 0.062%, the 15 weighted residuals of data by Scheffer and Meyer (14) show a SE of 0.083%, and the 16 weighted residuals of data by de Forcrand and Villard (10) show a SE of 0.047%. These low SE estimates, (0.062%, 0.083%, and 0.047%) from the three sets of weighted residuals are all smaller than the overall SE estimate 0.11% and reflect the conservative low weights assigned to the less reliable measurements to reduce possible bias.

The four data at highest pressure by Scheffer (11) give unweighted residuals with SE 0.060%, clearly the most precise of all the measurements. The six data at lower pressure from ref. 11 are given weights equal to the inverse square of their deviations from eq. [6*a*]: these weights are converged to better than one part in 10^4. The six weighted residuals give SE 0.021%, mean bias 0.10% above and root mean squared (RMS) deviation 0.11% above eq. [6*a*]: the six unweighted residuals give SE 0.97%, mean bias 2.2% above and RMS deviation 2.5% above eq. [6*a*].

The four data of unit weight, using the Beckmann thermometer, from Table 6 of Scheffer and Meyer (14) show unweighted residuals with SE 0.095%. The six data with $w^{1/2} = 0.4$ from Tables 5 and 4 of ref. 14 show weighted residuals with SE 0.099% and unweighted residuals with SE 0.25%. The five data with $w^{1/2} = 0.01$ from Table 4 of ref. 14 give weighted residuals with SE 0.0063%, mean bias 0.020% above, and RMS deviation 0.022% above eq. [6*a*]: the five unweighted residuals give SE 0.63%, mean bias 2.0% above, and RMS deviation 2.2% above eq. [6*a*].

The sixteen data with $w^{1/2} = 0.1$ by de Forcrand and Villard (10) give weighted residuals with SE 0.047%, mean bias –0.12% below, and RMS deviation 0.14% below eq. [6*a*]: the sixteen unweighted residuals give SE 0.47%, mean bias –1.2% below, and RMS deviation 1.4% below eq. [6*a*].

Approximate formula number *r* for hydrogen sulfide hydrate

Table 5 presents estimates and SEs for the standard enthalpy change $\Delta H^{ot}(h{\rightarrow}l_1g)$, for the standard heat capacity change $\Delta Cp^{ot}(h{\rightarrow}l_1g)$, and for the approximate formula number $n = r$ for the standard dissociation of hydrogen sulfide hydrate into water and hydrogen sulfide gas. We note that the results listed in Tables 4 and 5 are biased estimates,

except for those given at the lower quadruple point $Q(hs_1l_1g)$ –0.413°C, where eq. [8] is exact and the estimates of $Kp(h \rightarrow l_1g)$, $\Delta H^{oq}(h \rightarrow l_1g)$, $\Delta Cp^{oq}(h \rightarrow l_1g)$, and of $n = r$ are true and unbiased.

One bias arises because it is assumed in eq. [8] that $\Delta H^{ot}(h \rightarrow s_1g)$ is temperature-invariant over the extrapolated temperature range –0.413° to 29.484°C, where it is possible that the standard heat capacity change may have a small negative value. This bias is assessed using the datum $\Delta Cp^{ot}(h \rightarrow s_1g) = –8.0$ with SE 24 J/mole deg, found but not significant for the hydrogen sulfide hydrate equilibrium with ice, eq. [3]. Evaluation of *r* at 29.484°C, using eq. [8] with $\Delta H^{ot}(h \rightarrow s1g) = (25\ 413 – 8t)$ J/mole at *t*°C, gives a converged $r = 5.896$ with SE 0.047: a result in agreement with, and not significantly different from, the 5.869 with SE 0.026 given in Table 5.

A second bias arises because it is assumed in eq. [8] that $\Delta H^{ot}(s_1 \rightarrow l_1)$ is given by the Taylor's series eq. [9] over the extrapolated temperature range –0.413° to 29.484°C. Classical error theory (22) shows that the SE on *r* at 29.484°C, due to errors on the Taylor's series parameters of eq. [9], is less than 0.0004 and is not significant. The SE's on the standard enthalpy changes for *r* at 29.484°C are, 145 J/mole on $\Delta H^{ot}(h \rightarrow l_1g)$, 52 J/mole on $\Delta H^{ot}(h \rightarrow s_1g)$, and 9 J/mole on

$\Delta H^{ot}(s_1 \rightarrow l_1)$, showing that the major contribution to the SE on r is the SE on the estimate of $\Delta H^{ot}(h \rightarrow l_1g)$.

It is shown in Table 5 that the value of r decreases monotonously with increasing temperature and asymptotically approaches its theoretical lower limit of 5.75, for a Structure I hydrate (28, 29), at some temperature above the quadruple point $Q(hl_1l_2g)$ at 29.484°C.

This shows a continuous increase with temperature in the number of H_2S hydrate-former molecules per unit cell of $46H_2O$, from 7.518 with SE 0.035 at –0.413°C to about 7.838 with SE 0.034 at 29.484°C, asymptotically trending towards an upper limit of 8.0 (28, 29) above 29.484°C. This requires that an increased fraction of cavities must be occupied by H_2S molecules to stabilize the solid hydrate lattice against collapse at higher temperatures. Although these numbers may be slightly biased, the overall effect of increasing temperature remains unchanged.

The equilibrium hydrogen sulfide hydrate composition at the quadruple point $Q(hl_1l_2g)$ 29.484°C occurs with 2.03% of empty and 97.97% of occupied cavities with SE 0.43% at the saturation activity of liquid H_2S (l_2). This occupancy level is not significantly different from the deuterium sulfide D-hydrate (7) which shows 1.65% of empty and 98.35% of occupied cavities with SE 0.31% at 29.375°C, and 1.54% of empty and 98.46% of occupied cavities with SE 0.32% at the quadruple point $Q(hl_1l_2g)$ 30.770°C.

This agrees well with the work of Scheffer (11), which shows that hydrostatic pressure increases the temperature for hydrogen sulfide hydrate stability above $Q(hl_1l_2g)$ along the three-phase (hl_1l_2) line, where presumably the empty cavities within the hydrate lattice are progressively being filled with additional hydrogen sulfide guest molecules at the higher pressures and temperatures.

The equilibrium hydrogen sulfide hydrate composition at the lower quadruple point $Q(hs_1l_1g)$ –0.413°C occurs with 6.03% of empty and 93.97% of occupied cavities with SE 0.44% at the equilibrium activity of ice H_2O (s_1). Since we considered that this hydrate composition might be a sensitive function of the relative weights assigned to the six data from Tables 5 & 4 by Scheffer and Meyer (14) this effect is tested.

Sensitivity tests are made using the weights $w^{1/2}$ = 0.3, 0.35, 0.4, and 0.5 for the six data: this implies that each of the four data of unit weight from Table 6 by Scheffer and Meyer (14) are, respectively, 11.1, 8.16, 6.25, and 4 times more accurate than each of the six data from Tables 5 and 4. Results indicate 5.97%, 6.00%, 6.03%, and 6.08% of empty cavities, with SE's 0.44%, 0.44%, 0.44%, and 0.43%, respectively, using weights $w^{1/2}$ = 0.3, 0.35, 0.4, and 0.5 for the six data. The hydrate composition at $Q(hs_1l_1g)$ –0.413°C is found not to be a sensitive function of the preferred weight $w^{1/2}$ = 0.4, chosen for the six measurements from Tables 5 and 4 by Scheffer and Meyer (14).

Deuterium sulfide D-hydrate (7) at $Q(hs_1l_1g)$ 3.392°C indicates 5.97% of empty cavities with SE 0.27%, which is not significantly different from the hydrogen sulfide hydrate at $Q(hs_1l_1g)$ –0.413°C.

Formula of hydrogen sulfide hydrate near –0.413°C

Since our (hl_1g) data analysis depends critically on the ten measurements by Scheffer and Meyer (14) taken together with the measurements of Scheffer (11), it is important to discover why our formula $H_2S{\cdot}6.119H_2O$ at –0.413°C does not agree with the earlier formula $H_2S{\cdot}6.06H_2O$ derived (14) and reconfirmed (15) by Scheffer et al. using the same measurements (14).

In the first place our value 25 416 J/mole for $\Delta H^{oq}(h \rightarrow s_1g)$ is 84 J/mole smaller than the 25 500 J/mole used by Scheffer et al. (14, 15): this leads to an increase of 0.014 with SE 0.0087 for n at –0.413°C and the earlier formula is modified to $H_2S{\cdot}6.074H_2O$. In attempts to obtain agreement with the earlier formula $H_2S{\cdot}6.074H_2O$ (14, 15), we have made

© 2000 NRC Canada

numerous least-squares analyses using the three data sets (10, 11, 14) with various relative weights to reduce the effect of all measurements other than the four most important measurements at low temperature (SM6-4, SM6-8, SM6-12, and SM6-15) and the four most important measurements at high temperature (S-11, S-10, S-9, and S-8).

For example, in a regression with the eight measurements (SM6-15, SM6-12, SM6-8, SM6-4, S-8, S-9, S-10, and S-11) with the weights shown in Table 4, with the twenty nine other measurements with their values of $w^{1/2}$ reduced by a factor of 10, and with the six measurements (S-1, S-2, S-3, S-4, S-6, and S-7) with their respective best values of $w^{1/2}$ (0.013, 0.010, 0.010, 0.014, 0.014, and 0.023), we find the SE 0.027% for a datum of unit weight and the parameters with (SE) $d1$ = 26.7292 (0.012) and $d2$ = 21.0337 (0.38) at 25°C. These parameters give estimates with (SE) for n of 6.073 (0.012) at –0.413°C and 5.893 (0.011) at 29.484°C.

The SE 0.027% for a measurement of unit weight is realistic for this extreme weighting scheme and is consistent with the SE 0.021% found for the four measurements (14) using the Beckmann thermometer (SM6–4, SM6–8, SM6–12, and SM6–15). The four measurements at high temperature (S-11, S-10, S-9, and S-8) systematically cut across the regression line and show a larger SE 0.083%.

The value of 21.0337 for the heat-capacity parameter $d2$ is improbably large, because it is significantly larger than the 20.0170 at 25°C found for deuterium sulfide D-hydrate (7), and because the heat capacities of water (23) and of ice (31) are significantly smaller than the heat capacities of liquid deuterium oxide and of D-ice (33).

The 6.073 value for n at –0.413°C is 0.042 smaller than, and the 5.893 value for n at 29.484°C is 0.053 larger than the corresponding values of n found at the quadruple points of deuterium sulfide D-hydrate (7): this cross-over of the values of n for hydrogen sulfide hydrate relative to those found for deuterium sulfide D-hydrate is improbable. The cross-over of the hydrate formulae is even more improbable recognizing that the vapor pressure of hydrogen sulfide hydrate between 2.798° and 29.484°C is an almost constant 14% higher than the vapor pressure of deuterium sulfide D-hydrate (6) at the same temperature.

Only by using the extreme weighting scheme described above, are we able to obtain agreement with the earlier formula (14, 15) $H_2S{\cdot}6.06H_2O$ at –0.4°C, and this extreme weighting scheme is both unreasonable and unrealistic for the three data sets (10, 11, and 14). Use of realistic relative weights always gives estimates for n which are significantly greater than $H_2S{\cdot}6.074H_2O$ at –0.413°C.

In conclusion we suggest that the preferred relative weights listed in Table 4 provide a good, self-consistent and non-unique solution to combine the three data sets (10, 11, and 14) to evaluate the hydrogen sulfide hydrate dissociation equilibrium constants and to derive valid formula for the hydrogen sulfide hydrate with water.

Synthesis, spectroscopic characterization and structural studies of organotin monothiocarbonates. Crystal structures of $Ph_3Sn[SCO_2Me]$ and $Ph_3Sn[SCO_2(i\text{-}Pr)]$

John E. Drake and Jincai Yang

Abstract: *O*-alkyl monothiocarbonate (monoxanthate) derivatives of tin were obtained by the reaction of a sodium salt of the monothiocarbonic acid with an organotin chloride to give $Ph_3Sn[SCO_2R]$, $Ph_2Sn[SCO_2R]_2$, and $Me_3Sn[SCO_2R]$, where R = Me and i-Pr. The compounds have been characterized by infrared, Raman, ^1H NMR, and ^{13}C NMR spectroscopy, as well as mass spectrometry, and in two cases by X-ray crystallography. $Ph_3Sn[SCO_2Me]$ (**1**) and $Ph_3Sn[SCO_2(i\text{-}Pr)]$ (**2**), crystallize in the triclinic space group $P\bar{1}$ (no. 2) with cell parameters a = 10.218(4), b = 10.568(6), c = 9.366(7) Å, α = 106.73(5), β = 96.99(5), γ = 85.55(4)°, V = 960(1) Å^3, and Z = 2 for **1**; and a = 14.793(2), b = 17.856(3), c = 9.813(3) Å, α = 103.86(5), β = 98.36(5), γ = 106.85(4)°, V = 2343(1) Å^3, and Z = 2 for **2**. The latter has two molecules in the asymmetric unit. The immediate environment about tin in both **1** and **2** is that of the expected distorted tetrahedron. However, the orientation of the monothiocarbonate group is such that there is an Sn-O intramolecular interaction of 3.040(8) for **1** and 3.05(2) Å on average for **2**. Thus, the considerable distortion is consistent with a tendency to form a five-coordinate, trigonal bipyramidal species with one of the O-Sn-C angles approaching 180° (153.4(4) for **1** and an average of 157.1(6) for **2**). Estimations of the Pauling partial bond orders suggest this weak Sn-O interaction is slightly stronger than the corresponding Ge-O interaction in the analogous germanium derivative, $Ph_3Ge[SCO_2Me]$.

Key words: structure, tin, methyl, phenyl, isopropyl, monothiocarbonates.

Résumé : On a préparé des dérivés de l'étain avec du monothicarbonate (monoxanthate) de *O*-alkyle ($Ph_3Sn[SCO_2R]$, $Ph_2Sn[SCO_2R]$ et $Me_3Sn[SCO_2R]$ dans lesquels R = Me ou i-Pr) en faisant réagit du sel de sodium de l'acide monothiocarbonique avec un chlorure d'organoétain. On a caractérisé ces composés par spectroscopies infrarouge, Raman et RMN du ^1H et du ^{13}C ainsi que par spectroscopie de masse et, dans deux cas, par diffraction des rayons X. Le $Ph_3Sn[SCO_2Me]$, **1**, et $Ph_3Sn[SCO_2i\text{-}Pr]$, **2**, cristallisent dans le groupe d'espace $P\bar{1}$ (no. 2) avec a = 10,218(4), b = 10,568(6) et c = 9,366(7) Å, α = 106,73(5), β = 96,99(5) et γ = 85,55(4)°, V = 960(1) Å^3 et Z = 2 pour le composé **1** et a = 14,793(2), b = 17,856(3) et c = 9,813(3) Å, α = 103,86(5), β = 98,36(5) et γ = 106,85(4)°, V = 2343(1) Å^3 et Z = 2 pour le composé **2**. Ce dernier composé comporte deux molécules dans la maille asymétrique. L'environnement immédiat autour de l'étain de ces deux composés correspond à celui attendu pour un tétraèdre déformé. Toutefois, l'orientation du groupe monothiocarbonate est tel que l'on observe une interaction Sn-O intramoléculaire de 3,040(8) Å pour **1** et de 3,05(2) Å pour **2**. La déformation importante est donc en accord avec une tendance à former une espèce pentacoordinée trigonale bipyramidale dans laquelle les angles O-Sn-C se rapprochent de 180° (153,4(4) pour **1** et une moyenne de 157,1(6) pour **2**). Des évaluations à partir des ordres partiels de liaison de Paulin suggèrent que cette interaction Sn-O faible est un peu plus forte que l'interaction correspondante Ge-O du composé germaniun analogue, $Ph_3Ge[SCO_2Me]$.

Mots clés : structure, étain, méthyle, phényle, isopropyle, monothiocarbonates.

[Traduit par la Rédaction]

Introduction

O-alkyl dithiocarbonate (xanthate) derivatives have been extensively studied but the chemistry of monothiocarbonates (monoxanthates) has received considerably less attention and most of the relatively few reports have involved transition metal complexes (1). In addition to reports on alkali salts (2), two reports by us have appeared on main group element monothiocarbonates describing some organotellurium (3) and organogermanium (4) derivatives. Considerably more

work has appeared on dithio derivatives of tin than of germanium, but we were unable to find any reports on monothiocarbonate organotin derivatives. Surprisingly, we found these even more difficult to isolate pure than their germanium analogues but we were able to confirm the formation of five *O*-alkyl monothiocarbonate derivatives $Ph_3Sn[SCO_2R]$ (R = Me and i-Pr), $Ph_2Sn[SCO_2(i\text{-}Pr)]_2$, $Ph_2SnCl[SCO_2(i\text{-}Pr)]$, and $MeSn[SCO_2Me]$ by NMR, infrared, and Raman spectroscopy, as well as mass spectrometry. We also have obtained the X-ray crystal structures of $Ph_3Sn[SCO_2Me]$(**1**) and $Ph_3Sn[SCO_2(i\text{-}Pr)]$(**2**).

Among the many reports on dithio derivatives of tin, those of relevance to this work include discussions of ligand coordination modes and coordination number in a variety of dithiocarbamates (5), a series of publications on dithiocarbonates (6), and a structural study of $Ph_3Sn[S_2CO(i\text{-}Pr)]$ (7). An examination of tin(IV) 1-pyrrolecarbothioates (8), including $Ph_3Sn[SOCNC_4H_4]$, and a comparison of the structures of the monothiocarbamate, $Ph_3Sn[SCON(CH_2)_4O]$, with the analogous dithiocarbamate are also of interest (9). Bidentate linkages appear to be favored in organotin derivatives with dithio-ligands as exemplified in dithiophosphates such as $Ph_2Sn[S_2P(Oi\text{-}Pr)_2]_2$ (10) and dithiocarbamates such as $BuSn[S_2CN(Et)_2]_3$ (11) in both of which tin atoms are in octahedral sites. However, monodentate linkages appear to be often found with triphenyltin derivatives such as in $Ph_3Sn[S_2P(OEt)_2]$ (12). The range of mono-, aniso-, and bidentate ligands will be discussed in some detail.

Experimental

Materials

The starting materials (Ph_3SnCl, Ph_2SnCl_2, and Me_3SnCl) were obtained from Aldrich; all starting materials being used as supplied. All solvents were dried and distilled prior to use and all reactions were carried out under anhydrous conditions. The salts, $NaSCO_2R$, where R = Me and i-Pr, were prepared as described in the literature (4) and their purity checked by ^1H and ^{13}C NMR spectroscopy. No further purification was necessary.

Preparation of $Ph_3Sn[SCO_2Me]$ (1) and $Ph_3Sn[SCO_2(i\text{-}Pr)]$ (2)

Typically, Ph_3SnCl (0.25 g, 0.65 mmol) and an excess of dried $NaSCO_2Me$ (0.10 g, 0.88 mmol) were placed in a previously evacuated flask and solvent (CH_2Cl_2, ca. 15 mL) was added under N_2. The mixture was stirred for 2 h at room temperature, followed by filtration to remove NaCl and excess of starting salt, and then evaporation under vacuum gave $Ph_3Sn[SCO_2Me]$ (**1**) as a colorless solid. Recrystallization from a CH_2Cl_2 – *n*-hexane mixture gave colorless crystals (0.20 g, 0.45 mmol), yield 70%, mp 86°C. Peaks in the mass spectrum corresponding to ^{120}Sn in a typical tin cluster were seen at *m*/*z* (relative intensity): 442 ($(Ph_3SnSCO_2Me)^+$, 3%), 365 ($(Ph_2SnSCO_2Me)^+$, 10%), 351 ($(Ph_3Sn)^+$, 100%), 305 ($(Ph_2SnOMe)^+$, 45%), 274 ($(Ph_2Sn)^+$, 30%), 197 ($(PhSn)^+$, 9%). IR (Raman) (cm^{-1}) main features: ν(O=CSOC) 1669 vs, ν(OSC-OMe) 1148 vs br, ν(OSO-CH_3) 1090 sh, *p*-phenyl [1002 (100)], π(SCO_2) 817 ms, *f*-phenyl 731 vs, *v*-phenyl 698 *vs*, ν(SnS-C) 658 m [658 (55)], *y*-phenyl 447 s, δ(SCO_2) 426 m, ν(Sn-S) [333 (10)]. ^1H NMR: ($CDCl_3$) δ 3.63 [3H, OCH_3, s]; 7.41–7.44 [9H, Sn-C_6H_5 – *meta* + *para*]; 7.63–7.68 [6H Sn-C_6H_5 – *ortho*]. ^{13}C NMR: ($CDCl_3$) δ 54.82 [OCH_3]; 129.03, 130.04, 136.57, 136.74 [Sn-C_6H_5]. In the same fashion $Ph_3Sn[SCO_2(i\text{-}Pr)]$ (**2**) was prepared as a colorless solid. Recrystallization from a CH_2Cl_2 – *n*-hexane mixture gave colorless crystals (0.30 g, 0.71 mmol, yield 86%), mp 92–93°C. Peaks in the mass spectrum corresponding to ^{120}Sn were seen at *m*/*z* (relative intensity): 469 ($(Ph_3SnSCO_2(i\text{-}Pr) - H)^+$, 2%), 393 ($(Ph_2SnSCO_2(i\text{-}Pr))^+$, 8%), 351 ($(Ph_3Sn)^+$, 100%), 333 ($(Ph_3SnO(i\text{-}Pr))^+$, 8%), 291 ($(Ph_2SnOH)^+$, 50%), 274 ($(Ph_2Sn)^+$, 30%), 197 ($(PhSn)^+$, 50%). IR (Raman) ($cm^{-1}$) main features: ν(O=CSOC) 1663 vs, ν((OSC-O(i-Pr)) 1169 vs, ν(OSO-CH(CH_3)$_2$) 1093 vs, *p*-phenyl [1001 (100)], π(SCO_2) 848 m, *f*-phenyl 731 s, *v*-phenyl 698 s, ν(SnS-C) 655 w [657 (45)], *y*-phenyl 446 ms, δ(SCO_2) 433 sh, ν(Sn-S) [335 (15)]. ^1H NMR: ($CDCl_3$) δ 1.04 [6H, OCH(CH_3)$_2$, d, *J*(HH) 6.2 Hz]; 4.88 [1H, OC*H*, sept, *J*(HH) 6.2 Hz]; 7.40–7.42 [9H, Sn-C_6H_5 – *meta* + *para*]; 7.64–7.67 [6H Sn-C_6H_5 – *ortho*]. ^{13}C NMR: ($CDCl_3$) δ 21.61 [OCCH_3]; 72.65 [O*C*H]; 129.98, 129.96, 136.47, 136.71 [Sn-C_6H_5].

Preparation of $Ph_2Sn[SCO_2(i\text{-}Pr)]_2$ (3)

Typically, Ph_2SnCl_2 (0.25 g, 0.72 mmol) and $NaSCO_2(i\text{-}Pr)$ (0.25 g, 1.76 mmol) were placed in a flask and solvent (CH_2Cl_2, ca. 15 mL) was added under N_2. The mixture was stirred for 2 h at room temperature, followed by filtration and evaporation under vacuum to give $Ph_2Sn[SCO_2(i\text{-}Pr)]_2$, **3**, (0.3 g, 0.59 mmol) as a colorless solid, (0.30 g, 0.59 mmol), yield 81.5%, mp 83–84°C. Peaks in the mass spectrum corresponding to ^{120}Sn in a typical tin cluster were seen at *m*/*z* (relative intensity): 512 ($(Ph_2Sn[SCO_2(i\text{-}Pr)]_2)^+$, 1%), 393 ($(Ph_2SnSCO_2(i\text{-}Pr))^+$, 30%), 333 ($(Ph_3SnO(i\text{-}Pr))^+$, 45%), 291 ($(Ph_2SnOH)^+$, 100%), 274 ($(Ph_2Sn)^+$, 65%), 197 ($(PhSn)^+$, 35%). Attempts at recrystallization failed to yield any X-ray quality crystals. IR (Raman) (cm^{-1}) main features: ν(O=CSOC) 1642 vs, ν((OSC-O(i-Pr)) 1176 vs, ν(OSO-CH(CH_3)$_2$) 1091 vs, *p*-phenyl [999 (100)], π(SCO_2) 847 ms, *f*-phenyl 732 ms, *v*-phenyl 695 ms, ν(SnS-C) 655 vw [658 (45)], *y*-phenyl 445 m, δ(SCO_2) 428 m, ν(Sn-S) [344 (15)]. ^1H NMR: ($CDCl_3$) δ 1.06 [12H, OCH(CH_3)$_2$, d, *J*(HH) 6.2 Hz]; 4.86 [2H, OC*H*, sept, *J*(HH) 6.2 Hz]; 7.43–7.45 [6H, Sn-C_6H_5 – *meta* + *para*]; 7.82–7.85 [4H Sn-C_6H_5 – *ortho*]. ^{13}C NMR: ($CDCl_3$) δ 21.58 [OCCH_3]; 73.48 [OCH_3]; 129.07, 130.46, 135.35, 135.73 [Sn-C_6H_5].

Formation and identification of $Ph_2SnCl[SCO_2(i\text{-}Pr)]$ (4) and $Me_3Sn[SCO_2Me]$ (5)

Typically, Ph_2SnCl_2 (0.30 g, 0.87 mmol) and dried $NaSCO_2(i\text{-}Pr)$ (0.12 g, 0.87 mmol) were introduced into a round-bottomed flask, followed by the addition of dried CH_2Cl_2 (ca. 15 mL). The mixture was stirred for ca. 2 h at which time the NaCl that had formed was filtered off and the solvent allowed to evaporate under vacuum to produce $Ph_2SnCl[SCO_2(i\text{-}Pr)]$ (**4**) as a white solid (0.31 g, 0.73 mmol, yield 83%). IR (Raman) (cm^{-1}) main features: ν(O=CSOC) 1629 ms, br, ν((OSC-O(i-Pr)) 1261 s, ν(OSO-CH(CH_3)$_2$) 1095 vs, *p*-phenyl [1000 (100)], π(SCO_2) 803 ms br, *f*-phenyl 728 vs, *v*-phenyl 692 vs, ν(SnS-C) 656 mw [658 (45)], *y*-phenyl 448 m br, δ(SCO_2) 430 sh, ν(Sn-S) [340 (5)], ν(Sn-Cl) [276 (9)]. ^1H NMR: ($CDCl_3$) δ 1.26 [6H,

OCH(CH_3)$_2$, d, *J*(HH) 6.2 Hz]; 5.00 [1H, OC*H*, sept, *J*(HH) 6.2 Hz]; 7.47–7.50 [6H, Sn-C_6H_5 – *meta* + *para*]; 7.84–7.87 [4H Sn-C_6H_5 – *ortho*]. ^{13}C NMR: ($CDCl_3$) δ 21.74 [OCCH_3]; 75.38 [OCH_3]; 129.26, 130.98, 135.19, 136.61 [Sn-C_6H_5]. Attempts at recrystallization did not yield any crystals, but rather resulted in decomposition. In a similar manner as described for the preparation of **1** and **2**, $Me_3Sn[SCO_2Me]$ (**5**), was formed as a colorless viscous liquid by starting with Me_3SnCl and an excess of $NaSCO_2Me$. IR (Raman) (cm^{-1}) main features: ν(O=CSOC) 1630 m, ν(OSC-OMe) 1260 vs, ν(OSO-CH_3) 1034 vs br, π(SCO_2) 865 s, ρ($SnCH_3$) 799 vs, ν(SnS-C) 662 m, ν(Sn-C_{asymm}) 532 m, ν(Sn-C_{symm}) 506 mw. ^{1}H NMR: ($CDCl_3$) δ 0.53 [9H, Sn(CH_3)$_3$, *J*(SnH) 64.2 Hz], 3.68 [3H, OCH_3]. ^{13}C NMR: ($CDCl_3$) δ –2.50 [SnCH_3], 53.51 [OCH_3]. For both **4** and **5**, the ^{1}H and ^{13}C NMR spectra taken immediately after separation indicated the presence of only one product.

Attempted formation and identification of $Ph_2Sn[SCO_2Me]_2$ and $Ph_2SnCl[SCO_2Me]$

In a manner similar to the successful preparation of **3** and **4**, substituting $NaSCO_2Me$ for $NaSCO_2(i\text{-}Pr)$ did not result in the formation of pure $Ph_2Sn[SCO_2Me]_2$ or $Ph_2SnCl[SCO_2Me]$ but rather in mixtures. The NMR spectra in each case were consistent with the presence of differing amounts of both of the desired compounds.

Physical measurements

Infrared spectra were recorded on a Nicolet 5DX FT spectrometer as KBr pellets or oils smeared between KBr windows in the region 4000–400 cm^{-1}, and far infrared spectra on a Bomem DA3 infrared spectrometer between polyethylene films as oils or Nujol mulls. The Raman spectra were recorded on samples in sealed glass capillaries on a JEOL-XY Raman spectrometer using the 5145 Å exciting line of an argon ion laser. The ^{1}H and ^{13}C {H} NMR spectra were recorded on a Bruker 300 FT/NMR spectrometer at 300.133 and 75.471 MHz, respectively, in $CDCl_3$ using Me_4Si as internal standard. All NMR spectra were run at ambient temperature and under standard operating conditions. The melting points were determined on a Fisher–Johns apparatus. The mass spectra were recorded on a Kratos Profile GC-MS Spectrometer.

X-ray crystallographic analysis

Colorless block crystals of $Ph_3Sn[SCO_2Me]$ (**1**) and $Ph_3Sn[SCO_2(i\text{-}Pr)]$ (**2**) were sealed in thin-walled glass capillaries and mounted on a Rigaku AFC6S diffractometer, with graphite-monochromated MoKα radiation. Operating at 50 kV and 35 mA.

Cell constants corresponded to triclinic cells whose dimensions are given in Table 1, along with other experimental details. Based on statistical analysis of intensity distribution

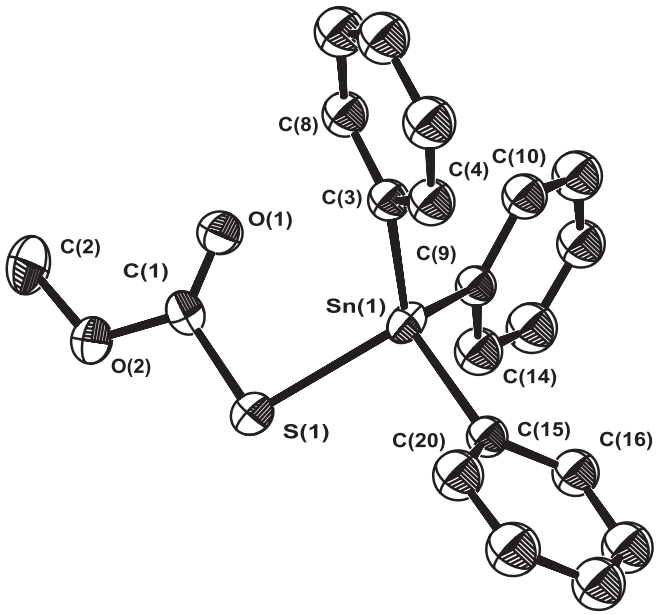
and the successful solution and refinement of the structures, the space group was determined to be $P\bar{1}$ (no. 2) for both **1** and **2**. The data were corrected for Lorentz and polarization effects and an empirical absorption correction was applied. In the case of **2**, data collection stopped automatically at 45.0° because the crystal had decayed, therefore a decay correction was applied.

The structure was solved by direct methods (13) and all calculations were performed using the TEXSAN (14) crystallographic software package of Molecular Structure Corp.[2] All of the non-hydrogen atoms were refined anisotropically for **1**, but for **2** only the thio carbon atom was treated anisotropically along with the other non-hydrogen atoms. The phenyl groups were treated as fixed rings with C—C distances set at 1.39 Å in **2** and an attempt was made to model the i-Pr group of one of the molecules in the asymmetric unit which was badly disordered. Hydrogen atoms, other than those of the disordered group, were included in their idealized position with C—H set at 0.95 Å and isotropic thermal parameters set at 1.2 times that of the carbon to which they were attached.

The unweighted and weighted agreement factors and standard deviation of an observation of unit weight[3] are given in Table 1. Plots of $\sum w(|F_o| - |F_c|)^2$ versus $|F_o|$, reflection order in data collection, $\sin\theta/\lambda$, and various classes of indices showed no unusual trends. Important distances and bond angles are given in Tables 2 and 3 and the molecular structures of the two compounds are displayed as ORTEP diagrams in Figs. 1–3. The final atomic coordinates and equivalent isotropic thermal parameters for the non-hydrogen atoms, anisotropic thermal parameters for non-hydrogen atoms, final fractional coordinates and thermal parameters for hydrogen atoms, and all bond distances and angles have been deposited.[4]

Calculation of Pauling partial bond orders

The formula proposed by Pauling (15) for calculating the bond orders of partial bonds is given by $d_n - d = -0.60 \log n$, where d_n is the bond length for bond number, n, and d is the length of the single bond of the same type. Based on the C—C single bond of 1.54 Å, Pauling's formula gives a bond length of 1.36 Å for $n = 2$; 1.72 Å for $n = 0.5$; and 1.90 Å for $n = 0.25$. These give percentage increases in bond length for the partial bonds of approximately 12 and 23% respectively for $n = 0.5$ and 0.25. It is reasonable to assume that similar relationships relating bond order to interatomic distances for the much longer secondary interactions or partial bonds involving Sn and S should utilize percentage differences "normalized" to 1.54 as follows rather than absolute differences. Pauling's relationship, which can be written as $n = 10^X$, where $X = (d - d_n)/0.6$, can be modified to allow



[2] Least-squares function minimized: $\sum w(|F_o| - |F_c|)^2$, where $w = 4F_o^2(F_o^2)$, $\sigma^2(F_o^2) = [S^2C + R^2B) + (pF_o^2)^2]/(Lp)^2$, S = scan rate, C = total integrated peak count, R = ratio of scan time to background counting time, Lp = Lorentz-polarization factor, and $p = p$ factor.

[3] Standard deviation of an observation of unit weight: $[\sum w(|F_o| - |F_c|)^2/N_o - N_v)^{1/2}$, where N_o = number of observations and N_v = number of variables.

for percentage differences "normalized" to 1.54 to give $X = [1.54(d - d_n)/d]/0.6$ or $X = 2.57(d - d_n)/d$. Assuming the Sn—S single bond length approximates to the sum of the respective covalent radii (16), the corresponding values for Sn—S single and partial bonds for various values of n are 2.40 Å (n = 1.0), 2.50 (0.75), 2.68 (0.50), 2.95 (0.25), and 3.33 Å (n = 0.10). Similarly, relative to a Sn—O single bond length of 2.14 Å, the corresponding values for Sn—O partial bonds are 2.24 (0.75), 2.40 (0.50) 2.65 (0.25), and 2.97 Å (n = 0.10); relative to a Ge—O single bond length of 1.96 Å, the Ge—O partial bonds are 2.05 (0.75), 2.19 (0.50), 2.43 (0.25), and 2.72 Å (n = 0.10); and relative to a Ge—S single bond length of 2.26 Å, the corresponding values for Ge—S partial bonds are 2.37 (0.75), 2.53 (0.50), 2.79 (0.25), and 3.13 Å (n = 0.10). These calculated values appear to be compatible with the sum of the van der Waals radii of Sn, Ge, S, and O (17) and by way of comparison, the "valencies" for partial Sn—O bonds have been calculated as 2.43 (0.30) and 2.66 (0.20) (18).

Results and discussion

The preparation of *O*-alkyl monothiocarbonate derivatives of triphenyl-, diphenyl-, and trimethyl-tin(IV) compounds was attempted by the reaction of the sodium salt of the monothiocarbonic acid in dried CH_2Cl_2 as solvent with the appropriate organotin chloride using a standard Schlenk line in accord with the reactions

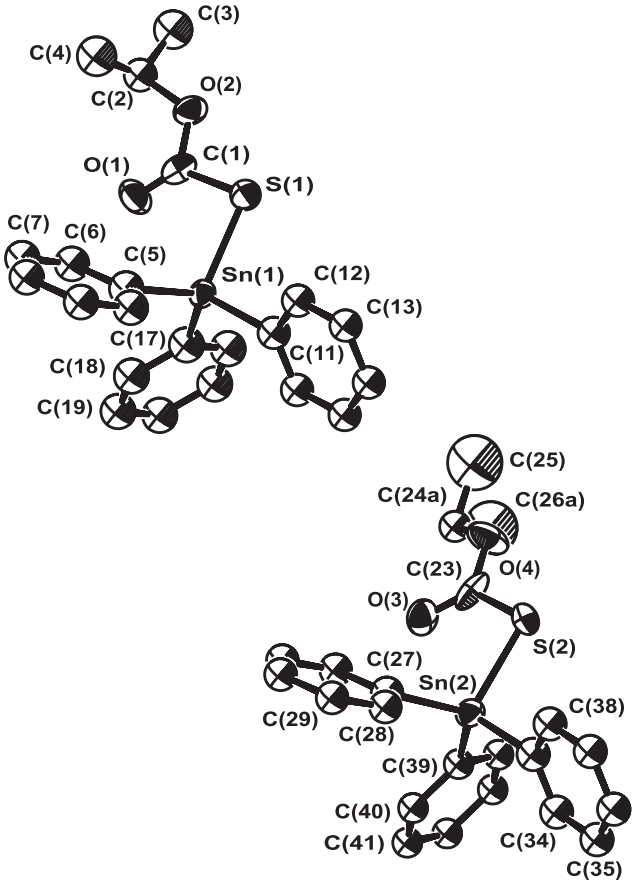
[1] $R_3SnCl + NaSCO_2R' \Rightarrow R_3Sn[SCO_2R'] + NaCl$

[2] $R_2SnCl_2 + 2NaSCO_2R' \Rightarrow R_2Sn[SCO_2R']_2 + 2NaCl$

[3] $R_2SnCl_2 + NaSCO_2R' \Rightarrow R_2SnCl[SCO_2R'] + NaCl$

where R = Me, Ph, R′ = Me, i-Pr.

Fig. 2. ORTEP plot of the two molecules of $Ph_3Sn[SCO_2(i\text{-}Pr)]$ (**2**) in the asymmetric unit. The atoms are drawn with 30% probability ellipsoids. Hydrogen atoms are omitted and only one set of the carbon atoms in partially occupied positions are shown for the disordered i-Pr group for clarity.



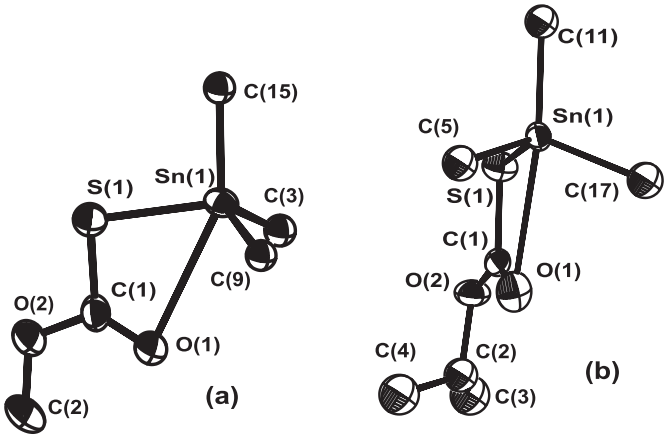


Fig. 3. ORTEP plots illustrating the core around tin including the Sn-O interaction for (*a*) the molecule $Ph_3Sn[SCO_2Me]$ (**1**) and (*b*) the molecule of $Ph_3Sn[SCO_2(i\text{-}Pr)]$ (**2**) that does not contain a disordered i-Pr group. The atoms are drawn with 30% probability ellipsoids. Hydrogen atoms and the carbon atoms of the phenyl rings other than those attached to tin omitted for clarity.

The compounds $Ph_3Sn[SCO_2Me]$ (**1**), $Ph_3Sn[SCO_2(i\text{-}Pr)]$ (**2**), $Ph_2Sn[SCO_2(i\text{-}Pr)]_2$ (**3**), $Ph_2SnCl[SCO_2(i\text{-}Pr)]$ (**4**), and $Me_3Sn[SCO_2Me]$ (**5**) were isolated but only **1** and **2** gave X-ray quality crystals. In reactions [1] and [2], the salts were used in considerable excess relative to the stoichiometric requirements to ensure complete reaction. By contrast, exact stoichiometric amounts were used in reaction [3] to favor the formation of the mixed chloro derivatives. When reactions [2] and [3] were attempted using $NaSCO_2Me$, only mixtures containing $Ph_2Sn[SCO_2Me]_2$ and $Ph_2SnCl[SCO_2Me]$ resulted in both cases. In general, all of the compounds are susceptible to moisture and air on exposure to the atmosphere, and all were readily dissolved in chloroform — which was therefore used as the preferred solvent for recording NMR spectra.

The ^1H NMR spectra of compounds **1**–**5** confirm that the products are over 98% pure relative to any hydrogen-containing impurities and integration ratios are as expected. The signals due to the phenyl groups in compounds **1** and **2** (two sets of peaks between 7.40 and 7.68 ppm) are very similar in appearance and position to those of the analogous germanium derivatives (two sets of peaks between 7.36 and 7.64 ppm) (4). The monothiocarbonate ligands give the expected first order spectra with chemical shifts comparable to those of the corresponding salts. As observed for the corresponding OCH_n-groups in the germanium analogues, the chemical shifts of hydrogen atoms on the carbon atom attached to oxygen are similar for a given monothiocarbonate regardless of the number of phenyl groups attached to tin (4.88 ppm for $Ph_3Sn[SCO_2CH(CH_3)_2]$ (**2**) and 4.86 ppm for $Ph_2Sn[SCO_2CH(CH_3)_2]_2$ (**3**). In $Ph_2SnCl[SCO_2CH(CH_3)_2]$ (**4**), the chemical shifts for the protons in both phenyl and ligand groups are slightly downfield compared to the bis compound, **3**, which is consistent with the electronegativity of Cl being slightly larger than that of the monothiocarbonate group. In $Me_3Sn[SCO_2Me]$ (**5**) the CH_3 chemical shift of the methyl group attached to tin is also very close to the value in $Me_3Ge[SCO_2Me]$ (0.57 ppm). The similarity of all of the spectra is indicative that the environments of the monothiocarbonate groups in solution are identical in all compounds. In the ^{13}C NMR spectra, the chemical shifts of monothiocarbonate groups are similar regardless of whether methyl or phenyl groups are attached to tin or the number of such groups, again as was observed in the analogous germanium derivatives. For the carbon atom in the SCO_2 groups, the chemical shifts range from 170.28 to 172.67 ppm for all compounds except for **4**; again reflecting the presence of the more electronegative Cl atom. The similar values of the ^{13}C NMR chemical shifts in the monothiocarbonate ligands is again consistent with the presence of similar monothiocarbonate linkages in solution.

The crystal structures of $Ph_3Sn[SCO_2Me]$ (1) and $Ph_3Sn[SCO_2(i\text{-}Pr)]$ (2)

Both $Ph_3Sn[SCO_2Me]$ (**1**) and $Ph_3Sn[SCO_2(i\text{-}Pr)]$ (**2**) crystallize in the space group $P\bar{1}$ (No. 2), but with two independent molecules in the asymmetric unit for **2**. The ORTEP diagrams in Figs. 1 and 2 illustrate that the immediate environments about tin in both $Ph_3Sn[SCO_2Me]$ (**1**) and $Ph_3Sn[SCO_2(i\text{-}Pr)]$ (**2**) are that of a distorted tetrahedron. As was found for the analogous germanium derivatives, $Ph_3Ge[SCO_2Me]$ and $Ph_3Ge[SCO_2(i\text{-}Pr)]$ (4), the three C-Sn-C angles range from 109.9(4) to 112.6(4)° in **1** and 106.7(9) to 114.3(7)° in **2** with averages of 111.3(14) and 111.3(29)°, respectively; while those of the S-Sn-C angles range from 97.5(3) to 112.3(3)° in **1** and 100.7(8) to 113.1(7)° in **2** with averages of 107(8) and 107(6)°, respectively. Alternatively, it is notable that one of the S-Sn-C angles is considerably smaller (97.5(3) in **1** and 100.5(3)° average in **2**) than the rest of the five angles around Sn (average 111.7(11) in **1** and 111.1(24)° in **2**); all five being close to or slightly larger than the all-tetrahedral angle. A similar phenomenon was noted for $Ph_3Sn[SCO_2N(CH_2)_4O]$, $Ph_3Sn[SOCNC_4H_4]$, $Ph_3Sn[S_2CO(i\text{-}Pr)]$, and $Ph_3Sn[S_2P(OEt)_2]$ where the smaller S-Sn-C angles were 95.7(1), 98.2(1), 100.0(1), and 100.09(1)°, respectively, (9, 8, 7, 12). The three Sn—C distances, ranging from 2.10(1) to 2.12(1) in **1** and 2.13(3) Å (average) in **2**, are among the shorter reported for the four triphenyltin derivatives mentioned above which range from 2.123(3) to 2.149(5) Å, and similar to that in the cyclic dithiophosphate derivative, $Ph_3Sn[S_2POCMe_2CMe_2O]$ (19) (2.106(8) to 2.134(9) Å).

The Sn—S bond lengths of 2.444(4) in **1** and 2.44(3) Å (average) in **2** are similar to those in $Ph_3Sn[SCO_2N(CH_2)_4O]$ (2.446(2) Å), $Ph_3Sn[S_2CO(i\text{-}Pr)]$ (2.445(1) Å), $Ph_3Sn[SOCNC_4H_4]$ (2.453(1) Å), $Ph_3Sn[S_2P(OEt)_2]$ (2.4582(9) Å), and $Ph_3Sn[S_2POCMe_2CMe_2O]$ (2.436(3) Å); all of which have been described as containing monodentate ligands. Bidentate ligands with essentially identical Sn—S bonds, for example $Ph_2Sn[S_2P(O(i\text{-}Pr)_2]_2$ (10) (2.689 (1) and 2.678 (1) Å), are appreciably longer than the 2.444 (4) Å found in **1**. These bidentate ligands have a partial Pauling bond order of ca. 0.50 compared to the Sn—S bonds in **1** and **2** with bond orders of ca. 0.91. However, examples of bidentate ligands with more variance in Sn—S bond lengths, also referred to as unsymmetrical or anisobidentate, are exemplified by $BuSn[S_2CN(Et)_2]_3$ (11), where Sn—S bonds range from 2.619(7) to 2.860(6) Å, and $Ph_2SnCl[S_2CO(i\text{-}Pr)]_2$ (20), where a range of 2.5 to 2.8 Å is quoted. These have bond orders ranging from ca. 0.78 to 0.32. In $Sn[S_2COEt]_4$ (21), two types of Sn—S distances are reported: those in bidentate ligands ranging from 2.562(2) to 2.627(2) Å) and those in monodentate ligands being 2.494 (2) Å. However, the second sulfur atoms in the latter cases are 2.916(10) Å from tin, giving an Sn—S distance that is only marginally longer than in species where the ligands are described as unsymmetrical bidentate ligands. Given that wave functions are continuous, it is reasonable to assume ever weakening partial bonds as the Sn—S distances increase. Our simplistic calculations based on Pauling's method (15) gave partial bond orders of 0.80 to 0.28 for Sn—S distances of 2.49–2.92 Å.

In the absence of a second sulfur atom, the terminal O atom in both **1** and **2** is oriented towards tin; the Sn—O distances of 3.040(8) and 3.05(1) Å (average) in **1** and **2**, respectively being significantly less than the sum of the van der Waals radii of 3.57 Å. In Fig. 3 and Table 4, the core about tin is shown with the inclusion of the Sn—O bond in the coordination sphere. Similarly, in $Ph_3Sn[S_2CO(i\text{-}Pr)]$ the O atom of the propoxy group, rather than the terminal S atom as is normally the case, is oriented toward tin, and it was proposed that the Sn—O distance of 2.950(3) Å was sufficiently shorter than the sum of the Van der Waals radii

[c]Ref. (9).

[d]Ref. (4).

to indicate a significant degree of interaction between the Sn and O atoms (7). Hence the environment around tin can be described as a distorted trigonal bipyramid. By contrast, in a study of organotin(IV)1-pyrrolecarbothioates (8) Sn—O distances ranging from 2.424(3) to 2.523(2) Å were considered bonding, while those from 2.65 to 3.242 Å were described as non-bonding (8), as was the distance of 2.809(4) Å in $Ph_3Sn[SCOCN(CH_2)_4O]$ (9). As discussed above for Sn—S partial bonds, it is reasonable to simply assume that the partial bonds get weaker as the Sn—O distance gets longer. Thus, Sn—O distances of 2.424(3) to 2.523(2) can be assigned partial bond orders of 0.46 to 0.35 and those from 2.65 to 3.242 bond orders from 0.24 to 0.05. This is essentially a spherical model therefore the bond orders are probably underestimated. The Sn—O distance in $Ph_3Sn[SCO_2Me]$ (**1**) of 3.040(8) Å corresponds to a bond order of 0.08 to complement the Sn—S bond length of 2.444(4) Å with a bond order of 0.91. The corresponding Ge—O distance in $Ph_3Ge[SCO_2Me]$ (3.112(7) Å) can be assigned a bond order of only 0.03, compared with a bond order for the Ge—S bond (2.253(3) Å) of 1.02, so on a relative scale the interaction with the terminal C=O bond is less significant for germanium. The comparative features presented in Table 4 for $Ph_3Sn[SCO_2Me]$ (**1**), $Ph_3Sn[SCO_2(i\text{-}Pr)]$ (**2**), $Ph_3Sn[SCON(CH_2)_4O]$, and $Ph_3Ge[SCO_2Me]$ show striking similarities. Quite clearly, each molecule has one O-Sn-C angle much closer to 180° (153.4(4) to 157.1(6)°) and the other two much closer to 90° (75.4 to 89.0°) as expected for distortion based on the trigonal bipyramid.

The terminal C=O bond length of 1.20(1) Å in **1** is similar to that in $Ph_2Te[SCO_2(i\text{-}Pr)]_2$ (1.203(9) Å), where the ligand was considered to be anisobidentate (4). The SC—O bond of 1.34(1) is significantly shorter than the SCO—C bond of 1.43(1) Å. The shortening of the SC—O bond relative to the SCO—C bond is also clear in **2**, despite the poorer refinement, and is consistent with the π-bond character being only of significance within the planar SCO_2 core. The angles in the planar core (e.g., O=C-O (126(1)°), O=C-O (125(1)° and O-C-S 109.2° for **1**) indicate that the C=O bond is clearly most strongly involved in the delocalized π-bonding, as was found for the organogermanium- and organotellurium-monothiocarbonates (3,4). The SnS—C distance of 1.76(1) Å for **1**, which is marginally shorter than the sum of the covalent radii of S and C is also essentially the same as in the Ge and Te analogues, close to the value found in $Ph_3Sn[S_2CO(i\text{-}Pr)]$ (1.748(5) Å), and longer than the typical value (ca. 1.70 Å) for a symmetrical bidentate dithiocarbonate.

Infrared and Raman spectra

In general, monothiocarbonates appear to be relatively poor scatterers and the quality of the Raman spectra is such that no attempt is made at extensive assignments. However, the assignment of distinctive characteristic features is possible by using the same factors described for the analogous germanium (4) and tellurium (3) derivatives, along with comparisons with other related dithioacid tin species (6, 21), and these are provided in linear form for each compound in the experimental section. There is a marked similarity between the spectra of $Ph_2Sn[SCO_2(i\text{-}Pr)]_2$ (**3**) and $Ph_2Te[SCO_2(i\text{-}Pr)]_2$ (3) which is consistent with the similar atomic masses of tin and tellurium and with the similar orientations of the monothiocarbonate groups despite the differences in overall structure. While it is reasonable to assume that there will be significant coupling between the four stretching vibrations of the SCO_2C unit, the positions of the three peaks that dominate the infrared spectra in the 1700–1000 cm^{-1} region suggest these arise primarily from the stretching of the three C—O bonds. Thus, for example, in $Ph_2Sn[SCO_2(i\text{-}Pr)]_2$ (**3**) the three very strong broad peaks are seen at 1642 (mainly C=O stretching), 1176 (mainly C—O stretching), and 1091 cm^{-1} (mainly O—$CH(CH_3)_2$ stretching); compared with 1653, 1149, and 1088 cm^{-1} in $Ph_2Te[SCO_2(i\text{-}Pr)]_2$ and 1698, 1159, and 1087 cm^{-1} in $Ph_2Ge[SCO_2(i\text{-}Pr)]_2$. The strong band corresponding to that at 1640 cm^{-1} is observed at lower wave-number, between 1550 and 1614 cm^{-1}, in $NaSCO_2R$ salts (4), which is consistent with the presence of a strong terminal C=O bond in the monothiocarbonate derivatives. Any association with the metal is apparently similar for tin and titanium and least significant for germanium, as shown by the bond orders calculated for the structures of $Ph_3Sn[SCO_2Me]$ (**1**) in which the band is seen at 1669 cm^{-1} and that of $Ph_3Ge[SCO_2Me]$ in which it is at 1695 cm^{-1}. The fourth stretching vibration associated with the SCO_2C core, which is presumably primarily ν(SnS-C), is seen between 655 and 662 cm^{-1} as a weaker feature in the infrared and

© 2000 NRC Canada

fairly strong feature in the Raman effect. This is within the expected region for a C—S single bond stretch and is at lower wave number than in the salts where the C—S bond would have more partial π-bond character. Two distinctive peaks seen in **1**–**4** within the ranges 813–848 and 412–418 cm^{-1} can be assigned to the out-of-plane mode, $\pi(SCO_2)$, and to one of the in-plane bends, $\delta(SCO_2)$, which were similarly assigned in the tellurium derivatives to ca. 848 and 416 cm^{-1}. The assignment of $\pi(CO_3)$ in a variety of carbonate salts is in the region of 830–873 cm^{-1} suggesting that the π-electron delocalization is similar in all of these planar groups. In **5**, the feature attributable to $\pi(SCO_2)$ is obscured by the very intense and typical peaks assignable to the CH_3 rocking modes of the methyl groups attached to tin.

In the phenyltin derivatives (**1**–**4**) the characteristic and very distinctive *f*-phenyl and *v*-phenyl modes, which are both of similar intensity, are observed at ca. 736 and 695 cm^{-1}, along with *y*-phenyl at ca. 447 cm^{-1}; all three features being essentially the same in the tellurium and germanium analogues (3, 4). In $Me_3Sn[SCO_2Me]$ (**5**) two peaks are seen at 532 and 506 cm^{-1}, which are not seen in the spectra of the phenyltin derivatives. These clearly correspond to the asymmetric and symmetric Sn—C stretching vibrations at almost identical positions to those in Me_3SnSMe (531 and 509 cm^{-1}) (22) suggesting very similar environments about Sn in **5** and the simple sulfide. In the latter, ν(Sn-S) is seen at 341 cm^{-1} but generally for dithioacid derivatives it is assigned at higher wave-number as exemplified by the range 356–394 cm^{-1} for a variety of tin dithiocarbamate derivatives (23). In organotin chlorides, the Sn—Cl stretching vibrations have been typically assigned to the 344–360 cm^{-1} region as they were in a detailed examination of low frequency vibrational spectra of group 14 phenyl compounds including Ph_3SnCl and Ph_2SnCl_2 (24). By contrast, in mixed halide ligand derivatives such as $Me_2SnCl[S_2CNMe_2]$, ν(SnCl) is assigned at a much lower wave-number, 268 cm^{-1}. This was the basis of our assignment of the low frequency modes in **4**.

Concluding comments

The isolation of organotin monothiocarbonates proved to be more difficult than for the corresponding organogermanium derivatives. The X-ray structures of $Ph_3Sn[SCO_2Me]$ (**1**) and $Ph_3Sn[SCO_2(i\text{-}Pr)]$ (**2**) demonstrate a preference for the orientation of the terminal C=O oxygen atom towards tin, at least in the solid state. The resulting weak intermolecular interaction indicates an anisobidentate link that is relatively more significant than in the corresponding germanium derivative. Thus the distortions from "all-tetrahedral" angles around tin are consistent with the formation of a weak Sn—O link that gives a distorted trigonal bipyramidal arrangement around tin. In dithio derivatives, there is often a tendency for Ph_3SnL species with symmetrical bidentate ligands to disproportionate to the bis species, Ph_2SnL_2 on recrystallization giving rise to a trans octahedral structure. This clearly is not the case for $Ph_3Sn[SCO_2Me]$ and $Ph_3Sn[SCO_2(i\text{-}Pr)]$ and indeed we were not able to isolate X-ray quality crystals for $Ph_2Sn[SCO_2Me]_2$ or $Ph_2Sn[SCO_2(i\text{-}Pr)]_2$; consistent with the ligands being essentially monodentate in solution as is indicated by the NMR spectra.

A study of micellization and the thermodynamic properties of a series of aqueous sodium cyclohexyl alkanoate surfactants

Judith A. MacInnis, D. Gerrard Marangoni, and R. Palepu

Abstract: The micellization and the thermodynamic properties of a series of sodium cyclohexyl alkanoates of the general formula $C_6H_{11}(CH_2)_nCOONa$ (where n = 1, 2, 3, 4) were investigated employing conductivity, density, surface tension, viscosity, speed of sound, luminescence probing experiments, and Fourier transform infrared (FT-IR) spectroscopy. The critical micelle concentrations (cmcs) and the aggregation numbers indicate that these surfactants have high cmc values and low aggregation numbers when compared to other single-headed surfactants (most notably the sodium alkanoates). Thermodynamic properties, obtained from the mass action model, indicate that micellization is spontaneous and entropically driven. The saturation area per molecule, the free energies of adsorption, and the efficiency and effectiveness of adsorption were determined through surface tension measurements. The presence of the cylcohexyl ring appears to influence the surface properties of micellization. Both the effectiveness and the efficiency of these surfactants, in lowering the surface tension of water, are lower than that of the straight chain alkanoates.

Key words: thermodynamics, micellization, aggregation numbers, speed of sound, and spectroscopy.

Résumé : Faisant appel à la conductivité, la densité, la tension superficielle, la viscosité, la vitesse du son, des expériences de luminescence ainsi que la spectroscopie infrarouge par transformation de Fourier (« FT-IR »), on a étudié la micellisation et les propriétés thermodynamiques d'une série de cyclohexylalcanoates de sodium de formule générale $C_6H_{11}(CH_2)_nCOONa$ (où n = 1, 2, 3, 4). Par comparaison avec les valeurs correspondantes pour d'autres agents de surface à une seule tête (plus particulièrement les alcanoates de sodium), les concentrations micellaires critiques (cmc) sont élevées alors que les nombres d'agrégation sont faibles. Les propriétés thermodynamiques, obtenues à partir du modèle d'action de masse, indiquent que la micellisation est spontanée et sous l'influence de l'entropie. On a déterminé la superficie de saturation, les énergies libres d'adsorption et l'efficacité de l'adsorption à l'aide de mesures de la tension superficielle. La présence de noyaux cyclohexyles semble influencer les propriétés de surface de micellisation. L'efficacité de ces agents de surface à diminuer la tension superficielle dans l'eau est inférieure à celle des alcanoates en chaîne droite.

Mots clés : thermodynamique, micellisation, nombres d'agrégation, vitesse du son, spectroscopie.

1. Introduction

The study of micellization of aqueous solutions of surfactants in the literature is well established (1–18). The dependence of interfacial activity and micellization on the structure of the hydrophobic part of the surfactant is an area of research that has been receiving increased attention in recent years. The bulk properties of *n*-alkanoate surfactants with linear alkyl chains have been extensively reported in the literature (19–24), however, very little attention has been given to the alkanoate surfactants that contain a cyclohexyl ring. The sodium cyclohexyl alkanoate surfactants have structures similar to those of the petroleum acids. The latter contain mainly short alkyl chains that are attached to various saturated, partially saturated, and aromatic structures. These compounds play an important role in the reduction of interfacial tension during alkaline water flooding of oil reservoirs (10).

Employing techniques such as density, viscosity, conductivity, surface tension, speed of sound, FT-IR spectroscopy, and fluorescence spectroscopy, this paper investigates the bulk thermodynamic and micellar properties of a family of alkanoate surfactants, which contain a cyclohexyl ring in place of a long hydrocarbon chain to address the effects of the cyclohexyl ring and of increasing alkyl chain length on these properties.

2. Experimental

The cyclohexyl acids were purchased from Aldrich (99% pure). They were dissolved in deionized water, equivalent to triply glass-distilled, and were then converted to the corresponding sodium salts. All of the dried salts were soxhlet extracted with diethyl ether for 2–5 days, dried and stored

under vacuum. Pyrene was also purchased from Aldrich (99%) was purified, by sublimation and recrystallization (twice) from ethanol.

Surface tension measurements were performed on a Fisher surface tensiometer Model 21, equipped with a 13 mm-diameter DuNuoy ring. The solutions were carefully transferred into a double-walled vessel, which was maintained at the appropriate temperature (±0.02°C) with a Haake 4000 temperature bath. The surface tension measurements were carried out at 298.15, 308.15, and 318.15 K. Adsorption processes at the air–water interface were generally completed in 10 min. The repetition rate of individual readings was about 15 min.

The absolute surface tension values (γ) were obtained from the apparent values following the procedure as described in the manual supplied with the instrument. The surface tension of pure water was measured periodically as a calibration. The surface tension measurements of sodium cyclohexyl pentanoate aqueous solutions were performed in a slightly basic solution (pH = 10) to minimize hydrolysis.

The conductivity measurements were made in a thermostated–jacketed beaker with a dip cell having a cell constant of 1.11 cm^{-1}, and an automatic CDM83 conductivity bridge (Radiometer) operating at 1000 Hz. Specific conductivity values, of each set, containing 20–25 different concentrations of surfactant, were measured at different temperatures.

The density measurements at various temperatures were obtained using an Anton–Parr digital densimeter DMA 45 operating in the static mode.

Viscosities of the sodium cyclohexyl salts in water at various concentrations were determined using modified Ostwald viscometers and a viscosity bath (Koehler Instrument), to control temperature.

Speed of sound was measured using a Nusonics (model 6080) concentration analyzer employing the sing around technique. Rapid and accurate measurements of sound velocity as a function of surfactant concentration were made by successive additions of known weights of the surfactant to the water contained in the thermostatted beaker. Speeds of sound measurements are accurate to ±0.10 m s^{-1}.

The FT-IR spectra were obtained using a Biorad FT-IR spectrophotometer (1000 scans at 4 cm^{-1} resolution, triangular apodization) using an ATR cell manufactured by Spectra-Tech Inc. (Stamford, CT: Circle® cell). The reference element of the cell is 45° angle-of-incidence zinc selenide. The reference spectra of pure water and the background spectra of air were obtained at the start of each run. Five hundred to 1000 scans were carried out on each set of solutions. The spectra were obtained by subtracting the water spectra that was run under the same experimental conditions.

For the fluorescence measurements the pyrene probe was held at a constant concentration of 2.5×10^{-5} M. The monolayer method was used to prepare the solutions for fluorescence measurements. Steady state pyrene fluorescence spectra were recorded on a Perkin–Elmer MPF-66 spectrophotometer, using an excitation wavelength of 338 nm and the emission spectra was recorded from 350 to 500 nm. The intensities of the first and third vibronic peaks were recorded and employed to calculate the I_1/I_3 ratio. This ratio gives an indication of the micropolarity sensed by the probe in the micellar solutions. Fluorescence measurements were also used to determine the critical micelle concentration (CMC). The pyrene concentration was again kept constant at 2.0×10^{-5} M. At least 12 solutions were prepared, up to a final concentration of twice the CMC.

3. Results

3.1 Conductivity

Plots of specific conductance (κ) against the concentration of surfactant indicate a break at the CMC, which is temperature dependent for each of the surfactants under study (Fig. 1).

The apparent degree of micelle ionization (α) was taken as the ratio of the slopes of the lines above and below the CMC in the plots of conductance (κ) vs. concentration and are presented in Table 1.

3.2 Surface tension

Representative surface tension plots of the cyclohexyl salts, at various temperatures, (298.15, 308.15, and 318.15 K) are given in Figs. 2(*a*), 2(*b*), and 2(*c*). The maximum surface excess concentration, Γ_{max}, the minimum area per surfactant molecule, A_{min} (m^2) at the surfactant–solvent interface, and the values of surface pressure at the CMC, Π_{CMC}, were obtained employing the surface tension data and the following equations (3, 9, 14):

$$[1] \qquad \Gamma_{max} = -\frac{1}{vRT}\left[\frac{\delta\gamma}{\delta \ln C_{T,P}}\right]$$

$$[2] \qquad A_{min} = 1/N_a\Gamma_{max}$$

and

$$[3] \qquad \Pi_{CMC} = \gamma_o - \gamma_{CMC}$$

where v is the number of ions per surfactant molecule, R is the universal gas constant, T is the temperature in K, N_a is Avagadro's number, γ is the surface tension of the solution, and γ_o is the surface tension of the pure solvent. The values of A_{min} are shown in Table 2. The equilibrium surface tension concentration isotherms of the carboxylate salts were analyzed employing the simplified form of the Temkin (14) isotherm (eq. [4]):

$$[4] \qquad \ln X = -\ln B + \Pi^{1/2}\frac{g}{RT}$$

where X is the mol fraction of the compound in the bulk solution, Π is the surface pressure (mN m^{-1}), which is defined as $\Pi = \gamma_{water} - \gamma_{solution}$, B denotes the equilibrium constant of the adsorption process, g is a constant characteristic of each surfactant system. The constant B is related to the extrapolated standard free energy of adsorption:

$$[5] \qquad B = \exp(-\Delta G^{\circ}_{\Pi\rightarrow 0}/RT)$$

Fig. 3. Standard free energies of adsorption at 298.15 K as a function of chain length.

From the plots of $\Pi^{1/2}$ vs. ln X, the values of constants B and g were calculated employing the least-squares regression analysis. The values of g and B are also presented in Table 2.

For the sodium carboxylates, v = 2, which accounts for the complete ionization of these salts. At these relatively high concentrations, it is reasonable to assume that the pH is relatively constant and the hydrolysis of the carboxylate ion can be neglected. The values of the standard free energies of adsorption, ΔG°_{ads}, obtained from eq. [5] are presented in Fig. 3, as a function of the number of carbon atoms (excluding the headgroup carbon).

The efficiency of the surface tension reduction, at 298.15 K, was calculated by:

$$[6] \qquad pC_{20} = -\log C_{20}$$

where C_{20} is the surfactant concentration when the surface tension of water is reduced (10) by 20 mN m^{-1} and the values are presented in Table 2.

3.3 Viscosity

The values of the aggregation numbers for the cyclohexyl salts were estimated through the shear solution viscosity assuming the micelles to be spherical and the electroviscous effect to be negligible. The volume fraction of spherical particles (ϕ) was calculated employing the Guth–Simha equation (17):

$$[7] \qquad \eta = \eta_o(1 + 5\phi/2 + 109\phi^2/14)$$

where η and η_o are the shear viscosity of the solution and at the critical micelle concentration, respectively. The volume fraction (ϕ) is related to the aggregation number (N_{agg}) by:

$$[8] \qquad \phi = \frac{4\pi \ell^3 N_a(C_{surf} - CMC)}{3N_{agg}}$$

where ℓ is the length of the hydrated micelle, N_a is Avagadro's number, and C_{surf} is the total surfactant concentration. In this study the value of ℓ was approximated using the dry length of the surfactant from the computer-modeling program "HyperChem" (version 5 AM1 approximation). From this estimate of ℓ, the values of the aggregation

number were obtained from the slope of the linear plots of ϕ vs. C_{surf} – CMC. The values of N_{agg} and η_o are given in Table 3.

3.4 Apparent molar volumes

Apparent molar volumes, ϕ_v, were calculated from the experimental density data employing the following equation:

$$[9] \qquad \phi_v = \frac{M}{d} - \frac{10^3(\rho - \rho_0)}{m\rho\rho_0}$$

where M is the molecular weight of the surfactant, ρ and ρ_o are the densities of the solution and the solvent, and m is the molality. When ϕ_v is plotted against $C^{1/2,}$ the gradient approaches zero at higher surfactant concentration and this limiting value is subjectively chosen as the apparent molar volume of the micelle (ϕ_v^{mic}) (3, 21).

An alternate method (22) is to fit the data, in the concentration region $m \leq$ CMC, to the following function:

$$[10] \qquad \frac{\phi_v}{\phi_v^{mic}} = \frac{m}{(a + m)}$$

where a is an empirical constant. Rearrangement of eq. [10] in the following form:

$$[11] \qquad \phi_v = -a\left(\frac{\phi_v}{m}\right) + \phi_v^{mic}$$

allows ϕ_v^{mic} to be extrapolated from the plots of ϕ_v, vs. ϕ_v/m.

The values of the apparent molar volumes at infinite dilution, ϕ_v^o, were determined numerically using the following equation:

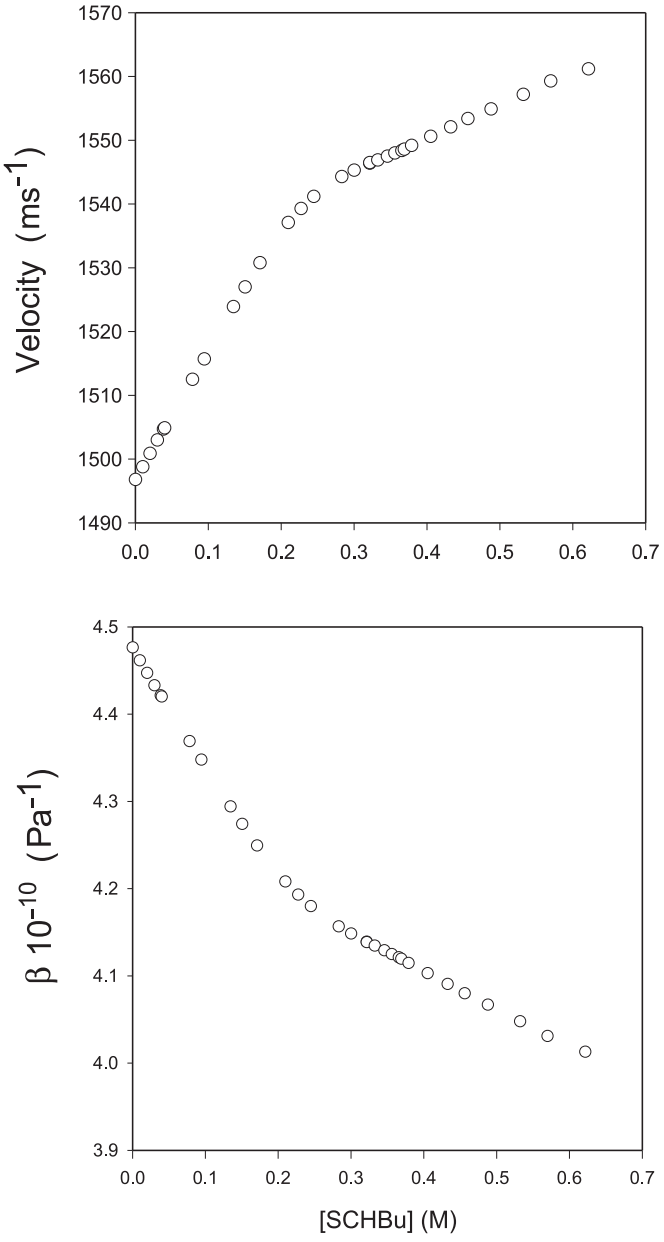
$$[12] \qquad \phi_v = \phi_v^o + A_v C^{1/2} + B_v C$$

where A_v is the Debye–Huckel limiting law coefficient (1.865 $cm^3\ kg^{1/2}\ mol^{-3/2}$ for a 1:1 electrolyte at 298.15 K), B_v is an adjustable parameter, which measures the deviations from the limiting law, and ϕ_v^o is the apparent molar volume at infinite dilution.

The values of volume change, $\Delta V_m = \phi_v^{mic} - \phi_v^o$, associated with the formation of micelles in the sodium cyclohexyl surfactant solutions are shown in Table 3.

3.5 Speed of sound

The plots of speed of sound against concentration show two linear segments with the intersection occurring at the CMC (Fig. 4(*a*)). Density and speed of sound measurements were combined to calculate the adiabatic compressibility for the sodium cyclohexyl alkanoates using the Laplace equation (Fig. 4(*b*)):



$$[13] \qquad k_s = \frac{1}{\rho u^2}$$

The linear regions may be assigned to the monomeric and micellar forms of the surfactant. The values for the apparent adiabatic compressibilities of the monomeric and micellar forms (11–12) may be calculated from the gradients of the relevant portions of the plots of k_s vs. surfactant concentration using the following equation:

$$[14] \qquad k_s = k_{s,0} + (\tilde{k}_{s,1} - k_{s,0})\tilde{v}_1 c_1 + (\tilde{k}_{s,2} - k_{s,0})\tilde{v}_2 c_2$$

© 2000 NRC Canada

Fig. 4. (*a*) Ultrasonic velocity of sodium cyclohexylbutanoate 298.15 K. (*b*) Adiabatic compressibility of sodium cyclohexylacetate 298.15 K.

where $k_{s,0}$ is the adiabatic compressibility of the solvent, $\tilde{v}_1$ and $\tilde{v}_2$ are the apparent specific volumes of the monomer and the micelle, c_1 and c_2 are the monomer and the micelle concentrations (in g cm^{-3}). The apparent adiabatic compressibilities of the monomer ($\tilde{k}_{s,1}$) and micellar species ($\tilde{k}_{s,2}$) are defined as:

$$[15] \quad \tilde{k}_{s,1} = -\frac{1}{\tilde{v}_1}\left(\frac{\partial \tilde{v}_1}{\partial p}\right)_s$$

and

$$[16] \quad \tilde{k}_{s,2} = -\frac{1}{\tilde{v}_2}\left(\frac{\partial \tilde{v}_2}{\partial p}\right)_s$$

The values of the apparent specific volumes of the monomer, $\tilde{v}_1$ and micelles, $\tilde{v}_2$ required for the calculation of the adiabatic compressibilities were determined from the gradients of linear portions of plots of density against concentration below and above the CMC using eq. [17]:

$$[17] \quad \rho = \rho_0 + (1 - \tilde{v}_1 \rho_0)c_1 + (1 - \tilde{v}_2 \rho_0)c_2$$

The values of $\tilde{k}_{s,1}$, $\tilde{k}_{s,2}$, and $\Delta\kappa_s = \tilde{k}_{s,2} - \tilde{k}_{s,1}$, the change upon micelle formation, are presented in Table 3.

3.6 Fluorescence

The CMC of the sodium cyclohexyl alkanoates was determined using the pyrene I_1/I_3 micropolarity method (24). This procedure relies on the sensitivity of the pyrene vibrational structure to respond to the changes in the surrounding microenvironment. Below the CMC the pyrene fluorescence spectrum corresponds to a polar environment and in the presence of micelles, the probe is assumed to be solubilized in the palisade region and the polarity is drastically decreased, resulting in a lowering of the I_1/I_3 value. The pyrene I_1/I_3 ratios were monitored as a function of surfactant concentration in water and are presented in Table 3.

The CMC values were obtained from the break point as indicated in Fig. 5, and are listed in Table 1. These CMC values are in good agreement with those obtained from other methods.

3.7 FT-IR

The infrared spectra of the sodium cyclohexyl alkanoate surfactants contain various vibrational modes associated with the acyl chain and the carboxylate group. The strongest bands that were used in this study were the antisymmetric CH_2 stretching mode and the antisymmetric and symmetric carboxylate stretching modes. These values are assigned in Table 4. Plots of frequency vs. concentration of the antisymmetrical CH_2, the antisymmetrical COO^- and the symmetrical stretching mode of COO^- for sodium cyclohexyl acetate are shown in Fig. 6. By examining these plots one can see the inflection points at ~1.0 M surfactant concentration. This indicates that the critical micelle concentration occurs at ~1.0 M. Plots of bandwidths at half-height (Fig. 7) also indicate a break point at the CMC.

3.8 Thermodynamics of micellization

The thermodynamic properties of micellization were derived by application of the mass action model as follows. The equilibrium constant, K_m, for the formation of micelles may be written (11–12):

$$[18] \quad \frac{1}{K_m} = \left[n\frac{(2n-z)(4n-2z-1)}{(2n-z-2)}\right] \times \left[\frac{(2n-z)(4n-2z-1)}{(2n-z-1)(4n-2z+2)}X_{cmc}\right]^{2n-z-1}$$

where z is the net charge of the micelle ($z = n\alpha$; n is the aggregation number and α is the fraction of free counterions), and X_{CMC} is the CMC expressed on the mol fraction scale. In the calculation of K_m the values of α and n were determined

through conductivity and viscosity measurements, respectively.

The standard Gibbs energy change ΔG_m°, the standard enthalpy change, ΔH_m°, and the standard entropy change, ΔS_m°, on micellization were determined employing the following equations:

[19] $$\Delta G_m^\circ = -(RT/n)\ \ln\ K_m$$

[20] $$\Delta H_m^\circ = -(2-a)RT^2\left(\frac{\partial \ln X_{cmc}}{\partial T}\right)$$

[21] $$\Delta S_m^\circ = \frac{-1}{T}(\Delta G_m^\circ - \Delta H_m^\circ)$$

These values are presented in Table 5.

4. Discussion

The critical micelle concentration has been determined in this study using a variety of experimental techniques including conductivity, density, viscosity, surface tension, speed of sound, FT-IR, and fluorescence (Table 1). All of the CMC values determined using these techniques are in good agreement with each other. Figure 8 shows a plot of log (CMC) against the number of carbon atoms in the surfactant (excluding the headgroup carbon) using the data from the above techniques.

The CMC values determined by the surface tension technique are slightly lower than expected. It is well known in the literature that the CMC values depend on the technique employed in the determination of the CMC (9). The CMC values decrease by approximately half upon the addition of one CH_2 group to the alkyl chain. Similar behavior was also observed for long-chain sodium alkanoate surfactants.

Based on the critical micelle concentration values, the cyclohexyl ring behaves in a similar manner to a five-member alkyl chain (1-CH_3 group and 4-CH_2 groups). The critical micelle concentrations decrease, in the same fashion for the cyclohexyl alkanoates, as for the homologous family of surfactants, sodium hexanoate to sodium decanoate.

An increase of α, as the length of the hydrocarbon chain is increased, is due to a decrease in the surface charge density or an increase in surface area per head group.

The differences between $\phi_{v,1}$ and $\phi_{v,2}$ increase with chain length (Table 3), the free monomer molar volumes being larger that those in the micellar state indicating that the

monomer in the micelle is in a more packed structure than the monomer in the free state. The difference between $\phi_{v,1}$ and $\phi_{v,2}$ becomes progressively smaller with the decrease of chain length (Fig. 9(*a*)) suggesting increasing constraints on molecular mobility as the micelle size decreases.

The speed of sound measurements of micellar solutions have been shown to be sensitive to the shape of the aggregate. In the present study, a definite break occurs at the CMC. The plots of adiabatic compressibility coefficients vs. concentration also show a small but definite change in the slopes at the CMC. The values of the apparent adiabatic compressibilities of the monomer $\tilde{k}_{s,1}$, and the micelle $\tilde{k}_{s,2}$, are listed in Table 3 and the values of $\tilde{k}_{s,1}$ decrease while the values for $\tilde{k}_{s,2}$ increase with an increase in chain length.

Adiabatic compressibility is a function of the composition of the system under study and is strongly dependent on the nature and intensity of the molecular interactions. It refers to a volume unit of solution and does not take into account the number of interacting molecules. Changes in adiabatic compressibility may be explained by considering two types of hydration. The monomer in the micellar state has only hydrophilic (or ionic) hydration, whereas the monomer in the free state has both hydrophilic and hydrophobic hydration. In the present study, the hydrophilic hydration would refer to the hydrogen bond interactions between the water molecules and the carboxylate group. The hydrophobic hydration is caused by the strong association of water molecules around the hydrophobe. The increase of hydrophobic interaction with

© 2000 NRC Canada

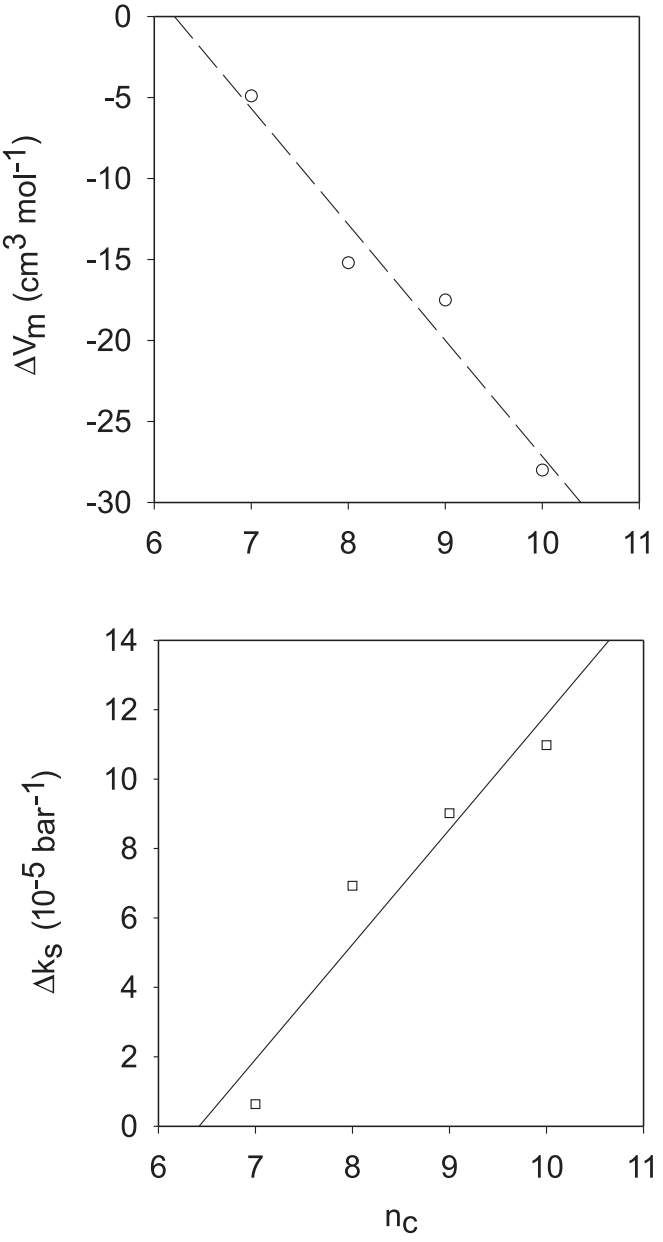
alkyl chain length leads to the increasing negative values of $\tilde{k}_{s,1}$, as the number of carbon atoms is increased in the alkyl chain. The relatively small difference between $\tilde{k}_{s,1}$ and $\tilde{k}_{s,2}$ for sodium cyclohexyl acetate suggests a higher degree of hydration of the monomer within the micelle. This may be due to the low hydrophobicity of the small alkyl chain in sodium cyclohexyl acetate and the small size makes the aggregates more penetrable to water.

Figure 9(*b*) shows the change of apparent adiabatic compressibility as a result of micelle formation; $\Delta\tilde{k}_2$ is plotted as a function of the number of carbon atoms. The increase of compressibility as the alkyl chain length is increased indicates a transition from an organized micellar structure at low aggregation number to a more fluid structure as the alkyl chain length increases and the monomers have increased mobility.

The standard thermodynamic quantities for this family of surfactants are shown in Table 5. The ΔG_m° values conform to the empirical relationship:

$$[22] \quad \Delta G_m^\circ = s_1 + s_0 n_c$$

where s_1 is a constant which depends on the nature of the ionic headgroup and s_0 is interpreted as the CH_2 (–1.72 kJ per CH_2 group) group contribution to the Gibbs energy of micellization. This is in excellent agreement with the value determined through surface tension measurements. The ΔG_m° is negative and becomes increasingly more negative as the length of the hydrocarbon chain is increased. This suggests that the micelles are readily formed. The increasingly positive value of ΔS_m° indicates an increasing randomness upon transfer of the monomers from the bulk to the micellar interior. For this micellization process $T\Delta S_m$ is much greater than ΔH_m indicating that micellization is primarily governed by entropy.



The efficiency and effectiveness of adsorption of the cyclohexyl salts increases with increasing chain length at a constant temperature. The areas decrease as the length of the hydrocarbon chain is increased. This indicates an increasing attraction between the cyclohexyl rings as they are expelled from the aqueous environment by adding CH_2 groups to the alkyl chain.

The free energies of adsorption are plotted in Fig. 3 where the slope is $d(\Delta G_{ad}^\circ)/dN$ is –2.43 KJ per CH_2 group and this is in reasonably good agreement with the "rule of two" ($-RT$ ln 2). From this information it can be concluded that the saturation areas are dependent on the chain length of the alkyl chain. One can conclude, therefore, that the decreasing curvature of the micellar surface, as CH_2 groups are added to the interior of a micelle, does not play a significant role in the micellization process.

The pyrene I_1/I_3 ratio reflects the polarity of the microenvironment around the pyrene probe. For the family of sodium cyclohexyl alkanoates the I_1/I_3 ratios all fall within the same range. Therefore this ratio is essentially constant for the members of this surfactant family.

The aggregation numbers were determined through viscosity measurements and range from four (sodium cyclohexyl acetate) to 14 (sodium cyclohexyl pentanoate). The lower than expected value for sodium cyclohexyl pentanoate is most likely due to the fact that the electroviscous effect

Fig. 9. (*a*) Change in apparent molar volume upon micellization as a function of chain length at 298.15 K. (*b*) Change of adiabatic compressibilities upon micellization as a function of chain length at 298.15 K.

cannot be neglected in solutions of low ionic strength such as these dilute micellar solutions. The aggregation numbers do show an increase as the length of the hydrocarbon chain is increased. These values are in very good agreement with values that were obtained employing NMR (Table 3) methods (25).

From the FT-IR data, the highest CH_2 antisymmetrical stretching mode frequencies occur at low concentrations of surfactant (0.1–0.8 M). It is possible to conclude that the nature of the solvent effect is minimal and that the surfactant is mainly present as monomers. The shift of these values to lower frequencies demonstrates a reduction in the

© 2000 NRC Canada

cyclohexanoate–water interactions. The bandwidths at lower concentration have greater uncertainty and remain relatively constant. The narrowing of bandwidths above the CMC are related to the rates of rotational relaxation of the acyl chain. This is due to the increased solute–solute interactions above the CMC (15). From the FT-IR studies it is clearly evident that micelle formation occurs at ~1.0 M for cyclohexyl acetic acid sodium salt and at ~0.39 M for cyclohexyl propionic acid sodium salt. This is seen as an inflection point in all frequency plots.

The absorption bands of the aggregates (micelles) occur at slightly lower frequency than the monomers. The interactions of the surfactants in solution can be further examined by looking at the density and (or) speed of sound of the cyclohexyl alkanoates at 298.15 K. From the adiabatic compressibility values, the hydration numbers can be calculated using the following equation:

$$[23] \qquad n_h = \frac{x_1}{x_2}\left(1 - \frac{\beta}{\beta_o}\right)$$

n_h is the hydration number, x_1 is the mol fraction of solute, x_2 is the mol fraction of solvent, β is the adiabatic compressibility of the solution, and β_o is the adiabatic compressibility of the solvent. The number of water molecules per surfactant molecule decreases for these surfactants (Table 3) upon micelle formation. Increasing the number of acyl chain carbons, in the hydrocarbon chain that is attached to the cyclohexyl ring, also increases the degree of hydration for the free monomer and surfactant micelles.

5. Conclusion

The presence of the cyclohexyl ring, in the family of sodium cyclohexyl alkanoate surfactants, appears to influence the surface properties of micellization, by lowering both the efficiency and effectiveness of adsorption when compared to that of the straight chain alkanoates. Increasing the chain length of the alkyl chain, which is attached to the cyclohexyl ring, also influences the micellar properties (CMC, degree of counter ion binding, hydration numbers, and aggregation numbers). This family of surfactants tends to be characterized by small degrees of binding, small aggregation numbers, and larger CMC values. These observed micellar properties may find applications in alkaline water flooding of oil reservoirs.

Solvation thermodynamics of cyclohexane

Giuseppe Graziano

Abstract: The solvation thermodynamics of cyclohexane in pure liquid phase and in water is analyzed by means of the theoretical approach developed by Lee. The sum of the work of cavity creation and the dispersive solute–solvent interaction energy reproduces well the experimental Gibbs energy values over the whole temperature range 5–100°C. This implies that the purely structural solvent reorganization is an exactly compensating process in both liquids. The dispersive solute–solvent interaction energy is larger in magnitude in cyclohexane than in water, whereas the work of cavity creation is larger in water than in cyclohexane. Therefore, both terms contrast the transfer of cyclohexane from pure liquid phase to water, determining its hydrophobicity. This mechanism qualitatively corresponds to that operative in the case of benzene.

Key words: hydrophobicity, cavity creation, excluded volume, dispersive interactions, enthalpy–entropy compensation.

Résumé : On a fait appel à l'approche théorique développée par Lee pour analyser les données thermodynamiques de solvatation du cyclohexane en phase pure et dans l'eau. La somme de travail pour la création d'une cavité et l'énergie d'interaction de dispersion soluté–solvant permet de bien reproduire les valeurs expérimentales de l'énergie de Gibbs sur l'ensemble des températures entre 5 et 100°C. Ceci implique que la réorganisation purement structurelle du solvant est un processus de compensation exacte dans les deux liquides. L'amplitude de l''énergie d'interaction de dispersion soluté–solvant est plus importante dans le cyclohexane que dans l'eau alors que le travail de création de cavité est plus important dans l'eau que dans le cyclohexane. On peut en déduire que les deux termes sont un reflet du transfert du cyclohexane de la phase liquide pure vers l'eau, ce qui détermine son caractère hydrophobe. Ce mécanisme correspond qualitativement à celui qui influence dans le cas du benzène.

Mots clés : caractère hydrophobe, création de cavité, volume exclu, interactions de dispersion, compensation enthalpie–entropie.

[Traduit par la Rédaction]

Introduction

Recently, we (1) reported on the molecular origin of benzene hydrophobicity, the poor solubility of benzene in water. Such poor solubility is usually called hydrophobicity (2), and according to Ben-Naim (3), is measured by the Gibbs energy change associated with the transfer of a solute molecule from a fixed position in pure liquid phase to a fixed position in water. In performing that study we surprisingly recognized that several physical properties of benzene and cyclohexane are very similar on a quantitative basis. A comprehensive comparison is shown in Table 1. For instance, the normal fusion and boiling points are nearly identical, the vaporization enthalpy changes at 25°C, the critical constants, and the values of surface tension and dielectric constant prove to be close.

The solubility of aromatic and aliphatic rings in water is of great importance: the side-chains of several amino acids consist of aromatic rings, and the cyclohexane ring is the backbone of many sugars. Radzicka and Wolfenden (4), to construct a hydrophobicity scale based on a truly nonpolar reference liquid, determined the distribution coefficients of amino acid side-chains between water and cyclohexane. The latter proved to be closely related to the inside-outside side-chain distribution observed in globular proteins (4), and numerically similar to changes in denaturation Gibbs energy that result from mutating nonpolar side-chains in protein interiors (5). Recently, Wolfenden and co-workers (6) determined also the distribution coefficients of the nucleic acid bases between water and cyclohexane. Thus, a careful analysis of the solvation thermodynamics of cyclohexane and a comparison with that of benzene should be important and useful. This task has recently been attempted by means of sophisticated computer simulations and new intermolecular potential functions; the results were encouraging, and provided satisfactory physical insights (7). We tried to perform the same task by means of the theoretical approach developed by Lee (8), which seemed able to interpret and explain most features of the hydrophobicity puzzle (1, 8–11).

The paper is organized as follows. First, a general theory of solvation is described. Then, the procedures used to perform calculations and to obtain the solvation thermodynamic quantities from experimental data are explained. Next, the solvation processes of cyclohexane in pure liquid phase and in water, in the temperature range 5–100°C, are analyzed.

Table 1. Some physical properties of cyclohexane and benzene. They come from ref. (53), except the values of the hard-sphere diameter, σ, and molar liquid volume, v_1, which are from ref. (20), those of N_{H2O} that are from ref. (29), and those of $\Delta_{vap}H$ coming from ref. (30).

	Cyclohexane	Benzene
M_w	84.16	78.12
σ (Å)	5.63	5.26
N_{H_2O}	31.0	26.7
v_1 (25°C, cm^3 mol^{-1})	108.75	89.40
T_c (°C)	280.4	288.9
P_c (atm)	40.0	48.6
mp (°C)	6.6	5.5
bp (°C)	80.7	80.1
$\Delta_{fus}H$ (25°C, kJ mol^{-1})	2.6	10.0
$\Delta_{vap}H$ (25°C, kJ mol^{-1})	33.0	33.8
$C_{p,l}$ at (25°C, J K^{-1} mol^{-1})	152	136
γ (20°C, dynes cm^{-1})	25.5	28.9
n_D (25°C)	1.424	1.498
ε (25°C)	2.015	2.274

Finally, the transfer of cyclohexane from pure liquid phase to water is studied and the results are contrasted with those previously obtained for benzene.

Theory of solvation

The process of inserting a solute molecule at a fixed position in a solvent is dissected in two subprocesses that have a clear physical meaning (8): (*i*) creation of a cavity to suitably accommodate the solute molecule; (*ii*) insertion of the solute molecule into the cavity and turning on the solute–solvent interactions. The solvation Gibbs energy change, $\Delta G^{\cdot}$, is:

$$[1] \qquad \Delta G^{\cdot} = \Delta G_c + E_a$$

where ΔG_c, the work of cavity creation, is a positive quantity, and E_a, the average dispersive solute–solvent interaction energy, is a negative quantity. A straightforward application of equilibrium statistical mechanics allows one to demonstrate that the work of cavity creation is purely entropic (12). ΔG_c is a measure of the excluded volume effect due to the reduction in spatial configurations accessible to solvent molecules. Moreover, Madan and Lee (13*a*), and Shimizu and co-workers (13*b*), by means of Monte Carlo computer simulations, showed that the ΔG_c values, at a given density, are similar in both water models and Lennard–Jones fluids constituted by particles having the same size of water molecules. This means that, once the solvent density is fixed, ΔG_c proves to be independent of the intermolecular potential energy existing among the solvent molecules. As a consequence, we set (1, 11)

$$[2] \qquad \Delta G_c = -T\Delta S_x$$

where ΔS_x is the excluded volume entropy contribution. The two terms, ΔG_c and E_a, have to be considered the direct perturbation of the solvent caused by solute insertion; E_a being the enthalpic part, and ΔG_c the entropic one (see the Appendix section). In response to such direct perturbation, the solvent molecules undergo a further reorganization with an associated enthalpy ΔH_r and entropy ΔS_{nx} contributions. Therefore, the total solvation enthalpy and entropy changes are:

$$[3] \qquad \Delta H^{\cdot} = E_a + \Delta H_r$$

$$[4] \qquad \Delta S^{\cdot} = \Delta S_x + \Delta S_{nx}$$

We prefer to use the notation ΔS_{nx} to emphasize that this is the nonexcluded volume entropy contribution, by recognizing that ΔS_x also originates from a reorganization of solvent molecules (see the Appendix section). Lee (14) demonstrated that the solvent response (i.e., which is called the purely structural solvent reorganization) is a compensating process at any temperature when the perturbing potential is weak

$$[5] \qquad T\Delta S_{nx} = \Delta H_r$$

Actually, several authors, using different theoretical approaches, have shown that the purely structural solvent reorganization is a compensating process (15). This physically means that, when the interaction of the inserted solute molecule with the surrounding solvent molecules is given solely by dispersive interactions, the compensation relation is operative (see the Appendix section). Clearly, for nonpolar molecules, such as hydrocarbons, this condition is fulfilled in both pure liquid phase and water (1, 8–11).

Therefore, the purely structural solvent reorganization does not affect the solvation Gibbs energy change and $\Delta G^{\cdot}$, as emphasized by eq. [1], takes into account solely the direct perturbation of the solvent: (*i*) the excluded volume effect due to cavity creation, opposing solvation; (*ii*) the dispersive solute–solvent interactions, favouring solvation. As a consequence, hydrophobicity is mainly determined by the very small size of water molecules, which exaggerates the excluded volume effect with respect to the other solvents (8).

The solvation of cyclohexane in pure liquid phase and in water is analyzed by means of the above equations. For the analysis of the transfer from pure liquid phase to water, we consider that, for all the thermodynamic functions, the following equation holds:

$$[6] \qquad \Delta X^{\cdot}(l\rightarrow w) = \Delta X^{\cdot}(g\rightarrow w) - \Delta X^{\cdot}(g\rightarrow l)$$

where X stands for C_p, H, S, and G. Actually, eq. [6] is only valid when the mutual solubility of the two solvents is very low, as for the pair water and cyclohexane (16). It is not valid for important cases such as the pair water and *n*-octanol, because the water solubility in *n*-octanol is quite large (16).

Calculation procedure

The work of cavity creation is calculated by means of the following equation from Scaled Particle Theory, SPT (17, 18):

$$[7] \qquad \Delta G_c = RT\cdot[K_0 + K_1(\sigma_2/\sigma_1) + K_2(\sigma_2/\sigma_1)^2 + K_3(\sigma_2/\sigma_1)^3]$$

where: $K_0 = -\ln(1-\xi)$, $K_1 = u = 3\xi/(1-\xi)$, $K_2 = u(u+2)/2$, $K_3 = \xi P v_1/RT$.

In these relations R is the gas constant, ξ is the volume packing density of pure solvent, which is defined as the ratio

© 2000 NRC Canada

of the physical volume of a mol of solvent molecules over the molar volume of the solvent, v_1 (i.e., $\xi = \pi\sigma_1^3 N_{Av}/6v_1$), P is the hydrostatic pressure over the liquid, σ_1 and σ_2 are the hard-sphere diameters of the solvent and solute molecules, respectively. For water we use σ = 2.75 Å (8, 9), close to the location of the first peak of the oxygen–oxygen radial distribution function of water (19). For cyclohexane we use σ = 5.63 Å, as determined by Wilhelm and Battino (20). Clearly, water and cyclohexane are not spherical molecules, as can be seen by the large deviations from the law of corresponding states. However, it is customary to consider spherical the water molecules in a series of applications, such as ASA and SPT calculations (21, 22). On the other hand, the local orientation order in liquid cyclohexane should be isotropic, as it is in liquid benzene (23), and thus the assumption of spherical molecules should be physically reliable.

Reiss (17) pointed out that, on increasing temperature, the molecules acquire sufficient kinetic energy to explore different regions of the potential energy surface, implying that the hard-sphere diameter should decrease. However, Wilhelm (24) determined that such a decrease is small for both cyclohexane and water (i.e., in a range of 100°C, the decrease of σ would amount to about 0.08 Å for cyclohexane, and 0.03 Å for water). Therefore, we consider the hard-sphere diameters of water and cyclohexane as temperature independent.

According to eq. [7], ΔG_c is given by the product of two factors: (*i*) the *RT* term, reflecting the kinetic energy contribution of solvent molecules bombarding the cavity surface (17), increases linearly with temperature; (*ii*) the term in square brackets, depending on ξ, a quantity proportional to the liquid density, decreases with temperature (i.e., in general, the liquid density decreases on raising temperature). The first term is equal for all liquids, whereas the density decrease on raising temperature is a specific property of each liquid. In performing calculations, we used the values of liquid density experimentally determined over a large temperature range for both cyclohexane (25), and water (26). In this manner, ξ passes from 0.530 at 5°C to 0.468 at 100°C for liquid cyclohexane; while it passes from 0.364 at 5°C to 0.349 at 100°C for liquid water.

The dispersive interaction energy E_a of cyclohexane in its pure liquid phase is calculated by means of Pierotti's formula (18):

$$[8] \qquad E_a = -(64/3)R\xi\varepsilon$$

where ε is the depth of the well in the Lennard–Jones potential, measuring the magnitude of the maximum attractive potential energy; we use ε/k = 540 K for cyclohexane. This value is reliable considering that the estimates existing in the literature range from 313 K to 573 K (20). The temperature dependence of E_a originates from that of the solvent packing density, which, in turn, reflects the temperature dependence of the liquid density. This is physically reasonable because the magnitude of the dispersive energy is strongly affected by the average distance between the interacting molecules (27).

Pierotti's formula, however, does not work well for hydrocarbons in water, as already pointed out and discussed (10). To calculate E_a for cyclohexane in water at 25°C we use the following relationship:

Table 2. Thermodynamic properties of pure liquid cyclohexane in the temperature range 5–100°C.

T (°C)	p_{eq} (atm)	v_1 (cm^3 mol^{-1})	$\alpha_1 \cdot 10^{-3}$ (K^{-1})	$\Delta_{vap}H$ (kJ mol^{-1})	B (cm^3 mol^{-1})
5	0.048	106.14	1.18	34.0	–2128
25	0.129	108.75	1.24	33.0	–1736
50	0.359	112.25	1.29	31.8	–1391
75	0.841	116.10	1.42	30.6	–1152
100	1.725	120.37	1.54	29.4	–976

Note: Thermodynamic properties are obtained by linear interpolation of the data compiled by Smith and Srivastava (25), and Wilhelm and Battino (30).

$$[9] \qquad E_a = (20.8 \pm 1.6) - (1.9 \pm 0.1)\cdot N_{H_2O} \quad (r = -0.9977)$$

obtained by performing a linear regression over the E_a values for the seven alkanes, computed by Jorgensen et al. (28), versus the hydration number, N_{H_2O}. The analysis of the size dependence of hydrophobic hydration suggested that eq. [9] should give reliable values (10). Accordingly, E_a = –38.1 kJ mol^{-1} for cyclohexane at 25°C, because N_{H_2O} = 31.0 (29). The temperature dependence of E_a for cyclohexane in water is estimated on the basis of the temperature dependence of liquid water density.

The excluded volume entropy contribution, ΔS_x, is calculated by means of eq. [2], and the nonexcluded volume entropy contribution, ΔS_{nx}, is obtained, at any temperature, by the difference $\Delta S^{\cdot} - \Delta S_x$. On the other hand, the contribution of solvent response to the enthalpy change, ΔH_r, is obtained, at any temperature, by the difference $\Delta H^{\cdot} - E_a$.

Experimental data

Thermodynamic solvation functions at a constant pressure for the g→l process of cyclohexane cannot be obtained because the experimental condensation data refer to different pressures. However, Ben-Naim (3) pointed out that a variation in pressure between zero and a few atmospheres causes a negligible effect on $\Delta G^{\cdot}$. Therefore, by assuming that the fugacity of cyclohexane can be represented by the following equation:

$$[10] \qquad f = p\cdot\exp(pB/RT)$$

where B is the second virial coefficient, $\Delta G^{\cdot}$ for the g→l process is given by (1, 8):

$$[11] \qquad \Delta G^{\cdot} = RT \ln (p_{eq}v_1/RT) + Bp_{eq}$$

where v_1 is the molar volume of the liquid and p_{eq} is the equilibrium vapour pressure. Then, by applying the Gibbs–Helmholtz equation, $\Delta H^{\cdot}$ is given by:

$$[12] \qquad \Delta H^{\cdot} = -\Delta_{vap}H + RT(1 - \alpha_1 T) + p_{eq}(B - B'T)$$

where $\Delta_{vap}H$ is the vaporization enthalpy change of the pure liquid, α_1 is its thermal expansion coefficient, and B' denotes the temperature derivative of B. Thermodynamic properties of liquid cyclohexane at different temperatures, obtained from tabulated data (25, 30), are listed in Table 2.

For the g→w process, we use the values of $\Delta H^{\cdot}$, $\Delta S^{\cdot}$, and $\Delta G^{\cdot}$ at 25°C reported by Abraham (31), after correction for

the Ben-Naim standard (3). For the hydration heat capacity change at 25°C, we add to the value measured for the l→w process by Wadso and co-workers (32), 360 J K^{-1} mol^{-1}, the value calculated by us for the g→l process, 40 J K^{-1} mol^{-1}, obtaining $\Delta C_p^\cdot$ = 400 J K^{-1} mol^{-1}. The temperature dependence of $\Delta C_p^\cdot$ over the range 5–100°C is estimated on the basis of the general relations given by Gill et al. (33) and Makhatadze and Privalov (34). These estimates of $\Delta C_p^\cdot$ are used to calculate $\Delta H^\cdot$, $\Delta S^\cdot$, and $\Delta G^\cdot$ in the whole temperature range 5–100°C, starting from their values at 25°C.

Analysis of the g→l and g→w processes

The experimental values of $\Delta C_p^\cdot$, $\Delta H^\cdot$, $\Delta S^\cdot$, and $\Delta G^\cdot$ for the solvation of cyclohexane in pure liquid phase and in water in the range 5–100°C are collected in Table 3. For the g→l process, it results that: (*i*) the $\Delta G^\cdot$ values are large and negative, and slowly decrease, in absolute value, as a function of temperature, i.e., $\Delta G^\cdot$ = –19.5 kJ mol^{-1} at 5°C and –15.7 kJ mol^{-1} at 100°C; (*ii*) the $\Delta H^\cdot$ and $\Delta S^\cdot$ values are negative and large, showing a temperature dependence similar to that of $\Delta G^\cdot$; (*iii*) $\Delta C_p^\cdot$ is positive and constant, equal to 40 J K^{-1} mol^{-1}. For the g→w process, it results that: (*i*) the $\Delta G^\cdot$ values are positive and increase with temperature, i.e., $\Delta G^\cdot$ = 2.5 kJ mol^{-1} at 5°C and 11.0 kJ mol^{-1} at 100°C; (*ii*) the $\Delta H^\cdot$ and $\Delta S^\cdot$ values are large and negative at 5°C, and increase strongly with temperature; (*iii*) the $\Delta C_p^\cdot$ values are large and positive and decrease with temperature, i.e., $\Delta C_p^\cdot$ = 420 J K^{-1} mol^{-1} at 5°C and 295 J K^{-1} mol^{-1} at 100°C. Under Ben-Naim standard state conditions, for cyclohexane, the g→l process is spontaneous, whereas the g→w process is nonspontaneous, over the whole temperature range 5–100°C.

The calculated values of ΔG_c and E_a, for both the processes, are listed in the second and third columns of Table 4. At any temperature, the ΔG_c estimates in cyclohexane are significantly smaller than those in water. This finding is expected because ΔG_c, being a measure of the excluded volume effect due to the creation of a region of space devoid of solvent molecules, is very large in liquid water owing to the small size of its molecules (8–14, 35). On the other hand, at any temperature, the estimates of E_a in cyclohexane are significantly larger, in absolute value, than those in water. This difference should be simply related to the larger polarizability of cyclohexane with respect to water, because E_a accounts solely for the dispersive solute–solvent interaction energy; such a conclusion agrees with the results of theoretical calculations by Floris and Tomasi (36).

Table 4. Calculated estimates of the Gibbs energy cost of cavity creation (ΔG_c) and of the dispersive interaction energy (E_a), for cyclohexane into pure liquid phase at equilibrium vapour pressure (*a*), and to water at 1 atm (*b*), in the temperature range 5–100°C.

	T (°C)	ΔG_c (kJ mol^{-1})	E_a (kJ mol^{-1})	$\Delta G_c + E_a$ (kJ mol^{-1})	$\Delta G^\cdot$ (kJ mol^{-1})
(*a*)	5	30.6	–50.7	–20.1	–19.5
	25	30.5	–49.5	–19.0	–18.5
	50	30.2	–48.0	–17.8	–17.5
	75	29.8	–46.4	–16.6	–16.5
	100	29.1	–44.8	–15.7	–15.7
(*b*)	5	40.1	–38.2	1.9	2.5
	25	42.7	–38.1	4.6	5.2
	50	45.5	–37.7	7.8	7.8
	75	47.6	–37.1	10.5	9.7
	100	49.3	–36.5	12.8	11.0

Note: The sum $\Delta G_c + E_a$ is also compared to the experimental $\Delta G^\cdot$ values in the same temperature range.

The calculated (i.e., $\Delta G_c + E_a$) and experimental values of $\Delta G^\cdot$ are listed in the fourth and fifth columns of Table 4. There is a very close agreement for both the g→l and g→w processes at any temperature; this has to be considered a demonstration of the general correctness of eq. [1]. Moreover, such good agreement implies that the purely structural solvent reorganization upon solute insertion is a compensating process, as required by eq. [5], in both cyclohexane and water. In particular, this proves that the H-bond reorganization in water upon solute insertion does not contribute to $\Delta G^\cdot$. It is worth mentioning that an essential ingredient of the successful integral equation theory by Pratt and Chandler (37) is the assumption that the contribution of H-bond reorganization can be neglected to calculate hydration Gibbs energies.

In the case of the g→l process, the ΔG_c values are large and positive and decrease very slightly with temperature, whereas the E_a values are large and negative and decrease, in absolute value, with temperature. It proves that $|E_a| > \Delta G_c$ at any temperature, so that $\Delta G^\cdot$ is always large and negative, and its temperature dependence parallels that of $|E_a|$. In the

	75	–29.5	16.9	–37.3	–85.6	48.3
	100	–28.6	16.2	–34.6	–78.0	43.4
(*b*)	5	–39.0	–0.8	–149.2	–144.2	–5.0
	25	–30.8	7.3	–120.7	–143.2	22.5
	50	–21.2	16.5	–89.7	–140.8	51.1
	75	–12.4	24.7	–63.4	–136.7	73.3
	100	–4.5	32.0	–41.6	–132.1	90.5

Note: The experimental solvation enthalpy and entropy changes are also reported. Specifically, $\Delta H_r = \Delta H^{\cdot} - E_a$, $\Delta S_x = -\Delta G_c/T$, and $\Delta S_{nx} = \Delta S^{\cdot} - \Delta S_x$.

case of the g→w process, the ΔG_c values are large and positive and increase with temperature, whereas the E_a estimates are large and negative and decrease very slightly, in absolute value, with temperature. It proves that $\Delta G_c > |E_a|$ at any temperature, so that $\Delta G^{\cdot}$ is always positive and its temperature dependence parallels that of ΔG_c. The physical origin of these findings relies in the temperature dependence of the density for the two liquids (1, 11, 38).

In the range 5–100°C the density of liquid cyclohexane decreases by 11.8% (25), causing a significant decrease of $|E_a|$ and a very small decrease of ΔG_c. In contrast, in the same temperature range, the density of liquid water decreases by 4.2% (26), causing a small decrease of $|E_a|$ and an increase of ΔG_c. Therefore, at any temperature, the g→l process is spontaneous because the dispersive interactions between cyclohexane molecules overwhelm the work of cavity creation, whereas the g→w process is non-spontaneous because the work of cavity creation overwhelms the dispersive interactions between cyclohexane and water molecules.

We now analyze the solvation enthalpy changes. The E_a estimates for both the g→l and g→w processes are larger, in absolute sense, than the $\Delta H^{\cdot}$ values, except at 5°C in the g→w case. In cyclohexane at 25°C, E_a = –49.5 kJ mol^{-1} whereas $\Delta H^{\cdot}$ = –31.6 kJ mol^{-1}; in water at 25°C, E_a = –38.1 kJ mol^{-1} whereas $\Delta H^{\cdot}$ = –30.8 kJ mol^{-1}. Therefore, the dispersive interactions of cyclohexane in pure liquid phase and in water are so large that the purely structural solvent reorganization proves to be an endothermic process in both solvents. The ΔH_r values, determined by means of eq. [3], using the experimental $\Delta H^{\cdot}$ values and the E_a estimates, are listed in the third column of Table 5. It proves that, over the range 5–100°C, ΔH_r slightly decreases for the g→l process, whereas it strongly increases for the g→w process (i.e., ΔH_r passes from 18.2 to 16.2 kJ mol^{-1} for the g→l process, whereas it passes from –0.8 to 32.0 kJ mol^{-1} for the g→w process). In this regard, it has to be noted that the purely structural solvent reorganization involves different intermolecular interactions in the two solvents: dispersive interactions in cyclohexane and H-bonds in water. For the g→w process, ΔH_r is slightly negative at 5°C and small positive around room temperature. This means that there is no significant rupture nor gain of H-bonds. Water molecules in the hydration shell, in view of their tetrahedral functionality, are able to avoid the loss of H-bonds by straddling the surface of nonpolar groups (2). This geometrical arrangement has definitely been established by means of direct neutron scattering and X-ray absorption spectroscopy measurements from Finney's group (39, 40). The data emphasized that the hydration shell around nonpolar moieties resembles a disordered clathrate cage, and is not characterized by an increased orientation order with respect to bulk water. In particular, the various radial distribution functions determined indicate that the orientation structure of water in the hydration shell is similar to that existing in the bulk (39, 40). Similar results have emerged from detailed computer simulations (41), confirming the plasticity of the H-bonded network of water. The thermodynamics of H-bond reorganization can be described by means of the modified Muller's model (42), considering that water H-bonds populate two distinct energy states, both in the bulk and in the hydration shell, whose energy gap is not large. Accordingly, the large positive temperature dependence of ΔH_r is simply due to the increase in the population of the higher energy state on raising temperature (11, 42). Recently, Dill and coworkers (43) have confirmed the reliability of the modified Muller's model, in view of its ability to reproduce specific results of Monte Carlo simulations on the Mercedes–Benz model of water.

The two contributions to the solvation entropy change are calculated by means of eqs. [2] and [4]; the values obtained are listed in the fifth and sixth columns of Table 5. The ΔS_x contribution is large and negative for both the g→l and g→w processes and increases with temperature. However, the increase is more pronounced in cyclohexane than in water, as a consequence of the different temperature dependence of ΔG_c in the two liquids, reflecting the different temperature dependence of their density (i.e., in the range 5–100°C, ΔS_x passes from –110.0 to –78.0 J K^{-1} mol^{-1} in cyclohexane, and from –144.2 to –132.1 J K^{-1} mol^{-1} in water). These values indicate unequivocally that the excluded volume effect is the physical cause of the negative solvation entropies of cyclohexane in both pure liquid phase and water (1, 8). The ΔS_{nx} contribution is always positive, except at 5°C for the g→w process; the purely structural solvent reorganization leads to an entropy increase. This term decreases with temperature in

Table 6. Ben-Naim standard thermodynamic quantities for the transfer of cyclohexane from pure liquid phase at equilibrium vapour pressure to water at 1 atm, in the temperature range 5–100°C.

T (°C)	$\Delta C_p^{\cdot}$ (J K^{-1} mol^{-1})	$\Delta H^{\cdot}$ (kJ mol^{-1})	$\Delta S^{\cdot}$ (J K^{-1} mol^{-1})	$\Delta G^{\cdot}$ (kJ mol^{-1})
5	380	–6.5	–102.5	22.0
25	360	0.8	–76.8	23.7
50	330	9.2	–49.8	25.3
75	295	17.1	–26.1	26.2
100	255	24.1	–7.0	26.7

cyclohexane, whereas it strongly increases in water (i.e., in the range 5–100°C, ΔS_{nx} passes from 63.3 to 43.4 J K^{-1} mol^{-1} in cyclohexane, and from –5.0 to 90.5 J K^{-1} mol^{-1} in water); the different temperature dependence corresponds to that of ΔH_r because eq. [5] holds. Overall our work shows that the excluded volume entropy dominates over the entropy of the purely structural solvent reorganization. This analysis of the solvation entropy contrasts with the claims advanced by Frank and co-workers (44), but accords well with the previous analyses of aliphatic hydrocarbons, noble gases, aliphatic alcohols, and benzene, reported in the literature (1, 8–11). Actually, it is strongly supported by direct structural measurements (39, 40), which failed to detect an increased order in the hydration shell of nonpolar groups. In addition, the fundamental role played by the work of cavity creation, and so by the excluded volume effect, in the solvation thermodynamics has been recognized by several scientists, such as Chandler and co-workers (45), Pratt and co-workers (46), Guillot and co-workers (47). Also Paulaitis and co-workers (48), using the multiparticle correlation function expansion for the solvation entropy, truncated at the level of pair correlations, found that the contribution of translational solute–solvent correlation functions, strictly related to the excluded volume effect, is dominant, and larger in water than in nonpolar solvents. Finally, several authors have concluded that the excluded volume effect dominates the energetics of hydrophobic interactions (49, 50), usually considered the partial reversal of hydrophobic hydration.

Analysis of the l→w process

The experimental values of thermodynamic functions associated with the l→w process, in the temperature range 5–100°C, obtained using eq. [6], are listed in Table 6. The process is characterized by a large and positive heat capacity change that leads to a marked temperature dependence of $\Delta H^{\cdot}$ and $\Delta S^{\cdot}$. However, due to an enthalpy–entropy compensation phenomenon, the $\Delta G^{\cdot}$ values increase weakly with temperature and are always large and positive (i.e., $\Delta G^{\cdot}$ passes from 22.0 to 26.7 kJ mol^{-1} in the range 5–100°C).

The values of $\Delta\Delta G_c = \Delta G_c$(water) – ΔG_c(cyclohexane) and $\Delta E_a = E_a$(water) – E_a(cyclohexane) are reported in the second and third columns of Table 7, part (*a*), respectively. Both such quantities are positive and substantial, in the temperature range 5–100°C, because: (*i*) the work of cavity creation is larger in water than in cyclohexane; (*ii*) the dispersive energetic interactions are stronger in cyclohexane than in water. Therefore, both the excluded volume effect and dispersive interactions contrast the transfer of cyclohexane from pure liquid phase to water. The values of $\Delta\Delta G_c + \Delta E_a$, listed in the fourth column of Table 7, part (*a*), prove to be very close to the experimental values of $\Delta G^{\cdot}$ over the whole temperature range considered. Around room temperature, the excluded volume effect and the dispersive interactions contribute roughly to the same extent in determining the positive $\Delta G^{\cdot}$ values, whereas, above 75°C, the excluded volume effect plays the dominant role (i.e., $\Delta\Delta G_c$ = 12.2 kJ mol^{-1} at 25°C and 20.2 kJ mol^{-1} at 100°C, while ΔE_a = 11.4 kJ mol^{-1} at 25°C and 8.3 kJ mol^{-1} at 100°C). It is worth noting that Lee (8), analyzing the l→w process of alkanes (i.e., propane, isobutane, and neopentane), found that the contribution from dispersive interactions was negligible, while the contribution from excluded volume effect was largely dominant in the whole temperature range 0–100°C.

Table 7. Calculated estimates of $\Delta\Delta G_c = \Delta G_c$(water) – ΔG_c(liquid phase) and $\Delta E_a = E_a$(water) – E_a(liquid phase) for the transfer process of cyclohexane (*a*) and benzene (*b*) from pure liquid phase at equilibrium vapour pressure to water at 1 atm, in the temperature range 5–100°C.

	T (°C)	$\Delta\Delta G_c$ (kJ mol^{-1})	ΔE_a (kJ mol^{-1})	$\Delta\Delta G_c + \Delta E_a$ (kJ mol^{-1})	$\Delta G^{\cdot}$ (kJ mol^{-1})
(*a*)	5	9.5	12.5	22.0	22.0
	25	12.2	11.4	23.6	23.7
	50	15.3	10.3	25.6	25.3
	75	17.8	9.3	27.1	26.2
	100	20.2	8.3	28.5	26.7
(*b*)	5	5.7	7.1	12.8	14.4
	25	8.2	6.0	14.2	15.5
	50	10.8	4.9	15.7	16.3
	75	13.1	3.9	17.0	16.7
	100	15.1	3.1	18.2	16.7

Note: The sum $\Delta\Delta G_c + \Delta E_a$ is also compared to the experimental $\Delta G^{\cdot}$ values in the same temperature range. The values for benzene are from ref. (1).

To perform a correct and meaningful comparison, the $\Delta\Delta G_c$ and ΔE_a values already determined for the l→w process of benzene (1) are listed in the second and third columns of Table 7, part (*b*). A look at such values leads to the conclusion that the physical mechanism determining the hydrophobicity of cyclohexane and benzene is identical; the excluded volume effect associated with cavity creation and the dispersive interactions are the solely determinant. Clearly, there are quantitative differences between cyclohexane and benzene, which are important because, at 25°C, $\Delta G^{\cdot}$ = 23.7 kJ mol^{-1} for cyclohexane, but 15.5 kJ mol^{-1} for benzene. In fact, both $\Delta\Delta G_c$ and ΔE_a, at any temperature, are larger for cyclohexane than benzene by about 5 kJ mol^{-1}. The values of both ΔG_c and E_a for benzene and cyclohexane in their own pure liquid phase prove to be closely similar (compare Table 4 with Table 3 of ref. (1)). Instead, the work for creating a cavity suitable to accommodate cyclohexane in water is larger, by about 5 kJ mol^{-1}, than the corresponding work for accommodating benzene (i.e., in water, at 25°C, ΔG_c = 42.7 kJ mol^{-1} for cyclohexane and 38.0 kJ mol^{-1} for benzene). The difference is simply caused by the larger

© 2000 NRC Canada

molecular size of cyclohexane with respect to benzene: σ = 5.63 Å vs. 5.26 Å. On the other hand, the E_a value for cyclohexane in water is smaller, in absolute value, by about 4 kJ mol^{-1} than the corresponding quantity for benzene (i.e., in water, at 25°C, E_a = –38.1 kJ mol^{-1} for cyclohexane and –42.3 kJ mol^{-1} for benzene). The estimate of E_a for benzene in water at 25°C is reliable because it is practically identical to the value, –42.6 kJ mol^{-1}, calculated by Linse (51). He used a modified benzene–water potential with the partial charges characteristic of the aromatic ring switched off (51), yielding an E_a for benzene based solely on dispersive contributions. As a result, the difference in E_a for cyclohexane and benzene should be related to the large polarizability of benzene's π electrons, which strengthen the aromatic ring–water dispersive interactions (i.e., according to the famous London theoretical treatment (27), the dispersive energy is proportional to the polarizabilities of interacting molecules).

In conclusion, the above analysis implies that the hydrophobicity of cyclohexane can be accounted for by only two factors: (*i*) the decrease in the entropy of water due to the excluded volume effect associated with the creation of a cavity suitable to host a cyclohexane molecule; (*ii*) the loss of favourable dispersive interactions among cyclohexane molecules in the pure liquid phase.

Appendix: Lee's theory of solvation

Inserting a solute molecule at a fixed point in a solvent corresponds to introducing a perturbing potential $\Psi(\boldsymbol{X})$, where $\boldsymbol{X}$ is a vector describing the position of each of the N molecules of the liquid solvent. According to Widom's (52) potential distribution theory, the standard Gibbs energy change is:

$$[A1] \quad \Delta G^{\cdot} = -RT\ln < \exp[-\Psi(\boldsymbol{X})/RT] >_p$$

where the subscript p means that the canonical average is carried out over the pure solvent configurations, assuming an NPT ensemble. Lee (8) devised the following expression for the perturbing potential:

$$[A2] \quad \exp[-\Psi(\boldsymbol{X})/RT] = \zeta(\boldsymbol{X})\ \exp[-\psi_a(\boldsymbol{X})/RT]$$

where $\zeta(\boldsymbol{X})$ of a configuration is equal to zero or one depending on whether or not the hard core of any solvent molecule in this configuration overlaps with that of the solute molecule, and $\psi_a(\boldsymbol{X})$ represents the attractive potential between the solute molecule and all the solvent molecules in the given configuration. Using eq. [A2], eq. [A1] becomes:

$$[A3] \quad \Delta G^{\cdot} = -RT\ln < \zeta(\boldsymbol{X}) >_p - RT\ln < \exp[-\psi_a(\boldsymbol{X})/RT] >_c$$

where the subscript c means that the canonical average is carried out over the solvent configurations which happen to have a cavity of the desired dimension. Thus, $\Delta G^{\cdot}$ is the sum of two terms: the first one corresponds to the work of creating the cavity, and the second one to the work of turning on the attractive potential around the cavity. Now, let us analyze in detail the two subprocesses.

Creation of the cavity. The work of cavity creation is:

$$[A4] \quad \Delta G_c = -RT\ln < \zeta(\boldsymbol{X}) >_p$$

and corresponds to the work of selecting the configurations containing the cavity from the ensemble of pure solvent configurations; this is an exact result of statistical mechanics (12). Application of equilibrium thermodynamics allows the derivation of the cavity enthalpy and entropy changes (12):

$$[A5] \quad \Delta H_c = < H(\boldsymbol{X}) >_c - < H(\boldsymbol{X}) >_p$$

$$[A6] \quad \Delta S_c = R\ln < \zeta(\boldsymbol{X}) >_p + (\Delta H_c/T) = \Delta S_x + (\Delta H_c/T)$$

The enthalpy change upon cavity creation is entirely due to solvent reorganization. Also the entropy change upon cavity creation is entirely due to solvent reorganization; however, it is made up of two parts: the first one on the right-hand side of eq. [A6] due to the selection of the solvent configurations containing the cavity, and the other due to the reorganization of solvent molecules around the cavity. The latter contribution perfectly cancels the change in enthalpy, so that the work of cavity creation is entirely entropic and due to the excluded volume effect associated with the reduction in the size of the configuration space accessible to the solvent molecules, $\Delta G_c = -T\Delta S_x$. The excluded volume effect has to be considered the entropic part of the perturbing potential.

Turning on the attractive potential. The work of turning on the attractive potential is:

$$[A7] \quad \Delta G_a = -RT\ln < \exp[-\psi_a(\boldsymbol{X})/RT] >_c$$

By applying the Gibbs–Helmholtz equation, the enthalpy change is:

$$[A8] \quad \Delta H_a = < \psi_a(\boldsymbol{X}) >_s + [< H(\boldsymbol{X}) >_s - < H(\boldsymbol{X}) >_c] = < \psi_a(\boldsymbol{X}) >_s + \Delta H_{ar}$$

where the subscript s means that the canonical average is carried out over the solvent configurations that happen to have a cavity occupied by a solute molecule interacting with all the solvent molecules. The enthalpy change is made up of two parts: the first is the average solute-solvent interaction energy, and the other is the enthalpic contribution arising from the solvent reorganization upon turning on the attractive potential. The entropy change is:

$$[A9] \quad \Delta S_a = R\ln < \exp[-\psi_a(\boldsymbol{X})/RT] >_c + [< \psi_a(\boldsymbol{X}) >_s/T] + (\Delta H_{ar}/T)$$

Using an inverse relationship demonstrated by Widom (52), eq. [A9] becomes:

$$[A10] \quad \Delta S_a = -R\ln < \exp[\psi_a(\boldsymbol{X})/RT] >_s + [< \psi_a(\boldsymbol{X}) >_s/T] + (\Delta H_{ar}/T)$$

By setting $\kappa = \psi_a(\boldsymbol{X}) - < \psi_a(\boldsymbol{X}) >_s$, expanding in power series the exponential function, and keeping in mind that $< \kappa >_s \equiv 0$, one obtains:

© 2000 NRC Canada

[A11] $-R\ln < \exp[\psi_a(\boldsymbol{X})/RT] >_s \approx -[< \psi_a(\boldsymbol{X}) >_s/T] - [< \kappa^2 >_s/2RT^2]$

When the attractive potential $\psi_a(\boldsymbol{X})$ is weak (14), the fluctuations in the value of $< \psi_a(\boldsymbol{X}) >_s$ are small, and the second term on the right-hand side of eq. [A11] can be neglected. Thus:

[A12] $\Delta S_a \approx (\Delta H_{ar}/T)$

and the solvent reorganization associated with the process of turning on the attractive potential is a compensating process, because the change in entropy cancels that in enthalpy. The condition of small fluctuations in the value of $< \psi_a(\boldsymbol{X}) >_s$ is verified for nonpolar compounds (8, 28, 36, 51), and the Gibbs energy change is simply given by the average solute–solvent interaction energy:

[A13] $\Delta G_a = < \psi_a(\boldsymbol{X}) >_s \equiv E_a$

Recapitulation. The total solvation Gibbs energy change is:

[A14] $\Delta G^{\cdot} = \Delta G_c + \Delta G_a = -T\Delta S_x + E_a$

The total enthalpy change upon solvation is:

[A15] $\Delta H^{\cdot} = E_a + \Delta H_r$

where E_a, the average solute–solvent interaction energy, has to be considered the enthalpic part of the perturbing potential. The term $\Delta H_r \equiv \Delta H_c + \Delta H_{ar}$ is the enthalpy change due to the purely structural solvent reorganization that happens as a response to full perturbation. The total solvation entropy change is:

[A16] $\Delta S^{\cdot} = \Delta S_r = \Delta S_x + \Delta S_{nx}$

it is entirely due to solvent reorganization because the solute molecule is fixed in space adopting the standard state of Ben-Naim (3, 8). However, the excluded volume effect for cavity creation has to be considered the entropic part of the perturbing potential, not a solvent response; the ΔS_x term is the corresponding entropy contribution. A further reorganization of solvent molecules around the solute happens as a response to full perturbation, both volume exclusion and turning on solute–solvent interaction; the ΔS_{nx} term represents this nonexcluded volume contribution to the total entropy change upon solvation. Finally, it proves that the compensation relation, $T\Delta S_{nx} = \Delta H_r$, is operative for the solvent response.

A study of hydrogenation of benzhydrols in the presence of catalytic amount of triflic acid

Christophe Waterlot, Daniel Couturier, Marc De Backer, and Benoît Rigo

Abstract: The ionic hydrogenation of diarylcarbinols by triethylsilane, in the presence of catalytic amount of triflic acid proceeds via dibenzhydryl ethers. These ethers do not disproportionate to benzophenones and diphenylmethanes but are reduced by triethylsilane to diarylmethanes.

Key words: catalytic reduction, benzhydrols, dibenzhydryl ethers, triethylsilane.

Résumé : L'hydrogénation ionique des benzhydrols par le triéthylsilane en présence d'une quantité catalytique d'acide triflique, passe par la formation d'éthers de dibenzhydryles. Ces éthers ne se dismutent pas en benzophénones et diphénylméthanes correspondants mais sont directement réduit en diarylméthanes par le triéthylsilane.

Mots clés : réduction catalytique, benzhydrols, éthers de dibenzhydryles, triéthylsilane.

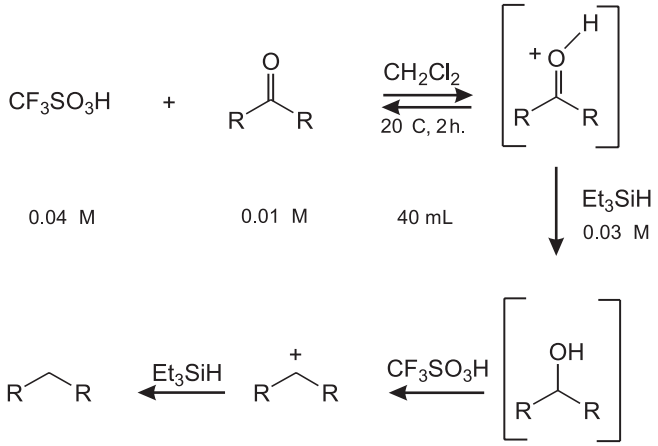
1. Introduction

During the course of a program requiring the use of diarylcarbinols (1), we were puzzled by some differences between the reported chemistry (2–6) of these compounds and some of our results (7).

Ionic hydrogenation of ketones (2) and alcohols (3) by triethylsilane can be realized by using four molar equiv. of triflic acid, and is assumed to proceed through carbocations (3, 4) (Scheme 1).

In similar reactions, no symmetrical ethers were observed during the reductions of diaryl ketones by triethylsilane – trifluoroacetic acid (5). In the case of aliphatic or aryl aliphatic ketones only, the reduction performed with triethylsilane – trimethylsilyl triflate yielded symmetrical ethers (6).

It is also reported that in acidic media diarylcarbinols **1** easily yielded dibenzhydryl ethers **2** (8) which rapidly disproportionated into diphenylmethanes **3** and benzophenones **4** (9). These triflic acid-catalyzed disproportionations proceeded via hydride transfer (10). In a previous work (7), it was found that a quantity as low as 0.06 molar equiv. of triflic acid in a chloroform solution of dibenzhydryl ethers **2** promoted this disproportionation. (Scheme 2).



The work reported here is an attempt to elucidate which reaction route is the most probable with the very small amount of triflic acid utilized in the previous works (7). Experimental conditions were selected to answer the following questions

(1) Are the benzhydrols **1**, after protonation, directly reduced to diphenylmethanes **3** (Scheme 3, path A)?

(2) Or do dibenzhydryl ethers **2**, formed in a first step, disproportionate into diphenylmethanes **3** and benzophenones **4**, whose further reduction recycles the starting benzhydrols **1** (Scheme 3, path B)?

(3) Alternatively, are the dibenzhydryl ethers **2** reduced to diphenylmethanes **3** and triethylsilyl benzhydryl ethers which again disproportionate to dibenzhydryl ether **2** (7) (Scheme 3, path C)?

2. Results and discussions

2.1 Reduction of substituted benzhydrols to diarylmethane

To lower the reaction rates and to observe the intermediate products, the reduction of substituted benzhydrols **1** to diarylmethanes **3** was realized with a small amount of triflic acid (benzhydrol – triethylsilane – triflic acid, 1:3:0.3) that is thirteen times lower than that used by others (3) for the

reduction of benzophenones (1:3:4) as it was described in Scheme 1. It is shown in Table 1 that dibenzhydryl ethers **2** are important intermediates in the reaction. This is well evidenced by comparing the results in rows 4 and 5; 6–8 where the same reaction has been performed at two different temperatures and for various lengths of time. The same conclusion may be drawn from rows 9 and 10. Thus the already known path A is not the only route for this reaction.

presence of triethylsilane, was studied. Four dibenzhydryl ethers bearing various groups were chosen in such a way that it was possible to identify the reaction intermediates. The reaction was studied at two different temperatures and for various lengths of time. In the absence of triethylsilane, the disproportionation reaction leading to **3** and **4** is the most important while reduction to **3** is preponderant in its presence.

Path B implies that substituted 4,4′-dimethoxybenzophenone **4** should be an important intermediate in this reaction.

© 2000 NRC Canada

However under experimental conditions similar to ours, it has been shown that the reduction of **4** (R = OMe) did not take place[3] due to the extreme stability of the intermediate carbocation formed by the protonation of the carbonyl group (3). If path B was important, there should be in this case an accumulation of **4** (R = OMe) in the course of the reaction. As it can be seen in Table 2 during the reduction of tetramethoxy-dibenzhydryl ether **2** (R1 = R2 = OMe) (rows 13 and 14) benzophenone **4** was never observed when triethylsilane was present; this result allows us to exclude path B.

This point can be further strengthened by observing that in the presence of triethylsilane the production of other substituted benzophenone **4** was never observed. Also, the rate of reduction of dibenzhydryl ethers **2** was greater than the rate of the disproportionation reaction (compare entries 4, 7, 10 with entries 3, 6, 9).

3. Conclusion

Although no formal kinetic studies were reported here, the results presented in Tables 1 and 2 indicate that path C is a favored process when only a small amount of triflic acid is used. In a first step of the ionic reduction of benzhydrols by $Et_3SiH–CF_3SO_3H$, dibenzhydryl ethers are formed and reduction of these ethers is faster than their disproportionation reaction (path C). However, the formation of dibenzhydryl ether is not always considerably faster than the reduction (Table 1, entries 2 and 3). It is then possible that path A contributes in part, to the reduction process. It also must be stressed that the experimental conditions used here are different from previous reported works (3, 11) where super acidic conditions promoted other reaction paths.

4. Experimental

Materials

All benzhydrols were commercially available, except for compounds **1** (R1 = H, R2 = Cl; R1 = H, R2 = I; R1 = H, R2 = Br). Melting points were determined with a Mettler FP1 and are uncorrected. ^{1}H NMR and ^{13}C NMR spectra were recorded on a Brücker AC300 spectrometer operating at, respectively, 300.133 and 75.47 MHz using trimethylsilane as an internal reference. Coupling constants are given in Hz. IR spectra were recorded on a Brücker IFS 48 spectrometer. The reaction mixtures were analyzed by ^{1}H NMR and ^{13}C NMR and by liquid chromatography (C_{18} column and a 60:40 acetonitrile–water as mobile phase). Elemental analyses were performed by the "Service Central de Microanalyses" of CNRS, in Vernaison, France.

Procedure

*4′-Chloro-2,5-dimethoxybenzhydrol (**1**:R1 = H, R2 = Cl)*

To a stirred solution of 2,5-dimethoxy-1-(4′-chlorobenzoyl)benzene (17 g, 0.615 mol) in methanol (160 mL), sodium borohydride (2.8 g, 0.738 mol) was added at 5°C over a period of 15 min. The reaction mixture was then stirred for 60 min at 5°C and brought to room temperature. After removing the methanol, the crude product was quenched with a solution of 1N HCl. The mixture was extracted with diethyl ether (3 × 20 mL), dried over $CaCl_2$, and solvents were evaporated in vacuo; mp 65°C (petroleum ether – diethyl ether), yield 93%. IR (KBr) ν (cm^{-1}): 3419, 3003, 2836, 1591, 1500, 1447, 1276, 1217, 1046, 711. ^{1}H NMR ($CDCl_3$) δ (ppm): 3.24 (s, 1H), 3.73 (s, 6H), 5.95 (s, 1H), 6.80 (m, 3H), 7,27 (m, 4H). ^{13}C NMR ($CDCl_3$) δ (ppm): 55.7, 55.9, 71.6, 111.9, 112.9, 114.0, 127.9, 128.3, 132.6, 132.9, 141.7, 150.7, 153.8 Anal. calcd. for $C_{15}H_{15}ClO_3$: C 64.64, H 5.42, O 17.22; found: C 64.60, H 5.40, O 17.23.

*4′-Iodo-2,5-dimethoxybenzhydrol (**1**:R1 = H, R2 = I)*

This compound was obtained following the same procedure as 4′-chloro-2,5-dimethoxy-benzhydrol; mp 86°C (petroleum ether – diethyl ether), yield 88%. IR (KBr) ν (cm^{-1}): 3345, 3000, 2831, 1590, 1502, 1451, 1278, 1223, 1048, 505. ^{1}H NMR ($CDCl_3$) δ (ppm): 3.35 (s, 1H), 3.64 (s, 6H), 5.83 (s, 1H), 6.68 (m, 2H), 6.77 (d, *J* = 2.7 Hz, 1H), 7.02 (d, *J* = 8.3 Hz, 2H), 7.53 (d, *J* = 8,3 Hz, 2H). ^{13}C NMR ($CDCl_3$) δ (ppm): 55.7, 55.9, 71.6, 92.7, 111.8, 112.9, 113.9, 128.6, 132.5, 137.2, 143.0, 150.7, 153.7.; Anal. calcd. for $C_{15}H_{15}IO_3$: C 48.67, H 4.08, O 12.97; found: C 48.69, H 4.10, O 12.95.

*4′-Bromo-2,5-dimethoxybenzhydrol (**1**:R1 = H, R2 = Br)*

Sodium borohydride (0.85 g, 0.225 mol) was added at 25°C, over a period of 15 min, to a solution of 2,5-dimethoxy-1-(4′-bromobenzoyl)benzene (6 g, 0.187 mol) in methanol (80 mL). The reaction mixture was then stirred for another 90 min at room temperature. After removing the methanol, the crude product was washed with a solution of 1N HCl and the product was extracted with diethyl ether (3 × 10 mL). After drying the organic phase over $CaCl_2$ and evaporating the solvents, the benzhydrol was obtained as an oil which crystallized in a petroleum ether and diethyl ether mixture; mp 70°C (petroleum ether – diethyl ether), yield 92%. IR (KBr) ν (cm^{-1}): 3300, 3000, 2831, 1583, 1499, 1456, 1271, 1223, 1042, 701. ^{1}H NMR ($CDCl_3$) δ (ppm): 3.12 (s, 1H), 3.71 (s, 3H), 3.72 (s, 3H), 5.93 (s, 1H), 6.78 (m, 2H), 6.85 (d, *J* = 2.4 Hz, 1H), 7.24 (d, *J* = 8.4 Hz, 2H), 7.41 (d, *J* = 8.4 Hz, 2H). ^{13}C NMR ($CDCl_3$) δ (ppm): 55.7, 55.9, 71.6, 111.9, 112.9, 113.9, 121.0, 128.3, 131.2, 132.6, 142.3, 150.7, 153.7. Anal. calcd. for $C_{15}H_{15}BrO_3$: C 55.75, H 4.68, O 14.85; found: C 55.72, H 4.69, O 14.87.

Disproportionation of bis-4,4′-dimethoxybenzhydryl ether (2:R1 = R2 = OMe)

A solution of bis-4,4′-dimethoxybenzhydryl ether (4.7 g, 10 mmol) and triflic acid (0.09 mL, 0.1 mmol) in chloroform (5 mL) was heated at 60°C for 15 min. Methylene dichloride (40 mL) and water (40 mL) were added. After washing, the organic phase was dried then evaporated. The solid obtained was filtered, then washed with heptane giving a 42% yield in 4,4′-dimethoxybenzophenone identical to the commercial compound. The heptane solution was evaporated,

[3] We have repeated the reduction of 4,4′-dimethoxybenzophenone in the described conditions (3). After 30 h of reflux, the yield of 4,4′-dimethoxydiphenylmethane was less than 10%.

© 2000 NRC Canada

giving a 44% yield in dianisylmethane, identical to the known compound (9*b*).

Typical procedure: reduction of bis-4,4′-dimethoxybenzhydryl ether (2:R1 = R2 = OMe)

Triflic acid (0.09 mL, 0.1 mmol) was slowly added to a solution of bis-4,4′-dimethoxybenzhydril ether (4.7 g, 10 mmol) and triethylsilane (3.5 mL, 22 mmol) in chloroform (5 mL). The mixture was stirred at room temperature for 45 min. The organic phase was washed with a sodium carbonate solution (30 mL) and dried. After evaporation, the solid was filtered to give a 96% yield in 4,4′-dianisylmethane, identical to the known compound (9*b*).

Typical procedure: reduction of 4,4′-dimethoxybenzhydrol (1:R1 = R2 = OMe)

Triflic acid (0.25 mL, 0.3 mmol) was slowly added (2 min) via syringe, to a stirred solution of 4,4′-dimethoxybenzhydrol (2.5 g, 1 mmol) and triethylsilane (4.8 mL, 3 mmol) in chloroform (40 mL), and the mixture was stirred at 20°C for 90 min. The composition of the solution was obtained by HPLC analysis (C_{18} column, 60:40 acetonitrile–water as the mobile phase, flow 1.3 $mLmin^{-1}$): (*i*) 4.2 min (4,4′-dimethoxybenzhydrol, 10%); (*ii*) 10.8 min (4,4′-dimethoxydiphenylmethane, 73%); and (*iii*) 38.3 min (4,4′-dimethoxydibenzhydryl ether, 17%).

*2,5-Dimethoxy-1-(4′-chlorobenzyl)benzene (**3**:R1 = H, R2 = Cl)*

Triflic acid (0.26 mL, 3 mmol) was added (syringe) at room temperature, to a stirred solution of 2,5-dimethoxy-4′-chlorobenzhydrol (2.8 g, 10 mmol) in dichloromethane (30 mL). The color of the solution turned yellow-red. Subsequently, a solution of triethylsilane (4.02 mL, 25 mmol) in dry dichloromethane (10 mL) was added dropwise. An exothermic reaction took place while the temperature was maintained at 20°C. After 45 min, the mixture was poured into cold saturated sodium hydrogen carbonate solution (20 mL) and extracted with dichloromethane (3 × 10 mL). The organic layer was dried with magnesium sulfate, and evaporated; mp 42°C (petroleum ether – diethyl ether), yield 84%. IR (KBr) ν (cm^{-1}): 2998, 2947, 2831, 1590, 1495, 1459, 1437, 1219, 1045, 711. ^{1}H NMR ($CDCl_3$) δ (ppm): 3.74 (s, 3H), 3.76 (s, 3H), 3.91 (s, 1H),), 6.66 (d, *J* = 3.0 Hz, 1H), 6.73 (dd, *J* = 8.8 Hz, *J* = 3.0 Hz, 1H), 6.80 (d, *J* = 8.8 Hz, 1H), 7.14 (d, *J* = 8.5 Hz, 2H), 7.20 (d, *J* = 8.5 Hz, 2H). ^{13}C NMR ($CDCl_3$) δ (ppm): 35.5, 55.6, 56.0, 111.4, 116.8, 128.3, 130.2, 130.3, 131.6, 139.1, 151.6, 153.5. Anal. calcd. for $C_{15}H_{15}ClO_2$: C 68.57, H 5.75, O 12.18; found: C 68.60, H 5.71, O 12.20.

Catalysis of the methanolysis of acetylimidazole by lanthanum triflate

Alexei A. Neverov and R.S. Brown

Abstract: Methanolysis of acetylimidazole (**1**) and *N*-acetylimidazolepentamine-Co(III) (**2**) was found to be markedly accelerated in the presence of $La(OTf)_3$. Potentiometric titration of a solution of $La^{3+}(OTf^-)_3$ gave a pK_a for the metal bound CH_3OH of 7.22. The kinetics of methanolysis of **1** and **2** were measured at 25°C at various pH under buffered conditions as a function of increasing La^{3+}. Analysis of both the kinetic and potentiometric data indicates that the catalytically active species is a La^{3+}-dimer, bridged by two methoxides, $(CH_3OH)_nLa^{3+}(CH_3O^-)_2La^{3+}(CH_3OH)_n$. The maximum second-order rate constants for attack of the dimer on **1** and **2** are 1.50×10^3 M^{-1} s^{-1} and 1.42×10^2 M^{-1} s^{-1} respectively and both processes adhere to titration of a $La^{3+}(CH_3OH)$ to generate the active form. The results are explained in terms of a mechanism where the methoxy-bridged La^{3+} dimer transiently breaks a La^{3+}-OCH_3 bond to expose both a CH_3O^- nucleophile and a La^{3+} which can act as a Lewis acid. Unlike the situation in water, the methanol results indicate that the medium greatly stabilizes and solubilizes the active dimer without the necessity of creating specially designed ligands to stabilize the dinuclear core.

Key words: lanthanum ion, catalysis, methanolysis, activated amide.

Résumé : On a observé que la méthanolyse de l'acétylimidazole (**1**) et du *N*-acétylimidazopepentamine-Co(III) (**2**) est fortement accéléré par la présence de $La(OTf)_3$. Un titrage potentiométrique d'une solution de $La^{3+}(OTf^-)_3$ permet d'établir que le pK_a du métal lié au CH_3OH est de 7,22. Opérant à divers pH, dans des conditions tamponnées, on a mesuré les cinétiques de méthanolyse des composés **1** et **2** en fonction d'une concentration croissante de La^{3+}. L'analyse des données tant cinétiques que potentiométriques indique que l'espèce catalytiquement active est un dimère de La^{3+} comportant un pont par deux molécules de méthylates, $(CH_3O)_nLa^{3+}(CH_3O^-)_2La^{3+}(CH_3OH)_n$. Les constantes de vitesse maximales pour les attaques des composés **1** et **2** sont respectivement de $1{,}50 \times 10^3$ M^{-1} s^{-1} et $1{,}42 \times 10^2$ M^{-1} s^{-1} et les deux processus adhèrent au titrage d'un $La^{3+}(CH_3OH)$ pour générer la forme active. On explique les résultats en fonction d'un mécanisme dans lequel il se produit une dissociation transitoire d'une liaison La^{3+}-OCH_3 du dimère de La^{3+} relié par un pont méthoxy qui permet d'exposer un nucléophile CH_3O^- et d'un La^{3+} qui peut agir comme acide de Lewis. Par opposition à la situation dans l'eau, les résultats obtenus avec le méthanol indiquent que le milieu stabilise grandement et solubilise le dimère actif sans avoir à créer des ligands appropriés pour stabiliser le coeur dinucléaire.

Mots clés : ion lanthane, catalyse, méthanolyse, amide activé.

Much recent attention was focussed on the remarkable acceleration provided by lanthanide cations (Ln^{X+}) for the hydrolysis of phosphate esters (1) and, to a lesser degree, amides and peptides (2). However mechanistic study of these Ln^{X+}-promoted hydrolyses is hindered by the fact that in water, formation of insoluble hydroxides and gels of poor definition is a problem, particularly under basic conditions. A few attempts have been made to stabilize the active forms of $Ln^{X+}(OH^-)_n$ by encapsulation into cyclodextrins (1*h*, 2*a*), macrocycles (1*g*), or micelles (1*d*) but most research has been done at neutral or acidic conditions which limits the catalytic ability of those ions. Only a few examples of Ln^{X+}-catalysis of amide bond hydrolysis are known (2), probably due to the poorer M^{X+}-coordinating ability of the neutral > N-C=O moiety compared to that of negatively charged di- and monophosphate esters. Indeed, the reported cases of strong M^{X+}-promoted hydrolysis of amide (peptide) substrates are limited to those having additional binding centers that promote preassociation of the metal (3).

Herein we focus on the La^{3+}-catalyzed methanolysis of the simple activated amide, acetylimidazole, (**1**), and its ligand exchange inert Co^{3+}-complex, *N*-acetylimidazolepentamine-Co(III), ($AcImCo(NH_3)_5^{3+}$, (**2**)) (4). These were chosen because their aqueous hydrolyses are well understood, and because it has yet to be shown that the parent compound

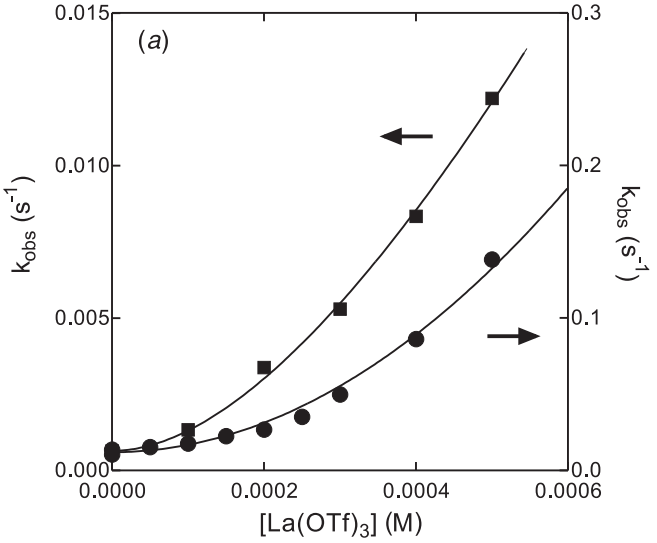
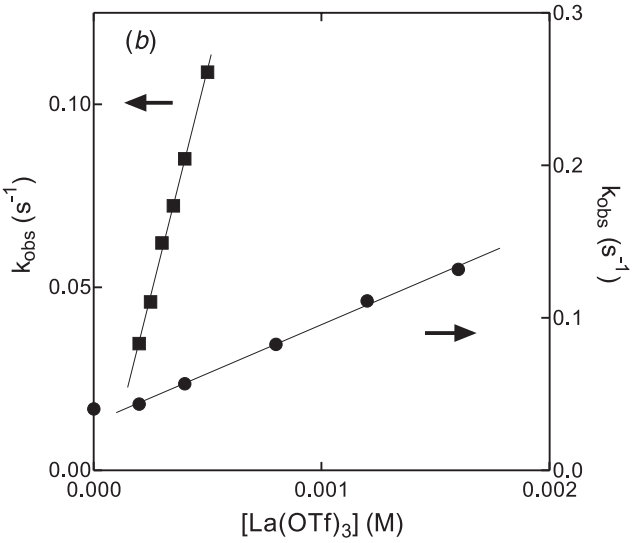
(**1**) is subject to metal ion catalysis in water. This combination allows us to investigate the role of electrostatic effects and the possibility of catalysis arising from the binding of the metal ion to the distal nitrogen of **1**. We report here that in methanol, homogeneous solutions can be obtained throughout the entire pH range surrounding ionization of $La^{3+}(CH_3OH)$. Moreover, through the use of buffered media to control the pH, which can be easily measured using a recently reported glass electrode technique (5), we can study the reaction kinetics in methanol as simply as in water without the annoying problems of metal–alkoxide precipitation. To the best of our knowledge, this is the first time such an approach has been used for kinetic investigations in methanol solutions.[2]





1 **2**

Our preliminary results show that the methanolysis rates[3] of **1** and **2** markedly increase in the presence of lanthanum trifluoromethanesulphonate ($La(OTf)_3$), and this process is very sensitive to pH_{MeOH}. Pseudo-first-order rate constants, k_{obs}, obtained for the methanolysis of **1** and **2** (Fig. 1*a*, *b*) show strong catalysis by $La(OTf)_3$, with the effect being linearly proportional to $[La(OTf)_3]$ at higher concentrations of metal salt but with significant curvature at concentrations lower than $\sim 2 \times 10^{-4}$ M. This indicates the involvement of second- or possibly higher order terms in $[La(OTf)_3]$. Unfortunately, direct analysis of all the experimental k_{obs} vs. $[La^{3+}]_t$ data does not provide us with reliable kinetic parameters, particularly in the case of **2** due to the high rate of the background reaction. However the fact that the k_{obs} vs. $[La(OTf)_3]_t$ dependencies look very similar for both substrates eliminates the possibility that the higher reaction order in $[La^{3+}]$ is due to complexation of a La^{3+} ion by the distal nitrogen of **1**, and rather indicates the catalysis is due to a concentration dependent change in speciation of La^{3+} in methanol such as formation of active dimers. Dimeric structures were previously observed in methanol solutions of $LaCl_3$ using La^{139} and Cl^{35} NMR (6).

Analysis of the linear parts of the plots ($[La^3]_t > 2 \times 10^{-4}$ M, Fig. 1*b*) gives the second-order rate constants (k_2) which are then plotted vs. pH_{MeOH} (as in Fig. 2) to reveal similar profiles for both substrates with apparent kinetic pK_as of 7–7.5. In a separate experiment (not shown), potentiometric titration of $La(OTf)_3$ (1.33 mmol) between pH_{MeOH} 6 and 9 shows ionization of one proton per metal ion with $pK_a^{MeOH} = 7.22$. In combination with the pH-rate profiles (Fig. 2) and k_{obs} vs. $[La(OTf)_3]$ dependencies (Fig. 1*a*, *b*),

Fig. 1. (*a*) Plots of pseudo-first-order rate constants for the methanolysis of AcIm (pH_{MeOH} = 6.7, ■, left axis)) and $AcImCo(NH_3)_5^{3+}$ (pH_{MeOH} = 7.6, μ = 0.2 ($NaClO_4$) ●, right axis) as a function of concentration of $[La(OTf)_3]$ at 25°C. (*b*) Plots of the pseudo-first-order rate constants for methanolysis of AcIm (pH_{MeOH} = 7.33 ■g, left axis) and $AcImCo(NH_3)_5^{3+}$ (pH_{MeOH} = 7.6 ●, right axis) vs. $[La(OTf)_3]$, at 25°C.

this indicates that the kinetically active species is a dimeric complex consisting of two solvated La^{3+} ions and two methoxide anions as shown in Scheme 1.

The equations for the equilibrium constants and the conservation of mass pertaining to the process in Scheme 1 provide the expression given in eq. [1] where k_o is the

[2] *N*-methylimidazole (pK_a^{MeOH} = 7.60) and *N*-ethylmorpholine (pK_a^{MeOH} = 8.28) were used to buffer methanol solutions. Total buffer concentrations were varied between 10^{-3} M and 10^{-2} M, and no buffer catalysis was observed. The $[CH_3OH_2^+]$ was determined using a combination (glass/calomel) electrode, calibrated with Fisher Certified standard aqueous buffers. Values of pH_{MeOH} were calculated by adding a correction constant (2.24) to the experimental meter reading. (R.G. Bates. *In* Determination of pH. Theory and practice. Wiley, New York. (1973); E. Bosch, private communication.)

[3] UV kinetics were monitored by observing the rate of loss of starting material at 240 nm, under pseudo-first-order conditions of excess metal ([amide] = 0.5 – 1.0 × 10^{-4} M) at 25°C. Pseudo-first-order rate constants (k_{obs}) were evaluated by fitting the Abs. vs. time traces to a standard exponential model.

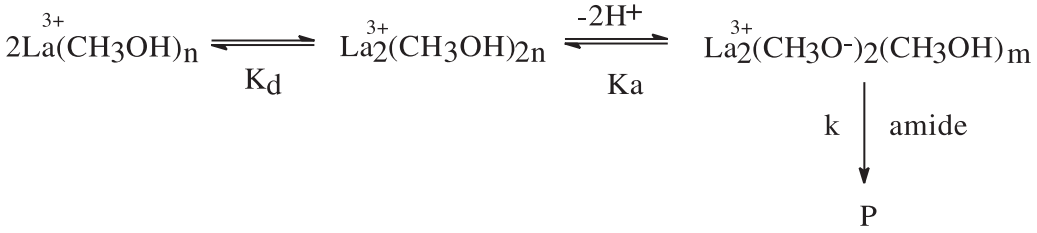
Scheme 1.



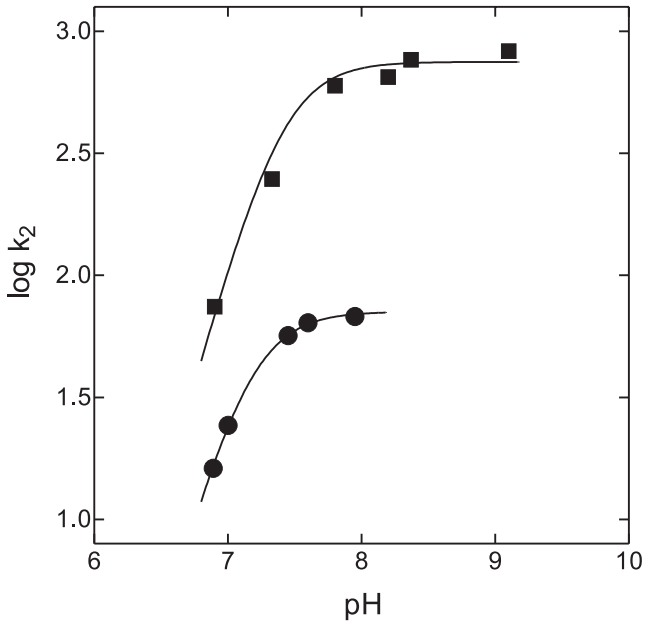


Fig. 2. pH–Second-order rate constant profiles for $La(OTf)_3$-catalyzed methanolysis of AcIm (■) and $AcImCo(NH_3)_5^{3+}$ (●). Curves are the result of NLLSQ fitting of experimental data to eq. [3].

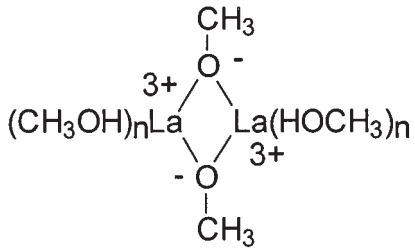
spontaneous rate constant for methanolysis in the absence of metal ion.

$$[1] \quad k_{obs} = k_0 + (kK_a[H^+]^2/K_d)((1 + 8(K_a + [H^+]^2)K_d[La^{3+}]_t/[H^+]^2)^{0.5} - 1)^2/(4(K_a + [H^+]^2))^2$$

The linear part of the plots of k_{obs} vs. $[La^{3+}]_t$, (Fig. 1*b*), used to calculate the second-order rate constant k_2, describe the conditions where $\delta k_{obs}/\delta[La^{3+}]_t$ is constant (eq. [2]),

$$[2] \quad k_2 = \delta k_{obs}/\delta[La]_t = k\alpha\beta(1 - 1/(1 - \beta[La^{3+}]_t)^{0.5})$$



where $\alpha = K_a[H^+]^2/(16K_d(K_d + [H^+]^2)^2)$, and $\beta = 8K_d(K_a + [H^+]^2)/[H^+]^2$.

To satisfy the condition that $\delta k_{obs}/\delta[La^{3+}]_t$ is constant, the range of $[La^{3+}]_t$ for analysis must be chosen such that $(1 - \beta[La^{3+}]_t)^{0.5}$ must be much bigger than 1, thereby providing an expression relating k_2 to K_a, the ionization constant of $La^{3+}(HOCH_3)$, eq. [3].

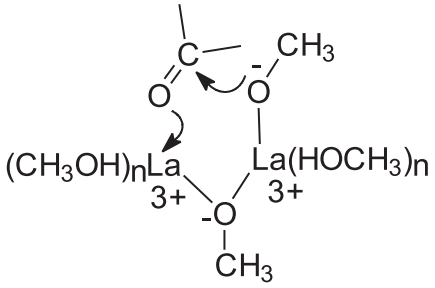
$$[3] \quad k_2 = kK_a/(2(K_a + [H^+]^2))$$

NLLSQ fitting of pH–k_2 data to eq. [3] gives the following parameters: $k = (1.50 \pm 0.1) \times 10^3\ M^{-1}\ s^{-1}$, $K_a = 10^{(-14.8 \pm 0.1)}\ M^2$ (kinetic $pK_a = 7.40$) for **1**, and $k = (1.42 \pm 0.02) \times 10^2\ M^{-1}\ s^{-1}$, $K_a = 10^{(-14.30 \pm 0.02)}\ M^2$ (kinetic $pK_a = 7.15$) for **2**. The lines through the data in Fig. 2 are those generated by the fits to eq. [3]. That the computed kinetic pK_as are in good agreement with the pK_a^{MeOH} obtained from the potentiometric titration lends strong credence to the idea that both processes relate to the ionization of metal-coordinated methanol. Further, the fact that only one inflection point is present in the potentiometric titration curve indicates strong cooperation between dissociation of both protons from a dimeric species. While the exact structure of this dimer is uncertain, most reasonable is one having two La^{3+} ions bridged by two methoxide anions as in **3**.

Similar double-bridge structures were suggested for $La_2Cl_6(CH_3OH)_{10}$ (6) (with bridging chloride ions) and a

3

La^{3+}-peroxide complex (with bridging peroxide dianions) (7). Hurst et al. (8), from a study of the hydrolysis of an RNA model dimer promoted by La^{3+} in water, proposed a similar catalytically active metal dimer structure having two lanthanide ions bridged by five HO^-.



Comparison of the second-order rate constants for La^{3+}-promoted methanolysis of **1** and **2** ($(1.50 \pm 0.1) \times 10^3\ M^{-1}\ s^{-1}$ and $(1.42 \pm 0.02) \times 10^2\ M^{-1}\ s^{-1}$) clearly indicates that coordination of the $(NH_3)_5Co^{3+}$ to the distal nitrogen does not provide any enhancement of the catalytic effect of La^{3+}. Even though **2** has a much better leaving group than does **1** ($pK_a = 10.0$ for $^-ImCo(NH_3)_5^{3+}$ (4) vs. 14 for Im^- (9)), the rate of its La^{3+}-promoted reaction is 10-fold slower. This is in contrast to our results for CH_3O^--catalyzed methanolysis of **2** where the second-order rate constant ($k_{CH3O} = 4.69 \times 10^7\ M^{-1}\ s^{-1}$) is four orders of magnitude higher than that for CH_3O^- attack on **1** ($k_{CH3O} = 7.9 \times 10^3\ M^{-1}\ s^{-1}$).[4] Strong acceleration of methoxide attack on **2** relative to **1** can be explained by a combination of leaving group effects and electrostatic interaction between the positively charged substrate (**2**) and a negatively charged nucleophile. The latter

[4] A.A. Neverov, P. Montoya-Paelez, and R.S. Brown. Submitted for publication.

© 2000 NRC Canada

result thus shows that the La^{3+}-promoted methanolysis mechanism cannot involve attack of free methoxide ion since that should result in much higher rate constants for **2** than for **1**, contrary to what is observed. The slower reaction of the lanthanide reaction with **2** can be accommodated by a process involving the dimeric complex $(La^{3+}{}_2(CH_3O^-)_2(CH_3OH)_m)$ (**3**), having a total positive charge of +4, wherein electrostatic repulsion causes a decrease in the rate for the positively charged substrate **2** relative to neutral **1**.

It has been shown in the case of a structurally similar Co^{3+}-hydroxide dimeric complex, that bridging hydroxides do not possess nucleophilic activity, being at least 10^{10} times less active than the deprotonated oxo-bridged forms (10). For the present methoxy-bridged dimer (**3**) deprotonation is impossible so the only way to generate an active nucleophile within the dimeric complex requires temporary breakage of a lanthanum—methoxy bond. This creates a scissors-like structure where the La^{3+}-bound CH_3O^- is delivered to the C=O carbon with the second La^{3+} functioning as a Lewis acid to stabilize the developing negative charge on the carbonyl oxygen as in **4**.

4

The above study indicates several beneficial features stemming from studying La^{3+}-promoted methanolysis relative to La^{3+} in water. Methanolyses have not been studied as extensively as hydrolyses, undoubtedly due to the problems of controlling and measuring the pH which now have been overcome (5). By a combination of potentiometric titration and kinetic data, we have shown that catalytically active La^{3+} dimers (**3**) are formed above the pK_a of the metal bound CH_3OH. The fact that these dimers are far more soluble in methanol than the corresponding La^{3+}-hydroxides are in aqueous solution simplifies kinetic studies and obviates the necessity of creating complex ligands to stabilize the dinuclear catalytically active core, as is the case in aqueous studies (1, 8, 10). The success observed here with the simple amides and the fact that the La^{3+}-dimer acts on the C=O unit suggests that La^{3+}-catalyzed methanolyses of more biologically relevant amides, peptides, and oligonucleotides would be interesting, and we will report on these studies in due course.

1999 R.U. Lemieux Award Lecture Adventures with azo-, azoxy-, and hydrazoarenes: from the Wallach to the benzidine rearrangement. Molecular electronics[1]

Erwin Buncel

Abstract: The author's studies with aromatic azo-, azoxy-, and hydrazo-dye molecules, comprising kinetic and equilibrium investigations, as well as synthesis of novel molecules having photogenic properties, are described under the following highlights: **A.** *Wallach rearrangement and cognate studies with azoxyarenes* — (1) Elucidation of the mechanism of the Wallach rearrangement of azoxybenzene through the kinetic observation of a two-proton process which, together with a pK_a study, was interpreted on the basis of formation of a deoxygenated, dicationic, symmetrical species as a key, short-lived reaction intermediate. (2) The proposal of a general acid-catalyzed pathway in concentrated sulfuric acid (catalysis by H_2SO_4 and $H_3SO_4^+$). (3) Elucidation of the consecutive sulfonations of reaction products of azoxybenzene in the 100% H_2SO_4 region, and the diprotonation equilibria for *p*-hydroxyazobenzene, thus shedding light on past reaction pathway and product studies. (4) The observation of a novel reaction pathway for 2,4,6,2′,4′,6′-hexamethylazoxybenzene. (5) The observation of a dichotomy of reaction pathways for α- and β-2-phenylazoxynaphthalenes: reaction via the dicationic intermediate and via quinoid intermediate species; comprising two isomeric compounds reacting by different pathways to give the same product. (6) Identification and structure proof of α- and β-isomers observed for the first time in the peracid oxidation of phenylazopyridine. (7) Observation of a rate constant ratio of 22 000 in the rearrangement of these α- and β-isomers, and the proposal of differential barriers for transition states leading to a tricationic intermediate. **B.** *Benzidine rearrangement and cognate studies* — (8) Observation of the acid-catalyzed hydroxylation of phenylazopyridine to *p*-hydroxyphenylazopyridine and the proposal of an S_NAr mechanism with formation of an intermediate hydrazo species in the reaction. (9) First study of benzidine type rearrangement–disproportionation of phenylhydrazopyridine in acid media. (10) Proposal of a A → B → C → D type reaction profile for the consecutive hydroxylation→disproportionation processes of phenylazopyridine in aq H_2SO_4. (11) Proposal of 10-π and 14π-electron electrocyclic processes in the benzidine type rearrangement–disproportionation of phenylhydrazopyridine. (12) Identification and structural elucidation of a dimer formed from phenylazopyridine as a minor product and proposal of a reaction mechanism. **C.** *Facile acid-catalyzed demethylation via S_NAr/A-S_E2 mechanisms and studies of tautomerism* — (13) Observation of an abnormally facile acid-catalyzed cleavage (demethylation) of 4-methoxyphenylazopyridine via an S_NAr mechanism. (14) Observation of two reaction pathways, S_NAr and A-S_E2, for the consecutive demethylations of 3,4-dimethoxyphenylazopyridine, with rate constant ratio of 7 000:1 favoring the S_NAr process. (15) Quantitation of the tautomeric and protonation equilibria of 4-hydroxyphenylazopyridine, produced in (13). **D.** *A new solvent polarity scale, molecular switches, and molecular electronics* — (16) Establishment of a π^*_{azo} solvent polarity scale based on solvatochromism of a series of azomerocyanine molecules ("Buncel's dye"). (17) Some glimpses are presented of current forays into molecular electronics, as emanating from the above studies: (*a*) spiropyran (SP) ⇔ merocyanine (MC) thermo- and photochromic "molecular switch" systems; (*b*) synthesis and characterization of azo-functionalized star-burst dendrimers with photoswitchable properties and potential applications in optical data storage systems, holographic gratings, and drug delivery systems as host molecules.

Key words: Wallach rearrangement, benzidine disproportionation, azoarenes, azoxyarenes, dendrimers, hydrazoarenes, dendrimers, solvatochromism, photochromism, thermochromism, spiropyran–merocyanine molecular switch.

Résumé : Dans ce travail, on décrit les travaux de l'auteur avec des molécules de colorants aromatiques de la famille des azo, azoxy et hydrazo, comprenant des études cinétiques et d'équilibres ainsi que les synthèses de nouvelles molécules possédant des propriétés photogéniques; en particulier: **A.** *Réarrangement de Wallach et études apparentées avec des azoxyarènes* — (1) Élucidation du mécanisme du réarrangement de Wallach de l'azoxybenzène par le biais de

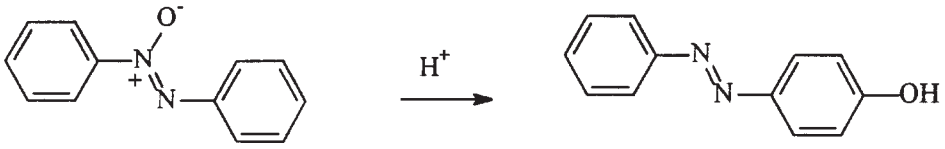
l'observation cinétique d'un processus à deux protons qui, combinée à une étude de pK_a, a été interprétée sur la base de la formation d'une espèce symétrique, dicationique, désoxygénée comme intermédiaire réactionnel clé, de courte durée de vie. (2) La proposition, pour les réactions en milieu acide sulfurique concentré, d'une voie de réaction impliquant une catalyse acide générale (catalyse par H_2SO_4 et $H_3SO_4^+$). (3) L'élucidation des sulfonations consécutives des produits de réaction du *p*-azoxybenzène qui a permis de voir sous un nouveau jour les voies réactionnelles et les études de produits antérieures. (4) L'observation d'une nouvelle voie réactionnelle pour le 2,4,6,2′,4′,6′-hexaméthylazoxybenzène. (5) L'observation d'une dichotomie dans les voies réactionnelles des α- et β-2-phénylazoxynaphtalènes : une réaction par le biais de l'intermédiaire dicationique et une autre via des espèces intermédiaires quinonoïdes comportant deux composés isomères qui réagissent par des voies différentes pour donner le même produit. (6) L'identification et la preuve de structure des isomères α et β observés pour la première fois lors de l'oxydation de la phénylazopyridine par un peracide. (7) L'observation d'un rapport de constantes de vitesses de 22 000 lors du réarrangement des ces isomères α et β et la proposition de barrières différentielles pour les états de transition conduisant à un intermédiaire tricationique. **B.** *Le réarrangement de la benzidine et les études apparentées* — (8) L'observation d'une hydroxylation catalysée par les acides de la phénylazopyridine en *p*-hydroxyphénylazopyridine et la proposition d'un mécanisme S_NAr avec formation d'une espèce hydrazo intermédiaire au cours de la réaction. (9) La première étude d'un réarrangement/disproportionation de phénylazopyridine de type benzidine en milieu acide. (10) La proposition d'un profile de réaction de type A → B → C → D pour les processus d'hydroxylation–disproportionation consécutives de la phénylazoxypyridine en milieu H_2SO_4 aqueux. (11) La proposition de processus électrocycliques 10-π et 14-π lors de réarrangement–disproportionation de type benzidine de la phénylhydrazopyridine. (12) L'identification et l'élucidation de la structure d'un dimère qui se forme comme produit mineur à partir de la phénylazopyridine et la proposition d'un mécanisme réactionnel. **C.** *La déméthylation acidocatalysée facile par le biais de mécanismes S_NAr/A-S_E2 et les études de tautomérie* — (13) L'observation d'un clivage (déméthylation) acidocatalysée anormalement facile de la 4-méthoxyphénylazopyridine par le biais d'un mécanisme S_NAr. (14) L'observation de deux voies réactionnelles, S_NAr et A-S_E2, pour les déméthylations consécutives de la 3,4-diméthoxyphénylazopyridine pour lesquelles le rapport des constantes de vitesses de 7 000/1 favorise le processus S_NAr. (15) La quantification de l'équilibre tautomère et de protonation de la 4-hydroxyphénylazopyridine obtenue dans la section 13. **D.** *Une nouvelle échelle de polarité des solvants, les commutateurs moléculaires et l'électronique moléculaire* — (16) La mise au point d'une échelle de polarité des solvants π^*_{azo} basée sur la solvatochromie d'une série de molécules azomérocyanines (« colorant de Buncel »). (17) On présente aussi des aperçus des domaines actuels de recherches en électronique moléculaire, telles qu'elles émanent des études mentionnées plus haut: (*a*) systèmes de "commutateurs moléculaires" thermo- et photochromiques spinopyrane (SP) ⇔ mérocyanine (MC); (*b*) synthèse et caractérisation de dendrimères azo fonctionnalisés ayant des propriétés comme commutateurs moléculaires et évaluation des applications potentielles dans le stockage de données optiques, holographiques et dans les systèmes de mises en disponibilité de médicaments comme molécules hôtes.

Mots clés : réarrangement de Wallach, disproportionation de la benzidine, azoarènes, azoxyarènes, hydrazoarènes, dendrimers, solvatochromie, photochromie, thermochromie, commutateur moléculaire spirane–mérocyanine.

1. Introduction

(*a*) Historical



Over the 100 years since the discovery by Peter Griess (1) in 1858 of the versatile diazotization-coupling procedure for the synthesis of aromatic azo compounds, these molecules have earned the distinction of reaching the first rank among industrial dyes and pigments (2). The rich mechanistic chemistry surrounding azoarenes is well documented in texts by Zollinger (3) and the works edited by Patai (4).

The discovery of the transformation of azoxybenzene into *p*-hydroxyazobenzene (eq. [1]) by Wallach and Belli (5) in 1880 has become known as the Wallach rearrangement (WR henceforth). The reaction was found to occur simply by heating in concentrated sulfuric acid.

It was suggested that an initial disproportionation to phenol and diazosulfonic acid would be followed by their recombination to products. Azoxybenzene was formulated as a symmetrical structure which had been proposed by Kekule and Hidegh (6) in 1870; the currently accepted unsymmetrical structure of azoxybenzene (eq. [1]) was established later, 1910–1933 (7). It took roughly 100 years following Wallach's initial discovery for meaningful mechanisms to be proposed (8).

Since the observation by Hoffmann (9) in 1863 of the conversion of hydrazobenzene by dilute acid to 4,4′-diaminobiphenyl, commonly known as benzidine, the mechanism of the rearrangement (BR henceforth) has fascinated chemists for over 100 years. Part of the fascination has been the finding of a variety of products (Scheme 1),

Scheme 1.

complex kinetics, and the intramolecular nature of the processes. The BR thus became regarded as the "holy grail" of molecular rearrangements (10). In that light, Ingold (11) after several decades of study of the BR produced a reaction profile which depicted the transition state as lost in the clouds. Fortunately, recent work has allowed light to filter through the clouds and the holy grail has become within reach.

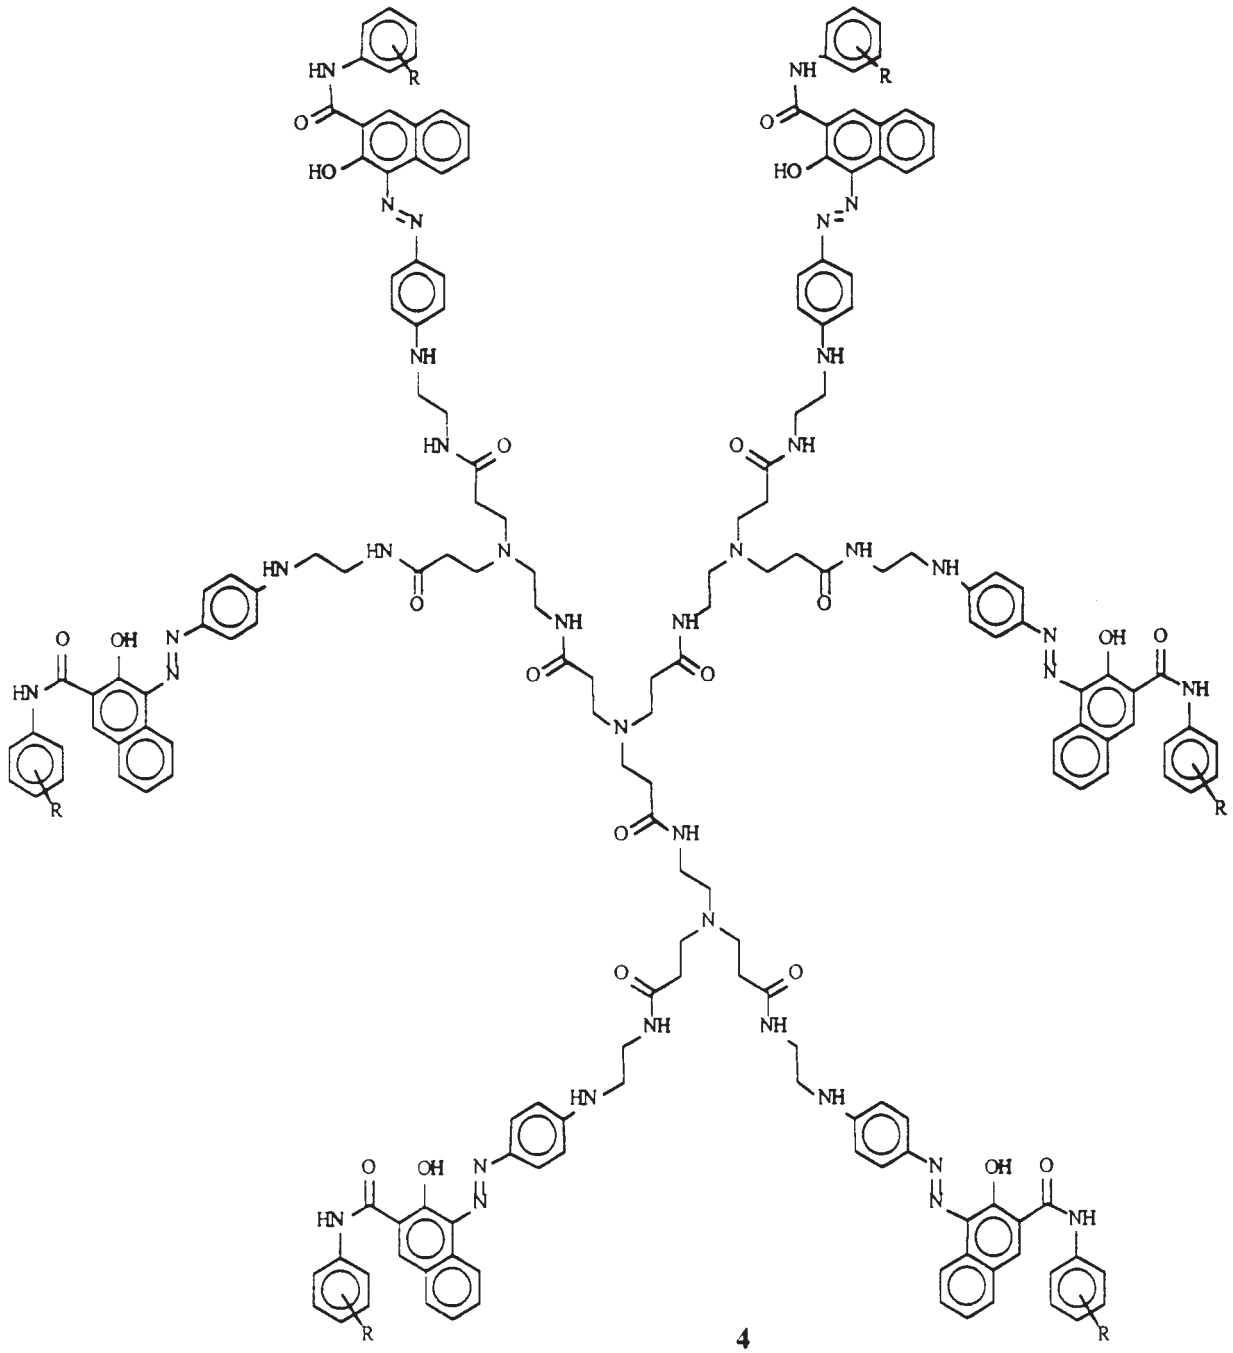
(*b*) Overview

The author was initiated into the field of azo dyes through a study of the abnormally facile hydrolysis of azoaryl ethers (vide infra), under the guidance of Professor Joseph Bunnett, forming part of the basis of mechanistic criteria for acid-catalyzed processes (12, 13). Azoarenes are found throughout this account, being the precursors of azoxyarenes and the products of their rearrangements, as well as of the rearrangements of hydrazoarenes.

The first project of my independent research at Queen's was directed at a mechanistic study of the WR. Surprisingly, a review of the literature revealed that no kinetic study had as yet been reported of this reaction. This was surprising because proposals of mechanism including postulation of various reaction intermediates were put forward by workers in Australia, Japan, and Russia, without invoking any role of acid!

In the course of our work on the WR during the following years, various structure–reactivity relationships were realized from rate–pK_a studies, including correlations with MO calculations (vide infra). Serendipitous discoveries led us eventually to the benzidine rearrangement (in the heteroaromatic series, which turned out to be even more complex), after we had extended a study of the WR to the two isomers (α and β) of phenylazopyridine (**2a**, **b**). It was envisaged that the WR product, as the deprotonated *N*-alkyl derivative, would exhibit solvatochromic properties due to varying contributions of the zwitterionic merocyanine (**3b**), and quinoid (**3a**), resonance structures (Scheme 2).

The UV–vis spectrum of compound **3** (R = CH_3) exhibited, providentially, one of the largest variations in λ_{max} with solvent polarity (14). This prompted us to synthesize a series of azomerocyanines and to use the solvatochromic method (15) to establish a new solvent polarity scale, π^*_{azo} (16).



The potential of merocyanines (MCs) in the area of molecular electronics (17) now beckoned us, especially in their usage as the basis of a molecular switch. This would be possible through the interconversion of the colored MC and a

© 2000 NRC Canada

colorless species, as in the case of the spiropyran (SP) structure. The SP ⇔ MC system (18) offers possibilities of thermo- and photochromic interconversion (Scheme 3) and various methods have been explored to stabilize the two forms, including, in our laboratory, chelation of the ring-opened MC form with divalent metal ions.

Azobenzene-functionalized molecules have also been exploited as photoswitches by taking advantage of the azo-functionality as a photoresponsive moiety. Thus, modification of the periphery of dendrimers with azo-functionalities offers applications in materials science — optical data storage, holography, and drug delivery (19). An example from our work is the azobenzene-functionalized polyamide (PAMAM) dendrimer **4**.[3]

With this overview, from the beginning of our work to the present, and having come full circle in these meanderings with the current study of structure properties of azo-functionalities in dendrimers, we can now proceed to flesh

out this account. It will be seen that most of our studies did not follow a logical plan but, rather, developed from unexpected observations which then took on a life of their own. Of course, most of the credit goes to the enthusiasm of my co-workers over the years, who will be thanked formally at the end of this account.

2. Wallach rearrangement of azoxyarenes

The Wallach rearrangement (WR) of azoxybenzene in aq H_2SO_4 gives rise, apparently exclusively, to *p*-hydroxyazobenzene (eq. [1]). A small amount of *o*-hydroxyazobenzene has been reported by some workers but this is believed to be formed in a photochemical process. Sulfonated hydroxyazobenzene, also reported previously (20), is, however, a secondary product (21) as a result of the rather harsh conditions typically used in preparative experiments (concd H_2SO_4, elevated temperature, extended reaction time). Contrastingly, kinetic studies performed spectrophotometrically showed that the half-life of the primary reaction in 99.9% H_2SO_4 at 25°C was of the order of 1 min (22). Studies with a number of substituted azoxybenzenes have been reported (23)[4]; these have been reviewed previously (8*a*) and will be referred to only in passing in this account.

Questions that are also pertinent to other molecular rearrangements must be addressed. Is the WR an intramolecular or intermolecular process? Is there evidence for any reaction intermediates? What is the role of acid in the reaction mechanism?

Isotopic tracer studies (24) provide a powerful tool in determination of intra- or inter-molecularity of rearrangement processes. Oxygen-18 tracer studies (25), using labelled substrate and isotopically normal reaction medium, or the reverse, have shown that the *p*-hydroxyazobenzene product

derives its oxygen from the medium, i.e., an intramolecular process. ^{15}N tracer studies (26) with azoxybenzene specifically labelled on one nitrogen produced *p*-hydroxyazobenzene in which the label was equalized on both Ns, pointing to a symmetrical intermediate on the reaction pathway, for which the *N*,*N*-oxide structure **5** was proposed (26). Similar equalization results were obtained on using ^{13}C specifically labelled azoxybenzene (27). Gore (28) was the first to propose the dicationic structure **9** as being in accord with the ^{15}N equalization result and product studies; this structure was later endorsed by Buncel and Lawton (29) on the basis of kinetic studies. However, unsymmetrical intermediates such as **10** continued to be advanced (30). An attempt at assigning the role of acid was made through the proposal of the protonated *N*,*N*-oxide species, i.e., **6, 7**, and **8** (31). Scheme 4 shows the structures of the different intermediates.

It appeared to us that more definitive information concerning the role of acid would be garnered from a kinetic study of the reaction, for which the spectrophotometric method should be ideal. Azoxybenzene in ethanol or in dilute H_2SO_4 (or in basic medium) has an absorption at 323 nm but in strongly acid media protonation occurs on the azoxy function and λ_{max} shifts to 390 nm. A separate pK_a study showed there is 50% O-protonation in 65% H_2SO_4, corresponding to a pK_a of –5.1 (32). The *p*-hydroxyazobenzene product is N-protonated in the acid media with λ_{max} at 460 nm, so the reaction can readily be followed directly (or by quenching in base, with λ_{max} for the azophenolate ion at 430 nm).

In Table 1 are recorded the rate data at various acid concentrations and values of the classical Hammett acidity function H_o (33) as well as the more recent Cox–Yates Excess Acidity X (34) which provide alternate measures of

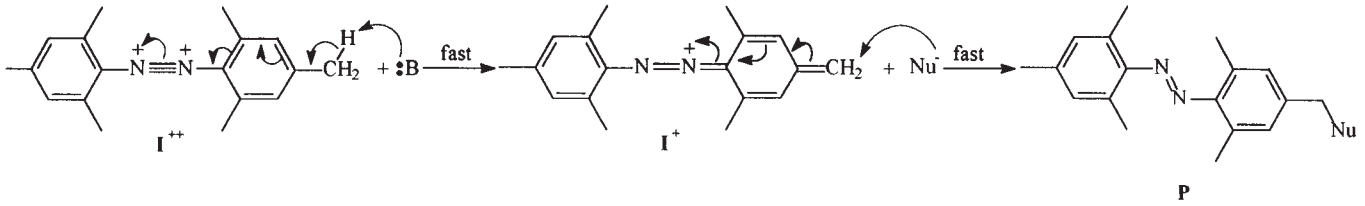
Scheme 6.

the acidity of the medium. Also shown is the extent of protonation as the quotient $[SH^+]/([S + SH^+])$. The striking result emerges that the rate increases by over 100 000-fold over the acid range studied but the percent protonation increases only very slightly, by 3%. From 85% H_2SO_4 up, there is virtually no increase in protonation but the rate keeps on increasing. Hence a second proton transfer, in addition to the equilibrium protonation must be involved in the overall process.

The mechanism which we proposed as a result of the kinetic study coupled with equilibrium protonation data is shown in Scheme 5 (32). An initial equilibrium protonation on oxygen is followed by a second proton transfer, either as another equilibrium protonation (similar to the protonation of an alcohol) and followed by loss of H_2O, or as a slow process involving concerted general acid-catalyzed removal of H_2O. In either case one obtains the dicationic species **9** as a transient intermediate which is rapidly attacked by solvent on the ring *para* carbon position, followed by rearomatization and hydrolysis to give the final *p*-hydroxyazobenzene product.

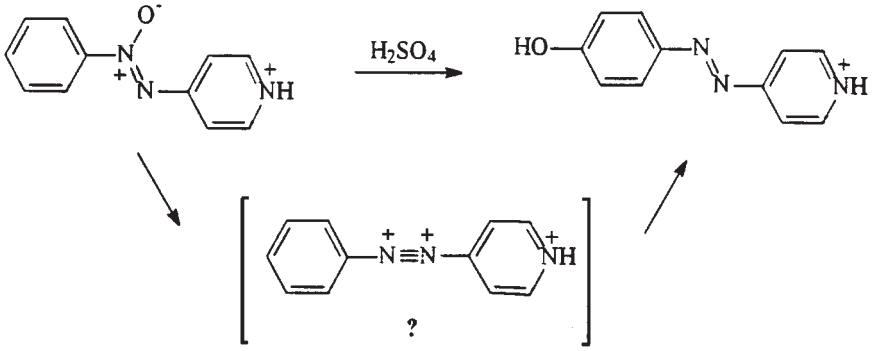
The idea of general acid catalysis in concentrated sulfuric acid media, i.e., that undissociated and protonated H_2SO_4 molecules are taking part in rate-determining proton transfer, though unusual, receives support from Fig. 1 (32*b*). This shows that there is good linear correlation of rate with log a_{H2SO4} until 96% of H_2SO_4, when $H_3SO_4^+$ takes over.

The proposal of the dicationic intermediate in the WR appeared to be consistent with other extant studies including the aforementioned isotopic tracer studies, and has also been the subject of a molecular orbital treatment (35). Nevertheless, certain structural features in the substrate could favour a pathway proceeding via an unsymmetrical intermediate.



Thus, interestingly, the two isomeric α- and β-2-phenylazoxynaphthalenes, **11** and **12**, were found to react by different mechanisms (36). According to the Cox–Yates excess acidity treatment, **12** reacts by the dicationic mechanism at all acidities but **11** does so at high acidities while the quinoid mechanism shown in Scheme 6 is followed in the low acid regime. Thus for **11** the quinoid intermediate provides a lower energy pathway. Note that **12** cannot react via the quinoid intermediate since the protonated NO function in SH^+ is not correctly oriented with respect to the naphthyl ring for nucleophilic attack, while the phenyl moiety is insufficiently activated to form quinoid intermediates. Hence **12** will react by another mode, namely the dicationic intermediate mechanism as followed by azoxybenzene itself. Thus the two isomeric compounds **11** and **12** react by different mechanisms to give the same product.

In an attempt to stabilize the dicationic intermediate, and possibly have it as a spectroscopically observable species, reaction was performed with 2,4,6,2′,4′,6′-hexamethylazoxybenzene on the basis that, with the *ortho* and *para* positions blocked, attack by solvent should be precluded. The actual result, shown in Scheme 7, was proton loss from a *para* methyl group followed by solvent attack to yield the product corresponding to Nu = OH, thus thwarting observation of the dicationic intermediate (37).



The classical approach by Olah et al. (38) solved the search: when the reaction with azoxybenzene was carried

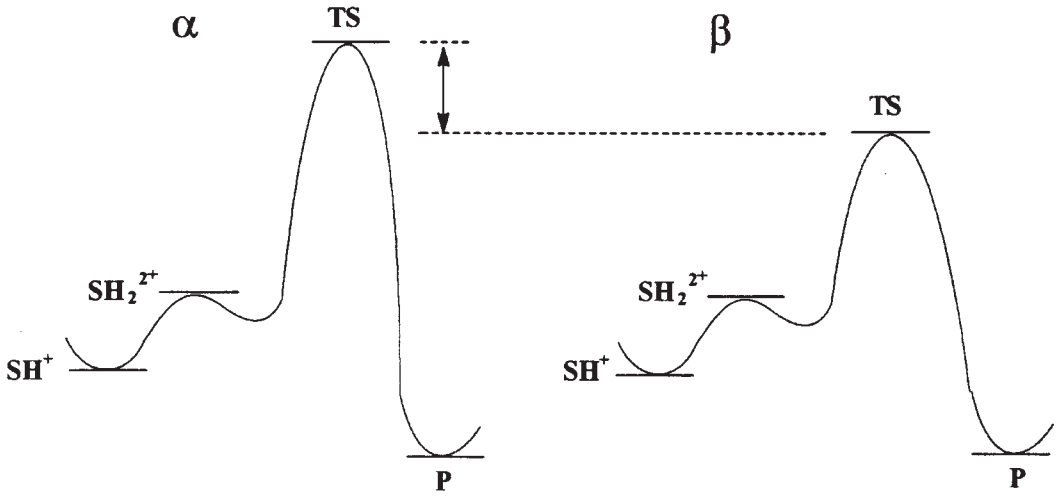
Scheme 10.

out in "magic acid," a non-nucleophilic medium, the dicationic intermediate could be observed by its ^{1}H NMR spectrum. Thus ended one chapter on the WR mechanism.

3. Rearrangement of phenylazoxypyridine

We anticipated that a major structural change in substrate could be harnessed toward new questions about products, kinetics, and mechanistic consequences, through extension of the work to the phenylazoxypyridine series. As shown in Scheme 8, an analogous pathway to that of azoxybenzene would now entail formation of a tricationic intermediate. As well, one could envisage the possibility of solvatochromism in the hydroxyazo product in its O-deprotonated, zwitterionic form.

Azoxybenzenes are generally obtained by the peracid oxidation of azobenzenes, and in the case of unsymmetrically substituted azo compounds the reaction usually gives rise to a mixture of isomeric α- and β-azoxybenzenes (Scheme 9). In contrast, oxidation of phenylazopyridine was reported to give rise only to the α-isomer (as the *N*-oxide) and none of the isomeric β-product (39). In our hands, reaction of the oxidation product, under WR conditions and using the usual spectrophotometric method, proceeded to half completion only, approximately half the starting material remaining unreactive. Intuitively, on the assumption that oxidation gave rise in fact to *both* isomeric azoxy compounds only one of which was reactive, the material was chromatographed, yielding two portions whose structures were confirmed by X-ray analysis as the isomeric α- and β-phenylazoxypyridine-*N*-oxides (40).



Kinetic study of the authentic α- and β-azoxy isomers then revealed the anticipated remarkable difference in reactivity of these isomeric compounds. In 99.6% of H_2SO_4, at 25°C, the rate constant ratio was found to be 22 000 in favour of the β-isomer (41)[5].

The observed reactivity difference of the α- and β-isomers can be accounted for in terms of the mechanisms illustrated in Scheme 10 in which formation of the tricationic intermediate follows the general acid-catalyzed pathway. Note that

in the TS for formation of the trication the nitrogen removed from the azoxy function develops positive charge. In the case of the β-isomer this positive charge can be delocalized on the adjacent phenyl group so this process is facilitated. However, in the case of the α-isomer the positive charge is being developed on the N adjacent to the pyridine nucleus

© 2000 NRC Canada

Scheme 12.

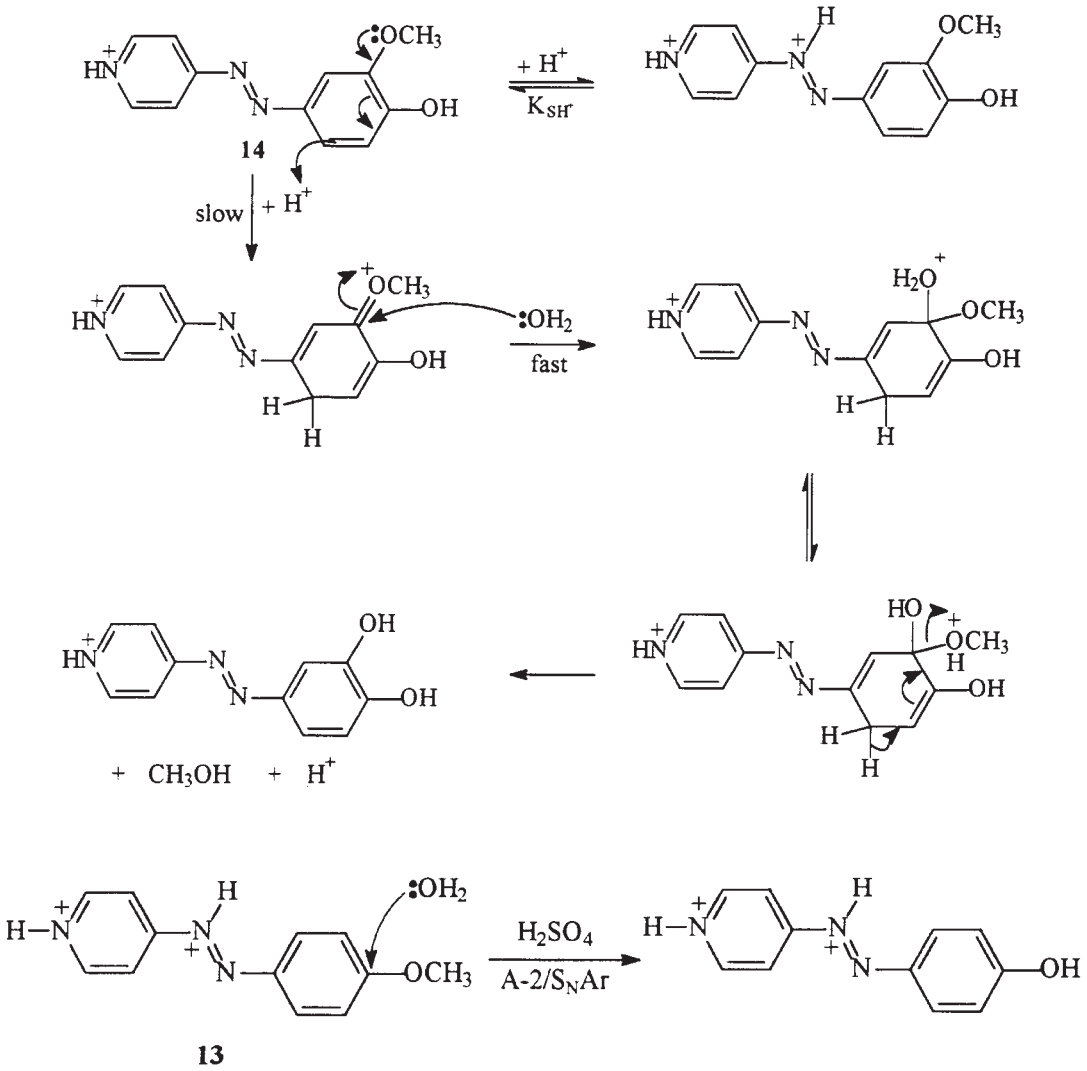
which itself carries a positive charge, so this process will be highly unfavorable, exhibiting a higher energy TS than for the β-isomer, as illustrated in the reaction coordinate diagram in Fig. 2.

4. Meanderings

With the unravelling of the mechanism of rearrangement, first of azoxybenzene and its analogues in the naphthylazoxy series, then of the phenylazoxypyridine compounds, our original aims were essentially completed. However, before closing this chapter altogether it seemed desirable to follow up several avenues which had come to light in the meanwhile. These took on a life of their own, as often happens, and in this section are recorded some of these meanderings. As well, it will be seen that, serependitiously, these meanderings led us eventually to the discovery of novel aspects of the benzidine rearrangement, one of the "holy grails" in organic chemistry.

(*a*) Solvatochromism of azomerocyanines: π^*_{azo} scale

The possible solvatochromic properties of WR products of phenylazoxypyridines in their zwitterionic form was envisaged earlier. Thus, the *N*-methyl betaine **3** was found to exhibit a very large spectral shift with solvent polarity, comparable to Reichardt's well known pyridinium betaine (42). A quantum mechanical study of the solvatochromism in **3** (named "Buncel's dye" by Timothy Clark) yielded satisfactory agreement between calculated and observed solvent-induced spectral shifts (43). The changes in position of the UV–vis absorption band in different polarity solvents result from varying electron distributions in the molecule in response to solvent polarity changes, i.e., varying contributions of the zwitterionic and quinoidal forms **3a** and **3b**, as shown in Scheme 2.



It appeared of interest to utilize a family of azomerocyanines toward establishing a new solvent polarity scale. This was done with the series shown in Scheme 11 and the resulting scale was called π^*_{azo}, following Taft's π^* scale which was established using the solvatochromic method with six compounds of diverse structures (44). The π^*_{azo} scale correlates reasonably well with other solvent polarity scales (15).

(*b*) Sensitivity of azo ethers to acid-catalyzed hydrolysis

The account in the previous section concerning the hydroxyphenylazopyridine system was incomplete in one sense, i.e., that, for completeness, it was desirable to quantitate the various tautomeric and protonation equilibria illustrated in Fig. 3. The spectrophotometrically measured pK_as refer to the macroscopic equilibria on the right hand side, while the microscopic equilibria are shown on the left side; these can be related by standard methods (45). However, to characterize spectrally all species in this system it was required to determine the spectra of a number of model compounds. Unexpectedly, this supposedly routine work led to novel discoveries, ending ultimately with our foray into benzidine rearrangement studies.

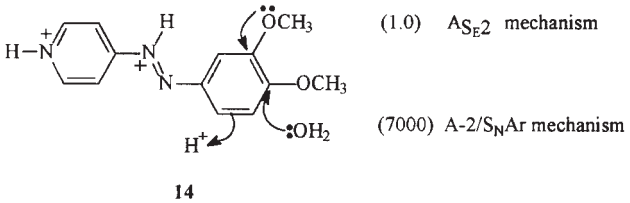
Scheme 13.



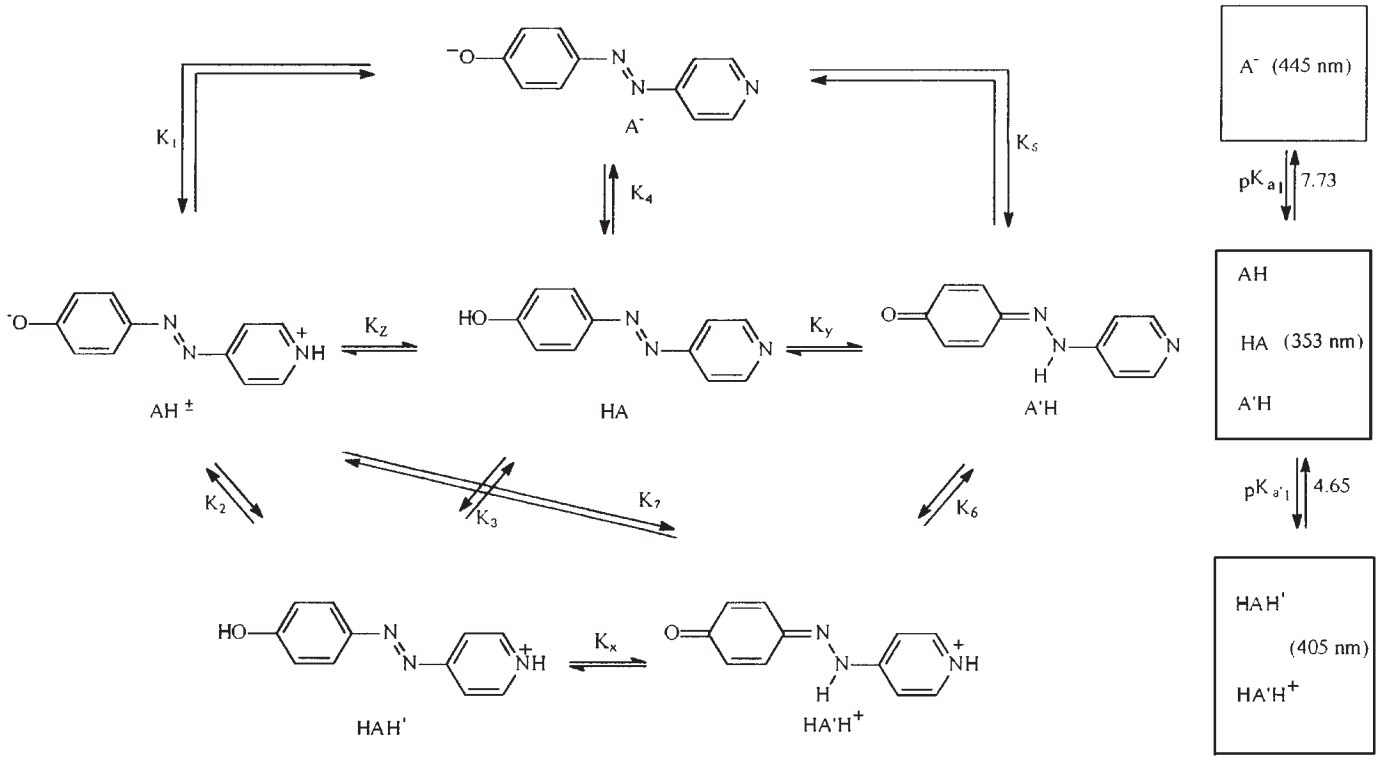
[2]

The first observation was that *p*-methoxyphenylazopyridine **13** undergoes facile hydrolysis in acid media (46) (eq. [2]).

The rate profile exhibited a maximum as a function of percent H_2SO_4, reminiscent of A-2 reactions. One can also view this as an S_NAr process where nucleophilic attack is activated by the protonated azo- and pyridyl-functionality, as illustrated in Scheme 12 (47).

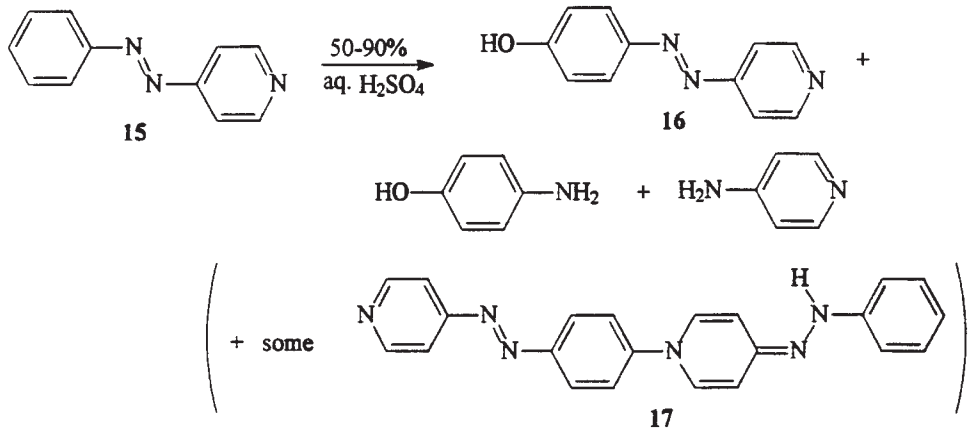
It was of interest to examine the reactivity of a second methoxy group, in the *meta* position, which is not positioned properly with respect to the protonated azopyridyl moiety for the S_NAr mechanism. In fact, the *meta* methoxy group in **14** reacts very much more slowly, with a ratio of 1:7 000 compared with the *para* methoxy group. However, even more interestingly, the Cox–Yates method of analysis showed that the slower reaction followed an A-S_E2 mechanism, i.e., rate-determining proton transfer on the aromatic ring as shown in Scheme 13 (47). The methoxy group activates the aromatic ring towards protonation, which is followed by fast reaction with H_2O and expulsion of methanol concurrent with rearomatization.

The next model compound examined, phenylazopyridine, gave some totally unexpected results which led us to a new facet of the benzidine rearrangement.



14

5. The benzidine rearrangement and disproportionation of phenylhydrazopyridine



Phenylazopyridine (**15**), when examined spectrophotometrically in acid media was found to be unstable, undergoing hydroxylation to *p*-hydroxyphenylazopyridine (**16**). Chromatographic product analysis showed that the *p*-hydroxyphenylazopyridine is not the sole product, being formed only

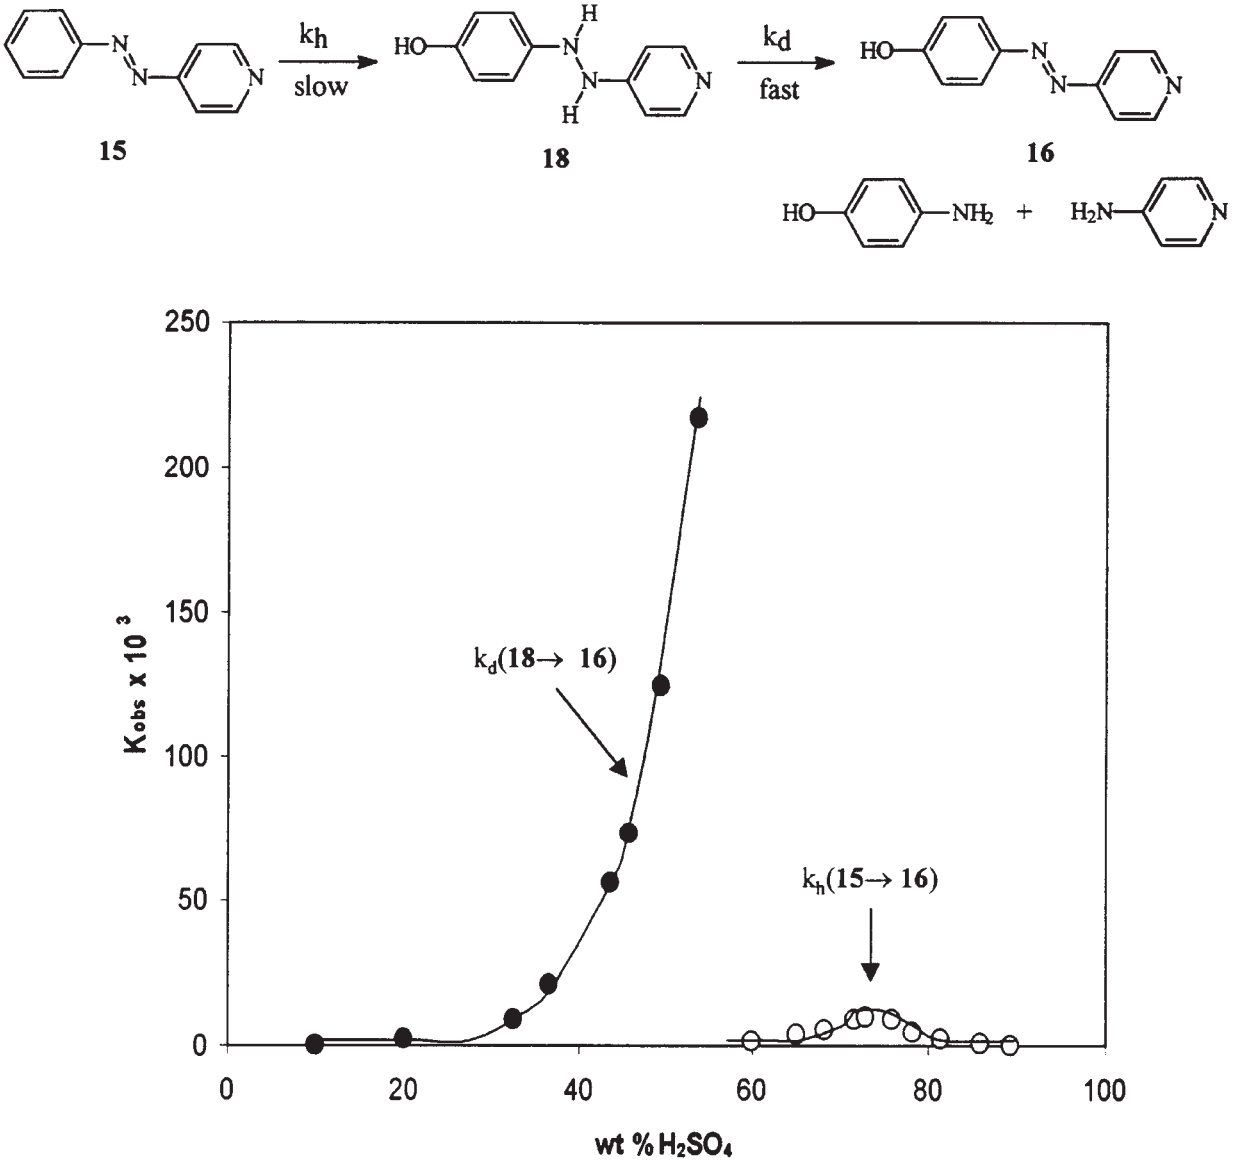
Scheme 14.



in ca. 45% yield, with *p*-aminophenol and *p*-aminopyridine in 45% yield, while a small amount (5–10%) of a dimeric product, **17**, whose structure was eventually established by NMR and MS, was also obtained (Scheme 14). Disregarding for the moment the latter, it was apparent that a *disproportionation* was occurring, one molecule of reactant being oxidized and another reduced. It is recalled that a similar disproportionation occurs in parallel with the benzidine rearrangement in which hydrazobenzene reacts in acid media to give a variety of products including those from disproportionation (Scheme 1). The classic work of Ingold (11, 48), Banthorpe (49), Shine (10), Olah et al. (38), Bunton and Rubin (51), Dewar (52), Hammond and Claris (53), Vecera (54), Lupes (55), and others (56) revealed different facets of this fascinating intramolecular process, proceeding via 1- and 2-proton pathways.

One could then propose the hypothesis illustrated in Scheme 15, that the overall hydroxylation in our system occurs in two steps: the hydrazo species **18** is formed as an intermediate in a slow step, to be followed by fast disproportionation to products. Accordingly, when the authentic hydrazo compound was subjected to a kinetic and product

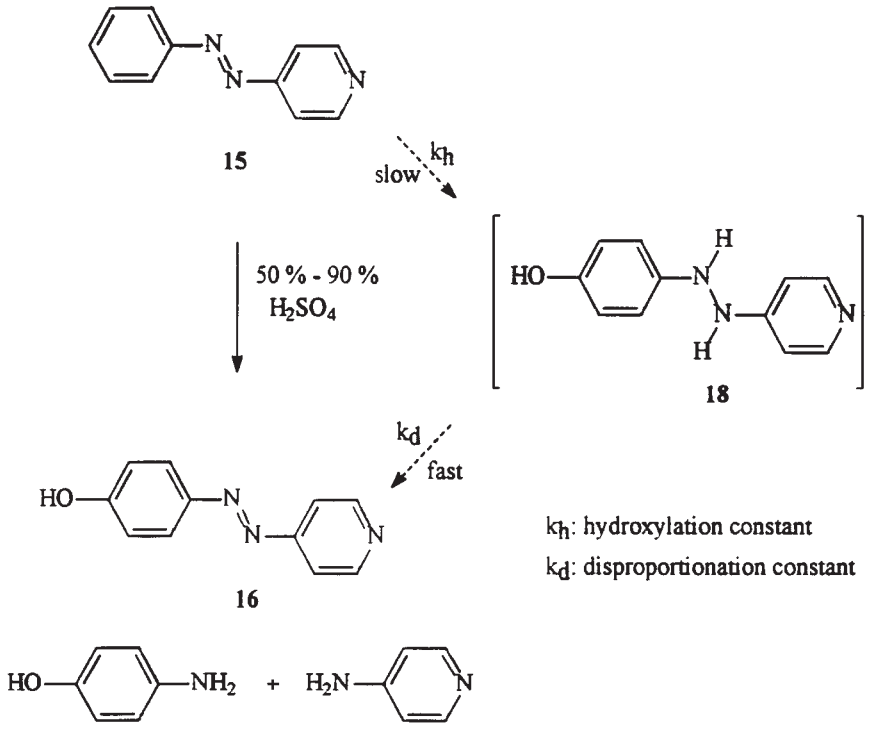
Fig. 4. Kinetic behaviour as function of acid concentration of phenylazopyridine and *p*-hydroxyphenylhydrazinopyridine.

analysis study, it was found, indeed, to give the same products of disproportionation as when starting with phenylazopyridine, confirming the validity of Scheme 15 (57).

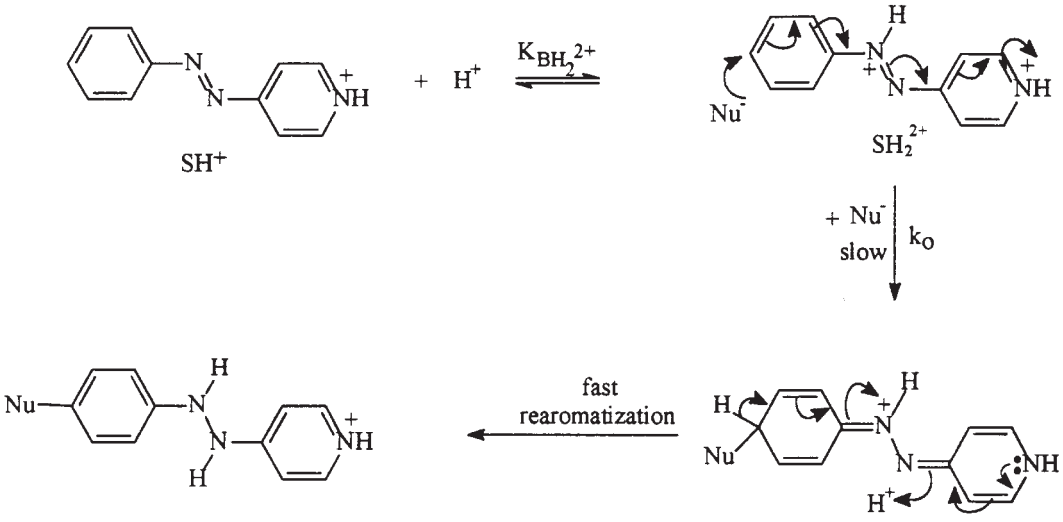
A plausible mechanism for formation of the hydrazo compound can be proposed, as shown in Scheme 16, i.e., nucleophilic attack of solvent on the activated protonated substrate followed by tautomerization.

The kinetic behaviour for the two processes, hydroxylation and disproportionation, as a function of acid concentration is shown in Fig. 4. The disproportionation of the hydrazo compound **18** occurs readily in the 10–50% H_2SO_4 region and is very fast relative to the hydroxylation of phenylazopyridine **15** for which much higher acidities are required.



One can now construct a potential energy diagram for these processes (58). As illustrated in Fig. 5, the disproportionation **18** → **16** which occurs in the dilute acid regime is energetically much less demanding than the hydroxylation process **15** → **18** which requires concentrated acid. Thus the hydrazo species **18** becomes a transient intermediate in the **15** → **16** process at the higher acidities.

It then occurred to us to go one step back; that if the hydroxyphenylhydrazopyridine **18** undergoes this disproportionation, then so should also the parent unsubstituted phenylhydrazopyridine **19**, for which one anticipates the reaction sequence **19** → **15** → **18** → **16.** Accordingly, phenylhydrazopyridine was prepared and subjected to kinetic study. In the dilute acid region, the disproportionation **19** → **15** followed similar kinetic behaviour as **18** → **16**, though somewhat slower. As before, **19** undergoes slow hydroxylation to 4-hydroxyphenylazopyridine **16**, for which a higher acid concentration is required. Also in the high acid concentration regime, the **19** → **16** rate is indistinguishable from the **15** → **16** rate. The various kinetic processes are included in Fig. 6.

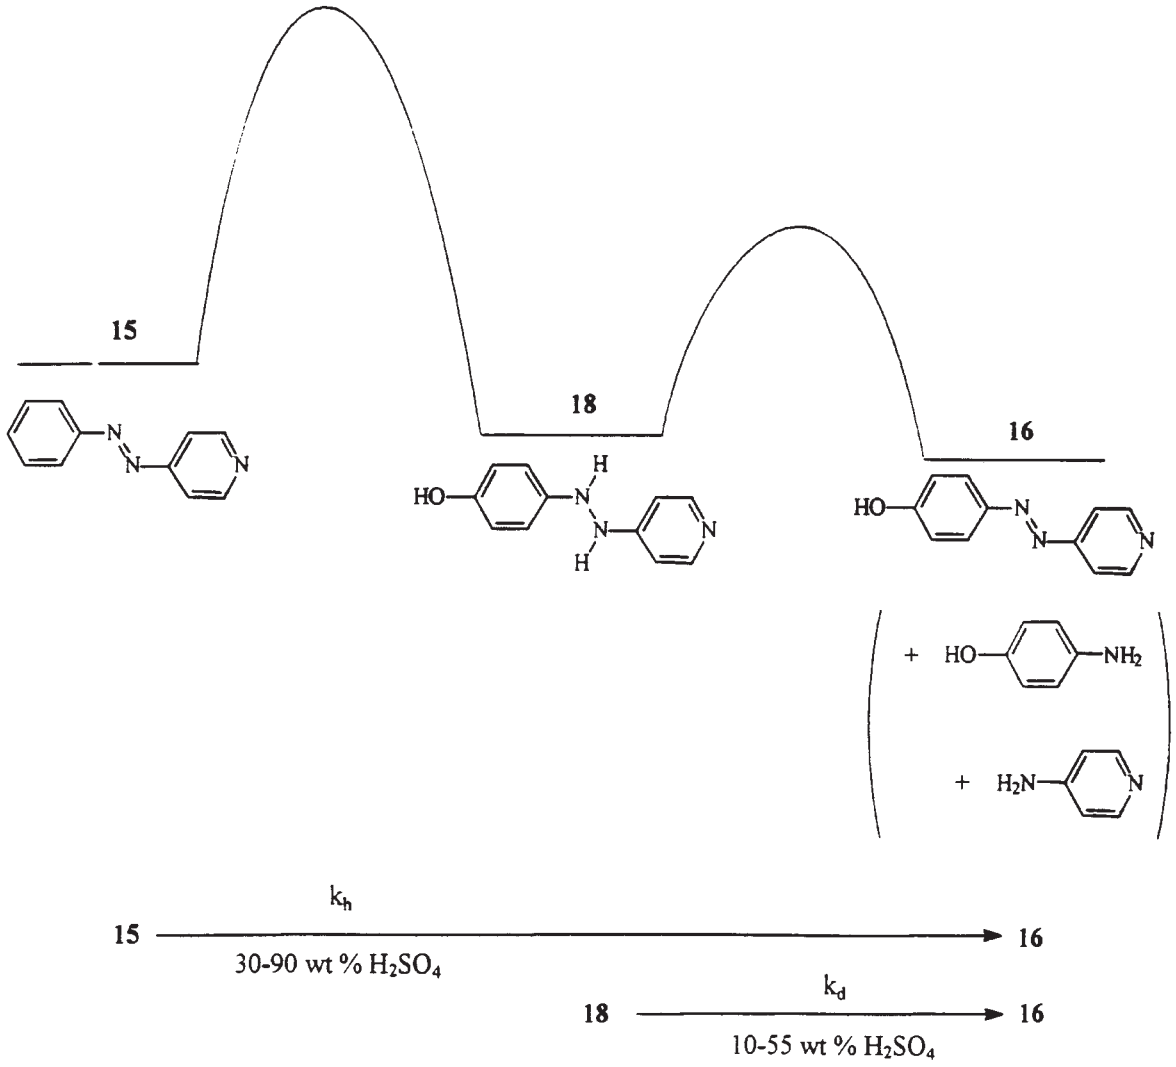


A complete energy profile could then be constructed (Fig. 7) to include the family of azo and hydrazo dyes, starting from **19** going to **15** by disproportionation, then to **18** through

© 2000 NRC Canada

Scheme 15.

Scheme 16.



hydroxylation, and finally its disproportionation to **16** (i.e., an A → B → C → D process).

Clearly, Fig. 7 represents a finely balanced series of processes — a cascade — in which some intermediates may be transient under given conditions. For example, **18** is an unobservable, transient intermediate in the reaction **15** → **16** or **19** → **16** in the high acid regime. On the other hand, with **19** as the reactant in the high acid concentration regime, there is an immediate formation of **15** followed by its slow transformation to **16**.

The benzidine rearrangement has been a prolific area of study for over 100 years, and a number of different mechanisms have been proposed (10, 48–59) to account for the variety of products and the unusual kinetic features. The currently most widely accepted mechanism is that due to Henry Shine and his co-workers (50) and this can be nicely adapted to the present system, as shown in Scheme 17. Essentially, there is depicted a rate-determining step involving a thermally allowed 10-electron electrocyclic reaction of the diprotonated substrate giving rise to intermediate **20** which reacts with another molecule of protonated substrate in a thermally allowed 14-electron electrocyclic process to give the observed products of disproportionation. In the case of hydrazobenzene itself, this intermediate would simply rearomatize to

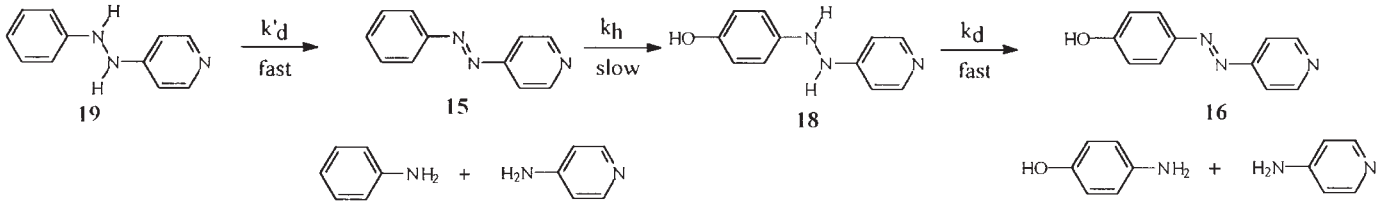
Fig. 5. Energy profiles for the hydroxylation and disproportionation reactions of phenylazopyridine and *p*-hydroxyphenylhydrazinopyridine.

the biphenyl product but this is not possible with the pyridine system (or with 4,4′-disubstituted hydrazobenzenes) so disproportionation results.

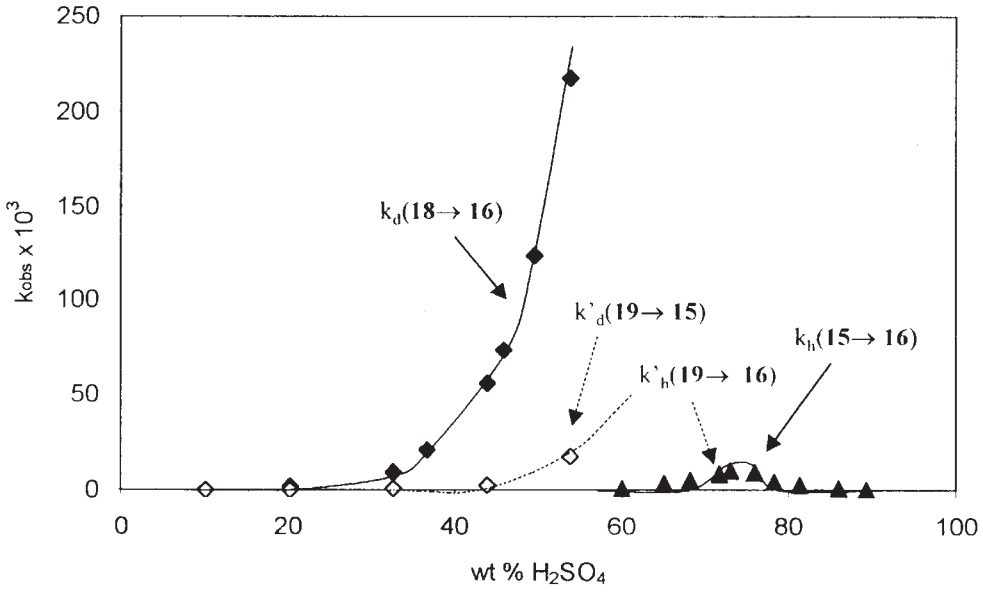
The rate equation applicable to the mechanism in Scheme 17 is given by eq. [3]:

$$[3] \quad \log k_\psi - \log (C_{BH_2^{++}}/(C_{BH^+} + C_{BH_2^{++}})) = \log k_o + (m^{\#} - 1)m^* X$$

which correlates the rate constant k_ψ with the excess acidity X. The plot corresponding to eq. [5] is shown in Fig. 8 where PCT is the correction factor for partial protonation. The figure includes results for the *p*-chlorosubstituted substrate, also shown in Scheme 17; clearly a satisfactory correlation is obtained. Other possible mechanisms have been considered as well but could not satisfy the observations (59).



At the outset of this section it was stated that a dimeric product, **17**, was formed in the disproportionation reaction, to a maximum of 10% depending on conditions — acidity and substrate concentration. The mechanism favored for formation of the dimer is shown in Scheme 18 for the *p*-chloro system and involves nucleophilic attack of the pyridino-nitrogen on the *para* carbon of a second molecule of substrate followed by loss of Cl^-. On this basis, dimerization would become less important as the acidity increases since the probability of having an unprotonated pyridine nitrogen present descreases with increasing acidity and, being bimolecular, the reaction would only occur to a detectable extent at the higher substrate concentrations used for the product analysis but not under the kinetic conditions. This is in accord with experimental observations (59).



Ackowledgements

I am deeply indebted to a number of co-workers who over the years have worked with me on the related projects described here and without whom none of this would have been possible. The individuals concerned are: B.T. Lawton, W.M.J. Strachan, A. Dolenko, K. Mahendran, S. Rajagopal, S.-R. Keum, K.-S. Cheon, K.-T. Park, J. Wojtyk, M.A.A. Ghani, A. Wasey, I. Onyido, and R.A. Cox. Grateful

Thermodynamics of mixtures with strongly negative deviations from Raoult's law. Part 3. Application of the DISQUAC model to mixtures of triethylamine with alkanols. Comparison with Dortmund UNIFAC and ERAS results

Juan Antonio González, Isaias Garcia de la Fuente, and Jose Carlos Cobos

Abstract: Binary mixtures of triethylamine (TEA) and alkanols have been investigated in the framework of DISQUAC. The systems are built by three contacts: aliphatic–hydroxyl, aliphatic–nitrogen, and hydroxyl–nitrogen. The corresponding interaction parameters are reported and discussed. The former are avalilable in the literature but were modified (particularly the third dispersive (DIS) and quasichemical (QUAC) interchange coefficients) for *sec*- and *tert*-alkanols + *n*-alkanes using recent data on excess heat capacities at constant pressure (C_p^E) for systems of these alkanols with *n*-heptane. The interaction parameters for aliphatic–nitrogen contacts are purely dispersive. The structure dependence of the DIS and QUAC interchange coefficients of the hydroxyl–nitrogen contacts in 1-alkanols + TEA systems is similar to that found in other solutions previously investigated. The QUAC interchange coefficients remain constant from ethanol and are also valid for 2-alkanols and *tert*-butanol. Methanol behaves differently. A short discussion in terms of effective dipole moments is also included. DISQUAC represents well the thermodynamic properties examined: vapor-liquid equilibria (VLE), molar excess Gibbs energies (G^E) and molar excess enthalpies (H^E). DISQUAC provides better results than the Dortmund version of UNIFAC using the published geometrical and interaction parameters. ERAS parameters for 1-alkanols + TEA systems are also reported. Interactions between unlike molecules are stronger for solutions with methanol or ethanol. DISQUAC improves ERAS results on H^E, while both models give similar results for G^E. However, ERAS needs an specific parameter, with unknown temperature-dependence, to describe properly G^E. The main advantage of ERAS is its ability to provide information on V^E. Its main limitation is that can be only applied to those systems where association is expected. DISQUAC, a purely physical model, can be applied to any type of binary mixture, as it is followed from this and previous studies.

Key words: theory, liquids, associated, thermodynamics, group contributions.

Résumé : On a étudié des mélanges binaires de triéthylamine (TEA) et d'alkanols dans le cadre du DISQUAC. On a construit les systèmes par trois contacts : aliphatique–hydroxyle, aliphatique–azote et hydroxyle–azote. On rapporte et on discute des paramètres d'interaction correspondants. Les premiers sont disponibles dans la littérature, mais on les a modifiés [en particulier, les troisièmes coefficients d'échange dispersifs (« DIS ») et quasichimiques (« QUAC »)] pour les alcanols (secondaires et tertaires) + alcanes en utilisant des données récentes sur les capacités calorifiques en excès à pression constante (C_p^E) pour les systèmes de ces alcanols dans l'heptane. Les paramètres d'interaction pour les contacts aliphatique–azote sont strictement dispersifs. La relation entre la structure et les d'échange « DIS » et « QUAC » pour les systèmes alcan-1-ols + TEA sont semblables à ceux observés avec d'autres systèmes étudiés antérieurement. Les coefficients d'échange « QUAC » demeurent constants à partir de l'éthanol et ils sont aussi valides pour la alcan-2-ols et pour le *tert*-butanol. Le méthanol se comporte différemment. On inclut aussi une courte discussion en termes des moments dipolaires effectifs. Le modèle « DISQUAC » permet de bien représenter les propriétés thermodynamiques examinées : équilibre vapeur-liquide (EVL), énergies molaires de Gibbs en excès (G^E) et les enthalpies molaires en excès (H^E). Il donne de meilleurs résultats que la version de Dortmund de l'« UNIFAC » en utilisant les paramètres géométriques et d'interaction publiés. On rapporte aussi les paramètres « ERAS » pour les systèmes alcan-1-ols + TEA. Les interactions entre les molécules dissemblables sont plus fortes pour des solutions avec du méthanol ou de l'éthanol. La méthode « DISQUAC » améliore les résultats « ERAS » pour H^E alors que les deux modèles conduisent à des résultats semblables pour G^E. Toutefois, « ERAS » nécessite un paramètre spécifique, pour lequel on ne connaît pas la relation avec la température qui permettrait de décrire correctement G^E. Le principal

avantage de « ERAS » réside dans sa facilité de fournir des informations sur V^E. Sa principale limitation a trait au fait qu'on ne peut l'appliquer qu'aux systèmes où on prévoit des associations. Comme il en découle de la présente étude et des autres faites antérieurement, « DISQUAC » est un modèle purement physique qui peut être appliqué à tous les types de systèmes binaires.

Mots clés : théorie, liquides, associés, thermodynamique, contributions de groupes.

1 Introduction

Alkanols and TEA are polar compounds which differ substantially in their permanent dipole moment (μ) and consequently also in their effective dipole moment ($\bar{\mu}$ (Table 1)) a useful magnitude to investigate the impact of polarity in bulk properties (1–6). It is defined as (5)

$$[1] \qquad \bar{\mu} = [\mu^2 N_A / 4\pi\varepsilon_0 V k_B T]^{1/2}$$

where N_A is the Avogadro's constant; ε_0, the permittivity of the vacuum; k_B, the Boltzmann's constant; V, the molar liquid volume; and T, the temperature.

In exchange, for the purpose of characterizing the effective polarity of a a single, isolated molecule with a given μ, it is defined a reduced dipole moment according to (3–5)

$$[2] \qquad \hat{\mu} = [\mu^2 / 4\pi\varepsilon_0 \sigma^3 \varepsilon]^{1/2}$$

where σ is an appropiate molecular size parameter, and ε the corresponding interaction energy parameter. This expression may advantageously be transformed by virtue of the corresponding states principle to

$$[3] \qquad \mu^* = [\mu^2 N_A / 4\pi\varepsilon_0 V_c k_B T_c]^{1/2}$$

$$[4] \qquad (\hat{\mu})' = [\mu^2 P_c / 4\pi\varepsilon_0 k_B^2 T_c^2]^{1/2}$$

Here V_c, T_c, and P_c are the critical values of molar volume, temperature, and pressure, respectively.

In the case of 1-alkanols + TEA mixtures, thermal and volumetric data (7–11) are indicative of strong intermolecular interactions between unlike molecules (negative deviations from Raoult's law) through the formation of hydrogen-bonded complexes. This may be related to amines (primary, secondary, tertiary, and aromatic) are good proton acceptors because the electrons around the N atoms have less *s* and more *p* character than in other groups (e.g., nitrile or carbonile groups) (12, 13).

DISQUAC (14, 15) a purely physical model based on the rigid lattice theory developed by Guggenheim (16) has been successfully applied to the characterization of other binary liquid mixtures which also show strong negative deviations from Raoult's law (1, 17) (parts I and II of this series). Particularly, the systems investigated so far are: methanol or ethanol with propanal (17), *n*-alkanones with $CHCl_3$ (17); or oxaalkanes (linear or cyclic) with $CHCl_3$ or CH_2Cl_2 (1). It is remarkable that DISQUAC and different continuous association models yield similar results for such systems (17). As a continuation, we now present the DISQUAC treatment of TEA + alkanols mixtures.

A systematic comparison between DISQUAC calculations and predictions from the Dortmund version of UNIFAC model (18) (hereafter, merely UNIFAC) is shown. At this end, the corresponding published geometrical and interaction parameters were used without modification (18).

Mixtures containing 1-alkanols and TEA have been studied (19, 20) in terms of the ERAS (21) model, which combines the real association solution model (22–25) with a physical term, namely the Flory's equation of state (26). In (19), the equation which represents the chemical contribution to V^E was incorrectly written (27), and solutions of

OH	0.46963	0.50345	(32)

methanol and TEA were not considered. So, here new ERAS parameters for 1-alkanols + TEA mixtures are reported.

Finally, it should be mentioned that the UNIQUAC associated solution model (28), which uses the UNIQUAC equation (29) to describe the physical contribution to the excess functions has been also applied to the 1-propanol + TEA system (28).

2. Theory

2.1 Disquac

In the framework of DISQUAC, mixtures of alkanols with TEA are regarded as possessing three types of surfaces: (*i*) type a, (aliphatic: CH_3, CH_2, CH, or C in alkanols or TEA); (*ii*) type n (nitrogen, N, in TEA); (*iii*) type h (hydroxyl, OH, in alkanols)

2.1.1 Assessment of geometrical parameters

When DISQUAC is applied, the total relative molecular volumes (r_i) surfaces (q_i) and the molecular surface fractions (α_{si}) of the compounds present in the mixture are usually calculated additively on the basis of the group volumes V_G and surfaces A_G, recommended by Bondi (1968) (30). As volume and surface units, the volume V_{CH_4} and surface A_{CH_4} of methane are taken arbitrarily (31). The geometrical parameters of the groups referred to in this work are listed in Table 2.

2.1.2 Equations

The equations used to calculate G^E and H^E are the same as in other applications (32). The interactional terms in the excess thermodynamic properties G^E and H^E contain a DIS and a QUAC contribution which are calculated independently by the classical formulas and then simply added. The degree of non-randomness is thus expressed by the relative amounts of dispersive and quasichemical terms

$$[5] \qquad G^E = G^{E,COMB} + G^{E,DIS} + G^{E,QUAC}$$

$$[6] \qquad H^E = H^{E,DIS} + H^{E,QUAC}$$

where $G^{E,COMB}$ is the Flory–Huggins combinatorial term (31, 33).

For the QUAC part, as coordination number the reference value was chosen, that is $z = 4$.

The temperature dependence of the interaction parameters g_{st}, h_{st}, and c_{pst} has been expressed in terms of the DIS and (or) QUAC interchange coefficients (32) $C_{st,1}^{DIS}$ and $C_{st,1}^{QUAC}$, where s, $t = a$; h, n, and $l = 1$ (Gibbs energy; $C_{st,1}^{DIS/QUAC} = g_{st}^{DIS/QUAC}(T_0)/RT_0$); $l = 2$ (enthalpy; $C_{st,2}^{DIS/QUAC} = h_{st}^{DIS/QUAC}(T_0)/RT_0$) and $l = 3$ (heat capacity; $C_{st,3}^{DIS/QUAC} = c_{pst}^{DIS/QUAC}(T_0)/R$).

$T_0 = 298.15$ K is the scaling temperature.

2.2 Modified UNIFAC (Dortmund version)

Modified UNIFAC (18) differs from the original UNIFAC (34) by the combinatorial term and the temperature dependence of the group interaction parameters (a_{nm}, b_{nm}, c_{nm}). This dependence is as follows

$$[7] \qquad \psi_{nm} = \exp[-(a_{nm} + b_{nm}T + c_{nm}T^2)/T]$$

The equations used to calculate G^E and H^E are obtained from the fundamental equation for the activity coefficient γ_i of component i

$$[8] \qquad \ln\gamma_i = \ln\gamma_i^{COMB} + \gamma_i^{RES}$$

where $\ln\gamma_i^{COMB}$ is the combinatorial term and $\ln\gamma_i^{RES}$ is the residual term.

2.2.1 Assessment of geometrical and interaction parameters

In modified UNIFAC, alkanols are characterized by two main groups, OH and CH_3OH. The former is subdivided in three subgroups: OH(p), OH(s), and OH(t), which represent the hydroxyl group in primary, secondary, and tertiary alcohols. CH_3OH is a group itself which characterizes methanol. Tertiary amines are characterized by the main group (C)3N, subdivided in two subgroups: CH_3N and CH_2N. The subgroups have different geometrical parameters, but the subgroups within the same main group are assumed to have identical group energy-interaction parameters. The geometrical parameters, the relative van der Waals volumes, and the relative van der Waals surfaces of the different subgroups are not calculated from molecular parameters like in the original UNIFAC but fit together with (a_{nm}, b_{nm}, c_{nm}) to the experimental values of the thermodynamic properties considered. The geometrical and interaction parameters are taken from literature (18) and used without modification.

2.3 The ERAS model

This model combines the real association solution model (22–25) with Flory's equation of state (26). The excess functions are written as

$$[9] \qquad X^E = X_{phys}^E + X_{chem}^E$$

where $X = G$ (Gibbs energy), H (enthalpy), V (volume). In eq. [9], X_{chem}^E is the chemical contribution, mainly due to association reactions, and X_{phys}^E represents the physical contribution, a consequence of the physical interactions between molecules. Correct expressions for these terms when cross-association between compounds exist are given elsewhere (27, 35, 36) for $X = H$ and V, and will not repeated here. The chemical contribution to the excess properties arises from chemical interactions between the molecules, in particular hydrogen bonding. It is assumed that TEA (B) molecules are not associated, while alcohol molecules (A) build linear chains of associated multimers

$$[10] \qquad A_n + A \xleftrightarrow{K_A} A_{n+1}$$

[a]Estimated value.

[b]The abbreviations used are: 2M-2-propanol, 2-methyl-2-propanol; 2M-2-butanol, 2-methyl-2-butanol; 2M-2-pentanol, 2-methyl-2-pentanol; 3M-3-pentanol, 3-methyl-3-pentanol;

where n is the degree of self association, ranging from 1 to ∞. The cross-association between A and B molecules is represented by

$$[11] \quad A_n + B \xleftrightarrow{K_{AB}} A_nB$$

The association constants K_i are assumed to be independent from the chain length. Their temperature dependence is given by

$$[12] \quad K_i = K_o \exp[-(\Delta h_i^*/R)(1/T - 1/T_o))$$

where K_o is the equilibrium constant at the standard temperature T_o and h_i^* is the enthalpy variation for reactions 10–11, which corresponds to the hydrogen bonds energy. Reactions 10–11 are also characterized by the volume change (Δv_i^*) which is related to the formation of the linear chains.

X_{phys}^E is derived from Flory's equation of state (26), which is assumed to be valid not only for pure components but also for the mixture

$$[13] \quad \overline{P}_i \overline{V}_i / \overline{T}_i = \overline{V}_i^{1/3}/(\overline{V}_i^{4/3} - 1) - 1/\overline{V}_i \overline{T}_i$$

where i = A, B, M(mixture). In eq. [13], $\overline{V}_i = V_i/V_i^*$; $\overline{P}_i = P/P_i^*$ and $\overline{T}_i = T/T_i^*$ are the reduced parameters, volume, pressure, and temperature, respectively. The reduction parameters for pure components V_i^*, P_i^*, and T_i^* are calculated previous determination of density, thermal expansion coefficient, and compressibility which can be obtained from experimental P-V-T data. They also depend on K_i, Δh_i^*, and Δv_i^*. The method is clearly explained elsewhere (35, 36). The reduction parameters for the mixture P_M^* and T_M^* are calculated via certain mixing rules (36–37), where X_{AB}, the energetic interaction parameter characterizing the difference of dispersive intermolecular interactions between molecules A and B in the solution and in the pure components is introduced. It is the only adjustable parameter of the physical part of H^E and V^E.

3. Estimation of models parameters

3.1 Disquac

The three types of surface generate three pairs of contacts: (a,n), (a,h) and (h,n).

3.1.1 Alkanols + n-alkane mixtures: the (a,h) contacts

In the framework of DISQUAC, primary, secondary, and tertiary alkanols differ by their interaction parameters obtained from data for alkanol + *n*-alkane systems (32, 38, 39). The respective $C_{ah,1}^{DIS/QUAC}$ coefficients change regularly with the alkanol structure (32, 38, 39). This approach has been shown to be successful in treating more complex mixtures: 1-alkanols + C_6H_6 or C_7H_8 (40), + CCl_4 (41), + linear monocarboxylic acids (42), + 1-alkanols (43), + ketones (44), or *sec*-alkanols + C_6H_6, + C_7H_8 or + ketones (45).

In this work, new values of $C_{ah,3}^{DIS/QUAC}$ for *sec*- or *tert*-alkanols were obtained on the basis of recent C_p^E data for the following systems: 2-propanol, 2-butanol, 2-pentanol, 3-pentanol, or *tert*-butanol + heptane (46). The $C_{ah,1}^{DIS/QUAC}$ coefficients for *sec*- and *tert*-alkanols are collected in Table 3. These new $C_{ah,3}^{DIS/QUAC}$ coefficients may modify interaction parameters of more complex mixtures where the (a,h) contacts are also involved. This occurs for *sec*-alkanols + cyclohexane, + C_6H_6, or + C_7H_8, or for *tert*-alkanols + cyclohexane (Tables 1 and 2 of Appendix 1). For *sec*-alkanols + ketones, the corresponding parameters remain unchanged (45).

3.1.2 N,N,N-trialkylamines + n-alkanes mixtures: the (a,n) contacts

Mixtures of tertiary amines with alkanes, particularly with homomorphic alkanes, are nearly ideal. It has been attributed

[a]Estimated values.

to physical properties of tertiary amines are close to those of the mentioned alkanes (47, 48). The very low polarity of amines, represented by small $\bar{\mu}$ values (Table 1), should be also remarked.

H^E measurements for *N*,*N*,*N*-trialkylamines + *n*-alkanes show that this magnitude depends rather strongly on the relative size of the components (49, 50). For shorter amines, TEA, tripropylamine (TPA), or tributylamine (TBA), which are globular molecules, H^E increases with the length of the *n*-alkane (49, 50). In exchange, an opposite behaviour is encountered for tridodecylamine + *n*-alkane systems (50).

These systems have been treated in the framework of the Flory theory (51). The main conclusion is that the shorter amines are order breakers of the long *n*-alkanes (Patterson effect, (52)) and that tridodecylamine is an ordered molecule and the shorter *n*-alkanes act as breakers of such order (51). This has been confirmed by H^E measurements of systems containing two *N*,*N*,*N*-trialkylamines (53).

In DISQUAC, the aliphatic–nitrogen (a,n) interactions in *N*,*N*,*N*-trialkylamines + *n*-alkane mixtures are represented by dispersive parameters which can be calculated using data on these type of solutions. The same procedure has been applied to *N*,*N*-dialkylmethylamines + *n*-alkanes (48); where the Patterson effect is of minor importance, probably due to the small degree of branching in the amines (48). Unfortunately, the available interaction parameters are not valid for *N*,*N*,*N*-trialkylamines (48).

Previous calculations show that, as a consequence of the Patterson's effect, each *N*,*N*,*N*-trialkylamine + *n*-alkane system should be characterized by its own set of interaction parameters. The same occurs in, for example, mixtures of cyclohexane (34), benzene, toluene, or CCl_4 (54) + *n*-alkanes, also studied in the zeroth approximation. For the present work, only the $C^{DIS}_{an,1}$ coefficients for TEA; TPA or TBA + *n*-C_6 are needed (see below). They were calculated using data from refs. (48–50) and are listed in Table 4.

3.1.3 Alcohols + triethylamine mixtures: the (h,n) contacts

These systems are characterized by three contacts: (a,h), (a,n) and (h,n). Because the (a,s) (s = h,n) parameters are known, only those for the (h,n) contacts must now be obtained. The general procedure applied has been explained in detail elsewhere (32, 33). Along with the fitting of the $C^{DIS/QUAC}_{hn,1}$ coefficients, the interaction parameters corresponding to TEA + *n*-hexane were used in spite of the rather different size of the other molecules involved (e.g., methanol and 1-butanol). Calculations show that the $C^{QUAC}_{hn,1}$ (l = 1, 2, 3) coefficients are not essentially affected by the $C^{DIS}_{an,1}$ values. As well the relative variation of the interaction parameters of the (h,n) contacts remains unchanged.

On the other hand, the estimation of the $C^{DIS/QUAC}_{hn,2}$ coefficients is somewhat difficult due to the lack of accurate experimental data (see the H^E values at equimolar composition from different sources in Table 9 for example). In solutions of 1-alkanols and secondary amines (e.g., dibutylamine) for example, the transition of H^E from methanol to ethanol is much steeper compared to the transition from ethanol to butanol (55, 56) (see below). The $C^{DIS/QUAC}_{hn,2}$ coefficients for 1-alkanols + TEA systems were estimated assuming that such fact is still valid, as it is suggested from measurements reported by Findlay (1961) (57).

To reduce the number of interaction parameters, it was assumed that the QUAC coefficients are common for all the alkanols. In absence of H^E data for *sec*- or *tert*-alkanols + TEA mixtures, the DIS enthalpic parameters were determined

in such way that the temperature dependence of VLE is well represented.

The calculated $C_{hn,1}^{DIS/QUAC}$ coefficients are listed in Table 4.

3.2 Estimation of the adjustable ERAS parameters

The parameters adjustable to excess properties are K_A, K_{AB}, Δh^*_A, Δh^*_{AB}, Δv^*_A, Δv^*_{AB}, X_{AB}, and Q_{AB} (needed to represent G^E (37, 58–63)). K_A, Δh^*_A, Δv^*_A are known for all alcohols and are fitted to H^E and V^E data of alcohol + alkane mixtures. The values used in this work are listed in Table 5. It is remarkable that Δh^*_A = –25.1 kJ mol^{-1} and Δv^*_A = –5.6 cm^3 mol^{-1} are values widely used (see 37, 58–63). On the contrary, in (20), Δv^*_A = –7.6 cm^3 mol^{-1} was applied.

The remaining parameters K_{AB}, Δh^*_{AB}, Δv^*_{AB}, X_{AB}, and Q_{AB} are adjusted to H^E, V^E, and VLE data of 1-alkanols + TEA systems. More details are given in literature (35, 37, 58–61). Final parameters are listed in Table 6. It is remarkable that the relative variation of Δh^*_{AB} with the size of the alcohol is similar to that found in 1-alkanols + primary amines systems (35).

4. Results

4.1 Comparison of DISQUAC with experiment

The new DIS and QUAC coefficients for hydroxyl–aliphatic contacts in *sec*- or *tert*-alkanols + *n*-alkanes mixtures improve results for the thermodynamic properties usually considered, G^E, H^E, C_p^E. So, the shape of C_p^E for 2-propanol or *tert*-butanol + *n*-C_7 systems is well represented (Fig. 1). The model also predicts a small region, at very high dilution of the alkanol, where $C_p^E < 0$ for mixtures of 2-butanol, 2-pentanol, or 3-pentanol with *n*-C_7. However, these systems show a point of inflection in the mole fraction range of alcohol >0.1 (46), which are not reproduced by the model.

Regarding alkanols + TEA mixtures, experimental data are compared to results obtained using DISQUAC along Tables 7–9, and shown graphically, for selected systems, in Figs. 2–7.

For the sake of clarity, Table 7 includes standard relative deviations in pressure (P) defined as

$$[14] \quad \sigma_r(P) = \{1/N \sum[P_{exp} - P_{calc}) / P_{exp}]^2\}^{1/2}$$

© 2000 NRC Canada

Fig. 1. C_p^E of alkanols + *n*-heptane mixtures at 298.15 K. Solid lines, DISQUAC results. Points, experimental data (46): (●), 2-propanol; and (▲), *tert*-butanol.

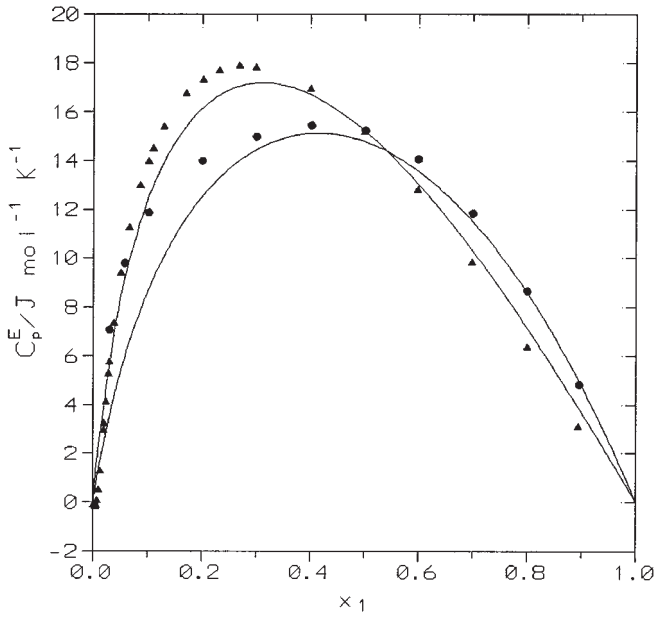

Fig. 2. VLE phase diagrams for methanol(1) or ethanol(1) + TEA(2) mixtures at several temperatures. Solid lines, DISQUAC results. Points, experimental results: (●), methanol (T = 313.15 K) (82); (■), ethanol (307.95 K) (82); and (▲), ethanol (322.75 K) (83).

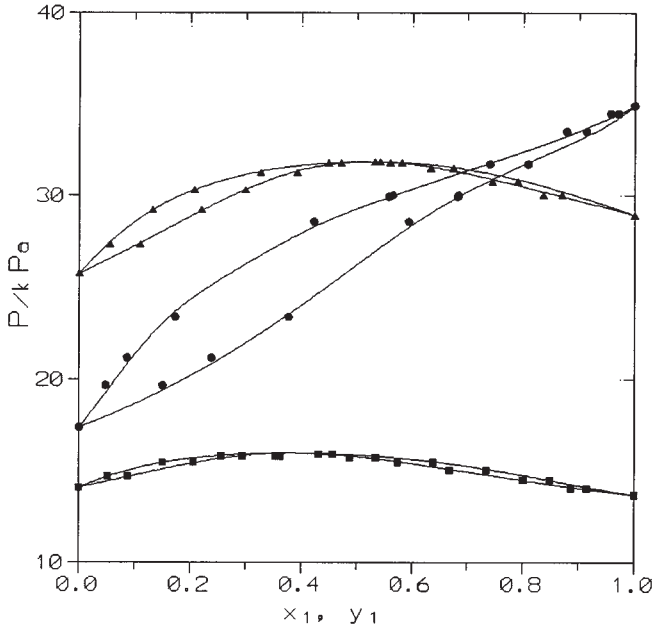

Table 9 lists the standard deviation for H^E:

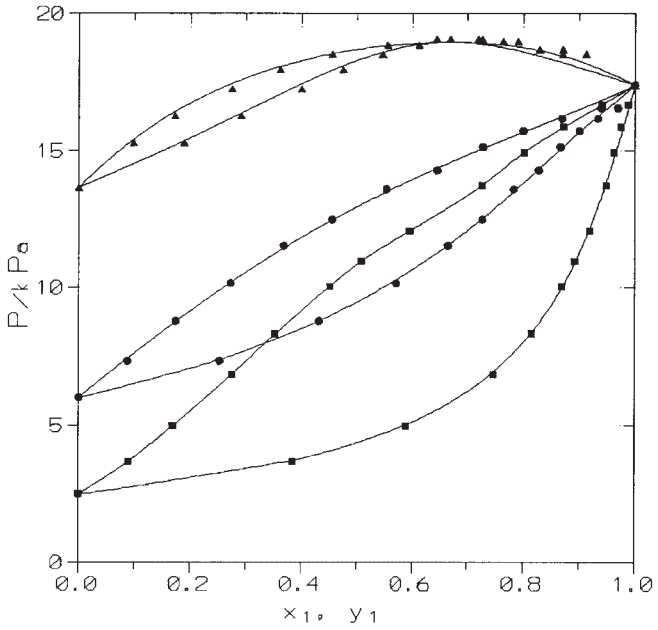
$$[15] \quad \sigma(H^E) = [1/N \sum H^E_{exp} - H^E_{calc})^2]^{1/2}$$

In eqs. [14] and [15], N is the number of data points of each system. In view of the results, one can conclude that DISQUAC represents well the thermodynamic properties of the systems investigated over a rather wide range of temperature.

Fig. 3. VLE phase diagrams at 313.15 K for TEA(1) + butanols(2) mixtures. Solid lines, DISQUAC results. Points, experimental results (85): (■), 1-butanol; (●), 2-butanol; and (▲), *tert*-butanol



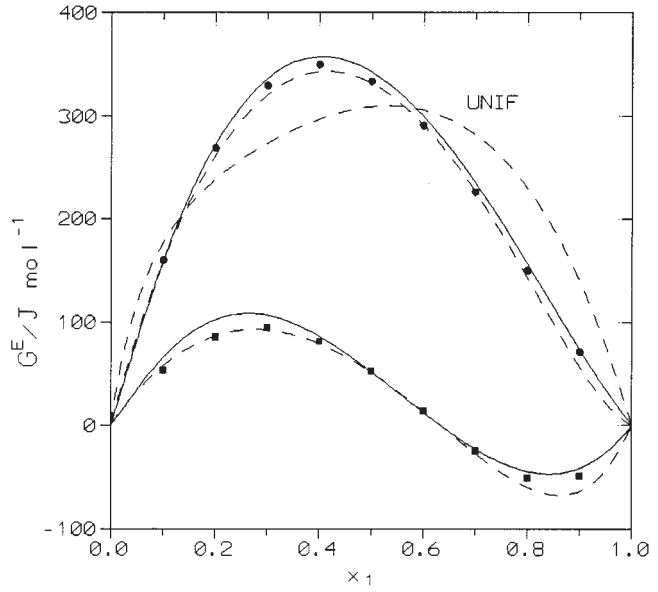


Fig. 4. G^E at several temperatures for 1-alkanols(1) + TEA(2) mixtures. Points, experimental data: (●), ethanol (307.95 K) (82) and (■), 1-propanol (293.15 K) (84). Solid lines, DISQUAC results; dashed lines, ERAS calculations or UNIFAC results with parameters from literature (18) for the system with ethanol.

4.2 Comparison between the DISQUAC and the UNIFAC models

This comparison is presented in detail in Tables 7–9 (see also Figs. 4–6). DISQUAC provides better results. The temperature dependence of the thermodynamic properties considered here is not well reproduced by UNIFAC, which predicts a decreasing of H^E when T increases. An opposite behaviour is expected, as it occurs in other similar systems.

[d]Calculated with $Q_{AB} = 0$.

It is interesting to compare results for mixtures containing methanol, considered in UNIFAC as a main group with interaction parameters which differ from those of other alcohols (18). So, both models are applied in a similar way. In the case of methanol, we note that UNIFAC does not represent simultaneously G^E and H^E (Tables 7–9). The use of the UNIFAC parameters lead, at low temperatures to erroneous results (Table 7, (18)). This may be due to the applied database in the determination of the UNIFAC parameters does not cover a wide enough range of temperature as to obtain six interaction parameters.

4.3 Comparison between DISQUAC and ERAS models

This comparison is shown in Tables 7 and 9 and Figs. 4–6. ERAS properly describes G^E while the results of H^E are improved by DISQUAC. ERAS can provide information on V^E

[b]Eq. [15].

[c]System used in the fitting of the interaction parameters.

(Fig. 7), which is its main advantage. The more important limitations are:

(*i*) The temperature dependence of properties of pure compounds is needed to determine the temperature dependence of thermodynamic properties.

(*ii*) The problems to simultaneously represent VLE and LLE for 1-alkanols + alkanes mixtures have been already underlined (37); and although $Q_{AB} = 0$ has been used to predict VLE for such systems (59), here Q_{AB} is needed to obtain an accurate representation of G^E (Table 7).

(*iii*) ERAS is only applicable to those systems where association is expected.

It should be mentioned that the ERAS parameters obtained in this work for 1-alkanols + TEA systems (Table 6) are valid only for such type of mixtures. While the Δh^*_{AB} and Δv^*_{AB} parameters are probably common to solutions with 2-alkanols, as it occurs for $\Delta h^*_A = -25\,100$ J mol^{-1} and $\Delta v^*_A = -5.6$ cm mol^{-1} in the case of alkanols + *n*-alkanes (58, 61), experimental data are needed to calculate K_{AB} and X_{AB}.

5. Discussion

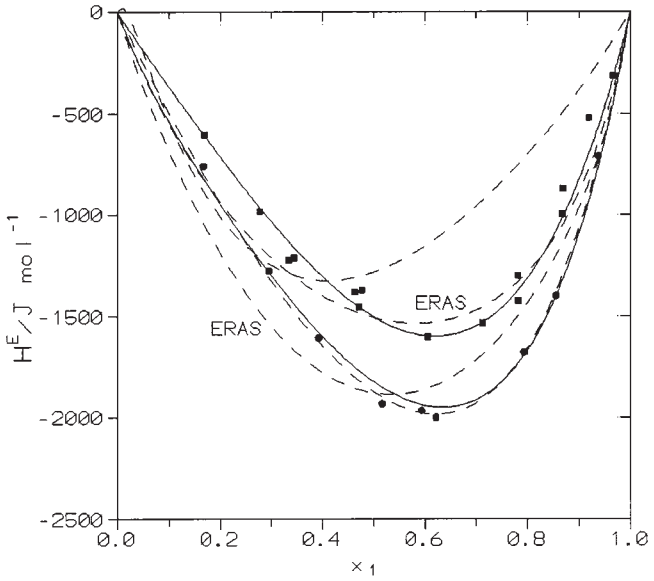
5.1 The effect of increasing the chain length of the alcohol for a given amine

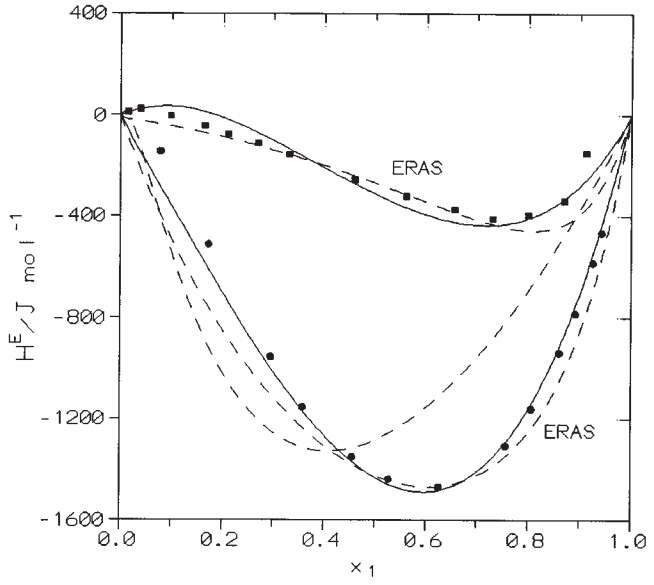
The $\bar{\mu}$ of alcohols decreases (Table 1) and consequently also the alcohol–alcohol interactions in the condensed phase in the sequence methanol > ethanol > … > decanol.

It seems that the H^E transition from methanol to ethanol is much steeper compared to the transition from ethanol to

© 2000 NRC Canada

Fig. 5. H^E at 298.15 K for 1-alkanols(1) + TEA(2) mixtures. Points, experimental data: (●), methanol (8) and (■), ethanol (57). Solid lines, DISQUAC calculations; dashed lines, ERAS results or UNIFAC calculations with parameters from literature (18).





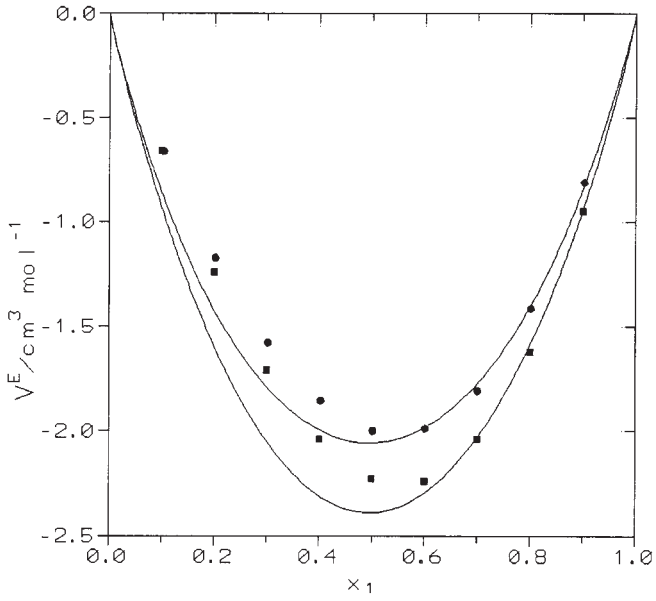


Fig. 6. H^E at 298.15 K for 1-propanol(1) + *N*,*N*,*N*-trialkylamines(2) mixtures. Points, experimental data: (●), TEA (20) and (■), TPA (71). Solid lines, DISQUAC calculations; dashed lines, ERAS results, or UNIFAC calculations for the system with TEA using parameters from literature (18).

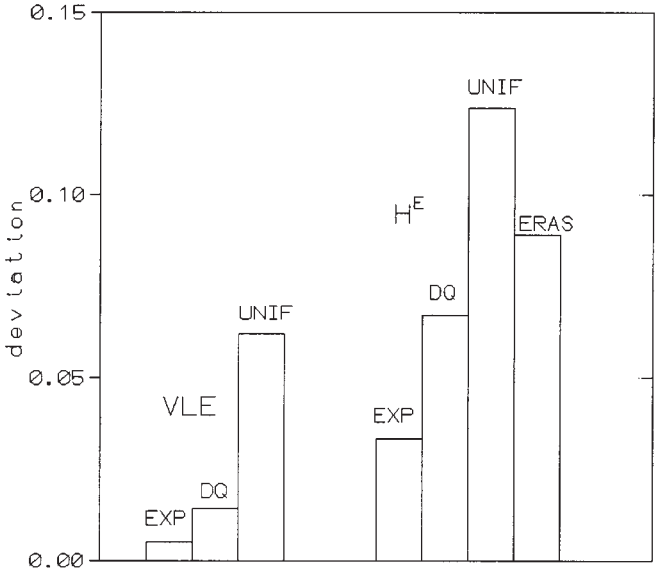
1-butanol (Table 9). Therefore it occurs, for example, in mixtures of methanol, ethanol, propanol, or butanol with propyl or butylamine (35). Systems of 1-alkanols and secondary amines (55, 56), pyridines (64, 65), or polyethers (66) behave similarly. Excess volumes confirm this point (11, 67–69). Therefore interactions between methanol and TEA (or primary or secondary amines) are much stronger than with other alcohols.

Fig. 7. V^E at 298.15 K for 1-alkanols(1) + TEA(2) mixtures. Points, experimental data: (■), methanol (10) and (●), 1-propanol (20). Solid lines, ERAS results.

5.2 The effect of passing from a primary alkanol to an isomeric secondary or tertiary alkanol

When passing from 1-alkanols to 2-alkanols, it is observed that not only the μ values of isomeric alkanols are constant, but also that their $\bar{\mu}$s have similar values (Table 1). Therefore, H^E (2-alkanols) > H^E (1-alkanols), as it occurs for solvents such as ketones, C_6H_6, or C_7H_8 (45), may be due to steric hindrance to H-bond formation (45, 70), in such a way that at a given alcohol concentration fewer hydrogen bonds would be formed in 2-butanol (or *tert*-butanol) (for example) than in 1-butanol. This implies that more bonds are also broken in 2-alkanols than in 1-alkanols (46), leading to a higher value of H^E. A similar behaviour is expected for TEA as solvent (Table 9).

5.3 The effect of increasing the size of the amine for a given alcohol



In this case, $\bar{\mu}$ of the amine decreases (Table 1) indicating that amine–amine interactions in the condensed phase decrease in the sequence TEA > TPA > TBA. Hence, H^E should increase in the inverse order. However, this increase in much stronger than the expected. At 298.15 K, atmospheric pressure, and equimolar composition H^E (J mol^{-1}) = –283 for 1-propanol + TPA (71), while for 1-propanol + TEA, this value is –1413 (20). This large difference underlines the fact that steric factors play a major role in mixtures containing tertiary amines (72).

5.4 Structure dependence of the DISQUAC interaction parameters

Strictly speaking, a comparison between interchange coefficients corresponding to different OH–X contacts (X being a given group) is not possible because they depend: (*i*) on the values of the interaction parameters of the remainder contacts which build the mixture; and (*ii*) on the geometrical

Fig. 8. Comparison between mean deviations (obtained as Σ deviations/number of systems) between experimental data and calculated values from different models. For VLE, mean standard relative deviations in pressure (eq. [14]) are given. For H^E, deviations for each system are calculated as $\sigma(H^E)$ (eq. [15]) / H^E_{exp} (x = 0.5)

parameters of the molecule where the X group is placed. Nevertheless, regarding the structure dependence of our interaction parameters, some results can be highlighted:

(*a*) the $C^{QUAC}_{hn,2}$ coefficients are negative. So it occurs in other solutions which show strong negative deviations from Raoult's law (1, 17). In contrast, mixtures with positive deviations from Raoult's law are characterized by positive enthalpic QUAC parameters. This is the case, for example, of OH–CO interactions in 1-alkanols + *n*-alkanones (44) or of OH–O interactions in 1-alkanols + monooxaalkanes (73).

(*b*) In 1-alkanols + TEA mixtures, the QUAC coefficients remain constant from ethanol. Similarly it occurs in other many alcoholic solutions previously investigated (seefor example (17, 39, 44)). The different values of the interchange coefficients for methanol merely underline the different character of this alcohol (stronger self-association and higher dielectric constants (74, Table 5) when compared to the longer ones. Similar effects appear when 1-alkanols + CCl_4 systems are treated using DISQUAC (41) or the Barker's theory (75), or from the analysis of 1-alkanols + aromatic mixtures in terms of DISQUAC (40), or in the framework of the quasilattice theory (76). From the point of view of ERAS, Δh^*_{AB} is lower for methanol or ethanol than for the remainder alcohols (Table 6), indicating that interactions between unlike molecules are stronger for mixtures with these two alkanols.

(*c*) The $C^{QUAC}_{hn,1}$ coefficients in alkanols + *N*,*N*,*N*-trialkylamines are independent of both components of the mixture. So, 1-propanol + TEA, or + TPA can be represented by the same coefficients (Table 4). That is, the increase of steric factors in the system, as occurs when 2-alkanols, *tert*-butanol or TPA are present, lead to an increase of the corresponding DIS coefficients (Table 4). However, this behaviour is not general, depending on the type of mixture considered. In the framework of ERAS, note that Δh^*_{AB} (1-propanol + TEA) = –33 200 J mol^{-1} (this work, Table 6) < Δh^*_{AB} (1-propanol + TPA) = –26 600 J mol^{-1} (77). That is, interactions between the hydroxyl and nitrogen groups are weaker for the latter system.

6. Conclusions

Figure 8 summarizes results obtained using the different models considered. It is concluded that DISQUAC is an useful tool to represent alkanol + TEA mixtures. DISQUAC improves ERAS results on H^E, while both models give similar results for G^E. However, ERAS needs a specific parameter, with an unknown temperature-dependence, to properly describe G^E. The main advantage of ERAS is its ability to provide information about V^E. Its main limitation is that can be only applied to those systems where association is expected. DISQUAC, a purely physical model, can be applied to any type of binary mixture because it is followed from this and previous studies (see for example 1, 2, 17).

Synthesis of 5-alkyl- and 5-aryl-1,5-dihydro-2*H*-pyrrol-2-ones via coupling of *5*-chloro-1,5-dihydro-2*H*-pyrrol-2-ones with organometallic compounds

Kirill V. Nikitin and Nonna P. Andryukhova

Abstract: 5-Chloro-1,5-dihydro-2*H*-pyrrol-2-ones are easily alkylated at the 5-position by organomagnesium or organozinc compounds and diethyl sodiomalonate leading to corresponding 5-alkyl-1,5-dihydro-2*H*-pyrrol-2-ones in high yields.

Key words: organometallic compounds, alkylation, 1,5-dihydro-2*H*-pyrrol-2-one.

Résumé : Les réactions du sodiomalonate de diéthyle ou de composés organomagnésiens ou organozinciques avec les 5-chloro-1,5-dihydro-2*H*-pyrrol-2-ones provoquent des réactions faciles d'alkylation en position 5 qui conduisent à la formation des 5-alkyl-1,5-dihydro-2*H*-pyrrol-2-ones avec des rendements élevés.

Mots clés : composés organométalliques, alkylation, 1,5-dihydro-2*H*-pyrrol-2-one.

Substituted 5-alkyl-1,5-dihydro-2*H*-pyrrol-2-ones (**2**) are well known as herbicides and can be prepared (1) by consecutive alkylation of an amine by an α-halogenated ketone followed by acylation of the product and final intramolecular condensation. Transformation of *exo* methylene isoindolin-1-one leading to **2** (R_2 + R_2 = fused benzene ring) was documented (2). Recently, an unusual [4+1] cyclization (3) was applied in the synthesis of **2**. To produce a wider variety of **2** a general method to introduce various R_3 groups is sought. Several known examples (4) of organometallic coupling at the 5-position of tetrahydropyrrol-2-ones (pyrrolidin-2-ones) show great synthetic potential of that method but no report has been documented for the alkylation of partially unsaturated 1,5-dihydro-2*H*-pyrrol-2-ones. Since α-halogenated amides (5) and imides (6) are versatile reactants under nucleophilic conditions and in organometallic coupling (7) the substitution of chlorine for an alkyl or an aryl moiety is expected to be useful pathway leading to **2**. The addition of RMgX to substituted phthalic (8) and succinic (9) imides has been studied and may lead to methylenation as an alternative to Tebbe reaction (10).

The starting material (**1)** can be easily prepared from the corresponding 5-hydroxy (11) as well as 5-methoxy derivative. Compounds **1** are readily hydrolyzed and should be handled in dry atmosphere.

In the present study compounds **1a** (R_1 = *t*-Bu, R_2 = Me), **1b** (R_1 = $PhCH_2$, R_2 + R_2 = fused benzene ring) and **1c** (R_1 = $PhCH_2$, R_2 = Me) were subjected to coupling with R_3MX organomagnesium (R_3 = Me, R_3 = Ph), organozinc (R_3 = Me, R_3 = Ph) reagents, and diethyl sodiomalonate (R_3 = $CH(COOEt)_2$). We also carried reactions of the same organometallics with *N*-chloromethylphthalimide (6, 7) (**3**) and compared the results.

We found that compounds **1** undergo cross-coupling with organometallic reagents leading to **2** in high yields (Table 1). The difference in product yields between organomagnesium and organozinc reagents may be accounted for by the considerable CH acidity at the 5-position of **1** and formation of 5–5 coupled dipyrrolines. Indeed a blue-colored byproduct was formed in the reaction of **1b** with Grignard reagents. The coupling with R_3ZnBr may be preferable in complex cases or for sensitive substituents. Reactions with diethyl sodiomalonate proceed unexpectedly fast and lead to products **2** in high yields (Table 1).

In contrast to the coupling of pyrrolinones **1**, reactions of *N*-chloromethylphthalimide (**3**) are diverse. Substrate **3** does not react with organozinc R_3ZnBr (R_3 = Me, Ph) under ambient conditions for 10 h and can be quantitatively recovered. We found that with MeMgCl, **3** undergoes consecutive chlorine substitution and carbonyl addition to furnish **4**, and elimination of water under mild acidic treatment leads to product **5**. Reaction of **3** with phenylmagnesium chloride leads to expected product **6** (substitution and addition) and unusual by-product **7** as a result of intermolecular coupling of **6** with **3**. These processes are illustrated by Scheme 2.

In conclusion the coupling of 5-chloropyrrolinones **1** with organometallic reagents is an effective method for the preparation of 5-alkyl-, 5-ethoxycarbonylmethyl-, and 5-aryl-pyrrolin-2-ones **2**.

Experimental

Commercially available reagents and solvents were used without further purification. Melting points were measured

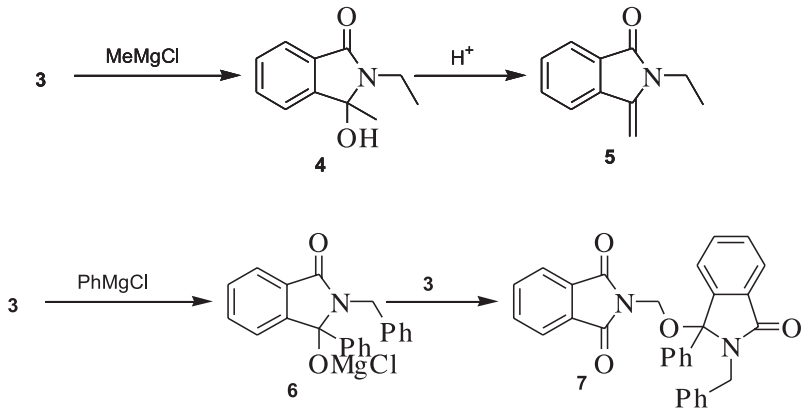
1 **2**

with a Thomas–Hoover capillary melting point apparatus and are not corrected. ^{1}H NMR specrta were recorded on a Varian GEMINI-200 with deuterochlorofom as solvent. All chemical shifts are in ppm (δ) downfield from tetramethylsilane and coupling constants are given in Hz. Mass spectra were recorded on a Shimadzu GCMS-OP 1000 mass spectrometer. FTIR spectra were recorded on a Mattson Genesis II spectrophotometer. Chromatographic separations were carried out on a silica gel column (Merck, 60 μm). Substituted 5-hydroxy and 5-methoxy-1,5-dihydro-2*H*-pyrrol-2-ones were prepared by known procedures (4, 5).



1-tert-*Butyl-5-chloro-3,4-dimethyl-1,5-dihydro-2*H-*pyrrol-2-one (**1a**)*: To a suspension of 1-*tert*-butyl-5-methoxy-3,4-dimethyl-1,5-dihydro-2*H*-pyrrol-2-one (3.94 g, 20 mmol) in hexane (40 mL), phosphorus pentachloride (4.4 g, 21 mmol) was added, and the mixture was heated under reflux for 2 h during which time PCl_5 dissolved completely. The mixture was evaporated at reduced pressure (1 torr, 1 torr = 133.322 Pa) to remove $POCl_3$ to afford **1a** (3.95 g, 98%) as a glassy solid. IR (KBr): 1681 (C=O) cm^{-1}. ^{1}H NMR ($CDCl_3$–TMS) δ: 1.55 (s, 9H), 1.78 (s, 3H), 1.99 (s, 3H), 5.94 (s, 1H). MS *m*/*z*: 201 (M^+).

*2-Benzyl-3-chloroisoindolin-1-one (**1b**)*: This compound was obtained in the same manner as described for **1a** as a glassy solid. IR (KBr): 1678 (C=O), 1439, 1065 cm^{-1}. ^{1}H NMR ($CDCl_3$–TMS) δ: 4.27 (d, 1H, *J* = 14.7 Hz), 5.40 (d, 1H, *J* = 14.7 Hz), 6.16 (s, 1H), 7.3–7.4 (m, 5H), 7.5–7.6 (m, 3H), 7.9 (d, 1H, *J* = 5.5 Hz). MS *m*/*z*: 257 (M^+).

*1-Benzyl-5-chloro-3,4-dimethyl-1,5-dihydro-2*H-*pyrrol-2-one (**1c**)*: This compound was obtained in the same manner as described for **1a** as a glassy solid. Co(II) and Mn(II) complexes of 2,2′-thiodiethanol: $[Co^{II}(2,2'\text{-thiodiethanol})_2Cl_2]$ and $[Mn(2,2'\text{-thiodiethanol})Cl_2]_n$

Yousheng Zhang, Suning Wang, Craig Bridges, and John E. Greedan

Abstract: $[Co(2,2'\text{-thiodiethanol})_2Cl_2]$ (**1**) and $[Mn(2,2'\text{-thiodiethanol})Cl_2]_n$ (**2**), have been synthesized and characterized structurally. Compound **1** is a six-coordinate, mononuclear Co(II) complex. The mononuclear units in the crystal lattice of **1** are linked together through intermolecular hydrogen bonds between hydroxy and chloride groups to form a three-dimensional array. Compound **2** consists of six-coordinate Mn(II) units that are linked by covalently bound 2,2′-thiodiethanol and chloride ligands to form an alternating one-dimensional chain, which is further linked together by inter-chain hydrogen bonds to form a two-dimensional sheet. Antiferromagnetic exchange is present in compound **2**.

Key words: cobalt, manganese, 2,2′-thiodiethanol, structure, magnetism.

Résumé : On a synthétisé les complexes $[Co(2,2'\text{-thiodiéthanol})_2Cl_2]$ (**1**) et $[Mn(2,2'\text{-thiodiéthanol})Cl_2]_n$ (**2**) et on en a caractérisé la structure. Le composé **1** est un complexe mononucléaire de Co(II) hexacoordiné. Les unités mononucléaires du réseau cristallin du composé **1** sont reliées par de liaisons hydrogènes intermoléculaires entre les groupes hydroxy et chlorure qui conduisent à la formation d'un arrangement tridimensionnel. Le composé **2** consiste d'unités Mn(II) hexacoordinées reliées par le 2,2′-thiodiéthanol attaché de façon covalente et par des ligands chlorures qui conduisent à la formation de chaînes unidimensionnelles alternantes qui sont liées entre elles par des liaisons hydrogènes interchaînes pour former un feuillet bidimensionnel. Le composé **2** donne lieu à un échange antiferromagnétique.

Mots clés : cobalt, manganèse, 2,2′-thioéthanol, structure, magnétisme.

Introduction

The construction of polynuclear metal complexes that display interesting structures and magnetic properties has been one of the research interests of our group. Previously we reported the results of our investigation on polynuclear copper(II) and cobalt(II) complexes where aminoalcohols or tetraacetylethane dianions are used as the bridging ligands (1). Recently we have been studying the syntheses and structures of polynuclear metal complexes that contain 2,2′-thiodiethanol ligands. 2,2′-Thiodiethanol has three potential binding sites, the sulfur atom and two hydroxy groups. Therefore, it can function as either a bidentate chelate ligand, a tridentate chelate ligand, or a bridging ligand. The removal of the proton from the hydroxy group can lead to additional bonding modes such as μ_2- or μ_3-bridging by the oxygen atom. Indeed our earlier study on lanthanide and copper polynuclear complexes containing 2,2′-thiodiethanol ligands confirmed the versatile bonding modes of 2,2′-thiodiethanol and its usefulness in the formation of polynuclear compounds (2). We report herein the structures and properties of a cobalt(II) complex and a Mn(II) complex of 2,2′-thiodiethanol.

Experimental

All syntheses were carried out under a dry nitrogen atmosphere by using the standard Schelenk line techniques. All chemicals and solvents used for syntheses were reagent grade. Elemental analyses were performed at Canadian Microanalytical Service Ltd. Delta, BC. Magnetic susceptibility measurements were carried out in the 4–300 K temperature range at 100 G on a SQUID magnetometer from Quantum Design.

Synthesis of $CoCl_2[S(CH_2CH_2OH)_2]_2$ (1)

200 mg of $CoCl_2 \cdot 6H_2O$ (0.73 mmol) was dissolved in 5 mL of methanol. With stirring, 10 mL of a methanol solution of 300 mg of 2,2′-thiodiethanol (excess) was added into the flask. The mixture was left stirring for one day, then concentrated to 5 mL in vacuo. Crystals of **1** were obtained under the slow diffusion of diethylether vapor into the solution with 87% yield. Anal. calcd. for $C_8H_{20}O_4S_2Cl_2Co$: C 25.68, H 5.39; found: C 25.41, H 5.19.

$^b wR_2 = [\Sigma w[(F_o^2 - F_c^2)^2] / \Sigma[w(F_o^2)^2]]^{1/2}$.

$w = 1/[\sigma^2(F_o^2) + (0.075P)^2]$, where $P = [\text{Max}(F_o^2, 0) + 2F_c^2]/3$.

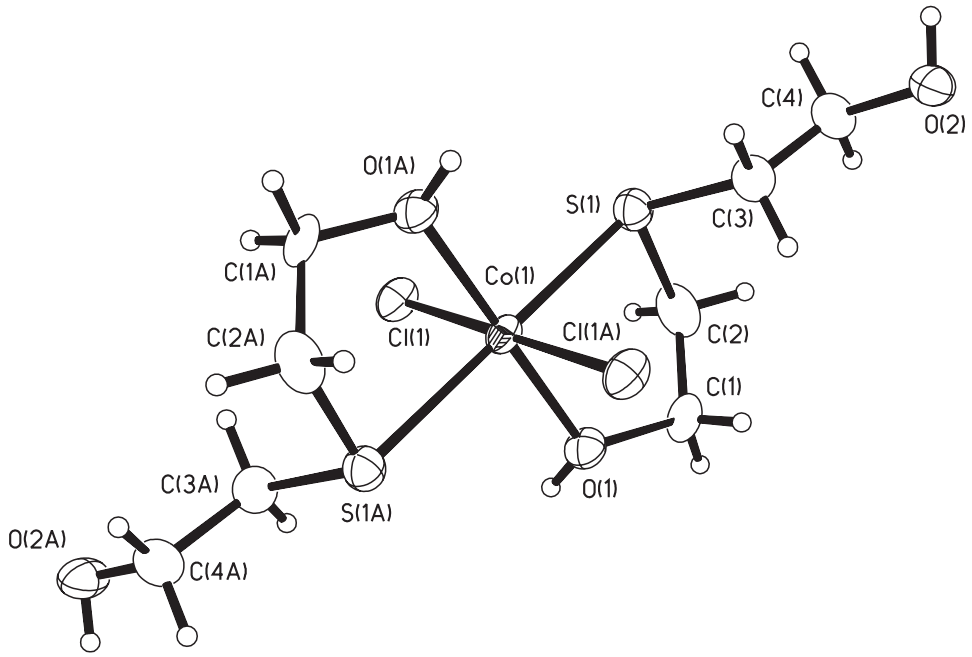
Synthesis of $\{MnCl_2[S(CH_2CH_2OH)_2]\}_n$ (2)

200 mg of $MnCl_2 \cdot 4H_2O$ (1.01 mmol) was ground first, then added into 2 mL of 2,2′-thiodiethanol (excess) with stirring. The color of the mixture changed to dark purple after being stirred for one day. The mixture was evacuated to dryness by vacuum overnight with stirring. 5 mL of methanol was added to dissolve the residue and a purple solution was obtained. The solution was left under diethylether vapor for one week. Pink crystals of **2** were obtained with 83% yield. Anal. calcd. for $C_4H_{10}O_2S_1Cl_2Mn$: C 19.37, H 4.06; found: C 19.66, H 4.08.

X-ray diffraction analyses

Crystals were obtained from the slow diffusion of diethylether into the methanol or methanol–water solution. The crystals were mounted on glass fibers with epoxy glue. All data was collected on a Siemens P4 single-crystal diffractometer with graphite-monochromated Mo-Kα radiation, operated at 50 kV and 35 mA at 23°C. The data for **1** and **2** were collected over 2θ 3–50°. Three standard reflections were measured every 197 reflections. No significant decay was observed for all samples during the data collection. Data were processed on a Pentium PC using Siemens SHELXTL software package (version 5.0) (3). The semiempirical from ψ-scans absorption corrections were applied for both compounds. Neutral atom scattering factors were taken from Cromer and Waber (4). The crystals of **1** and **2** belong to the monoclinic space group $P2_1/c$. The structures were solved by direct methods. The positions for all hydrogen atoms except those attached to the oxygen atoms were calculated and their contributions in structural factor calculation were included. The hydrogen atoms attached to the oxygen were located directly from difference Fourier maps and refined successfully. All non-hydrogen atoms in **1** and **2** were refined anisotropically. The crystal data for both compounds are given in Table 1.

Results and discussion



Structures

The title compounds were initially reported by Sen and Johnson (5). Based on analytical, IR, room temperature magnetic moments in solution, and conductivity data, Sen and Johnson (5) suggested that compound **1** is mononuclear and has an octahedral structure with two of the hydroxy groups of the two 2,2′-thiodiethanol lignads coordinating to the cobalt(II) center while compound **2** is also mononuclear with a five-coordinate structure. Our earlier work (2) on 2,2′-thiodiethanol copper(II) complexes indicates that 2,2′-thiodiethanol has a tendency to act as a bridiging ligand and form polynuclear compounds which contradicts the conclusions made by Sen and Johnson. We therefore decided to re-examine these two compounds.

Compounds **1** and **2** were obtained by a modified Sen and Johnson's (5) procedure. In Sen and Johnson's (5) report, only the 1:1 (metal:2,2′-thiodiethanol) compound **2** was described for manganese(II) while both 1:1 and 1:2 compounds were described for cobalt(II). As observed by Sen and Johnson (5), compound **2** is the only product that can be isolated from the reaction regardless of the ratio of Mn(II) to 2,2′-thiodiethanol used in the reaction, the cause of which has not been understood yet. The 1:1 cobalt(II) analog of **2** is

© 2000 NRC Canada

Fig. 1. A diagram showing the molecular structure of **1** with 50% thermal ellipsoids and labeling schemes.

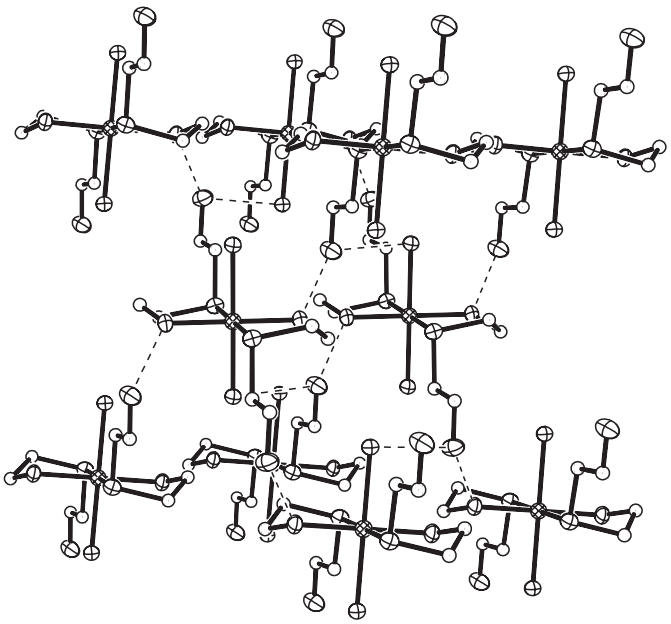
believed to have the same structure as that of **2**. Therefore, the structural study focused on compounds **1** and **2**.

The crystal structure of **1** is shown in Fig. 1. Selected bond lengths and angles are given in Table 2. The crystal structure of compound **1** is composed of discrete mononuclear molecules. The Co(II) atom is six-coordinate, in agreement with Sen and Johnson's (5) suggestions. The cobalt atom is located on the inversion center. Two 2,2′-thiodiethanol ligands are chelated to the Co(II) ion via one sulfur and one oxygen atom. Two chlorine ions are bound to the Co(II) ion in a *trans* fashion. The Co(1)—S, Co(1)—O, and Co(1)—Cl bond lengths are typical (1*b*, 1*c*, 6). The O(1)-Co(1)-Cl(1) angle is nearly 90° (90.66(7)°), but the O(1)-Co(1)-S(1) angle is slightly less than 90° (85.50(3)°). Thus, the geometry of the Co(II) ion is best described as a distorted octahedron.

In the crystal lattice of **1** the hydrogen atoms in the hydroxyl groups of the 2,2′-thiodiethanol ligand link the monomeric molecules through O—H···O hydrogen bonds (7) and O—H···Cl hydrogen bonds as evidenced by the distances of O(2)···O(1′) (2.626 Å) and O(2)···Cl(1′) (3.13 Å). As a result, compound **1** has a three-dimensional hydrogen bonded structure in the solid-state (Fig. 2). The Co—Co separation distances in the crystal lattice are 6.782(1) and 7.625(2) Å, respectively.

The structure of compound **2** is shown in Fig. 3. Selected bond lengths and angles are given in Table 2. As shown in Fig. 3, compound **2** has a polymeric structure. The unique portion of the structure is Mn(1) which is coordinated by three chlorine atoms, two oxygen atoms, and one sulfur atom from two 2,2′-thiodiethanol ligands. The Mn—Cl bond lengths vary considerably, (Mn(1)—Cl(1) = 2.4214(8) Å, Mn(1)—Cl(2) = 2.5125(10) Å, Mn(1)—Cl(2A) = 2.5603(8) Å) while the Mn—O bond lengths are quite similar (Mn(1)—O(1) = 2.234(2) Å and Mn(1)—O(2A) = 2.191(2) Å). The Mn(1)—S(1) bond is much longer than the Co—S bond in **1** but similar to previously reported values (8). The O(1)-Mn(1)-O(2A), Cl(2)-Mn(1)-S(1), and Cl(1)-Mn(1)-Cl(2A) bond angles are 167.98(8), 165.59(3), and 175.86(3)°, respectively, a substantial deviation from an ideal octahedral geometry. The geometry of the Mn(II) ion in compound **2** can be therefore also best described as a distorted octahedron. There are two possible geometric isomers for compound **2**, *fac* and *mer*. The observed structure of **2** is the *mer* isomer where two of the chlorine atoms are *trans* to each other.

The thiodiethanol ligand has three forms: (*i*) the neutral ligand ($S(CH_2CH_2OH)_2$ (H_2tde)); (*ii*) the anion ($S(CH_2CH_2OH)(CH_2CH_2O)^-$ ($Htde^-$)); and (*iii*) the dianion ($S(CH_2CH_2O)_2^{2-}$ (tde^{2-})). In addition being a chelate ligand, the $Htde^-$ and tde^{2-} ligands can function as a bridging ligand where the negatively charged oxygen atom binds two metal ions as established by our previous studies (2). $Htde^-$ and tde^{2-} are therefore excellent ligands for the formation of polynuclear metal complexes (2). In contrast, the oxygen atoms of the neutral H_2tde ligand in both compounds **1** and **2** function as terminal donors only, which could be attributed to the fact that the negatively charged oxygen of $Htde^-$ and tde^{2-} is a much better donor than the neutral OH group of H_2tde, hence capable of binding to two metal ions.



2,2′-Thiodiethanol in **2** functions as a chelating and bridging ligand. The second OH group of H_2tde in compound **2** is coordinated to a second Mn(II) ion of a neighboring Mn(II) unit, resulting in a cyclic dinuclear $Mn_2(H_2tde)_2Cl_4$ unit. The Mn(1)—Mn(1B) separation distance in the cyclic unit is 6.504(1) Å. The dimension of this 12-membered ring is approximately 6.50 × 3.90 Å. The cyclic dinuclear $Mn_2(H_2tde)_2Cl_4$ units are further linked together through two chloride bridges Cl(2) and Cl(2A). The chloride bridges are almost symmetric with the Mn(1)—Cl(2) bond length (2.5125(10) Å) being slightly longer than that of Mn(1)—Cl(2A) (2.5603(8) Å). The two metal ions, Mn(1)

Fig. 2. A diagram showing hydrogen bonds in the crystal lattice of **1**.

and Mn(1A) are separated by the two chloride bridges by 3.731(1) Å. As a result of the chloride bridges, compound **1** has a one-dimensional polymeric structure in the solid state.

There are extensive hydrogen bonds between the polymeric chains as shown in Fig. 4. The first type of hydrogen bond in **2** is between the bridging chlorine atoms Cl(2) and Cl(2A) and the terminal OH groups O(2) and O(2A) from two neighboring polymer chains, as evidenced by the distance of Cl(2)···O(2′) (3.223 Å). The second type of hydrogen bond in **2** is between the terminal chloride ligands Cl(1) and Cl(1A) and the chelate OH groups O(1) and O(1A) from neighboring chains (Cl(1)···O(1′) = 3.144 Å). The hydrogen bonds extend the polymeric structure of **2** into a two-dimensional infinite sheet. The shortest Mn···Mn separation distance between the hydrogen bonded polymer chains is 5.577(1) Å.

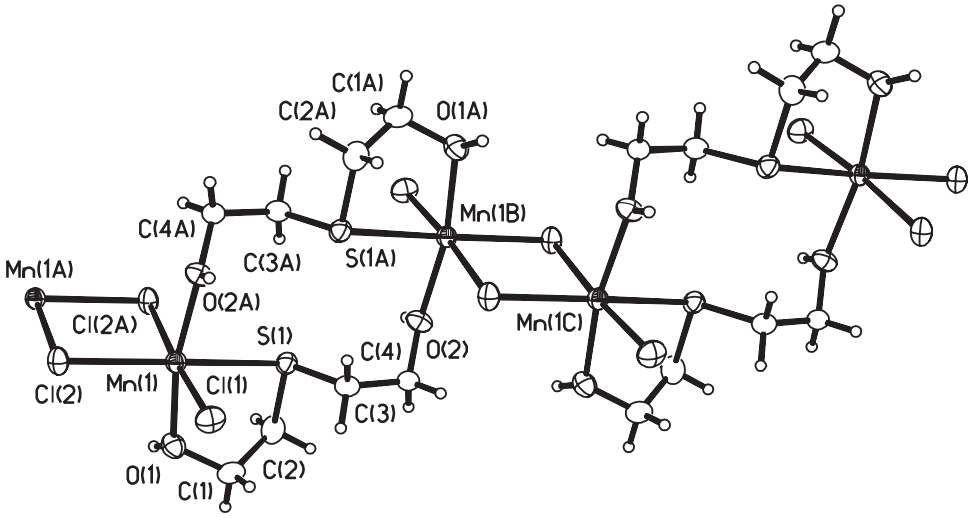
Sen and Johnson (5) suggested a five-coordinate trigonal bipyramidyl geometry for compound **2** based on electronic spectral data in solution and the solid state which contradicts the results of our investigation. Because the physical properties (IR, mp, and elemental analysis) of our compound **2** are identical to that reported by Sen and Johnson (5) they must have the same structure. Therefore, we believe that Sen and Johnson made an error in their assignment of the structure of compound **2**.

Magnetic properties

As established by Sen and Johnson (5), the cobalt(II) ion in compound **1** has a high spin configuration. Due to the lack of covalent bonds and the large separation distance between the mononuclear units, compound **1** is essentially paramagnetic with negligible intermolecular magnetic interactions as supported by Sen and Johnson's (5) data. Therefore, we did not study its magnetic properties in detail. On the other hand, the Mn(II) ions in compound **2** are covalently linked together by chloride and H_2tde ligands with

© 2000 NRC Canada

Fig. 3. A diagram showing a portion of the extended structure of **2** with 50% thermal ellipsoids and labeling schemes.



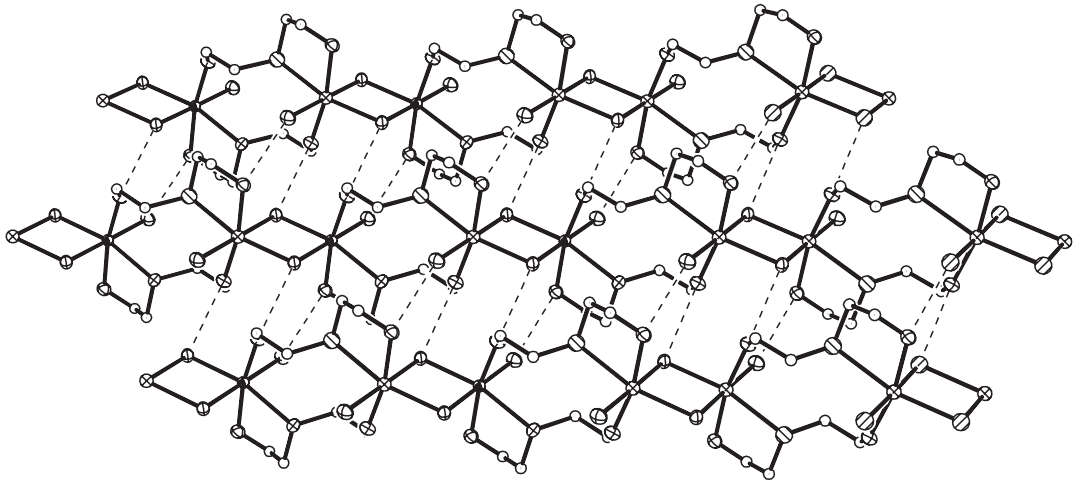


Fig. 4. A diagram showing interchain hydrogen bonds in the crystal lattice of **2**.

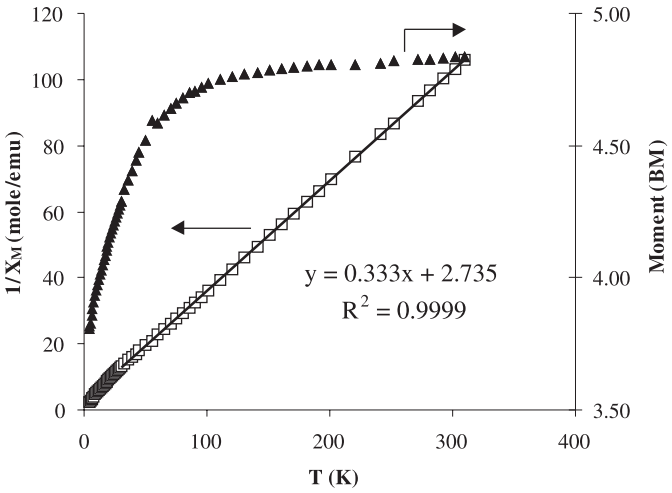

considerably shorter metal–metal separation distances (3.731 Å and 6.504 Å) within the one-dimensional chain than those of compound **1**. Some magnetic interactions between Mn(II) ions are therefore anticipated. Therefore, we examined the magnetic properties of compound **2** by measuring its magnetic susceptibility in the solid-state over the temperature range of 4–310 K. There is not a max in the χ_M vs. *T* plot. As a result, the data cannot be fitted into a $S = 5/2$ dimer model. The magnetic data (χ_M^{-1} and μ vs. *T*) corrected for diamagnetism by using Pascal constants of **2** is shown in Fig. 5. The magnetic moment at 310 K is 4.83 BM, much less than the expected value (5.90 BM) for a high spin and noninteracting Mn(II) ion. The magnetic moment of **2** decreases gradually from 310 to ~50 K, then decreases rapidly at temperatures below 50 K, indicative of the presence of antiferromagnetic exchange. The plot of the reciprocal molar susceptibility χ_M^{-1} vs. *T* is essentially a straight line from 30 to 310 K. There is a slight deviation from the straight line at temperatures below 30 K. The χ_M^{-1} vs. *T* plot in the 30–310 K range is fitted into a linear equation which produces a perfect fit ($R^2 = 0.9999$). From the fitting parameters, we obtained the θ value of Curie–Weiss law ($\chi_M = C/(T - \theta)$), $\theta = -8.213$ K), which further supports the presence of antiferromagnetic exchange in compound **2** (9). The antiferromagnetic exchange in **2** occurs most likely between the Mn(1) and Mn(1A) pair because they have the shortest Mn—Mn separation distance and are directly linked by two chloride ligands with a Mn-Cl-Mn bond angle of 94.70(3)° (9). Similar antiferromagnetic exchange has been observed in a number of chloride bridged, high spin Mn(II) compounds (10). The deviation of χ_M^{-1} vs. *T* plot from a straight line at temperatures below 30 K could be caused by additional magnetic interactions, perhaps magnetic interactions between the hydrogen bonded polymeric chains of **2**.

In summary, our studies have established unambiguously that the 1:2 compound **1** is a mononuclear, six-coordinate, and hydrogen bonded system while the 1:1 compound **2** is a six-coordinate covalent polymer. The neutral ligand 2,2′-thioethanol is capable of forming polynuclear complexes as the corresponding anion ($Htde^-$) and dianion (tde^{2-}) ligands are. Further investigation on 2,2′-thiodiethanol polynuclear complexes is in progress.

Thermodynamics of methanesulfonic acid revisited

J. Peter Guthrie and Roger T. Gallant

Abstract: Recently we reported a study of the thermodynamics of methanesulfonic acid and some of its derivatives. The foundation of these results was a measurement of the heat of reaction of *S*-methyl thioacetate with aq sodium hypochlorite, leading to methanesulfonic acid. We have reinvestigated this reaction and discovered that contrary to the initial stoichiometry experiments, the stoichiometry under the reaction conditions is not as was believed and that the heat of reaction observed was spuriously high. We have found a new reaction, that of sulfite ion with methyl methanesulfonate, which does allow a clean determination of the heat of formation of methanesulfonic acid. Revised thermodynamic quantities for methanesulfonic acid, methanesulfonyl chloride, and methyl methanesulfonate are reported here.

Key words: sulfonic acid, heat of reaction, free energy of formation, S_N2 reaction.

Résumé : On a récemment rapporté une étude sur les propriétés thermodynamiques de l'acide méthanesulfonique et de ses dérivés. La base de ces résultats était une mesure de la chaleur de réaction du thioacétate de *S*-méthyle avec de l'hypochlorite de sodium aqueux conduisant à la formation d'acide méthanesulfonique. On a repris l'étude de cette réaction et on a trouvé que, contrairement aux expériences initiales de stoechiométrie, cette dernière n'est pas toujours celle que l'on croyait et que la chaleur de réaction observée était faussement élevée. On a trouvé une nouvelle réaction, celle de l'ion sulfite avec le méthanesulfonate de méthyle qui permet de faire une détermination propre de la chaleur de formation de l'acide méthanesulfonique. On rapporte les valeurs révisées des quantités thermodynamiques pour l'acide méthanesulfonique, le chlorure de méthanesulfonyle et le méthanesulfonate de méthyle.

Mots clés : acide sulfonique, chaleur de réaction, énergie libre de formation, réaction S_N2.

Introduction

Recently we reported a study of the thermochemistry and thermodynamics of methaneulfonic acid and some of its derivatives (1). Two colleagues knowledgeable in this area pointed out that the heat of formation we reported was inconsistent with heats of formation of related compounds or other indirect sources of heat of formation data. To settle the point we have determined the heat of formation of methanesulfonic acid independently, by a reaction of sulfite ion with methyl methanesulfonate (methyl mesylate). With some embarrassment we now report that the initial value we reported was in error and herewith revise the thermochemistry of methanesulfonic acid.

Results

Heats of reaction were measured using a Tronac isoperibol calorimeter. The results are given in Table 1. The apparent heat of hydrolysis of methyl trifluoromethanesulfonate in pH 10 aq borate buffer was –7.85 ± 0.35 kcal mol^{-1}.

[1] $CH_3\text{-}O\text{-}SO_2\text{-}CF_3(1) + (HO)_4B^-(soln) \rightarrow CH_3\text{-}OH(soln) + {}^-O_3S\text{-}CF_3(soln) + (HO)_3B(soln)$

The heat of reaction of methyl trifluoromethanesulfonate with aq sodium sulfite was –11.76 ± 0.12 kcal mol^{-1}.

[2] $CH_3\text{-}O\text{-}SO_2\text{-}CF_3(1) + SO_3^{2-}(soln) \rightarrow CH_3\text{-}SO_3^-(soln) + {}^-O_3S\text{-}CF_3(soln) + (HO)_3B(soln)$

The heat of reaction of hydroxide with boric acid can be calculated from the known heats of ionization of boric acid and water (2) to be –9.97 ± 0.01 kcal mol^{-1}.

[3] $(HO)_3B(soln) + HO^-(soln) \rightarrow (HO)_4B^-(soln)$

Combining these values allows calculation of the heat of reaction for the convenient hypothetical process, [4], for which $\Delta H_{reaction}$ = +6.06 ± 0.37 kcal mol^{-1}. From the heats of formation of the other species involved (see Table 2), we can now calculate the heat of formation of methanesulfonate ion in aqueous solution as –149.64 ± 0.70 kcal mol^{-1}.

[4] $CH_3\text{-}OH(soln) + SO_3^{2-}(soln) \rightarrow CH_3 + SO_3^-(soln) + HO^-(soln)$

The heat of solution of methanesulfonic acid in water was –11.40 ± 0.41 kcal mol^{-1}.

Table 1. Heats of reaction and solution.[a]

Compound	ΔH	Av
$CH_3OSO_2CF_3$ + borate buffer	–7.92[b], –8.25[b], –7.39[b]	–7.85 ± 0.35[b]
$CH_3OSO_2CF_3$ + sulfite	–11.58[c], –11.93[c], –11.75[c], –11.75[c], –11.78[c]	–11.76 ± 0.12[c]
CH_3SO_3H	–11.70[d] –10.69[d], –11.51[d], –11.68[d]	–11.40 ± 0.41[d]
$CH_3OSO_2CH_3$ + sulfite	–37.89[e], –37.11[e], –36.80[e], –36.38[e]	–37.05 ± 0.55

[a]All at 25°C, units are kcal mol^{-1}; heat of reaction unless noted.
[b]In pH 10 aq borate buffer l.
[c]In 0.1 M aq Na_2SO_3.
[d]Heat of solution in water.
[e]In 0.5 M aq Na_2SO_3.

[5] $CH_3\text{-}SO_3H(1) \rightarrow CH_3\text{-}SO_3^-(soln) + H^+(soln)$

This permits calculation of the heat of formation of liquid methanesulfonic acid as –138.24 ± 0.81.

This value was closer to the previous literature estimates, but still differed by 10 kcal mol^{-1} from these estimates. Nagging concerns about this discrepancy, prompted by similar concerns expressed by a referee reviewing an early version of this paper, led us to do further analysis of the results, and then to do further experiments. From the previous results (1) we can calculate the heat of hydrolysis for methyl methanesulfonate. This heat of reaction does not depend on the absolute value of the heat of formation of methanesulfonic acid from our original paper, but only on the heats of reaction of methanesulfonyl chloride with water or methanol, and this heat of hydrolysis is consistent with the literature estimates. The heat of hydrolysis for the process

[6] $CH_3SO_2OCH_3(1) + HO^-(soln) \rightarrow CH_3SO_3^-(soln) + CH_3OH(soln)$

is –27.31 kcal mol^{-1}, while for the analogous reaction of methyl trifluoromethanesulfonate

[7] $CF_3SO_2OCH_3(1) + HO^-(soln) \rightarrow CF_3SO_3^-(soln) + CH_3OH(soln)$

we calculate from the results given above that the heat of hydrolysis is –17.82 kcal mol^{-1}. That the heat of hydrolysis of the ester of the stronger acid should be less than that of the ester of the weaker acid seems wildly unlikely.

We turned next to measurement of the heat of reaction of sulfite ion with methyl methanesulfonate. With 0.1 M sodium sulfite in water the reaction was not quite fast enough for convenient calorimetry, but at 0.5 M sodium sulfite the reaction was fast enough to give a well-defined post reaction trace and thus allow good determination of the heat of reaction. For the process:

[8] $CH_3\text{-}O\text{-}SO_2\text{-}CH_3(1) + SO_3^{2-}(soln) \rightarrow 2CH_3\text{-}SO_3^-(soln)$

the heat of reaction was –37.05 ± 0.55. This is much more exothermic than the corresponding value from experiments with methyl trifluoromethanesulfonate (–11.76 ± 0.12 kcal mol^{-1}). Again it seems wildly unlikely that the more reactive ester would have the smaller heat of reaction. These experiments with methyl methanesulfonate, also reported in Table 1, permitted calculation of the heat of reaction for the hypothetical process [4], based on the heat of reaction of methyl methanesulfonate, as –7.89 ± 0.85 kcal mol^{-1}, which is quite different from the value based on the heats of reaction of methyl trifluoromethanesulfonate, namely +6.06 ± 0.37 kcal mol^{-1}. In this calculation process [8] minus process [6] yields process [4].

Table 2. Heats of formation.[a]

Compound	Phase	$\Delta H_f°$
H_2O	l	–68.32 ± 0.01[b]
NaOH	soln	–112.36 ± 0.01[b]
NaCl	soln	–97.25 ± 0.02[b]
Na_2SO_3	l	–266.70 ± 0.59[b]

[a]All at 25°C, heats of formation in kcal mol^{-1}.
[b]Reference (10).

From the new value for the heat of reaction of process [4], we derive a heat of formation of methanesulfonate ion in aqueous solution as –163.79 ± 1.04 kcal mol^{-1}, and hence a value of –152.39 ± 1.12 kcal mol^{-1} for liquid methanesulfonic acid. This requires revision of all the thermodynamic quantities dependent upon the heat of formation of methane sulfonic acid, in Table 4 of ref. (1). The revised values are given in Table 3 below.

The stoichiometry of the reaction of methyl thioacetate with hypochlorite was reexamined. In the original work it had been demonstrated by NMR analysis that the only products were acetate and methanesulfonate, in equimolar amounts. This experiment involved reaction with full strength, 5%, hypochlorite solution, to allow concentrations of products high enough for analysis by 200 MHz ^{1}H NMR spectroscopy. However there was a difference in concentration between the stoichiometry determinations and the calorimetry, since full strength 5% sodium hypochlorite was used for stoichiometry determinations (ca. 0.67 M OCl^-, 0.11 M thioester), and 15:35 sodium hypochlorite:water was used for calorimetry (ca. 0.28 M OCl^-, 0.0054 M thioester). The distilled water could significantly lower the hydroxide concentration of this very weakly buffered solution, and thus have affect the relative rates of hydroxide dependent and hypochlorite dependent reactions.

When the analyses were repeated at lower concentrations of hypochlorite, and consequently lower concentrations of products, using 500 MHz ^{1}H NMR spectroscopy, we found that the amount of methane sulfonate was less than the amount of acetate. This result requires that there be a process consuming methanethiol equivalents which does not lead

[a]All at 25°C, enthalpies and free energies are in kcal mol^{-1}, entropies are in cal deg^{-1} mol^{-2}, standard states are the ideal gas at 1 atm and 1 M aqueous solution with an infinitely dilute reference state. Standard entropies in the gas-phase and free energies of transfer (from the gas at 1 atm to 1 M aqueuos solution) were calculated as described in the text. Free energies of formation in the gas-phase are calculated from the corresponding enthalpies of formation and the standard entropies, and free energies of formation in aqueous solution are calculated from the corresponding free energies of formation in the gas and free energies of transfer.

[b]Reference (1).

to methanesulfonate, and thus implies that the measured heat of reaction will be spuriously high.

In other experiments we measured the concentration of hypochlorite by UV before and after adding *S*-methyl thioacetate, and found that the amount of hypochlorite used was greater than required for the simple stoichiometry previously assumed.

Thus it seems clear that the basis for the initial calorimetry was incorrect, despite apparently clear evidence from a stoichiometry experiment carried out before these measurements were performed.

Discussion

It seems clear that we were mistaken in thinking that we knew the stoichiometry of the reaction used to determine the heat of formation of methanesulfonic acid. The distressing thing is that the stoichiometry had been determined by direct analysis for methanesulfonate and acetate, admittedly under slightly different conditions than were used for the actual calorimetry. The difference, amounting to a factor of 3.3 in hypochlorite concentration, had not seemed important but obviously was. In addition, the logical consistency of the results had been checked by a γ plot (3) (admittedly a novel extrapolation of the idea of a γ plot, but one which seemed reasonable). Clearly, this too was misleading. Work in progress suggests that γ is indeed relevant to these equilibria, but is not the whole story.

We do not know what reactions could have led to consumption of methanethiolate equivalents so that they did not become methanesulfonate, but it is tempting to speculate that under the alkaline reaction conditions elimination of HCl from an initial S^+Cl species could lead to a $CH_2{=}S^+$ species which would quickly release formaldehyde, and leave a sulfide equivalent. Oxidation of sulfide to sulfate is strongly exothermic.

The new calorimetric results reported here are for an inherently simpler reaction. When methyl trifluoromethanesulfonate was added to a 1 M solution of Na_2SO_3 in D_2O, to give a final concentration of organic material of 0.2 M, the ^1H NMR spectrum showed essentially only one peak, at the chemical shift expected for methanesulfonate ion. The only nucleophiles in the solution are water, hydroxide, and sulfite ion. Hydroxide is at quite low concentration and therefore should be of negligible significance. The Swain–Scott *n* value for sulfite ion is 5.1, (4), while that for water is 0.0. Thus it seems highly reasonable that the only reaction would be that of sulfite attacking methyl trifluoromethanesulfonate as was observed. Sulfite is potentially an oxygen nucleophile instead of a sulfur nucleophile, but as an oxygen nucleophile it would be expected to have a Swain–Scott n value, 3.8, similar to that of HPO_4^{2-} which has a very similar pK_a. This implies a reaction rate only one twentieth that of the sulfur. In any case NMR analysis of the product solution (for an experiment done in D_2O) showed only traces of additional products. There was about 2% of a peak which might be methanol, and an even tinier trace of a peak to lower field. An amount of competing hydrolysis or reaction at oxygen of sulfite amounting to no more than this would have an effect on the heat of reaction less than the observed experimental error.

NMR analysis of the product solution from the reaction of sulfite with methyl methanesulfonate shows only the peak expected for methanesulfonate ion, with no other products amounting to more than 0.5% of the total.

Why then are the results of reactions with methyl trifluoromethanesulfonate so out of line with expectations? The only explanation we have been able to devise is that the reactions are fast and exothermic, and so may have caused significant amounts of volatilization of ester before reaction, leading to anomalously low measured heats of reaction. Trifluoromethanesulfonic acid is 4 pK_a units stronger than methanesulfonic acid (5), so an initial guess using a Brønsted exponent of 0.5 suggests that the reactions of methyl trifluoromethanesulfonate would be 100 times faster than those of methyl methanesulfonate. Reactions of methanesulfonyl chloride with aqueous hydroxide could not be studied because of spattering from the exothermic reaction, leading to obvious scatter and unreacted droplets (1). This reaction could only be studied in solutions buffered at pH 10, and this experience guided our use of buffer for the hydrolysis reaction of methyl trifluoromethanesulfonate. Methyl trifluoromethanesulfonate boils at 95°C (6), and thus would volatilize before water, unlike methanesulfonyl chloride, bp 159 (7); this may explain the difference in behavior.

The present approach to the heat of formation of methanesulfonic acid, though free of the problems which affected the hypochlorite oxidation procedure, is less general, since it requires that there be a rapid nucleophilic displacement. Examination of the literature showed that the S_N2 reactions of CH_3X were not likely to be fast enough for calorimetry without an extremely good leaving group, such as trifluoromethanesulfonate or methanesulfonate. For alkyl groups other than methyl, the reaction becomes slower, and side reactions become increasingly likely as the group gets larger.

© 2000 NRC Canada

The values reported in the present paper for the heats of formation of liquid methanesulfonic acid, methyl methanesulfonate, and methanesulfonyl chloride are much closer to the values in the earlier literature than those in our original paper. The values we now report are respectively –152, –139, and –101 as opposed to –178, –164, and –127 (1) kcal mol^{-1}; Liebman(8) gave –147, –135, and –101 kcal mol^{-1}.

Experimental

Materials

S-Methyl thioacetate was a fresh bottle from Lancaster Chemicals, and was used without further purification. NMR spectroscopy showed no impurities. Sodium hypochlorite as a 5% solution in water was Malinckrodt analytical reagent grade. Methyl trifluoromethanesulfonate was a fresh bottle from Aldrich, used without further purification. ^{1}H and ^{19}F NMR spectra each showed only one peak with the expected chemical shift. Methyl methanesulfonate was taken from a fresh bottle (Aldrich 99%). The ^{1}H NMR spectrum showed only the two peaks expected for methyl methanesulfonate. Boric acid, potassium chloride, sodium hydroxide, and sodium sulfite were analytical reagent grade. pH 10 borate buffer was made up following ref. (9).

Methods

Reaction calorimetry was carried out as previously described (1). ^{1}H NMR spectra were recorded on Varian Gemini 200 or Unity 500 MHz spectrometers, the latter through the cooperation of Dr. G. Shaw, of the Departments of Biochemistry and Chemistry at this university.

Acknowledgments

We thank the Natural Sciences and Engineering Research Council of Canada for financial support of this work. We thank Dr. G. Shaw, Departments of Biochemistry and Chemistry, for recording the 500 MHz NMR spectra. We thank Professors John Bartmess and Joel Liebman for helpful discussions which provoked the work reported here.

Oxidative coupling-type mechanism of *N*,*N*-dialkylanilines in solvent-free conditions forming crystal violet derivatives. A clay-mediated and microwave-promoted approach

J.G. López-Cortés, G. Penieres-Carrillo, M.C. Ortega-Alfaro, R. Gutiérrez-Pérez, R.A. Toscano, and C. Alvarez-Toledano

Abstract: In the clay-mediated reaction of *N*,*N*-disubstituted anilines using microwave radiation as an energy source in the absence of solvent, crystal violet and derivatives, diphenylmethanes, and biphenyls were isolated along with intermediates supporting an oxidative coupling-type mechanism.

Key words: clay, dyes, microwave radiation, solvent-free reactions.

Résumé : Les réactions d'anilines *N*,*N*-disubstituées effectuées en présence d'argile, sans solvant et en utilisant un rayonnement de micro-ondes comme source d'énergie, on a isolé du cristal violet et de ses dérivés, des diphénylméthanes et des biphényles, en plus d'intermédiaires qui sont en accord avec un mécanisme de type couplage oxydant.

Mots clés : argile, colorants, rayonnement, réactions sans solvant.

Introduction

Much attention has been recently focused on bis(4-*N*,*N*-dialkylaminophenyl)methanes because these kinds of compounds are employed as precursors of dyes and (or) indicators (1), as well as in materials science and other fields (2). 4-Bis(*N*,*N*-dialkylamino)biphenyls also have many uses, such as nonaqueous electrolytes in lithium batteries (3), and in photosensitive reduction on de-chloration of chloroaromatic pesticides (4). On the other hand, crystal violet and analogues have also attracted considerable interest in recent years owing to their newer applications on surface phenomena in materials science (5), in biochemical genetics (6), etc. Some transformations of *N*,*N*-dialkylanilines to obtain the aforementioned compounds are, inter alia, oxidation reactions (7) and several oxidizing catalysts containing different metals (8). Some other methods involve e.g., the condensation of formaldehyde and aniline with concentrated HCl (9), the reduction of 4,4′-(*N*,*N*-dialkylamino)benzophenones (10), using heterocyclic compounds (11) or by alkylation of methylenebisanilines (12).

In the last years, our laboratory has been involved in the development of new synthetic strategies employing a bentonitic earth as catalyst and (or) reaction medium in solvent-free systems (13) and with the use of microwave (for leading reviews see ref. 14) or infrared energy sources. The simplicity of experimental conditions, ease of isolation of the end products, as well as avoidance of byproducts and likewise the availability of the clay, have been important and valuable features for the growing increase of studies with the bentonite-mediated approach as a performing and attracting synthetic tool for a wide-ranging assortment of organic reactions, such as oxidative couplings of naphthols, etc. (15, 16*a*, 16*b*; for reviews concerning oxidative couplings see ref. 16*c*). The vast majority of clay catalysts used in organic synthetic chemistry are based on the naturally occurring smectite clay, montmorillonite, also known as bentonite. Clay catalysts have been shown to contain both Brønsted and Lewis acid sites, with the Brønsted mainly associated

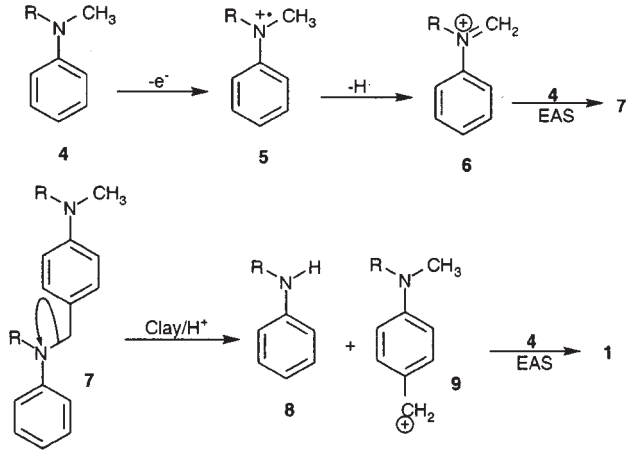
with the interlamellar region and the Lewis sites mainly associated with edge sites (17)[2].

Results and discussion

Thus, we wish to report our results concerning the reaction of several *N*,*N*-disubstituted anilines with a bentonitic clay in solvent-free conditions, using microwave radiation as an energy source affording diphenylmethanes (**1**), biphenyls (**2**), and crystal violet and analogues (**3**) (Scheme 1). Reactions were carried out by mixing *N*,*N*-dialkylaniline with bentonitic clay in the aforementioned conditions and irradiating in a conventional microwave oven at the higher power. It must be pointed out that the reactions were also performed employing infrared irradiation, but lower yields and longer reaction times than those observed by using microwave radiation were registered. On the other hand, unresolvable mixtures reactions were obtained by using conventional heating (oil bath) along with other serious inconveniences, as decomposition of the starting materials due to the severe and drastic conditions involved in slowly reaching the gradient temperature needed for such chemical transformations, and that can be easily accomplished by means of rapid microwave heating. The use of solvents such as xylene, hexane, DMSO, and methanol, etc. combined with bentonite was also tested but there was no reaction at all in any case, evidencing the important role of the substrate's adsorption over the clay. Finally, allowing the reaction to proceed with montmorillonite K-10,[3] the yields and reaction time were almost identical to those observed with our protocol, but the difference in prices address the bentonite as the best choice.

The structure of the products was established by spectroscopic techniques (IR, ^1H and ^{13}C NMR, and mass spectrometry). Compounds **1a**, **2a**, **3a**, and **1b** were found to be identical with authentic samples obtained from commercial suppliers (Aldrich and Fluka). With regard to compound **2b**, a spot was observed in TLC which could correspond to such a compound, but since it is formed in traces we were not able to isolate it from the reaction mixture. The novel compound **3b** displayed in its mass spectrum a molecular ion at 414 *m*/*z*, which corresponds to the expected molecular weight for the cationic structure. However, in the ^1H NMR spectrum each signal appeared as sets of four lines, suggesting that compound **3b** actually occurs as a mixture of rotamers in dynamic equilibrium (18). It must be pointed out that some authors have discussed the existence of isomers in solution of such compounds (19).



To observe the methyl group role, the *N*,*N*-diethylaniline was employed as substrate and there was no reaction at all, as stated by several authors (8*b*, 20, 21), indicating that the C atom between two or three aromatic rings stems from the methyl group of the aniline molecule and accordingly, if this

[2]Clay used is Tonsil Actisil FF (commercial name). Chemical composition: on examination by X-ray fluorescence, the clay employed in this study was found to have the following composition (in %): SiO_2 63.5, Al_2O_3 12.7, MgO 3.1, Fe_2O_3 4.9, CaO 1.5, K_2O 3.1, TiO_2 0.6, MnO 0.03, Na_2O 0.8, P_2O_5 0.1, H_2O (110°) 9.5. The commercial acid-activated material was obtained from Tonsil Mexicana and analyzed with a Phillips spectrometer using Cr primary radiation. The measured specific surface area was 161.074 $m^2\ g^{-1}$ (B.E.T. N_2), and the pore volume was 0.3235 $cm^3\ g^{-1}$. The acidity by NH_3 thermodesorption was 12.107 mmol mg^{-1}. The particle size was 325 mesh. Commercial price to date: $ 0.35 US/Kg.

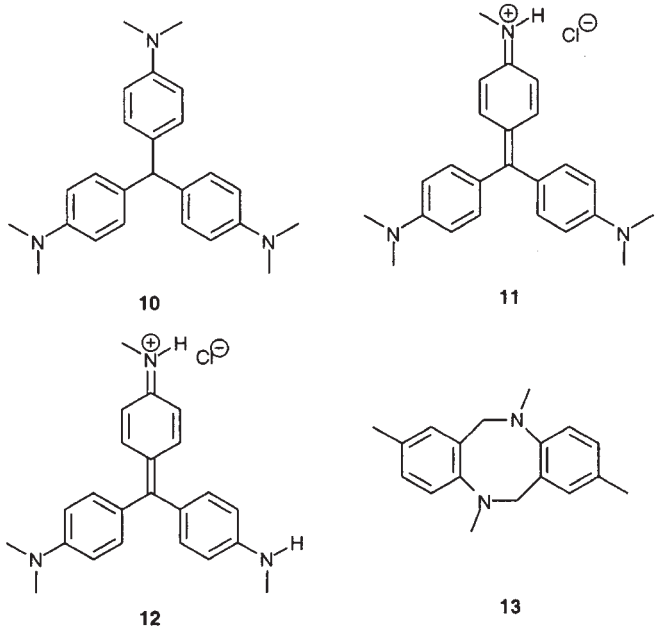
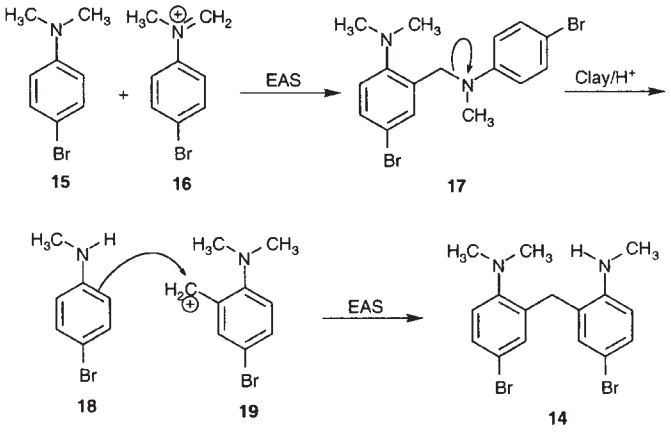
Scheme 2. Proposed formation of Michler's base derivative **1**.

methyl group is absent, the reaction does not proceed. A mechanism which would account for the formation of compounds **1** is proposed in Scheme 2.



The reaction proceeds by an oxidation of *N*-methyl-*N*-alkylaniline (**4**) forming the radical cation **5**, which we consider as the key intermediate in the reaction. This intermediate has recently been proposed in the N-dealkylation of methylanilines (22, 23) and gives rise to the cation **6** reacting by an electrophilic aromatic substitution (EAS) to generate the compound **7**. Further reaction on the clay acidic sites produces both the monoalkylaniline **8** and the benzylic cation **9**, which subsequently reacts with another aniline molecule **4** to yield **1**.

When *N*,*N*-dimethylaniline is employed as starting material, after 4 min the formation of diphenylmethane (**1a**) is observed. This compound is the prevailing product even after 10 min, and then the formation of another product corresponding to crystal violet (**3a**) is detected by TLC, as well as the formation of the crystal violet leucobase (**10**) (Fig. 1). If the reaction is stopped at this moment, the three aforementioned products can be isolated but, allowing the reaction to proceed, after 25 min the diphenylmethane spot begins to vanish and the formation of at least five byproducts is observed by TLC. After 1 h, diphenylmethane had completely disappeared and only two TLC spots became neatly visible besides the crystal violet spot. HPLC allows a 70% yield of crystal violet to be isolated along with the two byproducts **11** and **12**, formed by the incorporation of methylaniline (**8**) in the reaction. It must be pointed out that with the other substrate the yields are quite similar.

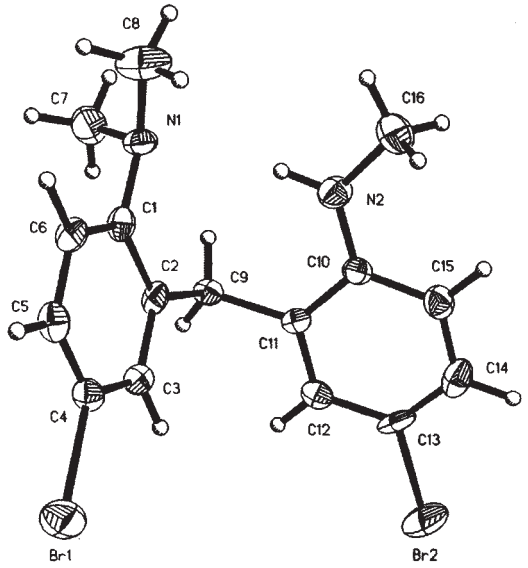


Furthermore, reaction with *p*-substituted anilines was also carried out to observe if the reaction proceeds when the key position is blocked. Thus, when *p*-methyl-*N*,*N*′-dimethylaniline was employed, compound **13** was obtained, whose structure was elucidated by spectroscopic methods and confirmed by single-crystal X-ray diffraction studies, finding the crystal data quite similar to those reported (24).

As can be seen, this compound presents the same structural sequence found in the intermediate **7** (consisting of an aromatic ring, a nitrogen atom, a methylene group, and an aromatic ring and so on). Isolation of this compound is significant given that it brings to light the existence of intermediate **7** and also by the fact that the carbon atom connecting

Fig. 1.

Scheme 3. Proposed formation of compound **14**.



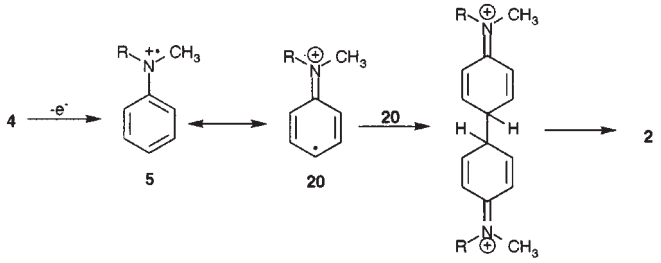
the aromatic rings in compounds **1** and **3** stems from the methyl group of aniline. It is worth notingthat this class of compounds have been obtained by other methods involving, inter alia, metallic salts (25), etc. and, in our case, there are just the bentonitic clay and microwave radiation, without any other reagents, and the role of such essential physical and chemical catalysts appear to be clearly established as fundamental. Also worth mentioning is that bentonite's oxidizing performance can be attributed to redox systems such as Fe^{2+}/Fe^{3+}, present in the clay, as reported by Chang and co-workers (26).

Other strong evidence supporting the proposed mechanism in the formation of **1** was the isolation of (2-*N*,*N*-dimethylamino-5-bromophenyl)-(2′-*N*-methylamino-5′-bromophenyl) methane (**14**) when the reaction was carried out with *N*,*N*-dimethylamino-4-bromobenzene (**15**), a molecule chosen because of the hindrance on the key position (Scheme 3).

© 2000 NRC Canada

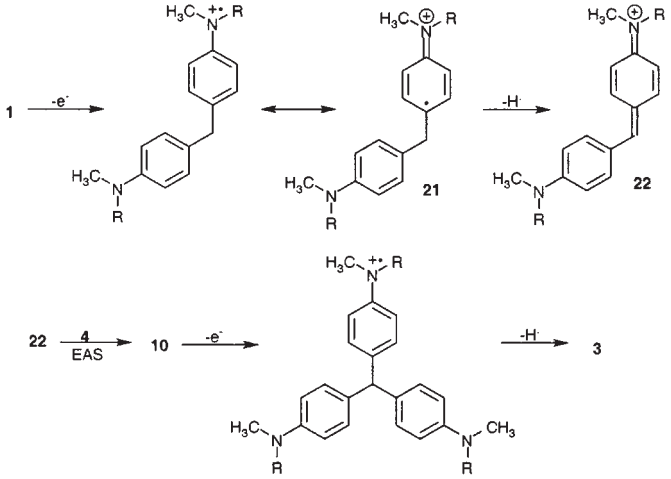
Fig. 2. ORTEP-type drawing of compoooound **14**. Thermal ellipsoids at 30% probability level.

Formation of **14** can be explained from intermediate **16**, an analogue of cation **6**, which reacts with another molecule of *N*,*N*-dimethylamino-4-bromobenzene (**15**) giving rise to **17**, which undergoes an heterolytic rupture on the C—N bond between the rings affording the secondary amine **18** and the benzylic cation **19**. Further EAS of this species on the *ortho* position of **18** leads finally to **14**.



On the other hand, **14** can also be considered as an *ortho* analogue of **1**, with one of the aniline moieties possessing two methyl groups and the other aniline molecule only one. The aniline moiety containing one methyl group must certainly be issued from the rupture of intermediate **17**, demonstrating that the methyl group of the aniline is lost giving rise to **18** and **19**.

Compound **14** was characterized by spectroscopic methods and its structure confirmed by an X-ray crystal analysis. Figure 2 shows compound **14** as possessing a *syn*-parallel orientation of the mono- and di-*N*-methylated *p*-bromoanilines, joined to the methylene group. This orientation seems to be locked by an intramolecular H—bond between the secondary and tertiary amine groups (H2···N1 2.23(11) Å, N2···N1 3.118(14) Å, N2-H2···N1 168(10)°). The angle between the phenyl rings (100.8°) deviates significantly from the tetrahedral value observed for the methylene C-atom (C2-C9-C11 111.9°). The sum of bond angles around the N-atoms clearly shows a different hybridization for N1 (sp^3, sum = 339.8°) and N2 (sp^2, sum = 359.6°) with an important interaction with the aromatic system for the latter, as judging by the shortening in the N—C_{phenyl} bond length (N1—C1 1.423(13) Å, N2—C10 1.369(14) Å).



With regard to compounds **2***a* and **2***b*, their formation can be explained by a coupling of radical ions such as **20** (Scheme 4), generated from radical cation **5,** involved as a key intermediate in our proposed mechanisms.

Concerning the crystal violet derivatives (Scheme 5), the formation of radical ion **21** from the Michler's base **1** leads to **22**, which reacts with a molecule of the starting material **4** via an EAS to give the leuco-base intermediate **10**.

Scheme 4. Proposed formation for compound **2**.

Scheme 5. Proposed formation of crystal violet derivatives **3**.

Further loss of an electron and a hydrogen atom affords, finally, the **3** derivatives. Intermediate **10** has been detected by TLC by comparison with a sample of commercial leucocrystal violet, i.e., when R is a methyl group. An interesting point is that crystal violet leuco-base **10** in the aforementioned conditions oxidizes to crystal violet almost quantitatively in 3 min.

In summary, crystal violet derivatives, diphenylmethanes, and biphenyls were isolated along with some important intermediates supporting a clay-mediated oxidative coupling of *N*,*N*-disubstituted anilines using microwave radiation as an energy source in solvent-free conditions.

Experimental section

Melting points, which are uncorrected, were determined using a MEL-TEMP II apparatus. Infrared spectra were obtained on a Perkin–Elmer 283-B instrument as KBr discs or liquid films. NMR spectra were recorded in $CDCl_3$ or CD_3CN solution on a JEOL GX300 or Varian ST spectrometer (500 MHz). Chemical shifts are reported in ppm while the coupling constant (*J* values) are in Hz. Mass spectra were measured on a JEOL JMS-AX505, using the technique of electronic impact. High-resolution mass spectrometry and FAB spectra were obtained at an accelerating voltage of 10 KV, samples were desorbed from a nitrobenzyl alcohol matrix using 6 KeV xenon atoms. Mass measurements in FAB were performed at 10 000 resolution using electric field scans and the polyethylene glycol ions as the reference material.

© 2000 NRC Canada

Reactions were carried out by mixing 1 g of *N*,*N*-dialkylaniline with 5 g of bentonitic clay in dry medium and irradiating with a conventional microwave oven (2450 MHz, Goldstar model NOMA-1465M, single phase) at the higher power. After extraction of the products in a Soxhlet apparatus for 30 min using ethyl acetate:hexane (20:80) and methanol as eluents, reaction products were separated by silica gel chromatography using as eluent either ethyl acetate–hexane or isopropanol–formic acid in different ratios.

HPLC (27) was carried out in a Waters Delta Prep 4000 apparatus, with a Waters 486 tunable absorbance detector. The detector was set at 560 nm of wavelength. Chromatographic separation was on a 19 × 300 mm Waters μBondapack C_{18} preparative column. Mobile phase was 80:20 acetonitrile–buffer, with a concentration of 0.1 M of ammonium acetate and pH was then adjusted to 3.6 with glacial acetic acid. Flow rate was 10 mL/min.

Compound 3b

Purple solid, (512 mg, 65% at 60 min), mp 278°C. MS–EI (*m*/*z*): 414 (M^+). IR ν_{max} (cm^{-1}) (film): 2924, 1581, 1368, 1186. ^{1}H NMR (500 MHz, CD_3CN) δ_H (ppm): 6.917, 7.312 (AB system, 12H, Ph), 6.741, 7.643 (AB system, 12H, Ph), 6.643, 6.917 (AB system, 12H, Ph), 6.66, 6.717 (AB system, 12H, Ph), 3.62 (q, 6H, NC*H*$_2$CH$_3$), 3.492 (q, 6H, NC*H*$_2$CH$_3$), 3.354 (q, 6H, NC*H*$_2$CH$_3$), 3.263 (q, 6H, NC*H*$_2$CH$_3$), 3.166 (s, 9H, NMe), 2.996 (s, 9H, NMe), 2.837 (s, 9H, NMe), 2.761 (s, 9H, NMe), 1.234 (t, 9H, NCH$_2$C*H*$_3$), 1.141 (t, 9H, NCH$_2$C*H*$_3$), 1.048 (t, 9H, NCH$_2$C*H*$_3$), 1.023 (t, 9H, NCH$_2$C*H*$_3$). ^{13}C NMR (125 MHz, CD_3CN) δ_C (ppm): 11.141 (NCH$_2$*C*H$_3$), 11.339 (NCH$_2$*C*H$_3$), 12.155 (NCH$_2$*C*H$_3$), 37.827 (NMe), 38.556 (NMe), 47.152 (N*C*H$_2$CH$_3$), 47.443 (N*C*H$_2$CH$_3$), 47.997 (N*C*H$_2$CH$_3$), 111.493 (*C*H$_{ar}$), 113.212 (*C*H$_{ar}$), 113.314 (*C*H$_{ar}$), 116.360 (*C*H$_{ar}$), 116.753(*C*H$_{ar}$), 127.331 (C_{ar}CPh), 130.667(*C*H$_{ar}$), 132.911(*C*H$_{ar}$), 140.721(*C*H$_{ar}$), 152.756 (*C*Ph$_3$), 155.903 (C_{ar}NMe). HR-MS $C_{28}H_{36}N_3$ (M^+) calcd.: 414.2909; found: 414.2900.

Compound 13

Colorless prism, (525 mg, 57%), mp 136°C. MS–EI (*m*/*z*): 266 (M^+). IR ν_{max} (cm^{-1}) (film): 2877, 1510, 1480. ^{1}H NMR (300 MHz, $CDCl_3$) δ_H (ppm): 7.0, 6.7 (m, 6H, Ph), 4.1 (s, 4H, C*H*$_2$), 2.8 (s, 6H, NMe), 2.3 (s, 6H, Me). ^{13}C NMR (75 MHz, $CDCl_3$) δ_C (ppm): 20 (*Me*Ph), 39 (*Me*N), 58 (PhCH$_2$N), 115 (*C*H$_{Ar}$), 127 (C_{Ar}), 128 (C_{Ar}), 129 (*C*H$_{Ar}$), 132 (*C*H$_{Ar}$), 145 (C_{Ar}N).

Compound 14

Yellow crystals, (605 mg, 63%). MS–EI (*m*/*z*): 398 (M^+). IR ν_{max} (cm^{-1}) (KBr): 3425, 2924, 1597, 1502, 1317, 812. ^{1}H NMR (300 MHz, $CDCl_3$) δ_H (ppm): 7.35 (dt, 1H, Ph), 7.21, (dt, 1H, Ph), 6.99 (d, 1H, Ph), 6.77 (dt, 1H, Ph), 6.52 (dt, 1H, Ph), 6.34 (d, 1H, Ph), 4.17 (s, 1H, N*H*), 3.73 (s, 2H, C*H*$_2$Ph), 2.80 (s, 3H, MeN), 2.75 (s, 6H, MeN). ^{13}C NMR (300 MHz, $CDCl_3$) δ_C (ppm): 37 (MeN), 30 (*C*H$_2$Ph), 45 (MeN), 110 (C_{ar}Br), 111 (C_{ar}Br), 116, (*C*H$_{ar}$), 117 (*C*H$_{ar}$) 130 (C_{ar}CH$_2$), 131 (C_{ar}CH$_2$), 132.0 (*C*H$_{ar}$), 132.1 (*C*H$_{ar}$), 132.8 (*C*H$_{ar}$), 133 (*C*H$_{ar}$), 146 (C_{ar}N), 147 (C_{ar}N).

X-ray crystallographic data for 14

14: $C_{16}H_{18}N_2Br_2$, MW = 398.14; light-yellow prism (0.44 × 0.28 × 0.28 mm); monoclinic, *P*2/*n*, *a* = 11.095 (2) Å, *b* = 9.008 (1) Å, *c* = 17.058 (2) Å, β = 105.93 (1), *V*= 1639.4 (4) Å^3; *Z*= 4, *D*c = 1.613 g cm^{-3}. Data were collected on a SIEMENS P4 diffractometer at room temperature, with graphite-monochromated Mo-Kα radiation (λ = 0.71073 Å). The cell parameters were obtained from 39 reflections in the range 9.62 < 2θ < 20.48. The data collection (2θ max= 50.0°, scans θ/2θ, range 0 < h < 13, 0 < k < 10, –20 < l < 19) give 2884 unique reflections (R_{int} = 5.25%) with 682 (F > 4.0 s(F)) observed reflections. All these reflections were used for structure refinement after the intensity data was corrected for background and Lorentz-polarization effects. Absorption correction based on ψ-scans (min/max transmission 0.346/0.254) and the crystal decay negligible. The structure was solved by Direct Methods and refined by full-matrix least-squares using the SHELXL-97 (28) program, which gave final discrepancy indices R = 7.45%, wR_2 = 12.54% for "observed" ($I > 2\sigma(I)$) data. Non-hydrogen atoms refinement anisotropically; the hydrogen atoms included in idealized positions with a fixed temperature factor U = 1.2 times the U_{eq} or the parent C-atom. Final difference Fourier map was 0.452 and –0.454 e Å^{-3}. Atomic coordinates, bond lengths and angles, and thermal parameters have been deposited at the Cambridge Crystallographic Data Centre (CCDC 146746). Copies of the data can be obtained, free of charge,

Molecular and electronic structure of $An^{IV}Fe^{II}(CN)_6 \cdot xH_2O$ (An = Th, U, Np) compounds: an X-ray absorption spectroscopy investigation

Isabelle Bonhoure, Christophe Den Auwer, Christophe Cartier dit Moulin, Philippe Moisy, Jean-Claude Berthet, and Charles Madic

Abstract: $An^{IV}Fe^{II}(CN)_6 \cdot xH_2O$ (An = Th, U, Np) molecular compounds have been prepared by precipitation from acidic media. These microcrystalline compounds have been characterized by infrared spectroscopy, X-ray diffraction, and X-ray absorption spectroscopy. They have been found to be isostructural with the $Ln^{III}KFe^{II}(CN)_6 \cdot 4H_2O$ compounds. The molecular structures of these compounds are presented and their chemical formulas are given: in all compounds, the $Fe(CN)_6$ octahedra is conserved and the An ion is linked to the N atoms of the CN ligands. The formal oxidation states are also discussed.

Key words: hexacyanoferrate, actinide, EXAFS, XANES, X-ray absorption spectroscopy.

Résumé : Les composés moléculaires $An^{IV}Fe^{II}(CN)_6 \cdot xH_2O$ (An = Th, U, Np) ont été synthétisés par précipitation en milieu acide. Ces composés microcristallins ont été caractérisés par spectroscopie infrarouge, diffraction des rayons X et par spectroscopie d'absorption des rayons X. Nous montrons que ces composés sont isostructuraux avec les composés $Ln^{III}KFe^{II}(CN)_6 \cdot 4H_2O$ correspondants. Leurs structures moléculaires et électroniques sont présentées et les formules chimiques sont proposées: dans tous les composés l'octaèdre $Fe(CN)_6$ est conservé et l'ion actinide est lié à l'azote du ligand cyano. Les degrés d'oxydation sont également discutés.

Mots clés : hexacyanoferrate, actinide, EXAFS, XANES, spectroscopie d'absorption des rayons X.

Introduction

It is well-known that new three-dimensional molecular structures can be obtained by using well-characterized building blocks (1, 2). Such methods have been widely used to obtain preorganized three-dimensional entities (3–8). Among the possible building blocks, the hexacyanometallate ions $[M(CN)_6]^{n-}$ are often used to form polymeric inorganic networks such as Prussian Blue ($Fe_4[Fe(CN)_6]_3 \cdot 15H_2O$). The structure of this compound is a cubic lattice in which alternating Fe^{II} and Fe^{III} ions are linked by cyanide bridges (9–11). A great number of isomorphic compounds called "Prussian Blue analogs" have also been intensively studied (12–17) and a wide number of structures containing $Fe(CN)_6$ units are known.

Among others, numerous studies report on mixed hexacyanoferrate ($M_x[Fe(CN)_6]_y \cdot zH_2O$ where M = transition metal or lanthanide). In particular, mixed transition metal hexacyanoferrates are studied for their magnetic properties. For instance, Sato et al. (18) recently reported the synthesis of a cobalt–iron cyanide compound that exhibits photoinduced long-range magnetic ordering. The interactions between the two metal atoms via the CN ligands have been also theoretically studied so as to predict the magnetic behavior of this kind of complexes (19). Mixed transition metal hexacyanoferrates are also known for their alkali metal cation storage capabilities (20) and it has been demonstrated that Cs could efficiently be sorbed on $Cu^{II}{}_2Fe^{II}(CN)_6 \cdot xH_2O$ complexes (21). In most cases, transition metal hexacyanoferrates exhibit a cubic structure (9–11, 22) but they can also present trigonal or rhomboedral structures (22, 23).

Lanthanide hexacyanoferrates are known for their possible semipermeable membrane (24) and ion-exchange properties (25). These properties are considered to be related to the nature of the zeolitic water molecules. As a consequence, great attention has been paid to the structure determination of these compounds so as to investigate the zeolitic water molecule environment. $Ln^{III}Fe^{III}(CN)_6 \cdot 5H_2O$ and $Ln^{III}KFe^{II}(CN)_6 \cdot 4H_2O$ (Ln = La, Ce, Pr, Nd) crystallize in the $P6_3/m$ group for the early lanthanide ions (26–30).

Hexacyanoferrate $Fe(CN)_6$ entities complexed with actinide ions (An = Pu) were first mentioned during the 1950s (31). Some various $M_x(UO_2)_y[Fe(CN)_6]_z{\cdot}wH_2O$ compounds have also been synthesized and used as sorbants (32, 33) but none of these $[An/Fe(CN)_6]$ complexes has been structurally characterized. Only the X-ray powder diffraction of the complex $Th^{IV}Fe^{II}(CN)_6{\cdot}5H_2O$ has been reported (34) showing that it crystallizes in the hexagonal $P6_3/m$ space group as $Ln^{III}KFe^{II}(CN)_6{\cdot}4H_2O$ (Ln = La...Nd) complexes do. However neither the nature of the Ln—NC bond nor the one of An—NC bond have been extensively investigated.

The structural study of these $[An/Fe(CN)_6]$ complexes is of great interest; all the more they have possible applications in nuclear fuel reprocessing. Indeed, in our group, fundamental studies in actinide inorganic chemistry are linked to further applications in the frame of nuclear fuel cycle. For instance, the selective complexation of the actinide vs. the lanthanide ions is one of the main challenges, the final purpose being the separation of the so-called minor actinides, americium (Am) and curium (Cm), from the abundant lanthanides fission products both present in the acidic highly radioactive effluents issuing the reprocessing of nuclear spent fuels. Recently, Kulyako et al. (35–37) used the $[Fe(CN)_6]^{3-}$ molecular entity to complex trivalent actinide ions (An = Am, Cm). They observed the different behavior of the Ln^{III} ions which do not form precipitates in the conditions used to perform the An^{III} precipitation. The potential different affinity of $[Fe(CN)_6]^{3-}$ for these two *f* elements series is at the starting point of this work.

The aim of this paper is to describe the molecular and electronic structure of the edifices formed by the $[Fe(CN)_6]^{n-}$ building blocks and the actinide ions (An = Th, U, Np) and to compare these new materials to the analogs obtained with lanthanide. We decided here to synthesize the $An^{IV}Fe^{II}(CN)_6{\cdot}xH_2O$ entities with An = Th^{IV}, U^{IV}, Np^{IV} so as to investigate the early actinide complexes of these series. For comparison, Np^{III} and Fe^{III} have also been used as starting materials to determine if the not so stable Np^{III} is maintained or oxidized into Np^{IV} in these compounds. The $La^{III}KFe^{II}(CN)_6{\cdot}4H_2O$ structurally well characterized compound has also been synthesized and investigated by the same spectroscopic techniques for further comparisons.

As microcrystalline materials were obtained, X-ray powder diffraction (XPD), infrared (IR), and X-ray absorption (XAS) spectroscopies were of particular help to probe the An and Fe environments. We investigated the long-range order by XRPD. The IR vibration bands of the cyano groups probe the chemical bonds of the carbon and nitrogen atoms in these new materials. XAS provides both information about the electronic structure via X-ray absorption near edge spectroscopy (XANES) and about the local structure around the metals via extended X-ray absorption fine structures spectroscopy (EXAFS).

Experimental section

Synthesis

The reference and starting compounds, $K_4Fe^{II}(CN)_6{\cdot}3H_2O$, $K_3Fe^{III}(CN)_6$, $UO_2(NO_3)_2{\cdot}6H_2O$ were commercially purchased (Aldrich) and used as received. $UO_{2.0}$ and NpO_2 (obtained from CEA inventory) were kindly supplied by the University of Rennes I (Pr. H. Noel, Matériaux intermétalliques d'éléments de transition *d* et (ou) *f*) and by the LCAA laboratory (DCC/DRRV/SEMP) of CEA Marcoule. $Np^{IV}(C_2O_4)_2{\cdot}6H_2O$ and UCl_4 were synthesized as described in the literature (38, 39).

Synthesis of the $[An/Fe(CN)_6]$ compounds were performed by precipitation upon the addition of hexacyanoferrate ions and actinide ions solutions. The actinide aqueous acid media allows the stabilization of the chosen actinide oxidation state. All Np solutions were handled in radiological glove boxes.

Hexacyanoferrate stock solutions were obtained by dissolving the corresponding solids in acidic or neutral distilled water (solution acidity specified below). Actinide stock solutions were obtained in the following way: the Th^{IV} initial solution ([Th] = 0.71 mmol g^{-1} in 4 M HCl obtained by attack of metallic Th by HCl) was diluted to obtain the final solution ([Th] = 0.079 mmol g^{-1} in 0.44 M HCl); U^{IV} solution was obtained by dissolving 1 g of UCl_4 in 30 mL 0.5 M HCl ([U] = 0.09 M) in a glove box filled with Ar; Np^{IV} solution was obtained by dissolving 73 mg of NpO_2 (obtained from CEA inventory) in $HClO_4$/HF (2.4 mL 9.37 M $HClO_4$ and 0.5 mL 2.3 M HF) under reflux. After evaporation of HF and dilution in 0.1 M $HClO_4$, the final solution was obtained: [Np] = 0.027 M in 10 mL 2.34 M $HClO_4$. Np^{III} solution was obtained by galvanostatic reduction of the former Np^{IV} solution under argon with a current fixed to –1 mA with platinum electrodes for working and separated auxiliary electrodes and a calomel electrode as reference. The exclusive presence of Np^{IV} or Np^{III} ions in the stock solutions was checked by UV–vis spectrometry (UV–vis–NIR SCHIMADZU 3101 PC spectrometer, characteristic absorption bands (nm): Np^{III}: 550, 601, 658, 783; Np^{IV}: 724, 939, 964; Np^{V}: 981)).

The $[An/Fe(CN)_6]$ precipitates were obtained at room temperature by the slow simultaneous addition of the two reagents (An solution and $Fe(CN)_6$ solution) in a vortex. After mixing (about 20 min), the solution was stirred for 30 min. After 12 h, a fine precipitate was separated from the solution by centrifugation, washed with ethanol and acetone, and dried at room temperature overnight. The synthesis of $Th^{IV}Fe^{II}(CN)_6{\cdot}5H_2O$ was carried out as described in the literature (34).

In the following, the compounds will be formally written as $An^I/Fe^J(CN)_6$, meaning that An ions at the +I oxidation state and Fe ions at the iron +J oxidation state were used as starting materials.

Compound 1: $Th^{IV}/Fe^{II}(CN)_6$

5.493 g of a colorless Th^{IV} solution was heated to 45°C and 5 mL of a pale yellow $K_4Fe^{II}(CN)_6$ neutral solution ([Fe] = 0.09 M) was slowly added. An abundant precipitate was immediately obtained. After washing (H_2O, EtOH) a blue solid was recovered. The X-ray diffraction pattern registered on this powder corresponds to the $P6_3/m$ space group and the found lattice parameters are close to those published by Xu and Hullinger (34) (present work: a = 7.38 ± 0.01 Å, c = 13.95 ± 0.02 Å; Xu. and Hullinger: a = 7.408 Å, c = 13.943 Å).

As elemental analysis was not available for thorium compounds, we evaluated the stoichiometry of the iron and

© 2000 NRC Canada

thorium elements in the material by measurement of the X-ray absorption atomic coefficients on both the Fe K edge and the Th L_3 edge. The McMaster atomic absorption parameters (40) have been used to extract the molar ratio corresponding to the edge jump. We found a molar ratio Th:Fe equal to 1.1 for compound **1**, which confirms the stoichiometry found by Xu and Hullinger (34).

Compound 2: $U^{IV}/Fe^{II}(CN)_6$

Synthesis was carried out in a glove box filled with Ar (less than 2 ppm O_2) because of the air sensitivity of U^{IV}. 15 mL of a pale yellow $K_4Fe^{II}(CN)_6$ solution (0.11 M in 0.5 M HCl) was mixed with 15 mL of the green U^{IV} solution and a green precipitate was instantaneously obtained. If exposed to air, the precipitate turned brown due to a massive oxidation of U^{IV} into U^{VI}. All the analyses were therefore carried out under argon or vacuum. Elemental analysis was performed at Analytische Laboratorien GMBH (Germany). Anal. calcd. for $UFeC_6N_6H_6O_3$: U 47.22, Fe 11.11, C 14.28, N 16.67; found: U 47.70, Fe 12.75, C 15.12, N 17.83. The U:Fe ratio was found equal to 0.9.

Compound 3: $Np^{IV}/Fe^{II}(CN)_6$

3 mL of the green Np^{IV} stock solution was mixed with 2 mL of a pale yellow $K_4Fe^{II}(CN)_6$ neutral solution (0.041 M) and a deep pink precipitate was instantaneously obtained.

Compound 4: $Np^{III}/Fe^{III}(CN)_6$

3 mL of the violet Np^{III} stock solution was mixed with 2 mL of a yellow $K_3Fe^{III}(CN)_6$ neutral solution (0.041 M) and a deep pink precipitate was instantaneously obtained.

The iron and Np stoichiometries for **3** and **4** were determined as for **1**. However, since McMaster coefficients are not available for Np, we used in first approximation the parameters tabulated for U element. We found a molar ratio Np:Fe equal to 1.1 for compound **3** and 1.0 for compound **4**.

It should be noted here that the reaction between Np^{III} and $Fe^{II}(CN)_6$ ions was not undertaken due to the lack of Np^{III}.

Compound 5: $La^{III}KFe^{II}(CN)_6.4H_2O$

Single crystals were obtained by very slow diffusion of dilute $LaCl_3$ and $K_4Fe^{II}(CN)_6$ water solutions into an U-tube filled with H_2O as described elsewhere (26). X-ray diffraction measurements on the single crystals allowed us to obtain the same crystallographic parameters as those previously published by Beall et al. (26).

IR spectroscopy

IR spectra were recorded between 400 and 4000 cm^{-1} on a Nicolet Magna 560 spectrometer equipped with a ZnSe horizontal attenuated transmitted reflectance crystal. The solid samples were crushed with Nujol (2 mg of solid sample into 100 μL of Nujol) and the mixture obtained positioned on the ZnSe crystal.

X-ray absorption spectroscopy

Data acquisition

EXAFS and XANES measurements were carried out at the LURE (Laboratoire pour l'Utilisation du Rayonnement Electromagnétique, France) facility on the DCI ring (1.8 GeV, λc = 3.7 keV) on D44 experimental hutch. Because all samples are radiologically hazardous, they were placed in a house-made shroud (41). Uranium air-sensitive samples were kept under primary vacuum during the experiment. A double crystal monochromator was used and X-ray absorption was measured in transmission mode with ionization chambers. For XANES measurements, a reference metallic foil was positioned after the second ionization chamber and its spectra was recorded simultaneously with a diode detector.

Actinide L_3 edge: A Si 311 monochromator for both EXAFS and XANES spectra and argon-filled ionization chambers were used. Calibration was done at the Zr K edge of a Zr metallic foil at 18014.0 eV (42) at the absorption maximum. The energy resolution was 8.4 eV at 17000 eV.

Iron K edge: A Si 111 monochromator for EXAFS spectra and a Si 311 monochromator for XANES spectra were used. The ionization chambers were filled with air. Harmonic rejection was achieved by detuning the two crystals of the monochromator (30% loss of flux). Energy calibration was done at the Eu L_3 edge of an $EuPd_2$ alloy foil at 6982.0 eV at the absorption maximum. Energy resolution at 7000 eV was 2.7 eV for Si 111 and 1.3 eV for Si 311 crystal.

EXAFS data treatment

EXAFS data treatments were carried out using the set of programs "EXAFS pour le Mac" (43). A linear function was used for pre-edge extrapolation, atomic absorption was modeled by a polynomial function of the 6th order for Fe and by spline smoothing for An (polynom of the 6th order, smoothing coefficient equal to 0.94 for **1**, 0.96 for **2**, 0.91 for **3**, 0.94 for **4**). The nonreduction of the neighbor contribution by the spline smoothing has been checked. Normalization was done using the Heitler–Heisenberger method. The pseudo-radial distribution functions (PRDF) were obtained by Fourier transformation (FT) of the EXAFS oscillations in k^3 space between 1.8 and 14.6 $Å^{-1}$ for Fe K edge and between 2.2 and 14.7 $Å^{-1}$ for An L_3 edge using a Kaiser window with $\tau = 3$ for the Fe K edge, $\tau = 5$[3] for the An L_3 edge.

XANES data treatment

After pre-edge linear extraction and energy calibration with respect to the in situ reference foil using the Bragg formula, the XANES spectra were normalized to 1.0 at the middle of the first EXAFS oscillation.

EXAFS data fitting procedure

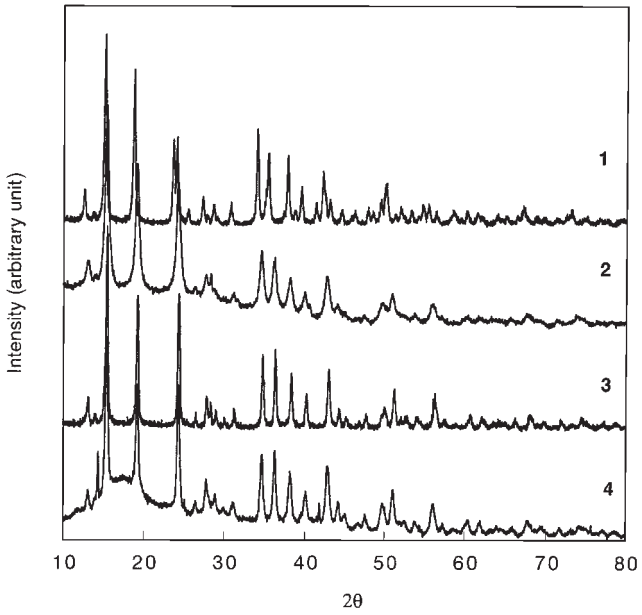
It is well known that EXAFS data analysis highly depends on the choice of reliable electronic parameters (backscattering phase $\varphi(\theta, k)$, backscattering amplitude $f(\theta, k)$, electron mean free path $\lambda(k)$, and inelastic losses S_0^2) (44). Best sets of such parameters are often extracted from model compounds that account for the electronic and crystallographic structures of the unknown compound. This is the case here where hexacyanoferrate starting material is the best candidate as a model compound at the Fe K edge. This is, however, not the case at the An L_3 edge since the synthesis of

[3] The high τ value for the actinide L_3 edge is made to decrease the effect of the side PRDF peaks.

© 2000 NRC Canada

reference compounds with only An—N bonds (such as ThN, UN, and NpN materials) required drastic conditions not available at the present time in our laboratory. To analyze the An L_3 EXAFS oscillations, calculated electronic parameters have to be used. In all cases, the EXAFS oscillations were back-Fourier transformed before adjustment. Fits of the $k\chi(k)$ EXAFS oscillations were carried out with the Round Midnight code[4] (43).

Fe K edge analysis: Fe-C and Fe-N electronic functions were extracted from the EXAFS spectrum of $K_3Fe^{III}(CN)_6$ complex ([1.23 Å, 2.00 Å] back-Fourier transformation for Fe-C, [2.00 Å, 3.10 Å] back-Fourier transformation for Fe-N). The electronic functions Fe-N contain several single and multiple scattering contributions which are known to be present for this kind of geometry (45, 46). A mean contribution is hence taken into account.



The fitted EXAFS oscillations of the first (C) and second (N) peaks of the PRDF of compounds **1** to **4** were obtained by inverse FT between 1.23 and 3.10 Å. Floating parameters in the 2-shell fit were: the two Debye–Waller factors $\sigma_{Fe\text{-}C}$ and $\sigma_{Fe\text{-}N}$, the global energy threshold ΔE_o, and the backscatterer distances R_C and R_N. N, the number of neighbors, was fixed to 6, S_0^2 and $\lambda(k)$ are included in the experimental amplitude.

An L_3 edge analysis: Calculated electronic parameters were obtained with Feff7.02 code (47). Many studies have already proved the efficiency of this code for actinide compounds (48–50). The amplitude and phase shift functions were obtained with one pair An/N with an An—N distance fixed reasonably to 2.50 Å, which is a typical An—N or An—O distance in compounds whose structures have been determined (38, 51–56). The Hedin–Lundqvist potential was used with Nleg = 2 (cf. appendix). The fitted EXAFS oscillations of the first peak of the PRDF were obtained by back-Fourier transformation of the FT between 1.38 and 2.37 Å. S_0^2 and Γ (= k/λ) functions calculated by Feff7.02 were fixed in the fit. Floating parameters in the 1-shell fit were: the Debye–Waller factor $\sigma_{An\text{-}N}$, the global energy threshold E, and the backscatterer distance R_N. The number of first neighbors around the actinide was fixed to nine by analogy to the corresponding lanthanide complexes. In a first approximation all the neighbors were considered equivalent. Then, to take into account the probable coordination of water molecules at different distances, two distances were fitted.

X-ray powder diffraction

The X-ray powder diffraction of **1**, **3**, and **4** were collected at COGEMA Marcoule with a Jobin-Yvon CGR apparatus in a glove box using a Cu Kα ray. The X-ray powder diffraction of **2** was collected on an INEL CPS120-equipped powder diffractometer set up in a horizontal Debye–Scherrer geometry (using the Cu $K\alpha_1$ radiation as incident beam, a sealed capillary of 0.1 mm internal diameter as sample holder, and a curved gaseous detector –6.5 × 10^5 Pa of 15% ethane and 85% argon).

Fig. 1. X-ray powder diffraction patterns for **1**, **2**, **3**, **4** (10° < 2θ < 70°). The refined lattice parameters are listed in Table 1. The spectra are shifted in ordinates for clarity.

Results

X-ray powder diffraction

The X-ray powder diffraction patterns of compounds **1**, **2**, **3**, and **4** are presented on Fig. 1. Compound **1** ($Th^{IV}Fe^{II}(CN)_6{\cdot}5H_2O$) is known to crystallize in the $P6_3/m$ space group (34) and contains most probably nine-coordinated $MN_6(H_2O)_3$ groups linked to octahedral FeC_6 groups by cyanide bridges like in the case of $KLa^{III}Fe^{II}(CN)_6{\cdot}4H_2O$ (26).

The structure of the X-ray patterns of **2**, **3**, and **4** are similar to those of **1**. This observation means that these complexes are isostructural with $La^{III}KFe^{II}(CN)_6{\cdot}4H_2O$. The lattice parameters have been determined with the ERACEL program (57). Moreover, all the peaks of the compound **3** spectrum are present in the spectrum of **4**, at the same 2θ values suggesting that, starting from different oxidation states for the metal ions, the precipitation reactions lead to the same compound.

The 2θ peaks are nevertheless shifted to higher θ values going from Th (**1**) to U (**2**) complexes and from U (**2**) to Np (**3** and **4**) complexes. This shift is due to a shortening of the lattice parameters from Th to Np complexes. The parameters range indeed from 7.38 to 7.30 Å for **a** and from 13.95 to 13.47 Å for **c** (Table 1) for U and Np, respectively.

Infrared spectroscopy

The absorption bands between 2000 and 2200 cm^{-1} for compounds **1**–**5** are listed in Table 2. There is only one peak in this energy range for each compound. This peak can be assigned to the cyano stretching vibration by analogy with the IR spectra of similar compounds found in the literature

[4] EXAFS fits were carried out in $(k^{q+1}/A)\text{chi}(k)$ weighting mode (where A is the mean of the standard deviation pondered by q which is equal to 1.5 for Fe K edge, 1 for An L_3 edge).

$R = \frac{\Sigma(\theta_{obs} - \theta_{calc})^2}{N_{reflexion} - N_{paramter}}$.

Table 2. Position of the CN infrared stretching mode in reference compounds and in complexes **1**–**5**.

Complexes	ν(CN) (cm^{-1})	References and notes
$K_3Fe^{III}(CN)_6$	2 118	(62)
$K_4Fe^{II}(CN)_6{\cdot}3H_2O$	2 044	(63)
$Pr^{III}KFe^{II}(CN)_6{\cdot}4H_2O$	2 061	(26)
$La^{III}KFe^{II}(CN)_6{\cdot}4H_2O$ (**5**)	2 064	this work
$Th^{IV}/Fe^{II}(CN)_6{\cdot}xH_2O$ (**1**)	2 059	this work
$U^{IV}/Fe^{II}(CN)_6{\cdot}xH_2O$ (**2**)	2 061	this work
$Np^{IV}/Fe^{II}(CN)_6{\cdot}xH_2O$ (**3**)	2 060	this work
$Np^{III}/Fe^{III}(CN)_6{\cdot}xH_2O$ (**4**)	2 060	this work

Note: The formal oxidation states of An and Fe in $An/Fe(CN)_6$ compounds in this table correspond to those of the starting ions.

(15, 18, 28, 58) and is located in the $Fe^{II}(CN)_6$ energy range since the peak position is known to be mostly sensitive to the oxidation state of the metal ion linked to the C atom (58, 59). These positions indicate then the presence of Fe^{II}-CN entities for **1**–**4**. While the band of non-bridging CN ligands (2044 cm^{-1} for Fe^{II}-CN) is not observed (58) in the spectra of compounds **1**–**5** higher energy shifted vibration bands of about 20 cm^{-1} (as observed here with respect to free CN ligands linked to Fe^{II} ion) indicates that all CN are bridging. This CN-bridging IR signature indicates that the actinide is linked to the nitrogen atom of the CN ligands. Moreover, this position is very close to the one of the CN stretching vibrations for $Ln^{III}KFe^{II}(CN)_6{\cdot}4H_2O$ (Ln = La, Pr) containing the Fe^{II}-CN-Ln^{III} motif.

XANES

It is well known that the X-ray absorption edge (position and structure) is sensitive to both local and electronic structure of the absorbing atom (symmetry, formal oxidation state of the metal, nature of the ligands, and distances (metal–ligands)). However, this sensitivity highly depends on the orbital probed. Here, we chose to probe: (*i*) the actinide L_3 edge ($2p^6 6d^n \rightarrow 2p^5 6d^{n+1}$ transition), since many studies have reported the influence of the actinide formal oxidation state on the L_3 edge position (50, 60–62); (*ii*) the iron K edge ($1s^2 4p^0 \rightarrow 1s^1 4p^1$ transitions), which is sensitive to both iron oxidation state (63, 64), point symmetry, and electronic structure (64–66) via the edge and pre-edge feature analysis.

A high-energy shift is generally to be expected with the increase of the oxidation state and (or) decrease of the metal–ligand distances (50, 60–64, 67).

Fig. 2. Iron K edge XANES spectra of compounds **1**, **2**, **3**, and **4**, and reference compounds $K_3Fe^{III}(CN)_6$ and $K_4Fe^{II}(CN)_6{\cdot}3H_2O$. The spectra are shifted in ordinates for clarity.

Compounds	E_{max} (eV) (±0.25 eV)
$K_3Fe^{III}(CN)_6$	7 130.5
$K_4Fe^{II}(CN)_6{\cdot}3H_2O$	7 129.5
1	7 130.2
2	7 130.0
3	7 130.2
4	7 130.0

Iron XANES

The iron K edge XANES spectra of compounds **1**–**4** are reported in Fig. 2 and compared to the reference compounds spectra of $K_3Fe^{III}(CN)_6$ and $K_4Fe^{II}(CN)_6{\cdot}3H_2O$. All the spectra resemble each other (presence of the principal structures B, C, and D) and are characteristic of the $Fe(CN)_6$ entity. Nevertheless, a weak structure A in the pre-edge is modified with respect to the two references. This prepeak A disappears in the spectra of compounds **1**–**4**.

The energies of the edge maxima are listed in Table 3. A high-energy shift of 1 eV is observed going from $Fe^{II}(CN)_6$ to $Fe^{III}(CN)_6$ references (67). The position of the edge maximum in the complexes **1**–**4** is intermediate between those of these two references.

Actinide XANES

The XANES of the three actinide ions (i.e., Th, U, and Np) are reported on Fig. 3 and compared to the spectra of reference compounds. First, note the similarity of all spectra. They present only two major features: the first one called white line is intense and relatively sharp; the second one corresponds to the first EXAFS oscillation. The Np L_3 edges of **3** and **4** (Fig. 3*c*) are identical which means that the two

Fig. 3. (*a*) An L_3 edge XANES spectra of compounds **1**. (*b*) **2**, $U^{IV}O_{2.0}$, and $U^{VI}O_2(NO_3)_2{\cdot}6H_2O$. **(*c*) 3**, **4**, and $Np^{IV}(C_2O_4)_2{\cdot}6H_2O$.

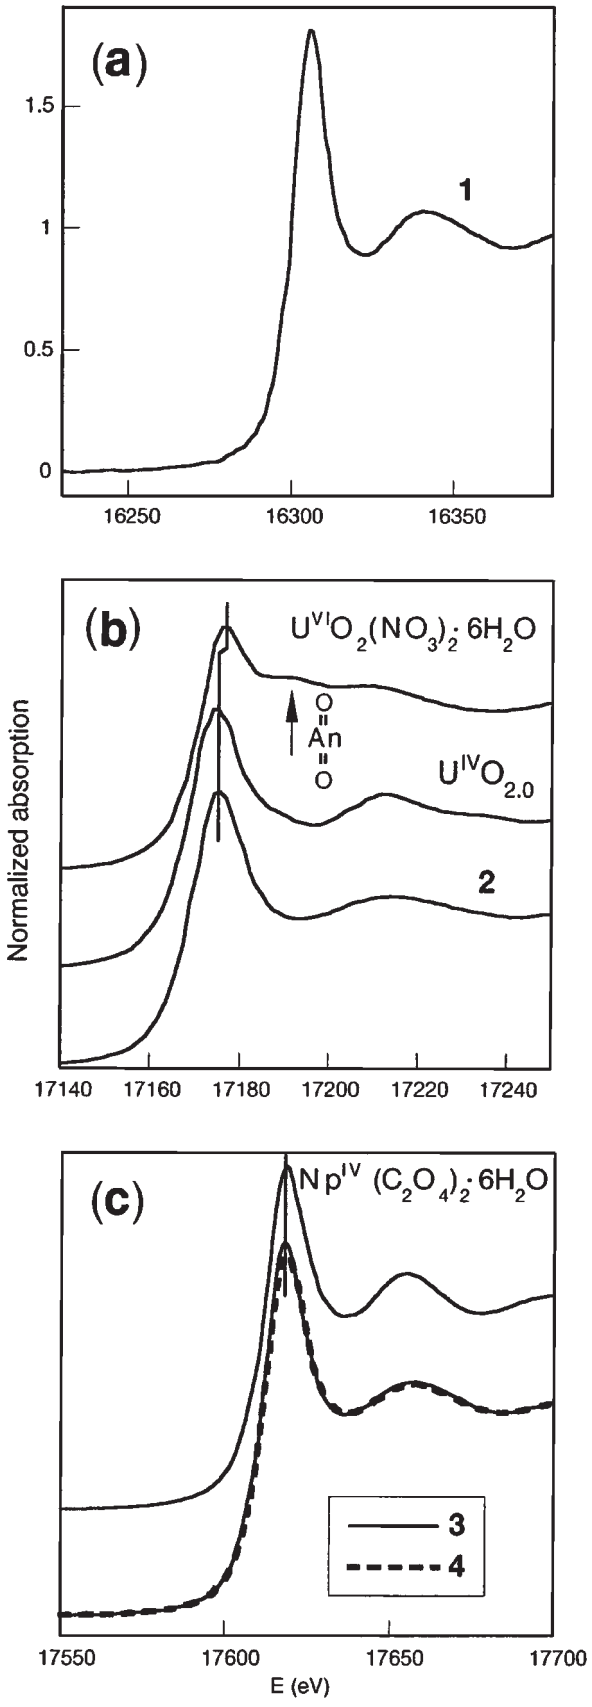

Table 4. Absorption edge maximum energy of the An L_3 edge XANES spectra (E_{max}).

Compounds	E_{max} (eV) (±0.5 eV)
1	16 305.8
$U^{VI}O_2(NO_3)_2{\cdot}6H_2O$	17 176.5
$U^{IV}O_{2.0}$	17 175.1
2	17 175.5
$Np^{IV}(C_2O_4)_2{\cdot}6H_2O$	17 618.5
3	17 618.1
4	17 618.5

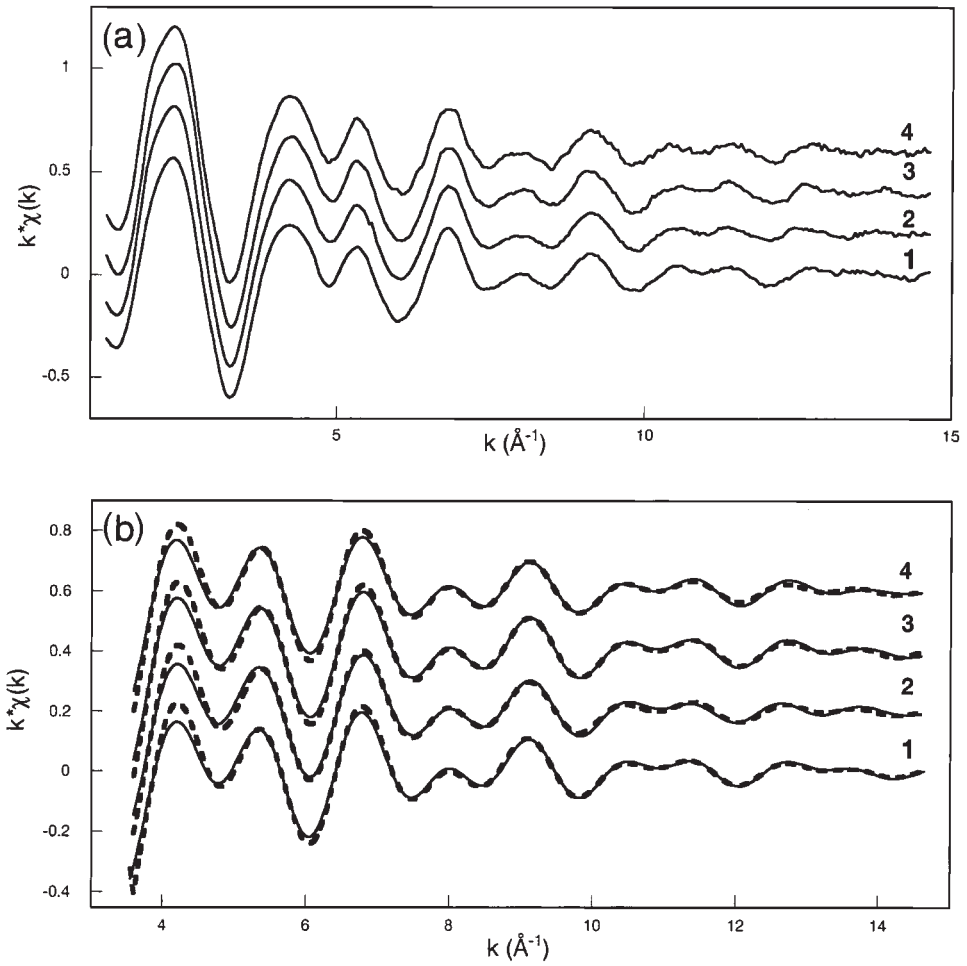
starting systems $Np^{III}/Fe^{III}(CN)_6$ or $Np^{IV}/Fe^{II}(CN)_6$ yield compounds with the same Np formal oxidation state and the same actinide environment. According to Table 4, the position of the Np absorption maximum of **3**, **4**, and Np^{IV} reference compounds are similar. Further proof is brought by the following: the XANES of the actinyl ion $[AnO_2]^{n+}$ (n = 1, 2) presents a typical signature (50, 62, 68). The multiple scattering along the linear O=An=O chain creates a shoulder at ~15 eV after the absorption maximum. This shoulder that is present in the spectrum of the reference compound $U^{VI}O_2(NO_3)_2{\cdot}6H_2O$ (Fig. 3*b*) is absent in the spectra of compounds **1**–**4**. The absence of such a feature in the XANES spectra precludes then the occurrence of +V or +VI oxidation states in compounds **1**–**4**.

Similarly, the XANES maximum position of compound **2** corresponds to U^{IV} with respect to the reference ($U^{IV}O_{2.0}$). The XANES spectrum of **1** (Fig. 3*a*) is not compared to the one of a reference compound since the formal oxidation state +IV is the only one possible for Th.

EXAFS

Fe K edge and An (Th, U, Np) L_3 edges were recorded for compounds **1**–**4** to investigate the local structure around these atoms. The pseudo-radial distribution function around Fe and An allows us, moreover, to study the geometry of the An-N-C-Fe motif.

Iron EXAFS



The EXAFS oscillations of **1**–**4** at the Fe K edge are presented in Fig. 4*a*. The EXAFS signals are quite similar. As the three PRDF are similar, only the PRDF of uranium compound **2** is presented on Fig. 5 for clarity.

Two major contributions A and B are present in the PRDF. Contribution A is assigned to the carbon first neighbors linked to the iron ion while contribution B is attributed to the nitrogen second neighbors. The second neighbor contribution is unusually high. The contribution of a second shell constituted of light atoms usually provides a less intense peak than the first shell due to the increase of the dumping factor $(1/kRj^2)\ e^{-2Rj/\lambda}$ of the EXAFS oscillations with R. Here, contribution B is as intense as A due to focusing effect along the Fe-C-N motif. It has been demonstrated that the linearity of this chain increases the number and the amplitudes of multiple scattering paths that occurs at the same frequency as the single scattering ones, thus increasing the contribution of the second shell atoms (45, 46).

Given the XANES results, the number of neighbors have been fixed to 6C and 6N in the two shell fitting procedure. With these values satisfactory fits have been obtained

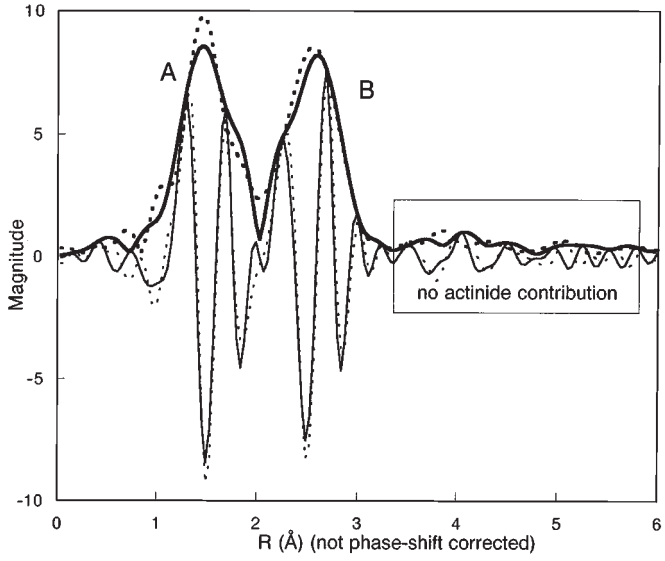
Fig. 4. (*a*) EXAFS oscillations at the Fe K Edge for complexes **1**–**4**. (*b*) Filtered (—) (first and second neighbors shells) and calculated (--) oscillations at the Fe K edge for complexes **1**, **2**, **3**, and **4** using a two-shell fit (cf. Table 5) (bottom). Oscillations are shifted in ordinate for clarity.



(Fig. 4*b* and Table 5). The Fe—C distances found by EXAFS (1.90 Å) in **1**–**4** are smaller to those of $K_3Fe^{III}(CN)_6$ (69) and $K_4Fe^{II}(CN)_6{\cdot}3H_2O$ (70) (1.94 and 1.93 Å, respectively). The Fe—N distances range from 3.05 to 3.06 Å. The deduced C—N distances range then from 1.15 to 1.16 Å supposing the linearity of the Fe-C-N chain. These fitted distances are in good agreement with those found by X-ray single crystal diffraction of $KLa^{III}Fe^{II}(CN)_6{\cdot}4H_2O$ which contains Fe-C-N-La chains ($R_{Fe\text{-}C}$ = 1.90 Å, $R_{C\text{-}N}$ = 1.15 Å, $R_{Fe\text{-}N}$ = 3.05 Å) (26).

Actinide EXAFS

The EXAFS oscillations at the An L_3 edge for complexes **1**–**4** are presented in Fig. 6*a*. The EXAFS oscillations of **1** are shifted to lower *k* in comparison with compounds **2**–**4** indicating a longer Th–ligand distance than U and Np–ligand distances. Given the similarity of the PRDF general shape for compounds **1**–**4**, only the PRDF of **2** is presented in Fig. 7. Three contributions D, E, and F are present in all PRDF. Contribution D is assigned to the nitrogen first neighbors and should probably contain oxygen neighbors of water molecules. Contribution E is due to the second carbon neighbors. The distances between the first two peaks of the nonphase shift corrected PRDF (i.e. 1.17 Å for **1**, 1.14 Å for

Fig. 7. Modulus (—) and imaginary part (--) of the PRDF of the U L_3 EXAFS oscillations for complex **2**.

2, 1.17 Å for **3** and **4**) which is close to the C—N distance in $Fe(CN)_6$ (1.14 Å) confirms this assignment. The third peak F has two possible origins: multiple scattering paths along the An-N-C chain or multiple scattering paths including the Fe atom along the An-N-C-Fe chain. These two assumptions can hardly be verified due to the great number of possible multiple scattering paths in this peak. In all cases, peak E intensity is weak, indicating the nonlinearity of the An-N-C chain which does not create an important focusing effect like at the Fe K edge where the Fe-C-N chain is quite linear. The best fit results of the first peak D filtered oscillations are presented in Table 6 and Fig. 6*b*. The number of neighbors has been fixed to nine in a first approximation (usual value between eight and nine) by structural analogy with corresponding $Ln^{III}KFe^{II}(CN)_6 \cdot 4H_2O$ complexes evidenced by our XPD measurements. This approximation is well beyond the EXAFS sensitivity to coordination numbers that is known to be at least 10%. Two types of fits have been performed: (*i*) using only one shell with nine atoms at the same *R* distance; and (*ii*) using two shells with six atoms at the R_1 distance and three atoms at R_2 (Fig. 6*b*). We suppose that the first nearest-neighbor shell contains both the An-N(NC) and An-O(OH_2) contributions. These two neighbors are not distinguishable by XAS due to their close *Z* numbers ($Z = 7$ and $Z = 8$). This first shell was hence analyzed using only the An-N parameters obtained with the Feff7.02 code. If all surrounding atoms are supposed to be equivalent, the average An—N distance is equal to 2.52 Å for Th (**1**), 2.44 Å for U (**2**), and 2.43 Å for Np (**3** and **4**). The high value of the Debye–Waller factor for this fit ($\sigma^2 = 0.0081$ Å^2) suggests, nevertheless, a large distribution of neighbor distances. In the two shell fit procedure: $R_{Th\text{-}O} = 2.61$ Å and $R_{Th\text{-}N} = 2.48$ Å are found in the thorium complex **1**; $R_{U\text{-}O} = 2.54$ Å and $R_{U\text{-}N} = 2.41$ Å are found in the uranium complex **2**; and $R_{Np\text{-}O} = 2.52$ Å and $R_{Np\text{-}N} = 2.40$ Å are obtained for the neptunium complexes **3** and **4**. The mean An—N,O distances decrease from Th to Np.

Discussion

The above spectroscopic results lead us to draw a structural and to a lesser extent electronic picture of these complexes that is discussed below.

First of all, the two neptunium complexes **3** and **4** exhibit equivalent spectroscopic results (IR, XANES, EXAFS, XRPD). Starting with two different couples of metal ions (Np^{III}/Fe^{III} and Np^{IV}/Fe^{II}) results in the formation of the same compound.

The An (Th, U, Np) XANES spectra (Fig. 3) suggest that the compounds contain Th^{IV} (**1**), U^{IV} (**2**), and Np^{IV} (**3**, **4**) ions. This tetravalent state is quite common in the complexes of U and Np and is the only one possible for Th (71). The chemical analysis for **2** and the molar ratio An/LFe for **1**, **2**, **3**, and **4** attest that there is one Fe for one An in **1**–**4**. To take into account the electroneutrality of the compounds, two possible formula can arise from this stoichiometry: $An^{IV}Fe^{II}(CN)_6 \cdot xH_2O$ or $An^{IV}XFe^{III}(CN)_6 \cdot xH_2O$ (X = Cl^-, ClO_4^-). As the possible X anions were not detected (absence of ClO_4^- characteristic vibration mode (72, 73) at 1099 cm^{-1} on the infrared spectra of **3** and **4**, absence of Cl in **2** elemental analysis) the second formula can be rejected. Thus,

© 2000 NRC Canada

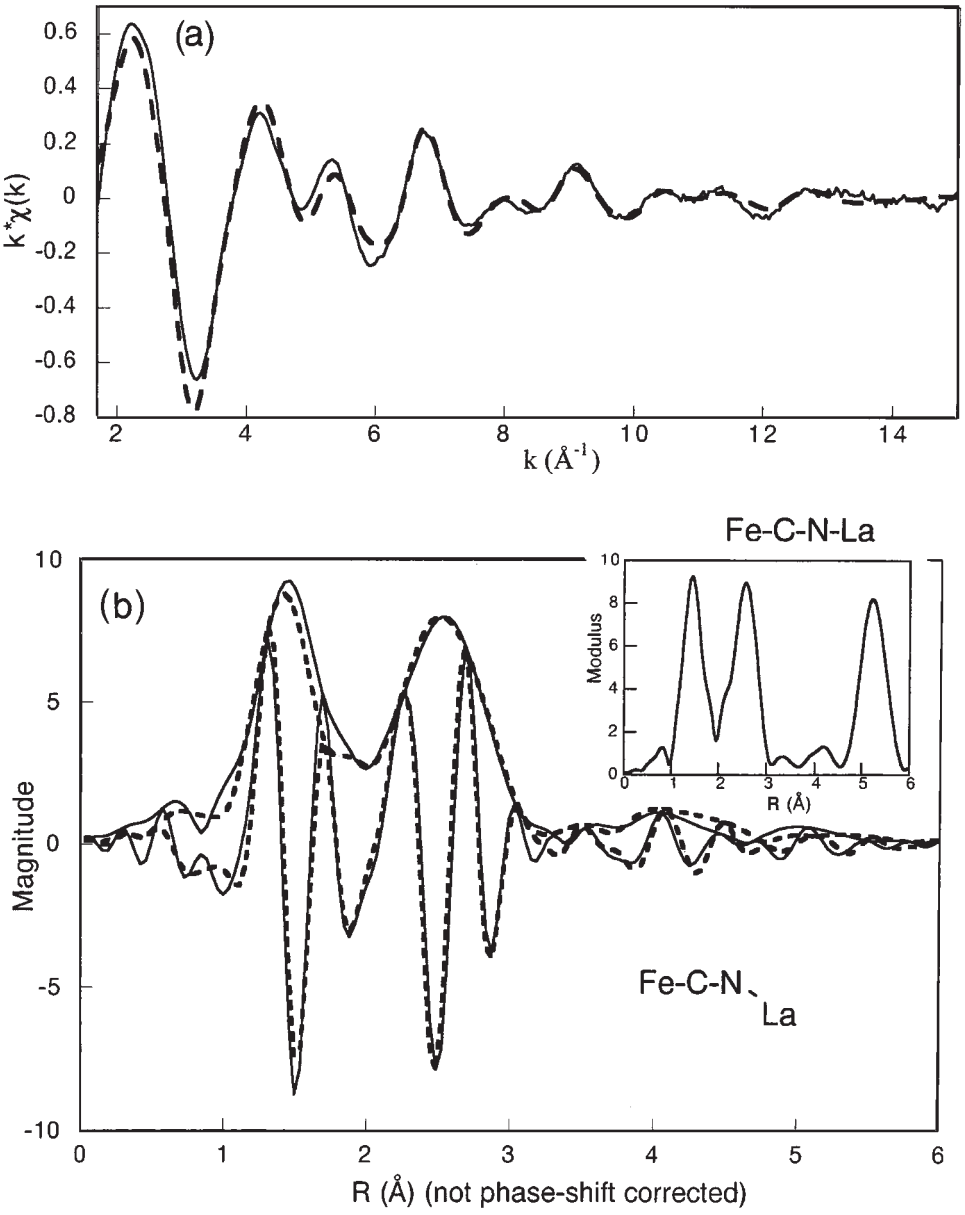
the Fe oxidation state is II in all the complexes. Nevertheless the Fe XANES maximum absorption of compounds **1**–**4** is shifted at higher energy (0.5 eV) compared to the Fe^{II} reference spectrum. This small but significant shift can be attributed to the decrease of the Fe—C distance, as emphasized by EXAFS analysis (67). The Fe^{II} oxidation state attribution is also in agreement with the infrared spectra. The position of the stretching mode ν_{CN} (2060 cm^{-1}) for **2**, **3**, and **4** is the same as the one observed for model compounds **1** and **5** for which the Fe oxidation state is II.

The formation of identical species (**3** and **4**) starting from Np^{III} or Np^{IV} is in agreement with the oxido-reduction potentials of the couples, i.e., 0.36 V/ENH for $Fe^{III}(CN)_6/Fe^{II}(CN)_6$ and 0.18V/ENH for Np^{IV}/Np^{III}. The oxido-redox process ($Fe^{III}(CN)_6 + Np^{III} \rightarrow Fe^{II}(CN)_6 + Np^{IV}$) might be thus invoked as a reaction driving force even if it can be considered as a schematic view of the reaction mechanism. Further experiments are in progress to clarify the features that govern the species formation. It should be noticed here that the unstable Np^{III} ions can be oxidized to Np^{IV} by air but that the $Fe^{III}(CN)_6$ ion is stable in solution. Thus this redox reaction can not be attributed to an air oxidation process.

As suggested by EXAFS and XANES Fe K edge analysis, the structural entity $Fe(CN)_6$ is conserved in compounds **1**–**4**. The IR spectroscopy shows besides that the six cyano ligands surrounding the iron are bridging as only one peak accounting for the ν_{CN} stretching vibration observed. The effect of this bridging is confirmed by the Fe pre-edge analysis: pre-peak A (Fig. 2) disappears in the Fe K edge XANES of complexes **1**, **2**, **3**, and **4** with respect to the two references in which the CN ligands are monodentates. This feature between 7118 and 7122 eV is principally attributed to the Fe 1*s*-4t_{1u} transition, the 4t_{1u} orbital being mainly built from the antibonding π^* orbitals of the CN ligands (64). According to the same author it may also contains dipole-forbidden transitions of the Fe 1*s* electron into nonbonding 2t_{1g} and 2t_{2u} and antibonding 3t_{2g}. The later are also mainly built from π^* orbitals of the CN ligands. Variations of A (position and occurrence) indicates a change in the molecular orbitals localized on the CN ligands due to the creation of an An—N bond. The formation of this bond changes the symmetry of the molecular orbitals and (or) due to actinide back-bonding into CN ligands, fills the empty orbitals. Moreover, the CN molecular orbitals are delocalized both on the actinide and the iron ion, which can explain the decrease of the intensity of the transition.

Given the CN ligands are linked by the carbon and the nitrogen atoms, the absence of the actinide contribution in the Fe PRDF which should appear near 5 Å could seem surprising (Fig. 5). In fact, the same kind of behavior has already been analyzed in a recent paper in the case of an Fe-C-N-Cu chain (74) where the decrease of the Cu-N-C angle from 174 to 147° creates the disappearance of the Cu contribution on the Fe PRDF. It has also been shown that the Cu-N-C bending could prevent copper signature to be observable in the iron PRDF. The interpretation of this phenomena has been checked on the $La^{III}KFe^{II}(CN)_6 \cdot 4H_2O$ (**5**) EXAFS spectrum: the contribution of La is absent on the Fe PRDF (Fig. 5). The absence of a visible La contribution is not surprising taking into account the Feff7.02 simulation results. Starting from the crystallographic Fe environment of **5** (6C at 1.90 Å, 6N at 3.05 Å, 6La at 5.52 Å), the Fe EXAFS oscillations were simulated using the Feff7.02 parameters described in Appendix. The simulated EXAFS oscillations (Fig. 8*a*) and PRDF (Fig. 8*b*) are in very good agreement with the experimental ones. However, when the Feff7.02 calculation is performed with a linear Fe-C-N-La geometry (180°), the PRDF reported in Fig. 8 shows a strong contribution from the La backscatter (very intense third peak). This is a nice illustration of the intensity decrease of the multiple scattering contributions when the geometry deviates from the linearity. The absence of the An signature in the iron PRDF of compounds **1**, **2**, **3**, and **4** therefore indicates that the An-N-C angle is most certainly smaller than 180°, as in the case of **5**.

The An L_3 edge EXAFS treatment allows to investigate the local environment of the An ions. The decrease of the average An-Ligands fitted distances (Table 6) from Th to Np (2.52 Å, 2.44 Å, and 2.43 Å, respectively) is significant from Th to U and of the uncertainty order from U to Np. This constant decrease is in agreement with the ionic radii actinide contraction from Th^{IV} to Np^{IV} (ionic radii of eight coordinate An^{IV} ions for Th, U, and Np are respectively, equal to 1.19, 1.14, and 1.12 Å) (75). This trend is the same when the two-shell model is used (3O + 6N) for **1**–**4** ($R_{Th\text{-}N}$ = 2.48 Å > $R_{U\text{-}N}$ = 2.41 Å > $R_{Np\text{-}N}$ = 2.40 Å and $R_{Th\text{-}O}$ = 2.61 Å > $R_{U\text{-}O}$ = 2.54 Å > $R_{Np\text{-}O}$ = 2.52 Å).



In Table 6, the two-shell fit procedure of the first peak (six nitrogen neighbors and three oxygen neighbors) is devoted to mimic the lanthanide coordination sphere. The distances obtained for **1**–**4** are smaller than in the case of $La^{III}KFe^{II}(CN)_6 \cdot 4H_2O$ (24) ($R_{La\text{-}N}$ = 2.60 Å, $R_{La\text{-}O}$ = 2.73 Å) which is consistent with the decrease of ionic radii from Ln to An. For instance, $R_{U\text{-}N}$ in **2** is found 0.19 Å shorter than $R_{La\text{-}N}$. This difference is very close to the difference in ionic radii between eight-coordinated La^{III} and U^{IV}: 0.16 Å (75). The distance difference between $O(H_2O)$ and N(NC) neighbors is found to be the same for all our complexes **1**–**4** (~0.13 Å) and is similar to the one obtained in lanthanide series (26–29). Our results show that the environment of An in **1**–**4** is probably constituted of six nitrogen atoms coming from the cyano ligands and of three water molecules to complete the coordination sphere number to 9. These distances are consistent with the An—N and An—O distances determined by X-ray diffraction analysis on other compounds (38, 51–56). Thermogravimetric measurements (that are not available at this moment for nuclear species in our laboratory) should confirm this water content.

X-ray powder diffraction also demonstrates that complexes **2**, **3**, and **4** are isostructural with the $Ln^{III}KFe^{II}(CN)_6 \cdot 4H_2O$ (Ln = La to Nd) family of complexes and with complex **1** whose structure was previously described (34). The lattice parameters of **2**, **3**, and **4** are found to be shorter than for $La^{III}KFe^{II}(CN)_6 \cdot 4H_2O$ (a = 7.412 Å, c = 13.943 Å). This result is consistent with the smaller An-ligands distances with respect to Ln-ligands distances.

The combination of the diffraction and the EXAFS results allows us to estimate a value for the (AnNC) angle. Knowing the space group ($P6_3/m$) and the An (1/3,2/3,1/4) and Fe (0,0,0) positions, the lattice parameters values lead to determine the An—Fe distance (5.51 Å for **1**, 5.42 Å for **2**, 5.40 Å for **3** and **4**). The (AnNC) angle is then deduced,

Fig. 8. (*a*) Experimental EXAFS oscillations (—) for complex **5** at the Fe K edge compared with calculated Feff7.02 oscillations (--) (cf. Appendix) (*b*) corresponding experimental (—) and calculated (--) PRDF. The insert corresponds to the PRDF obtained with Feff7.02 supposing that the entity Fe-C-N-La is linear.

thanks to the An—N and Fe—N EXAFS-fitted distances. We found angles equal to 168 ± 3° for **1**, 164 ± 3° for **2**, 163 ± 3° for **3** and **4**. All these angles are comparable and are however slightly higher than the (LnNC) angle in $LaKFe(CN)_6 \cdot 4H_2O$ (155°). These angles differ sufficiently from 180° to explain the absence of An contribution in Fe K edge PRDF.

Conclusion

Only a few three-dimensional structures have been reported with 5*f* elements. Neptunyl cation–cation complex with mellitic acid, $Na_4(NpO_2)_2C_{12}O_{12} \cdot 8H_2O$ (51), zeolitic actinide material (76, 77), and $Rb_4U_4P_4Se_{26}$ which contains pentavalent uranium (78) or neptunium perovskite structures (79) can be cited as examples. In this work, two new three-dimensional solid state complexes $An^{IV}Fe^{II}(CN)_6 \cdot xH_2O$ (An = U, Np) have been synthesized and characterized. Spectroscopic investigations (XAS, IR) of these complexes show that for the two complexes the $Fe(CN)_6$ entity is present in the network. The first shell An analysis is consistent with the presence of three water molecules linked to the actinide, to complete the coordination sphere to 9 which is the classical geometry for these ions. These complexes can be viewed as a three-dimensional framework where the building blocks ($Fe(CN)_6$ entities) are connected through the actinide ions via the cyano bridging ligands. Thus, all the cyano ligands are bridging and the powder X-ray diffractograms show that the 3D network is isostructural with the $Ln^{III}KFe^{II}(CN)_6 \cdot 4H_2O$ analogs network. The space group is $P6_3/m$ and the cell parameters have been determined and used to propose a (AnNC) angle value which is: 164° for **2**,

© 2000 NRC Canada

163° for **3** and **4**. This angle value also explains the absence of the An contribution in the iron PRDF as modeled by multiple scattering Feff7.02 simulations.

Clearly, the early actinide and lanthanide hexacyanoferrates exhibit structural similarities despite some electronic discrepancies between the Ln and early An ions that can be pointed out. For instance the redox process invoked to explain the formation of the $Np^{IV}[Fe^{II}(CN)_6]\cdot xH_2O$ species ($Fe^{III}(CN)_6 + Np^{III} \rightarrow Fe^{II}(CN)_6 + Np^{IV}$) is not acceptable with the lanthanide ions. Indeed, only oxidation state +III is available for the early lanthanide series except for the case of Ce^{IV}. The Fe^{II}/Ce^{IV} couple has been already investigated by Xu and Hullinger (34), however the solid compound $Ce^{IV}Fe^{II}(CN)_6\cdot xH_2O$ was not obtained.

The greater covalence within the An—N bond vs. the Ln—N bond (80) is not evidenced by our EXAFS analysis which reflects only the decrease of the ionic radii going from Ln^{III} to Th^{IV}, U^{IV}, and Np^{IV}. Such results may be surprising knowing that the early actinide ions are considered to have the possibility to form more covalent-like character bonds. This propensity is not shared by the later actinides (Am, Cm, Cf) (81, 82). Thus, comparison between Ln^{III} and Am^{III} or Cm^{III} hexacyanoferrate compounds needs to be investigated to see if the tuning of the An ion leads to structural discrepancies between Ln and An species. This would be however surprising, given the similarities between the later actinide ions and lanthanide ions, as evidenced by previous work on Nd/Am coordination complexes where no structural differences have been observed (83).

Acknowledgments

The authors are very grateful to J. Vaissermann (LCIMM, Jussieu) F. Boucher (IMN, Nantes), J.-M. Blanchard (COGEMA, Marcoule), and E. Elkaïm (LURE, Orsay) for their contribution in diffraction measurements and interpretation. They thank also N. Dacheux (IPN, Orsay), F. Villain (LCIMM, Jussieu), and C. Neskovic (Laboratoire Pierre Süe, Saclay) for very fruitful discussions.

The one-electron oxidation of hydroxy(tetramesitylporphyrinato)iron(III)

David H. Jones and A. Scott Hinman

Abstract: The oxidation of hydroxy(tetramesitylporphyrinato)Fe(III) ([Fe(tmp)]OH) has been investigated by voltammetric and spectroelectrochemical techniques in CH_2Cl_2 containing tetra(*n*-butyl)ammonium hexafluorophosphate as supporting electrolyte. In this medium, the first one-electron oxidation is reversible on the time scale of cyclic voltammetry. The UV–vis spectrum, as obtained by double potential step chronoabsorptometry, indicates that the oxidation is centered at the porphyrin ring to form the corresponding π-cation radical. At longer times, or higher potentials, oxidation of [Fe(tmp)]OH leads to loss of hydroxide and formation of [Fe(tmp$^+$)]PF_6 π-cation radical. The time-dependent process is consistent with an ECE type mechanism, with the chemical step being slow conversion to neutral [Fe(tmp)]PF_6. At higher potentials, the initial oxidation product loses a second electron. The overpotential dependent oxidation suggests an EEC type mechanism with the second electrochemical step being a slow heterogeneous electron transfer from the Fe-OH moiety.

Key words: hydroxy(tetramesitylporphyrinato)iron(III), oxidation, electrochemistry, spectroelectrochemistry, π-cation radical.

Résumé : Faisant appel à des techniques voltampérométriques et spectroélectrochimiques, on a étudié l'oxydation de l'hydroxy(tétramésitylporphyrinato)Fe(III) ([Fe(tmp]OH) dans du CH_2Cl_2 contenant de l'hexafluorophosphate de tétra(*n*-butyl)ammonium comme électrolyte de support. Dans ce milieu, à l'échelle de temps de la voltampérométrie cyclique, la première oxydation à un électron est réversible. Le spectre UV–vis, tel qu'obtenu par la chronoabsorptométrie, indique que l'oxydation est centrée sur le noyau porphyrine et qu'elle conduit au radical cation-π correspondant. À des temps plus grands ou à des potentiels plus élevés, l'oxydation du [Fe(tmp]OH conduit à une perte de l'hydroxyde et à la formation du radical cation-π [Fe(tmp$^+$)]PF_6. Le processus qui varie avec le temps est en accord avec un mécanisme de type ECE dans lequel la première étape est une transformation lente en [Fe(tmp)]PF_6 neutre. À des potentiels plus élevés, le produit de l'oxydation initiale perd un deuxième électron. L'oxydation qui varie avec le surpotentiel suggère que le mécanisme impliqué est de type EEC dans lequel la deuxième étape électrochimique est un transfert hétérogène lent à partir de la portion Fe-OH.

Mots clés : hydroxy(tétramésitylporphyrinato)fer(III), oxydation, électrochimie, spectroélectrochimie, radical cation-π.

Introduction

The anodic oxidation of the sterically bulky five-coordinate iron(III) tetramesitylporphyrin with hydroxide as the axial ligand ([Fe(tmp)]OH), was first reported by Bruice and co-workers (1) in 1985. The cyclic voltammetry in dichloromethane containing 0.1 M tetra(*n*-butyl)ammonium perchlorate (TBAP) showed two oxidations separated by ca. 140 mV in a potential region where the chloro derivative, [Fe(tmp)]Cl, showed a single oxidation. It was proposed that the two oxidation waves were associated with step-wise formation of an iron(IV) porphyrin and an iron(IV) porphyrin π-cation radical and low-temperature thin-layer UV–vis spectroelectrochemistry was subsequently used to spectrally characterize two electrogenerated intermediates (2).

Different cyclic voltammetry was reported by Groves and Gilbert (3) for [Fe(tmp)]OH in dichloromethane containing 0.1 M TBAP and saturated with Na_2CO_3. In this case only one oxidation process at 1.0 V vs. SCE was observed. Low-temperature bulk electrolysis of the hydroxy iron(III) porphyrin complex in the presence of excess tetra(*n*-butyl)ammonium hydroxide produced a species with a UV–vis spectrum reminiscent of an oxoferryl porphyrin and not a porphyrin π-cation radical.

The difference between Groves and Gilbert's (3) voltammetry and that of Bruice and co-workers (1) was ascribed by Groves to the presence of chloride in Bruice's experiments. In response to Groves and Gilbert's (3) report, Calderwood and Bruice (4) published evidence that no chloride was present in their system and that Groves and Gilbert's voltammetry could be reproduced if wet dichloromethane was used as solvent.

Following these communications Kadish and co-workers (5) described a thorough investigation of both the oxidative and reductive electrochemistry and spectroelectrochemistry of [Fe(tmp)]OH using dc and steady-state voltammetries as well as thin-layer UV–vis spectroelectrochemistry. Their work suggested that the one-electron oxidized hydroxy iron

 © 2000 NRC Canada

porphyrin was unstable at room temperature and underwent one or more reactions producing either the chloro- or the perchlorato derivative as the final product(s).

Groves et al. (6) more recently observed that the potentials for oxidation of a series of hydroxy iron(III) porphyrins with different ring substituents correlated linearly with the potentials of the same series of chloroiron(III) porphyrins. Since chloroiron(III) porphyrins are widely accepted to undergo one-electron oxidation at the porphyrin ring, this correlation of potentials was taken as evidence that hydroxy iron(III) porphyrins also underwent initial ring oxidation.

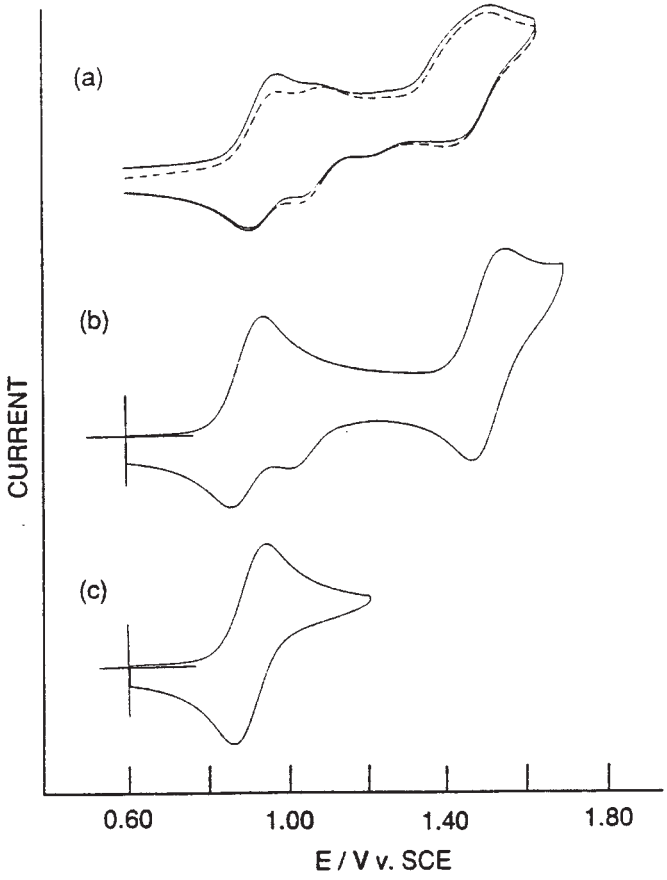
In the studies described above, spectral characterization of the electrogenerated intermediates was not possible on the voltammetric timescale at ambient temperature. In view of the reported instability of the initial electrode product (5, 6) it was felt that further study of the electrochemical oxidation of [Fe(tmp)]OH was in order. In addition to more conventional voltammetric and thin-layer spectroelectrochemical techniques, we have applied double potential step chronoabsorptometry (7) under conditions of semiinfinite linear diffusion to determine the UV–vis spectrum of the initial one-electron oxidation product.

Experimental

Materials

Tetramesitylporphyrin ($tmpH_2$)was prepared according to literature methods (8–10). Chloro(tetramesitylporphyrinato)iron(III) ([Fe(tmp)]Cl) was obtained from $tmpH_2$ and $FeCl_2 \cdot 4H_2O$ according to Adler et al.'s (11) DMF method. This material was converted to the hydroxide form by stirring a 1 mM toluene solution of the iron porphyrin against an equal volume of 1 M NaOH according to a published procedure (12). The UV–vis spectrum (toluene) was identical to that previously reported.

Dichloromethane was shaken with alumina, distilled from P_2O_5 onto CaH_2, and stored over CaH_2 prior to use. Tetra(*n*-butyl)ammonium perchlorate (TBAP) from Fluka was recrystallized from isopropanol–water and dried at 80°C in vacuo for several days. Tetra(*n*-butyl)ammonium hexafluorophosphate ($TBAPF_6$) was prepared as previously described (13).



Electrochemistry

The cells and instrumentation used for conventional cyclic voltammetry and potential pulse measurements (14), and for thin-layer voltammetric measurements (15) have been described previously. Either a homemade aqueous SCE (16) or a Ag–$AgPF_6$ quasi reference electrode was employed. The latter was prepared by immersing a Ag wire in CH_2Cl_2 containing $TBAPF_6$ and a crystal of $AgPF_6$ for 24 h prior to use.

Spectroelectrochemistry

Thin-layer UV–vis and in situ FTIR reflectance spectroelectrochemistry employed the same cell as used for thin-layer voltammetry (15). The instrumentation and methodology for the in situ FTIR measurements are as in ref. (15). For thin-layer UV–vis measurements, a reflectance optical arrangement was employed along with a spinning, grating monochromator to facilitate rapid spectral measurement. The instrumentation and methodology have been fully described elsewhere (17). The cell, instrumentation, and methodology for double potential step chronoabsorptometry are fully described in ref. (18).

Fig. 1. Cyclic voltammetry of 1 mM [Fe(tmp)]OH in dichloromethane containing (*a*) 0.1 M TBAP and (*b*), (*c*) 0.1 M $TBAPF_6$. The sweep rate for all experiments was 100 mV s^{-1}.

Results

Cyclic voltammetry

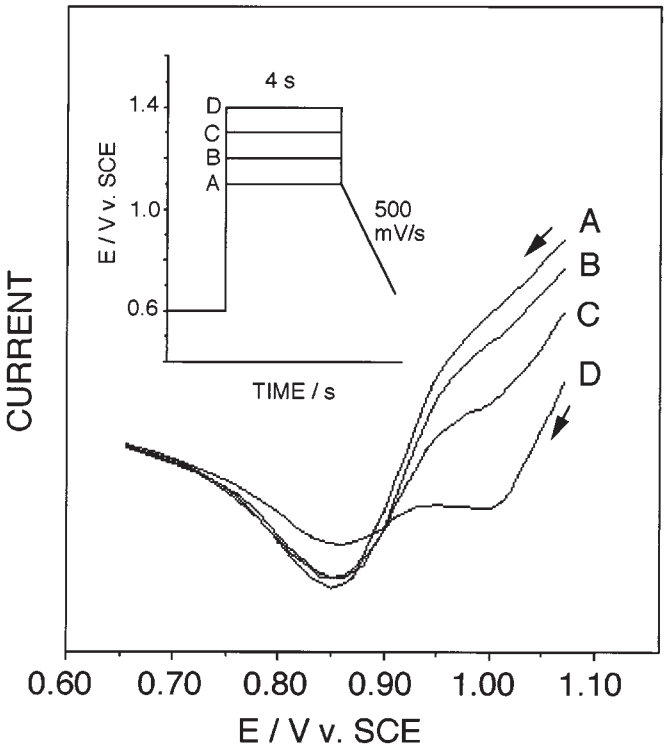
The room temperature dc cyclic voltammetry of [Fe(tmp)]OH in dichloromethane containing 0.1 M TBAP is shown in Fig. 1. The voltammetry is essentially identical to that previously reported by Kadish and co-workers (5) and shows two oxidation processes with half-wave potentials of 0.97 and 1.08 V vs. At higher potentials further oxidation is evident. Close inspection suggests the presence of a very weak anodic peak near 1.28 V apparently coupled to a cathodic peak at 1.22 V on the reverse scan. Another anodic peak at 1.55 V is coupled to a cathodic peak at 1.44 V. An apparent shoulder on the 1.55 V peak suggests there may be two closely spaced oxidations occuring in this potential region.

During a subsequent scan (Fig. 1*a*, dashed line) initiated immediately following completion of the first cycle, it is seen that the relative magnitude of the anodic peak currents corresponding to the oxidations at 0.97 and 1.08 V is altered. Thus, in the initial experiment the oxidation process at 0.97 V has the larger peak current (solid line). During the

© 2000 NRC Canada

repeat cycle (dashed line) it is the oxidation at 1.08 V which gives rise to the larger peak current.

The voltammetry of the hydroxide complex in CH_2Cl_2 containing $TBAPF_6$ is shown in Fig. 1*b*. The use of hexafluorophosphate over perchlorate as the supporting electrolyte anion produces significant changes in the voltammetry. Two oxidation processes are observed at 0.90 V and 1.51 V vs. SCE. In addition a cathodic wave is observed at 1.01 V. Thus, a comparison of Figs. 1*a* and 1*b* shows that the forward oxidation wave for the oxidation process at 1.08 V in CH_2Cl_2 containing 0.1 M TBAP is not clearly evident when $TBAPF_6$ is the supporting electrolyte. Steady-state cycling between 0.4 V and 1.7 V causes a new anodic peak at 1.08 V to grow in, resulting in voltammetry very similar to that observed in CH_2Cl_2 – 0.1 M TBAP. The half-wave potential of this oxidation in CH_2Cl_2 containing 0.1 M $TBAPF_6$ is estimated to be 1.04 V vs. SCE.



If the potential is switched at 1.20 V instead of 1.75 V then the initial oxidation process becomes completely reversible with a half-wave potential of 0.90 V vs. SCE (Fig. 1*c*). No evidence of the oxidation process at 1.04 V is seen. The reverse to forward peak current ratios for the process at 0.90 V are unity in the range 50–150 mV s^{-1}. The peak current is also proportional to the square root of the sweep rate for sweep rates in the range 50–150 mV s^{-1}. At a sweep rate of 25 mV s^{-1} the reverse to forward peak current ratio was 0.9. All subsequent electrochemical and spectroelectrochemical experiments utilized 0.1 M $TBAPF_6$ as supporting electrolyte.

In comparing the voltammetries of Figs. 1*b* and 1*c*, it is not clear whether the apparent irreversibility of the first oxidation and the appearance of the new cathodic peak at 1.01 V in 1*b* is due to the higher potentials reached on the anodic sweep, or to the longer time which the initial oxidation product exists in the diffusion layer prior to initiating its reduction. A combination of potential steps and a potential sweep was used to further probe the voltammetry of [Fe(tmp)]OH. In a first experiment (A), the potential was stepped from 0.6 V to 1.1 V for a 4 s period. The potential was then immediately swept back to 0.6 V at 500 mV s^{-1}. After a 30 s delay to allow the analyte solution to relax, experiment B was initiated whereby the potential was stepped from 0.6 V to 1.2 V for a 4 s period, and then immediately stepped back to 1.1 V and swept back to 0.6 V. Experiments C and D are similar to experiment B except that the potential steps were to 1.3 and 1.4 V, respectively. Thus, the overall time of the four experiments (A–D) is the same but the 4 s electrolysis occurs at increasingly positive potentials.

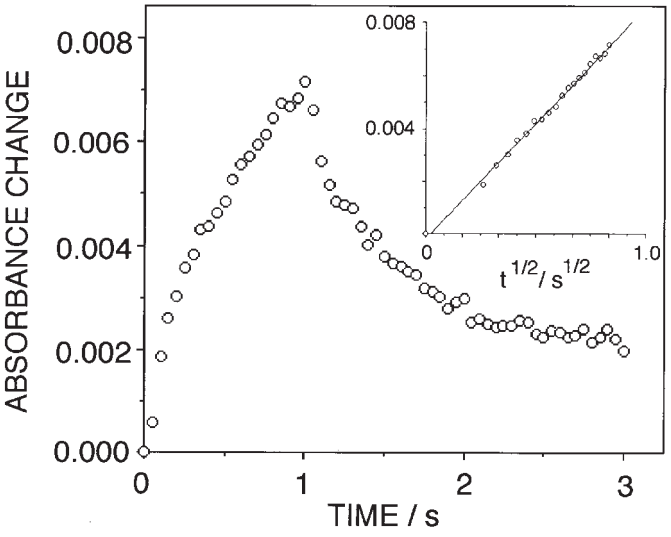
The potential sweeps from 1.1 V to 0.6 V resulting from experiments A–D are shown in Fig. 2. It is seen that the cathodic peak at 1.01 V increases as higher potentials are accessed, and this occurs concomitant with a decrease in the reduction wave for the initial oxidation process. This dependence on overpotential indicates that at least one step in the formation of the species giving rise to the reduction peak at 1.01 V involves a slow, irreversible heterogeneous electron transfer process

It was observed that over extended periods of time, [Fe(tmp)]OH in CH_2Cl_2 spontaneously converted to [Fe(tmp)]Cl. This is consistent with other workers' observations (6). In our case, the use of the aqueous SCE reference

Fig. 2. Current vs. potential during the potential sweep portion of the potential programs illustrated in the inset. The solution was 0.25 mM [Fe(tmp)]OH in CH_2Cl_2 – 0.1 M $TBAPF_6$.

electrode appeared to accelerate this problem, likely through slow leakage of either chloride or water into the CH_2Cl_2 solutions. Use of a Ag–$AgPF_6$ quasi reference electrode in subsequent electrochemical experiments prevented any observable formation of [Fe(tmp)]Cl.

Double potential step chronoabsorptometry



Since the initial oxidation wave with half-wave potential at 0.90 V is reversible at moderate sweep rates provided that the switching potential is not too positive, it was possible to generate the UV–vis spectrum of the one-electron oxidized species using short timescale chronoabsorptometric experiments carried out under conditions of semiinfinite linear diffusion. In this technique, a potential step is applied, and the change in absorbance (ΔA) of monochromatic light reflected from the electrode surface is monitored as function of time. For a reversible electron transfer process, the change in absorbance is given (7) by:

$$[1] \qquad \Delta A = \frac{4\Delta\varepsilon C D^{1/2} t^{1/2}}{\pi^{1/2}\cos\theta}$$

Here, $\Delta\varepsilon$ is the difference between the molar absorptivities of the product and starting material in the electrode reaction, D is the diffusion coefficient of the electroactive species, θ is the angle of incidence of the reflected light beam, and other terms have their usual significance. If the diffusion coefficient of the electroactive species is known, it is possible to determine the difference between molar absorptivities of the product and starting material for the electrode reaction from the slope of a plot of ΔA vs. $t^{1/2}$.

© 2000 NRC Canada

Fig. 3. Absorbance–time transient recorded at 350 nm for 0.05 mM [Fe(tmp)]OH during double potential step chronoabsorptometry of the first one-electron oxidation in CH_2Cl_2 containing 0.1 M $TBAPF_6$. The transient is the average of 64 experiments. Data reduction and smoothing was done with a 10 point box car averaging routine. The inset is a plot of the absorbance change against the square root of time for the forward step.

If the molar absorptivity of the starting material is known, then the molar absorptivity of the product is readily determined. Linearity of the ΔA vs. $t^{1/2}$ plot is an indication of reversibility of the electron transfer reaction. In double potential step chronoabsorptometry, the potential is stepped back to its intial value after a period τ. For a reversible reaction, the ratio ΔA ($t = 2\tau$)/ΔA ($t = \tau$) will be equal to 0.414, providing further indication of the reversibility.

Absorbance–time transients were recorded at single wavelengths in the range 350–690 nm at intervals of 20 nm. A total of 64 transients were collected at each wavelength and averaged. Data reduction and smoothing was done with a 10-point boxcar average. Analyte concentrations were adjusted to produce an absorbance in the range 1.0–1.5 in the chronoabsorptometric cell at the analytical wavelength and were in the range 10^{-4}–10^{-5} M. The potential was stepped to a point 120 mV beyond the forward voltammetric peak potential of the initial oxidation for 1 s and then stepped back to the base potential for 12 s prior to initiating a subsequent potential step. The spectra of the analyte solutions recorded prior to and after the experiments indicated that the iron(III) porphyrin remained in the hydroxide form. Cyclic voltammetry recorded before and after each spectroelectrochemical experiment indicated that reversibility was maintained and that there were no local fluctuations of the analyte concentration in the vicinity of the working electrode.

The absorbance–time transient for the experiment performed at 350 nm is shown in Fig. 3. The ratio of the absorbance at time 2τ relative to that at time τ is 0.414 ± 0.017 in excellent agreement with theory (0.414). Absorbance–time responses at other wavelengths also indicated that the absorbance changes were due to a reversible one-electron oxidation process without any complications during the timescale of the experiment.

A plot of the absorbance change for the forward step against the square root of the elapsed time is shown in the inset of Fig. 3. The plot is linear for data collected at 100 ms and beyond and yields a zero intercept as predicted by theory. Since the bulk analyte concentration is known, and the diffusion coefficient was determined by chronoamperometry to be 5.33×10^{-6} cm^2 s^{-1}, the change in molar absorptivity, $\Delta\varepsilon$ may be calculated from the slope according to eq. [1].

Figure 4 shows the UV–vis spectrum of the species produced from the reversible one-electron oxidation of [Fe(tmp)]OH (circles). The spectrum has been calculated from the molar absorptivity changes determined from chronoabsorptometric experiments carried out at different wavelengths. The spectrum of the parent hydroxy iron(III) porphyrin is shown for comparison (solid line). The spectral changes associated with the one-electron oxidation of [Fe(tmp)]Cl in dichloromethane containing TBAP as measured by time-resolved thin-layer UV–vis spectroelectrochemistry are also shown in the inset of Fig. 4. Chloroiron porphyrins are generally accepted to give π-cation radicals on one-electron oxidation. To confirm that [Fe(tmp)]Cl is not an exception, the in situ FTIR difference spectrum associated with its one-electron oxidation in CH_2Br_2 containing 0.1 M $TBAPF_6$ was carried out. The oxidized product had a strong new infrared band at 1280 cm^{-1} which is a marker for ring-oxidation in tetraphenylporphyrins (13).

The UV–vis spectral changes accompanying the 1 e^- oxidation of [Fe(tmp)]OH and [Fe(tmp)]Cl both involve a broadening and blue-shifting of the Soret band and the appearance of a broad absorbance in the visible region, as evident in Fig. 4. Such changes are characteristic of porphyrin π-cation radical formation. These results strongly suggest that the site of one-electron oxidation is the same for both complexes and is centred at the porphyrin ring forming iron(III) porphyrin π-cation radicals.

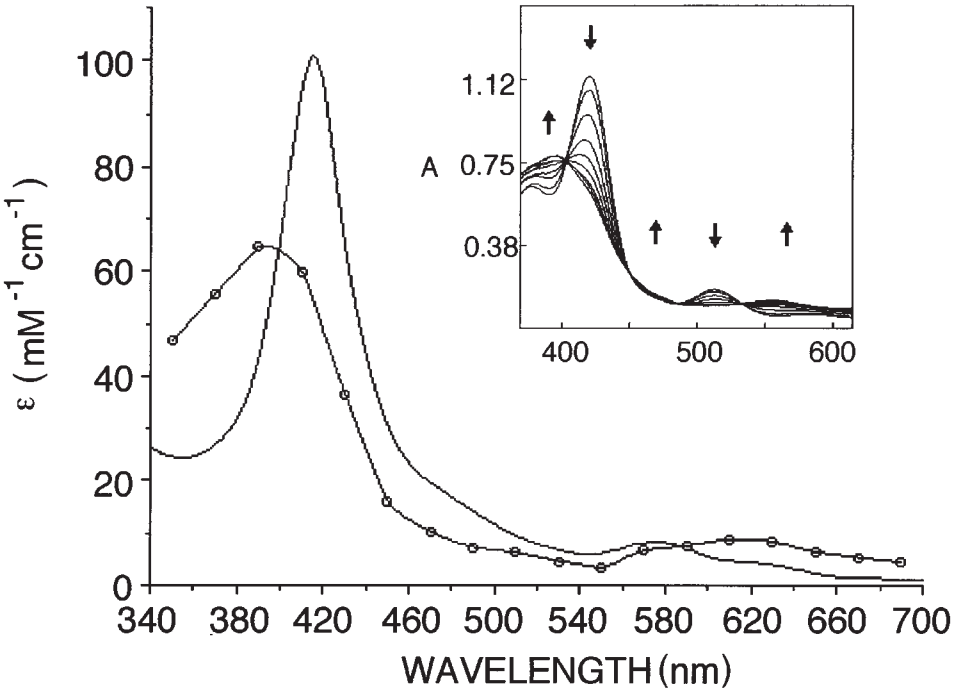
In situ FTIR spectroelectrochemistry of 2 mM [Fe(tmp)]OH in CH_2Br_2 containing 0.1 M $TBAPF_6$ was carried out. A band at 1278 cm^{-1} appeared during electrolysis at 1.1 V indicating formation of a porphyrin π-cation radical. However, this infrared band cannot be unambiguously ascribed to the $1e^-$ oxidized [Fe(tmp)]OH since there is evidence (vide infra) that hydroxide would not remain coordinated to the iron porphyrin during the thin-layer experiment.

Thin-layer voltammetry and simultaneous linear potential sweep UV–vis spectroelectrochemistry

Figure 5 shows the thin-layer voltammetry of 0.5 mM [Fe(tmp)]OH in dichloromethane containing 0.1 M $TBAPF_6$ carried out in an external reflectance thin-layer spectroelectrochemical cell. On the positive sweep it is seen that there are three major oxidation processes with anodic peak potentials at 0.26, ca. 0.35 (shoulder), and 0.53 V vs. the Ag–$AgPF_6$ quasi reference electrode. On the reverse sweep only one major reduction with a reverse peak potential at 0.26 V vs. the Ag–$AgPF_6$ quasi reference electrode is observed. It is notable that the main reduction peak is actually 10 mV *anodic* of the main oxidation peak. The theoretical response for a chemically reversible process is expected to

© 2000 NRC Canada

Fig. 4. UV–vis spectra of Fe(tmp)OH (solid line) and its one-electron oxidation product (circles) in dichloromethane solvent. The inset shows time-resolved thin-layer UV–visible spectra for the oxidation of Fe(tmp)Cl in dichloromethane containing 0.1 M TBAP. Thin-layer spectra were recorded at 2.7 s intervals.



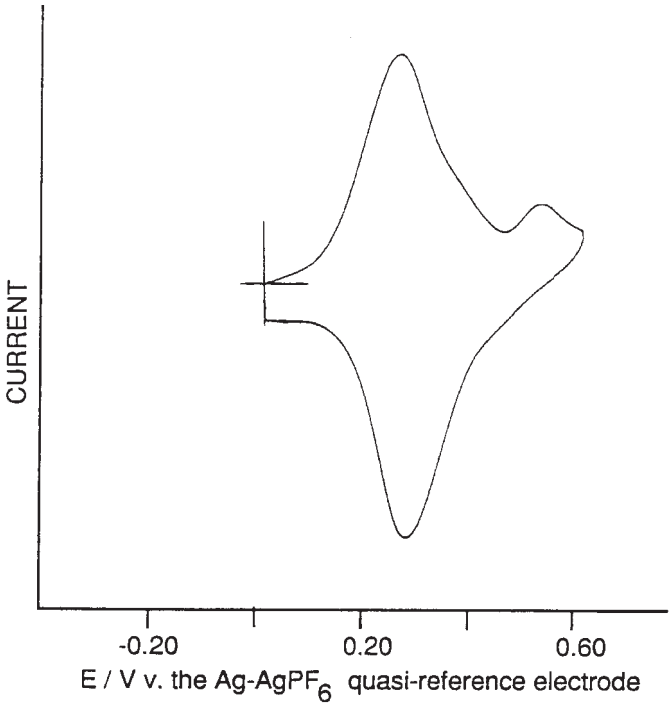


Fig. 5. Thin-layer cyclic voltammetry of 0.5 mM [Fe(tmp)]OH in CH_2Cl_2 containing 0.1 M Bu_4NPF_6. Sweep rate is 5 mV s^{-1}. Potentials are vs. the Ag–$AgPF_6$ quasi reference electrode.

have coincident forward and reverse peak potentials. However, in a real thin-layer cell iR drops arising from solution resistance will tend to make the reduction peak potential more cathodic than the corresponding oxidation peak potential. For this thin-layer cell and solvent system, the cathodic peak typically lies 100 mV negative of the anodic peak for a reversible redox couple under similar conditions. The clear inference here is that the reduction peak does not correspond to reduction of the initial oxidation product.

The thin layer UV–vis spectral changes recorded during the thin-layer cyclic voltammetry experiment shown in Fig. 5 at potentials between 0.00 V to 0.42 V vs. the Ag–$AgPF_6$ quasi reference electrode on the forward sweep are shown in Fig. 6*a*. The spectra show the average absorbance change in sequential 14 s time periods. This translates into a potential separation between spectra of ca. 70 mV. Comparison of the spectral changes with the calculated spectrum of one-electron oxidized [Fe(tmp)]OH (Fig. 4) show that this species is formed initially. However, loss of isosbestic points associated with the oxidation at ca. 0.35 V indicates that at least one additional porphyrin species is formed.

The thin-layer UV–vis spectral changes recorded during the thin-layer cyclic voltammetry experiment at potentials between 0.42 V on the forward sweep and 0.51 V on the reverse sweep show formation of another porphyrin species with peaks at 520 and 589 nm (Fig. 6*b*). This species is associated with the irreversible oxidation at 0.53 V. The thin-layer UV–vis spectral changes recorded during the thin-layer cyclic voltammetry experiment at potentials between 0.5 V and 0.00 V on the reverse scan are shown in Fig. 6*c*. This process shows loss of the species with bands at 520 and 589 nm and reduction of one or more oxidized porphyrin species to form a final spectrum of an unoxidized iron(III) porphyrin which is not due to either [Fe(tmp)]OH or

© 2000 NRC Canada

[Fe(tmp)]Cl. Since the only other counter-ion available is PF_6^-, the spectrum is indicated to be due to [Fe(tmp)]PF_6. This species has not, to our knowledge, been isolated, and its spectrum has not been previously reported.

Discussion

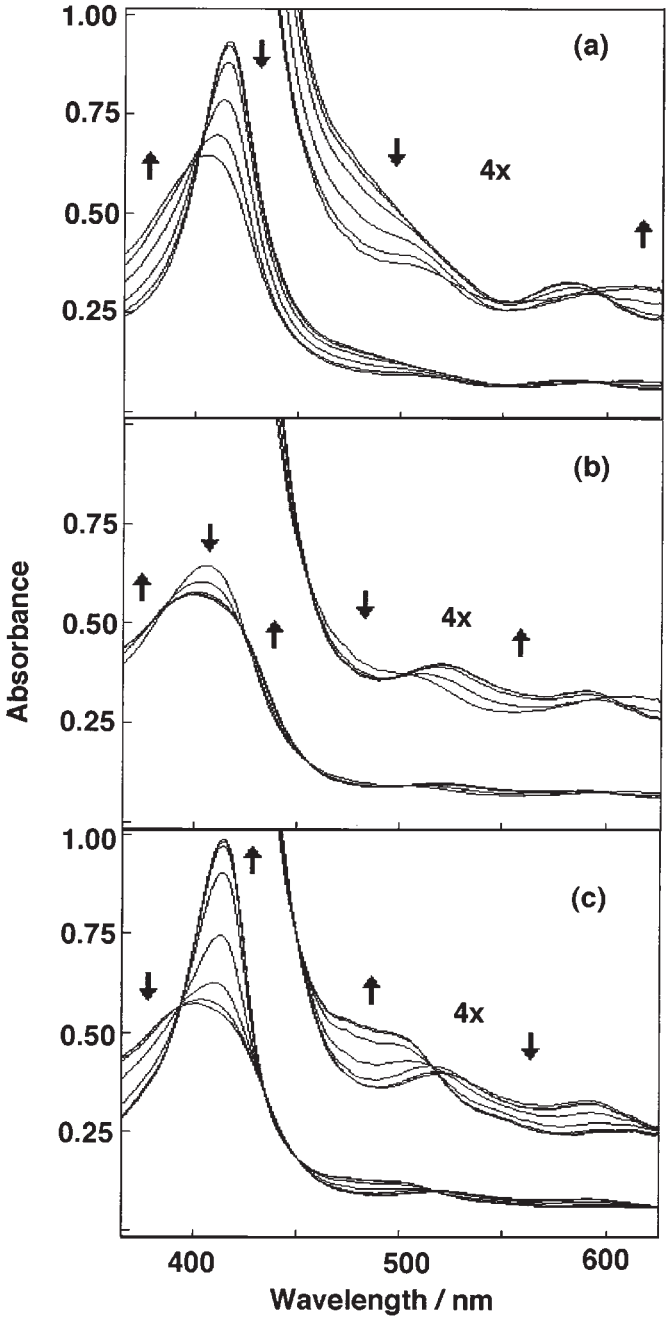
Cyclic voltammetry of [Fe(tmp)]OH shows that the first one-electron oxidation at 0.90 V vs. SCE is chemically reversible in dichloromethane at room temperature at moderate sweep rates provided $TBAPF_6$ is used as the supporting electrolyte and that potentials do not become too positive. The UV–vis spectrum of one-electron oxidized [Fe(tmp)]OH as evidenced by chronoabsorptometry is qualitatively similar to that of one-electron oxidized [Fe(tmp)]Cl and is typical of iron(III) porphyrin π-cation radicals (19). That one-electron oxidation of the chloro complex produces a porphyrin π-cation radical is further evidenced by the strong appearance band at 1280 cm^{-1} in the in situ FTIR difference spectrum associated with the electrode reaction. This clearly indicates that the changes occurring to the porphyrin infrared bands are consistent with a porphyrin ring-centred process (13).

On the basis of this evidence it is proposed that both [Fe(tmp)]Cl and [Fe(tmp)]OH undergo one-electron oxidation centred at the porphyrin ring to produce iron(III) porphyrin π-cation radicals. Thus, one hydroxide axial ligand does not appear capable of stabilizing an iron(IV) porphyrin under the experimental conditions.

At the lower sweep rates associated with thin-layer voltammetry, the first one-electron oxidation is no longer reversible. The initial oxidation product reacts to form a new species which undergoes a further oxidation, as indicated by the shoulder at 0.35 V vs. Ag–$AgPF_6$ quasi reference electrode (Fig. 5). Reduction of the product of this second oxidation produces an Fe(III) porphyrin which is neither the hydroxide nor the chloride, as evidenced by the spectral changes in Fig. 6*c*. In CH_2Cl_2 containing TBAP, the oxidation of [Fe(tmp)]OH has been suggested (5, 6) to follow an ECE mechanism in which hydroxide is lost to produce [Fe(tmp)]ClO_4, which is then subject to a further reversible one-electron oxidation. A similar mechanism in CH_2Cl_2–$TBAPF_6$ to produce [Fe(tmp)]PF_6, as indicated in rxns. [2]–[4], would account for our observations.

[2] [Fe(tmp)]OH – $1e^-$ ⇌ Fe(tmp^+)OH

[3] [Fe(tmp^+)]OH + PF_6^- → [Fe(tmp)]PF_6 + OH



[4] [Fe(tmp)]PF_6 $-1e^-$ ⇌ [Fe(tmp^+)]PF_6

Since PF_6^- is less strongly coordinating than ClO_4^-, rxn. [3] would be less favoured with PF_6^- as the supporting electrolyte anion than ClO_4^-. This would account for the greater stability of the [Fe(tmp^+)]OH π-cation radical observed in CH_2Cl_2–$TBAPF_6$.

We have not investigated supporting electrolyte anions other than perchlorate and hexafluorophosphate with this system.

The appearance of an additional anodic peak at 0.53 V vs. the Ag–$AgPF_6$ quasi reference electrode in the thin-layer voltammetry of Fig. 5 indicates that the initial one-electron oxidation product may also react by a different pathway than rxn. [4], to produce a species which oxidizes at higher potential than does [Fe(tmp)]PF_6. This oxidation is accompanied by the appearance of bands at 520 and 589 nm in the UV–vis. spectra of Fig. 6*b*. The identity of this porphyrin species cannot be unambiguously assigned on the basis of the results. The bands at 520 and 589 nm are not characteristic of either iron(III) porphyrin π-cation radicals (19) or oxoferryl porphyrins (20). On the other hand, the UV–vis spectrum of iron(III) tetramesitylporphyrin *N*-oxide — which

Fig. 6. Thin-layer UV–visible spectral changes recorded during the thin-layer cyclic voltammetry experiment shown in Fig. 5 at potentials between (*a*) 0.00–0.42 V vs. the Ag–$AgPF_6$ quasi reference electrode on the forward sweep; (*b*) 0.42 V on the forward sweep and 0.51 V on the reverse sweep; (*c*) 0.51 and 0.00 V on the reverse sweep.

© 2000 NRC Canada

has oxo-bridging iron and a pyrrole nitrogen — and that of the *N*-hydroxy cation formed by protonation of the *N*-oxide, do exhibit similar spectral features (21). These species are formed on oxidation of [Fe(tmp)]OH by *meta*-chloroperoxybenzoic acid. It seems possible that such species might also be formed on heterogeneous oxidation. Thus, rxns. [5] and [6], provide a plausible account for our observations.

[5] $[Fe(tmp^+)]OH + PF_6^- \rightarrow [Fe(tmpOH)]PF_6$

[6] $[Fe(tmpOH)]PF_6 - 1e^- \rightarrow [Fe(tmp^+OH)]PF_6$

In [5], hydroxide migrates from Fe to one of the pyrrole nitrogens of the porphyrin π-cation radical to give an *N*-hydroxy porphyrin. This could undergo electron loss to produce the *N*-hydroxy porphyrin cation, as in [6]. It is possible for the *N*-hydroxy cation to lose a proton to form the bridged *N*-oxide species.

The combined potential step – potential sweep experiments of Fig. 2 indicate that the initial one-electron oxidation product is susceptible to further oxidation. This process is over-potential dependent, indicating a slow heterogeneous electron transfer process, and results in loss of hydroxide to form $[Fe(tmp+)]PF_6$, as evident from its reduction potential. The process is represented in rxn. [7].

[7] $[Fe(tmp^+)]OH - 1e^- + PF_6^- \rightarrow [Fe(tmp^+)]PF_6 + OH$

The over-potential dependence of this process is not consistent with porphyrin ring oxidation, clearly suggesting the oxidation is associated with the Fe-OH moeity of the porphyrin complex to give, at least formally, a hydroxy iron(IV) species. This species then eliminates OH to give the Fe(III) cation-radical. The overall conversion of [Fe(tmp)]OH to the $[Fe(tmp^+)]PF_6$ π-cation radical in this case follows an EEC type mechanism.

Nitrones and oximes of bifunctional carbonyl compounds and their reaction products with diarylborinic acids. Crystal and molecular structure of examples of five-, six-, and seven-membered boron chelates[1]

Wolfgang Kliegel, Gottfried Lubkowitz, Jens O. Pokriefke, Steven J. Rettig, and James Trotter

Abstract: Synthesis has been carried out of diarylboron chelates of 2- and 3-hydroxynitrones, of 2- and 3-hydroxyoximes, and of 2-carboxynitrones and a 2-carboxyoxime. The structures have been determined from spectroscopic data and from X-ray analyses of **5*d***, **9*a***, **11*b***, and **19**. Crystals (at 180 K) of **5*d*** are monoclinic, a = 10.543(2), b = 19.085(4), c = 10.2667(3) Å, β = 90.4978(7)°, Z = 4, space group $P2_1/c$; those of **9*a*** are orthorhombic, a = 10.9913(5), b = 14.9329(7), c = 10.2460(13) Å, Z = 4, space group $P2_12_12_1$; those of **11*b*** are monoclinic, a = 11.227(2), b = 9.967(2), c = 17.0537(4) Å, β = 105.4179(5)°, Z = 4, space group $P2_1/n$; those of **19** are monoclinic, a = 11.1847(15), b = 13.715(3), c = 11.5559(5) Å, β = 104.8730(10)°, Z = 4, space group $P2_1/n$. The structures were solved by direct methods and refined by full-matrix least-squares procedures to $R(F, I \geq 3\sigma(I))$ = 0.049, 0.047, 0.042, and 0.047, respectively, for CCD data for **5*d***, **9*a***, **11*b***, and **19**. The four molecules contain five-, seven-, six-, and five-membered rings, respectively, with O-B-N groups in the **5*d***, **11*b***, and **19**, and O-B-O in **9*a***; the rings exhibit various deviations from planarity, particularly the seven-membered ring.

Key words: diarylboron chelates, hydroxyoximes, hydroxynitrones, carboxyoximes, carboxynitrones, organoboron compounds, crystal structure.

Resumé : On a réalisé la synthèse de chélates du diarylbore avec de 2- et 3-hydroxynitrones, de 2- et 3-hydroxyoximes, de 2-carboxynitrones et d'une 2-carboxyoxime. On a déterminé les structures à partir de données spectroscopiques et d'analyses par diffraction des rayons X des composés **5*d***, **9*a***, **11*b*** et **19**. Les cristaux du composé **5d** sont monocliniques (à 180 K), groupe d'espace $P2_1$/c avec a = 10,543(2), b = 19,085(4) et c = 10,2667(3) Å, β = 90,4978(7)° et Z = 4; ceux du composé **9*a*** sont orthorhombiques, groupe d'espace $P2_12_12_1$, avec a = 10,9913(5), b = 14,9329(7) et c = 10,2460(13) Å et Z = 4; ceux du composé **11*b*** sont monocliniques, groupe d'espace $P2_1/n$ avec a = 11,227(2), b = 9,967(2) et c = 17,0537(4) Å, β = 105,4179(5)° et Z = 4 et ceux du composé **19** sont monocliniques, groupe d'espace $P2_1/n$ avec a = 11,1847(15), b = 13,715(3) et c = 11,5559(5) Å, β = 104,8730(10)° et Z = 4. On a résolu les structures par des méthodes directes et on les a affinées par la méthode des moindres carrés (matrices entières) jusqu'à des valeurs de $R(F, I \geq 3\sigma(I))$ = 0,049, 0,047, 0,042 et 0,047 respectivement pour les données pour les molécules **5*d*, 9*a*, 11*b*** et **19**. Les quatre molécules comportent respectivement des cycles à cinq, sept, six et cinq chaînons et des groupes O-B-N dans les molécules **5*d*, 11*b*** et **19** et O-B-O pour la molécule **9*a***; les cycles présentent des déviations diverses par rapport à la planéité, en particulier pour le cycle à sept chaînons.

Mots Clés : chélates de dialkylbores, hydroxyoximes, hydroxynitrones, carboxyoximes, carboxynitrones, composés organiques du bore, structure cristalline.

Introduction

In the course of our investigations on cyclic boron nitrogen betaines (1) we synthesized a series of five-, six-, and seven-membered boron chelates containing bidentate nitrone ligands with an *N*-(1-hydroxyalkyl) group (2) (ring system **A**), an *N*-(2-hydroxylalkyl) group (3) or *N*-(1-carboxyalkyl) group (4) (ring system **B**), and an *N*-(3-hydroxylalkyl) group (5) (ring system **C**), all having the nitrone C=N bond located outside of the chelate ring ("exocyclic" or "semicyclic" (6, see footnote for exocyclic double bonds, p. 954)). As an extension of our work in this area we investigated comparable chelate ring structures with an "endocyclic" C=N double bond, as depicted in the ring systems **D**, **E**, and **F**. Five-membered boron chelates of type **D** had been obtained previously from various hydroxamic acid derivatives (7). We now report, continuing and completing this series, the synthesis and structural characteristics of six- and seven-membered boron chelates, type **E** and **F**, derived from the corresponding bidentate nitrones. In connection with these compounds we describe also the synthesis and structural features of several boron chelates of analogous bifunctional oximes. Unambiguous proof of coordination sites and ring geometries is furnished by X-ray crystallographic analyses in selected cases.

Experimental

General procedures

Oxybis(diphenylborane) was prepared according to literature methods (8). All reactions were carried out under normal conditions, without protective gas atmosphere. Melting points (uncorrected): Linström apparatus and Büchi SMP 20. IR: PYE-Unicam SP 3-200, Philips PU 9800 FT-IR-Spectrometer, V 3.00, and ATI Mattson Genesis Series FT-IR™ Rev. I. ^{1}H NMR: Varian EM 390 and Bruker AM 400. ^{11}B NMR: Bruker AC 200. Elemental analyses: Carlo Erba CHNO elemental analyzer 1106; boron and chlorine titrimetrically after Schöniger-oxidation with Metrohm Potentiograph E 536/Dosimat 655.

2-(Methylimino)ethanol *N*-oxide (2*a*)

Hydroxyacetaldehyde (1.20 g, 20 mmol) and *N*-methylhydroxylamine hydrochloride (1.67 g, 20 mmol) are dissolved in 20 mL of ethanol (96%) and mixed with a solution of K_2CO_3 (1.38 g, 10 mmol) in 5 mL of water under stirring. After 48 h, KCl is filtered off, the solvent removed in vacuo, and the residue taken up in 50 mL of absolute ethanol. After filtration the solvent is distilled off in vacuo. The remaining oil is not purified further, and is characterized only with NMR data. ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 3.65 (s, N-CH_3), 4.15 (s, broad, exchangeable, OH), 4.35 (d, J = 4 Hz, O-CH_2), 6.92 (t, J = 4 Hz, N=CH).

N-(Benzylimino)ethanol *N*-oxide (2*b*)

Hydroxyacetaldehyde (1.20 g, 20 mmol), *N*-benzylhydroxylamine hydrochloride (3.19 g, 20 mmol), and K_2CO_3 (1.38 g, 10 mmol) are reacted as described above for **2*a***. The remaining solid is recrystallized from ethanol–ether. Yield: 2.30 g (70%) of colorless plates, mp 82–84°C. IR (KBr, cm^{-1}): 3 300 and 3 170 (broad, O-H), 1610 (C=N). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 4–5 (s, very broad, exchangeable, OH), 4.35 (d, J = 4 Hz, O-CH_2), 4.83 (s, N-CH_2), 6.88 (t, J = 4 Hz, N=CH), 7.37 (s, C_6H_5). Anal. calcd. for $C_9H_{11}NO$: C 65.44, H 6.71, N 8.48; found: C 65.41, H 6.71, N 8.57.

1-(Methylimino)-2-propanol *N*-oxide (2*c*)[3]

This compound was prepared as described previously (9).

1-(*tert*-Butylimino)-2-propanol *N*-oxide (2*d*)

2-Hydroxypropanal (1.48 g, 20 mmol) and *N*-*tert*-butylhydroxylamine (1.80 g, 20 mmol) are dissolved in 20 mL of absolute ethanol and stirred for 48 h at room temperature. The solvent is distilled off in vacuo. The remaining oily residue is not purified further, and is characterized only with NMR data. ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.37 (d, J = 7 Hz, OC-CH_3), 1.51 (s, $C(CH_3)_3$), 4.68 (m, 1 H exchangeable, OH and O-CH), 6.93 (d, J = 5 Hz, N=CH).

1-(Cyclohexylimino)-2-propanol *N*-oxide (2*e*)

2-Hydroxypropanal (2.22 g, 30 mmol) and *N*-cyclohexylhydroxylamine (3.45 g, 30 mmol) are reacted as described above for **2*d***. The remaining solid is recrystallized from absolute ethanol. Yield: 4.42 g (86%) of colorless needles, mp 129°C. IR (KBr, cm^{-1}): 3 210 (broad, O-H), 1 600 (C=N). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.04–2.20 (m, $(CH_2)_5$), 1.39 (d, J = 7 Hz, CH_3), 3.64 (m, N-CH), 4.71 (m, O-CH), 5.61 (s, exchangeable, OH), 6.85 (d, J = 5 Hz, N=CH). Anal. calcd. for $C_9H_{17}NO_2$: C 63.13, H 10.01, N 8.18; found: C 63.09, H 10.15, N 7.97.

1-(Benzylimino)-2-propanol *N*-oxide (2*f*)

This compound was prepared as described previously (9).

[3] Alternative nomenclature for the compounds of type **2** (generally): *N*-(2-hydroxyalkylidene) alkanamine *N*-oxide, as used in ref. 9.

© 2000 NRC Canada

1-(Benzhydrylimino)-2-propanol *N*-oxide (2*g*)

2-Hydroxypropanal (1.48 g, 20 mmol) and *N*-benzhydrylhydroxylamine (3.98 g, 20 mmol) are reacted as described above for **2*d***. The remaining solid is recrystallized from ethanol–ether. Yield: 4.21 g (82%) of colorless crystals, mp 110–111°C. IR (KBr, cm^{-1}): 3 290 (broad, O-H), 1 590 (C=N). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.34 (d, J = 7 Hz, CH_3), 4.71 (m, O-CH), 5.47 (s, broad, exchangeable, OH), 6.15 (s, N-CH), 6.82 (d, J = 5 Hz, N=CH), 7.32 (s, $C(C_6H_5)_2$). Anal. calcd. for $C_{16}H_{17}NO_2$: C 75.27, H 6.71, N 5.49; found: C 75.47, H 6.71, N 5.64.

3-(Cyclohexylimino)-2-butanol *N*-oxide (2*h*)

3-Hydroxy-2-butanone (0.88 g, 10 mmol) and *N*-cyclohexylhydroxylamine (1.15 g, 10 mmol) are dissolved in 30 mL of benzene and refluxed for 5 h using a Dean–Stark trap for continuous removal of water. The solution is evaporated down to one-quarter of the initial volume. After addition of 10 mL of hexane and cooling down to –18°C crystallization starts after 48 h. The air-sensitive compound can be recrystallized carefully from chloroform–ether. Yield: 0.90 g (49%) of colorless crystals, mp 118°C. IR (KBr, cm^{-1}): 3 221 (broad, O-H), 1 587 (C=N). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.67–2.67 (m, $(CH_2)_5$), 1.37 (d, J = 6 Hz, OC-CH_3), 2.13 (s, NC-CH_3), 3.93 (m, N-CH), 4.67 (q, J = 6 Hz, O-CH), 6.53 (s, broad, exchangeable, OH). Anal. calcd. for $C_{10}H_{19}NO_2$: C 64.83, H 10.34, N 7.56; found: C 64.92, H 10.41, N 7.46.

4-Methyl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*a*)

2*a* (0.2 g of the crude product) in 1 mL of ethanol and oxybis(diphenylborane) (0.35 g, 1 mmol) in 1 mL ethanol are mixed under stirring. After 5 h at room temperature, the analytically pure crystals are filtered off and washed with ether.[4] Yield: 0.31 g (61%) of colorless crystals[6], mp 104–105°C (decomp.). IR (KBr, cm^{-1}): 1 665 (C=N). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 3.14 (s, CH_3), 4.23 (m, O-CH_2), 6.25 (s, N=CH), 6.87–7.40 (m, $B(C_6H_5)_2$). Anal. calcd. for $C_{15}H_{16}BNO_2$: C 71.18, H 6.37, N 5.53; found: C 71.17, H 6.37, N 5.49. (Boron elemental analyses and NMR data were obtained only for some of the examples of compounds of type **3**.)

4-Cyclohexyl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*b*)

Hydroxyacetaldehyde (0.12 g, 2 mmol) and *N*-cyclohexylhydroxylamine (0.23 g, 2 mmol) are dissolved in 5 mL of ethanol. After addition of oxybis(diphenylborane) (0.35 g, 1 mmol) in 1 mL of ethanol the crystallization commences at room temperature or after several hours of cooling. The analytically pure crystals are filtered off and washed with ether.[4] Yield: 0.43 g (77%) of colorless crystals[6], mp 131°C (decomp.). IR (KBr, cm^{-1}): 1 653 (C=N). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.80–2.47 (m, $(CH_2)_5$), 3.53 (m, N-CH), 4.47 (s, O-CH_2), 6.90 (s, N=CH), 6.97–7.67 (m, $B(C_6H_5)_2$). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 7.1 ($w_{1/2}$ = 300 Hz). Anal. calcd. for $C_{20}H_{24}BNO_2$: C 74.78, H 7.53, B 3.37, N 4.36; found: C 74.84, H 7.84, B 3.35, N 4.15.

4-Benzyl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*c*)

2*b* (0.33 g, 2 mmol) and oxybis(diphenylborane) (0.35 g, 1 mmol) are reacted as described above for **3*a***. Yield: 0.53 g (80%) of colorless needles[6], mp 125°C (decomp.). IR (KBr, cm^{-1}): 1 655 (C=N). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 4.49 (m, O-CH_2), 4.84 (s, N-CH_2), 6.92 (s, N=CH), 7.02–7.45 (m, 15 aromatic H). Anal. calcd. for $C_{21}H_{20}BNO_2$: C 76.62, H 6.12, N 4.26; found: C 76.60, H 6.15, N 4.19.

4-Benzhydryl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*d*)

Hydroxyacetaldehyde (0.30 g, 5 mmol), *N*-benzhydrylhydroxylamine (1.00 g, 5 mmol), and oxybis (diphenylborane) (0.87 g, 2.5 mmol) are reacted as described for **3*b***. Yield: 1.05 g (52%) of colorless crystals[6], mp 126°C. IR (KBr, cm^{-1}): 1 638 (C=N). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 4.60 (s, CH_2), 6.30 (s, N-CH), 7.00–7.67 (m, 20 aromatic H and N=CH). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 6.4 ($w_{1/2}$ = 257 Hz), 26.0, ratio of peak areas 20:1.[7] Anal. calcd. for $C_{27}H_{24}BNO_2$: C 80.00, H 5.97, B 2.67, N 3.46; found: C 80.08, H 6.04, B 2.68, N 3.34.

4-Cyclohexyl-2,2-di(4-chlorophenyl)-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*e*)

Hydroxyacetaldehyde (0.12 g, 2 mmol), *N*-cyclohexylhydroxylamine (0.23 g, 2 mmol), and di(4-chlorophenyl)borinic acid (11) (0.50 g, 2 mmol) are reacted as described for **3*b***. Yield: 0.55 g (71%) of colorless crystals[6], mp 141°C (decomp.). IR (KBr, cm^{-1}): 1 650 (C=N). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.93–2.43 (m, $(CH_2)_5$), 3.73 (m, N-CH), 4.60 (s, CH_2), 7.00–7.53 (m, aromatic H and N=CH). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 6.7 ($w_{1/2}$ = 300 Hz). Anal. calcd. for $C_{20}H_{22}BCl_2NO_2$: C 61.58, H 5.68, B 2.77, N 3.59; found: C 61.58, H 5.71, B 2.80, N 3.37.

4-Cyclohexyl-2,2-di(1′-naphthyl)-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*f*)

Hydroxyacetaldehyde (0.12 g, 2 mmol), *N*-cyclohexylhydroxylamine (0.23 g, 2 mmol), and di(1′-naphthyl)borinic acid (12) (0.56 g, 2 mmol) are reacted as described for **3*b***. Yield: 0.66 g (78%) of colorless crystals[6], mp 153°C (decomp.). IR (KBr, cm^{-1}): 1 640 (C=N). ^{1}H NMR

[4] Recrystallization should be avoided because of a thermally induced rearrangement reaction with an aryl 1,4-shift leading to heterocyclic arylboronates.[5] Very careful recrystallization without thermal stress or reprecipitation from chloroform with petroleum ether at mild temperature is possible in some cases.

[5] W. Kliegel, G. Lubkowitz, J.O. Pokriefke, S.J. Rettig, and J. Trotter. To be published.

[6] The product gives a blue-colored solution upon the addition of diphenylcarbazone in ethanol, indicating the presence of the chelated diarylborenium (Ar_2B^+) ion (10).

[7] The signals with very small peak areas originate from impurities caused by thermally induced rearrangement of the type **3** compounds, resulting in heterocyclic arylboronates **3**′ (see discussion below).

4-Benzhydryl-6-methyl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*l*) (·EtOH)

2*g* (0.51 g, 2 mmol) and oxybis(diphenylborane) (0.35 g, 1 mmol) are reacted as described for **3*a***. Yield: 0.85 g (91%) of slightly yellow plates[6], mp 86–90°C (decomp.). IR (KBr, cm^{-1}): 3 390 (broad, O-H), 1 650 (C=N). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.22 (t, J = 7 Hz, CH_3 of ethanol), 1.48 (d, J = 7 Hz, CH_3), 3.66 (q, J = 7 Hz, O-CH_2 of ethanol), 4.73 (m, O-CH), 6.31 (s, N-CH), 7.06–7.50 (m, 20 aromatic H, N=CH, and OH of ethanol). Anal. calcd. for $C_{28}H_{26}BNO_2$ + C_2H_5OH: C 77.42, H 6.93, N 3.01; found: C 77.30, H 6.94, N 3.22.

4-Cyclohexyl-5-methyl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*m*)

Hydroxyacetone (0.37 g, 5 mmol) and oxybis(diphenylborane) (0.87 g, 2.5 mmol) are dissolved in 5 mL of absolute ethanol, if necessary under slight warming. A solution of *N*-cyclohexylhydroxylamine (0.58 g, 5 mmol) in 5 mL of ethanol is added without stirring, after precooling of both solutions. At –18°C, crystallization starts spontaneously or after rubbing with a glass stick. The crystals are filtered off and are washed rapidly with a small amount of ethanol and small portions of ether.[4] Yield: 0.52 g (32%) of colorless crystals[6], mp 156°C (decomp.). IR (KBr, cm^{-1}): 1 647 (C=N). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.90–2.67 (m, $(CH_2)_5$), 1.83 (s, CH_3), 3.90 (m, N-CH), 4.50 (s, O-CH_2), 6.9 7.73 (m, $B(C_6H_5)_2$). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 6.4 ($w_{1/2}$ = 257 Hz). Anal. calcd. for $C_{21}H_{26}BNO_2$: C 75.24, H 7.82, B 3.22, N 4.18; found: C 75.24, H 7.96, B 3.22, N 3.98.

4-Benzyl-5-methyl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*n*)

Hydroxyacetone (0.37 g, 5 mmol) and oxybis(diphenylborane) (0.87 g, 2.5 mmol) are dissolved in 5 mL of absolute ethanol, if necessary under slight warming. To a solution of *N*-benzylhydroxylamine hydrochloride (0.80 g, 5 mmol), triethylamine (0.51 g, 5 mmol) is added. Both solutions are cooled and mixed without stirring. Crystallization starts during storage at –18°C spontaneously or upon rubbing with a glass stick. The crystals are filtered off and washed rapidly with a small amount of ethanol and small portions of ether.[4] Yield: 1.3 g (66%) of colorless crystals[6], mp 118°C. IR (KBr, cm^{-1}): 1 654 (C=N). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.93 (s, CH_3), 4.53 (s, O-CH_2), 5.07 (s, N-CH_2), 6.90–7.90 (m, 15 aromatic H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 6.9 ($w_{1/2}$ = 257 Hz), 27.0, ratio of peak areas 10:1.[7] Anal. calcd. for $C_{22}H_{22}BNO_2$: C 76.99, H 6.46, B 3.15, N 4.08; found: C 76.48, H 6.31, B 3.07, N 3.88.

2,2-Di(4′-chlorophenyl)-4-cyclohexyl-5,6-dimethyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*w*)

3-Hydroxy-2-butanone (0.18 g, 2 mmol), di(4-chlorophenyl)borinic acid (11) (0.5 g, 2 mmol), and *N*-cyclohexylhydroxylamine (0.23 g, 2 mmol) are reacted as described for **3*m***. Yield: 0.39 g (47%) of colorless crystals[6], mp 150°C. IR (KBr, cm^{-1}): 1 579 (C=N/C=C). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.90–2.50 (m, $(CH_2)_5$), 1.50 (d, *J* = 7 Hz, O-C-CH_3), 1.97 (s, N=C-CH_3), 3.90 (m, N-CH), 4.57 (q, *J* = 7 Hz, O-C-CH_3), 7.00–7.50 (m, 8 aromatic H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 5.7 ($w_{1/2}$ = 258 Hz). Anal. calcd. for $C_{22}H_{26}BCl_2NO_2$: C 63.19, H 6.27, B 2.59, N 3.35; found: C 63.21, H 7.03, B 2.64, N 3.14.

4-Benzhydryl-2,2-di(4-chlorophenyl)-5,6-dimethyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*x*)

3-Hydroxy-2-butanone (0.88 g, 10 mmol), di(4-chlorophenyl)borinic acid (11) (2.50 g, 10 mmol), and *N*-benzhydrylhydroxylamine (1.99 g, 10 mmol) are reacted as described for **3*m***. Yield: 2.42 g (48%) of colorless crystals[6], mp 130°C (rearr.). MS (CI, NH_3, pos. mode, 100°C) *m/z*: 502 (2%, M^+). IR (KBr, cm^{-1}): 1 578 (C=N/C=C). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.57 (d, *J* = 7 Hz, O-C-CH_3), 2.10 (s, N=C-CH_3), 4.67 (q, *J* = 7 Hz, O-C-CH), 6.43 (s, N-CH), 6.63–7.90 (m, 18 aromatic H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 6.9 ($w_{1/2}$ = 342 Hz). Anal. calcd. for $C_{29}H_{26}BCl_2NO_2$: C 69.35, H 5.22, B 2.15, Cl 14.12, N 2.79; found: C 69.29, H 5.20, B 2.28, Cl 14.22, N 2.71.

4-Cyclohexyl-5,6-dimethyl-2,2-di(1′-naphthyl)-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*y*)

3-Hydroxy-2-butanone (0.18 g, 2 mmol), di(1-naphthyl)borinic acid (11) (0.56 g, 2 mmol), and *N*-cyclohexylhydroxylamine (0.23 g, 2 mmol) are reacted as described for **3*m***. Yield: 0.51 g (57%) of colorless crystals[6], mp 157°C. IR (KBr, cm^{-1}): 1 625 (C=N). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.87–2.42 (m, $(CH_2)_5$), 1.47 (d, *J* = 7 Hz, O-C-CH_3), 1.87 (s, N=C-CH_3), 3.93 (m, N-CH), 4.37 (q, *J* = 7 Hz, O-CH), 7.00–8.00 (m, 12 aromatic H), 8.43–8.87 (m, 2 aromatic H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 9.2 ($w_{1/2}$ = 342 Hz). Anal. calcd. for $C_{30}H_{32}BNO_2$: C 80.18, H 7.18, B 2.41, N 3.12; found: C 80.21, H 7.25, B 2.45, N 3.00.

4-Cyclohexyl-5,6-tetramethylene-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*z*)

2-Hydroxycyclohexanone (0.57 g, 5 mmol) and oxybis(diphenylborane) (0.87 g, 2.5 mmol) are dissolved in 10 mL of absolute ethanol under slight heating and stirring for a further 10 min. After cooling down to room temperature, a solution of *N*-cyclohexylhydroxylamine (0.58 g, 5 mmol) in 5 mL of absolute ethanol is added, and the mixture stored at room temperature. Crystallization starts spontaneously or upon cooling. The usually analytically pure crystals are filtered off after 1 h and can be recrystallized from ethanol. Yield: 1.20 g (64%) of colorless crystals[6], mp 151°C. IR (KBr, cm^{-1}): 1 619 (C=N). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.00–2.90 (m, $(CH_2)_4$ and $(CH_2)_5$), 4.10 (m, N-CH), 4.47 (dd, *J* = 12 Hz, *J* = 7 Hz, O-CH), 6.83–7.67 (m, $B(C_6H_5)_2$). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 6.1 ($w_{1/2}$ = 214 Hz). Anal. calcd. for $C_{24}H_{30}BNO_2$: C 76.81, H 8.06, B 2.88, N 3.73; found: C 76.87, H 8.24, B 2.87, N 3.56.

4-Benzyl-5,6-tetramethylene-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*aa*)

2-Hydroxycyclohexanone (0.57 g, 5 mmol) and oxybis(diphenylborane) (0.87 g, 2.5 mmol) in 10 mL of ethanol are reacted with *N*-benzylhydroxylamine hydrochloride (0.80 g, 5 mmol) and triethylamine (0.51 g, 5 mmol) in 5 mL of ethanol as described for **3*z***. Yield: 1.50 g (78%) of colorless crystals[6], mp 138°C. IR (KBr, cm^{-1}): 1 632 (C=N). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.87–2.83 (m, $(CH_2)_4$), 4.40 (dd, *J* = 12 Hz, *J* = 6 Hz, O-CH), 5.03/5.17 (d/d, AB system, *J* = 15 Hz, N-CH_2), 6.87–7.87 (m, 15 aromatic H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 6.1 ($w_{1/2}$ = 257 Hz). Anal. calcd. for $C_{25}H_{26}BNO_2$: C 78.34, H 6.84, B 2.82, N 3.65; found: C 78.31, H 6.88, B 2.88, N 3.48.

4-Benzhydryl-5,6-tetramethylene-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*bb*)

2-Hydroxycyclohexanone (0.57 g, 5 mmol), oxybis(diphenylborane) (0.87 g, 2.5 mmol), and *N*-benzhydrylhydroxylamine (1.00 g, 5 mmol) are reacted as described for **3*z***. Yield: 1.50 g (65%) of colorless crystals[6], mp 144°C. IR (KBr, cm^{-1}): 1 610 (C=N/C=C). ^1H NMR (400 MHz, $CDCl_3$–TMS) δ (ppm): 0.94–2.91 (m, $(CH_2)_4$), 4.57 (dd, *J* = 12 Hz, *J* = 6 Hz, O-CH), 6.66 (s, N-CH), 6.90–7.82 (m, 20 aromatic H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 6.9 ($w_{1/2}$ = 257 Hz). Anal. calcd. for $C_{31}H_{30}BNO_2$: C 81.05, H 6.58, B 2.35, N 3.05; found: C 81.08, H 6.63, B 2.39, N 2.79.

5,5-Tetramethylene-4-(4′-methylphenyl)-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexene (3*cc*)

2-Hydroxycyclohexanone (0.57 g, 5 mmol), oxybis(diphenylborane) (0.87 g, 2.5 mmol), and *N*-(4-methylphenyl)hydroxylamine (0.62 g, 5 mmol) are reacted as described for **3*z***. Yield: 1.28 g (67%) of colorless crystals[6], mp 140°C. IR (KBr, cm^{-1}): 1 657 (C=N), 1625 (C=C). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.00–2.90 (m, $(CH_2)_4$), 2.40 (s, CH_3), 4.63 (dd, *J* = 12 Hz, *J* = 6 Hz, O-CH), 6.90–7.80 (m, 14 aromatic

[12]Additional small peaks at: 0.90 (d, *J* = 7 Hz, O-C-CH_3), 0.97 (s, N-C-CH_3), 4.97 (s, N-CH)[7].

H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 6.3 ($w_{1/2}$ = 299 Hz). Anal. calcd. for $C_{25}H_{26}BNO_2$: C 78.34, H 6.84, B 2.82, N 3.65; found: C 78.87, H 7.01, B 2.89, N 3.48.

4,5-Dimethyl-2,2-diphenyl-1-oxa-3-azonia-2-borata-3-cyclopenten-3-ol (5*a*)

3-Hydroxy-2-butanonoxime (13) (0.52 g, 5 mmol) and oxybis(diphenylborane) (0.87 g, 2.5 mmol) are dissolved separately in 5 mL of absolute ethanol each. The solutions are mixed at room temperature under continuous stirring. Crystallization commences after a few minutes, if necessary after slight cooling or addition of petroleum ether. The usually analytically pure substance can be recrystallized from ethanol. Yield: 1.02 g (76%) of colorless crystals[6], mp 170°C. IR (KBr, cm^{-1}): 2 598 (broad, O-H), 1 664 (C=N). ^{1}H NMR (90 MHz, DMSO-d_6–TMS) δ (ppm): 1.40 (d, J = 7 Hz, O-C-CH_3), 2.10 (s, N=C-CH_3), 4.83 (q, J = 7 Hz, O-CH), 6.80–7.80 (m, $B(C_6H_5)_2$), 11.93 (s, exchangeable, OH). ^{11}B NMR (64 MHz, DMSO-d_6–Et_2OBF_3) δ (ppm): 9.7 ($w_{1/2}$ = 385 Hz). Anal. calcd. for $C_{16}H_{18}BNO_2$: C 71.94, H 6.79, B 4.05, N 5.24; found: C 71.92, H 6.80, B 4.02, N 5.22.

4-Ethyl-2,2-diphenyl-1-oxa-3-azonia-2-borata-3-cyclopenten-3-ol (5*b*)

1-Hydroxy-2-butanonoxime (14) (0.52 g, 5 mmol) and oxybis(diphenylborane) (0.87 g, 2.5 mmol) are reacted as described for **5*a***. Yield: 0.35 g (26%) of colorless crystals[6], mp 145°C. IR (KBr, cm^{-1}): 2 775 (broad, O-H), 1 668 (C=N). ^{1}H NMR (90 MHz, DMSO-d_6–TMS) δ (ppm): 1.10 (t, J = 7 Hz, CH_3), 2.57 (q, J = 7 Hz, N=C-CH_2), 4.73 (s, O-CH_2), 7.00–8.00 (m, $B(C_6H_5)_2$), 11.9 (s, exchangeable, OH). ^{11}B NMR (64 MHz, DMSO-d_6–Et_2OBF_3) δ (ppm): 10.1 ($w_{1/2}$ = 470 Hz). Anal. calcd. for $C_{16}H_{18}BNO_2$: C 71.94, H 6.79, B 4.05, N 5.24; found: C 71.98, H 6.90, B 3.99, N 5.20.

4,5-Tetramethylene-2,2-diphenyl-1-oxa-3-azonia-2-borata-3-cyclopenten-3-ol (5*c*)

2-Hydroxycyclohexanonoxime (15) (0.39 g, 3 mmol) and oxybis(diphenylborane) (0.52 g, 1.5 mmol) are reacted as described for **5*a***. Yield: 0.71 g (81%) of colorless crystals[6], mp 180°C. IR (KBr, cm^{-1}): 2 472 (broad, O-H), 1 674 (C=N). ^{1}H NMR (90 MHz, DMSO-d_6–TMS) δ (ppm): 1.00–3.23 (m, $(CH_2)_4$), 4.60 (m, O-CH), 7.00–7.83 (m, $B(C_6H_5)_2$), 11.83 (s, exchangeable, OH). ^{11}B NMR (64 MHz, DMSO-d_6–Et_2OBF_3) δ (ppm): 10.2 ($w_{1/2}$ = 470 Hz). Anal. calcd. for $C_{18}H_{20}BNO_2$: C 73.75, H 6.88, B 3.69, N 4.78; found: C 73.67, H 6.99, B 3.69, N 4.74.

2,2,4,5-Tetraphenyl-1-oxa-3-azonia-2-borata-3-cyclopenten-3-ol (5*d*)

α-Benzoinoxime (commercial product "Cupron") (0.23 g, 1 mmol) and oxybis(diphenylborane) (0.17 g, 0.5 mmol) are reacted as described for **5*a***. Yield: 0.32 g (82%) of colorless crystals[6], mp 170°C. IR (KBr, cm^{-1}): 2 734 (broad, O-H), 1 637 (C=N), 1596 (C=C). ^{1}H NMR (90 MHz, DMSO-d_6–TMS) δ (ppm): 6.53 (s, O-CH), 6.93–7.90 (m, 20 aromatic H), 12.77 (s, exchangeable, OH). ^{11}B NMR (64 MHz, DMSO-d_6–Et_2OBF_3) δ (ppm): 8.0. Anal. calcd. for $C_{26}H_{22}BNO_2$: C 79.81, H 5.67, B 2.76, N 3.58; found: C 97.91, H 5.70, B 2.89, N 3.42. Single crystals suitable for X-ray crystallographic analysis were obtained by very slow crystallization from absolute ethanol.

3-(Methylimino)-2,2-dimethylpropanol *N*-oxide (8*a*)

3-Hydroxy-2,2-dimethylpropanal (16) (1.02 g, 10 mmol), *N*-methylhydroxylamine hydrochloride (0.84 g, 10 mmol), and K_2CO_3 (0.7 g) are suspended in 10 mol of water and stirred for 10 min. After addition of 20 mL of benzene the mixture is refluxed using a Dean–Stark trap for continuous removal of water. After 5 h, the precipitated KCl is filtered off and the solvents removed in vacuo. The oily residue is purified by destillation in vacuo. Yield: 0.61 g (47%) of slightly orange oil, bp 135°C/5 torr (1 torr = 133 Pa). MS (CI, NH_3, pos. mode) *m*/*z*: 132 (100%, M^+ + H). IR (NaCl, film, cm^{-1}): 3 323 (broad, O-H), 1 606 (C=N). ^{11}H NMR ($CDCl_3$–TMS) δ (ppm): 1.23 (s, $C(CH_3)_2$), 3.63 (s, O-CH_2), 3.70 (s, N-CH_3), 4.57 (s, broad, exchangeable, OH), 6.53 (s, N=CH). Anal. calcd. for $C_6H_{13}NO_2$: C 54.94, H 9.99, N 10.86; found: C 54.92, H 9.84, N 10.10.

3-(Propylimino)-2,2-dimethylpropanol *N*-oxide (8*b*)

3-Hydroxy-2,2-dimethylpropanol (1.02 g, 10 mmol), *N*-propylhydroxylamine hydrochloride (0.12 g, 10 mmol), and K_2CO_3 (0.7 g) are reacted as described for **8*a***. Yield: 0.75 g (47%) of a slightly yellow oil, bp 142°C/10 torr (1 torr = 133 Pa). MS (CI, NH_3, pos. mode) *m*/*z*: 160 (100%, M^+ + H). IR (NaCl, film, cm^{-1}): 3 338 (broad, O-H), 1 595 (C=N). ^{11}H NMR ($CDCl_3$–TMS) δ (ppm): 0.97 (t, J = 6 Hz, N-C-C-CH_3), 1.27 (s, $C(CH_3)_2$), 1.67–2.20 (m, N-C-CH_2), 3.57 (s, O-CH_2), 3.73 (t, J = 6 Hz, N-CH_2), 6.00 (s, broad, exchangeable, OH), 6.60 (s, N=CH). Anal. calcd. for $C_8H_{17}NO_2$: C 60.35, H 10.76, N 8.80; found: C 60.42, H 10.26, N 8.49.

3-(Cyclohexylimino)-2,2-dimethylpropanol *N*-oxide (8*c*)

3-Hydroxy-2,2-dimethylpropanal (1.02 g, 10 mmol) and *N*-cyclohexylhydroxylamine are refluxed in 20 mL of benzene using a Dean–Stark trap for continuous removal of water. After 5 h, the solvent is distilled off and the remaining orange-colored oil is dissolved in a small amount of ethanol. Crystallization is achieved upon cooling and addition of *n*-hexane. Yield: 1.30 g (66%) of colorless crystals, mp 72°C (from EtOH–hexane). IR (KBr, cm^{-1}): 3 284 (broad, O-H), 1 595 (C=N). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.57–2.33 (m, $(CH_2)_5$), 1.23 (s, $C(CH_3)_2$), 3.40–3.87 (m, N-CH), 3.60 (d, J = 6 Hz, O-CH_2), 6.07 (t, J = 6 Hz, broad, exchangeable, OH), 6.53 (s, N=CH). Anal. calcd. for $C_{11}H_{21}NO_2$: C 66.30, H 10.62, N 7.03; found: C 66.29, H 10.61, N 6.82.

3-(Benzylimino)-2,2-dimethylpropanol *N*-oxide (8*d*)

3-Hydroxy-2,2-dimethylpropanal (2.04 g, 20 mmol), *N*-benzylhydroxylamine hydrochloride (3.19 g, 20 mmol), and K_2CO_3 (1.40 g) are reacted as described for **8*a***. After the refluxing, about two-thirds of the benzene is distilled off and crystallization is achieved by addition of ether. Yield: 1.77 g (43%) of colorless crystals, mp 98°C (from benzene–ether). IR (KBr, cm^{-1}): 3 243 (broad, O-H), 1 600 (C=N/C=C). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.23

8*c* (0.20 g, 2 mmol) and oxybis(diphenylborane) (0.35 g, 1 mmol) are reacted as described for **9*a***. Yield: 0.64 g (88%) of colorless crystals[6], mp 178°C. IR (KBr, cm^{-1}): 1 636 (C=N). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.67–2.27 (m, $(CH_2)_5$), 1.30 (s, $C(CH_3)_2$), 2.97 (m, N-CH), 3.77 (s, O-CH_2), 6.93 (s, N=CH), 7.07–8.00 (m, $B(C_6H_5)_2$). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 10.6 ($w_{1/2}$ = 342 Hz), 46.7, ratio of peak areas 10:1.[13] Anal. calcd. for $C_{23}H_{30}BNO_2$: C 76.06, H 8.32, B 2.98, N 3.86; found: C 76.22, H 8.36, B 3.05, N 3.66.

4-Benzyl-6,6-dimethyl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cycloheptene (9*d*)

8*d* (0.42 g, 2 mmol) and oxybis(diphenylborane) (0.35 g, 1 mmol) are reacted as described for **9*a***. Yield: 0.73 g (98%) of colorless crystals[6], mp 174°C. IR (KBr, cm^{-1}): 1 652 (C=N), 1 605 (C=C). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.23 (s, $C(CH_3)_2$), 3.77 (s, O-CH_2), 4.27 (s, N-CH_2), 6.73 (s, N=CH), 6.93–8.00 (m, 15 aromatic H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 10.7 ($w_{1/2}$ = 258 Hz), 47.3, ratio of peak areas 10:1.[13] Anal. calcd. for $C_{24}H_{26}BNO_2$: C 77.64, H 7.06, B 2.91, N 3.77; found: C 77.75, H 7.21, B 3.01, N 3.69.

4-Benzhydryl-6,6-dimethyl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cycloheptene (9*e*)

8*e* (0.57 g, 2 mmol) and oxybis(diphenylborane) (0.35 g, 1 mmol) are reacted as described for **9*a***. Yield: 0.76 g (85%) of colorless crystals[6], mp 168°C. IR (KBr, cm^{-1}): 1 664 (C=N), 1 586 (C=C). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.30 (s, $C(CH_3)_2$), 3.83 (s, O-CH_2), 5.60 (s, N-CH), 6.67–8.00 (m, 20 aromatic H and N=CH). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 10.5 ($w_{1/2}$ = 342 Hz), 46.0, ratio of peak areas 10:1.[13] Anal. calcd. for $C_{30}H_{30}BNO_2$: C 80.54, H 6.76, B 2.42, N 3.13; found: C 80.37, H 6.80, B 2.49, N 2.91.

5,5-Dimethyl-2,2-diphenyl-1-oxa-3-azonia-2-borata-3-cyclohexen-3-ol (11*a*)

3-Hydroxy-2,2-dimethylpropionaldoxime (16) (0.12 g, 1 mmol) and oxybis(diphenylborane) (0.17 g, 0.5 mmol) are reacted as described for **5*a***. Yield: 0.25 g (89%) of colorless crystals[6], mp 165°C (from ethanol). IR (KBr, cm^{-1}): 2 566 (broad, O-H), 1 638 (C=N). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.30 (s, $C(CH_3)_2$), 3.57 (s, O-CH_2), 7.13–7.67 (m, 1 H exchangeable, OH and $B(C_6H_5)_2$, and N=CH). ^{1}H NMR (400 MHz, $CDCl_3$–TMS) δ (ppm): 1.30 (s, $C(CH_3)_2$), 3.53 (s, O-CH_2), 7.13 (m, exchangeable, OH), 7.23–7.57 (m, $B(C_6H_5)_2$), 7.60 (s, N=CH). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 4.00 ($w_{1/2}$ = 257 Hz). Anal. calcd. for $C_{17}H_{20}BNO_2$: C 72.62, H 7.17, B 3.84, N 4.98; found: C 72.67, H 7.22, B 3.98, N 4.84.

2,2-Di(4′-methoxyphenyl)-5,5-dimethyl-1-oxa-3-azonia-2-borata-3-cyclohexen-3-ol (11*b*)

3-Hydroxy-2,2-dimethylpropionaldoxime (16) (0.23 g, 2 mmol) and di(4-methoxyphenyl)-borinic acid (obtained from the 2-aminoethyl ester (19) by hydrolysis (11)) (0.48 g, 2 mmol) are reacted as described for **5*a***. Yield: 0.33 g (49%)

[13]Side signals with a small peak area at about 46 ppm have also been observed in the ^{11}B NMR spectra of diphenylboron chelates from other nitrone ligands (17) indicating a trivalent (sp^2) boron atom of a Ph_2B-O-R species (18). It is not yet clear whether the signal originates from an open-chain diphenylborinate (scission of the nitrone O-B coordination in **9**), or from free diphenylborinic acid caused by partial solvolysis.

© 2000 NRC Canada

of colorless crystals[6], mp 128°C (from ethanol). IR (KBr, cm^{-1}): 2 517 (broad, O-H), 1 640 (C=N), 1 599 (C=C). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.27 (s, $C(CH_3)_2$), 3.60 (s, O-CH_2-C), 6.67–8.00 (m, 1 H exchangeable, OH and N=CH, and 8 aromatic H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 9.9 ($w_{1/2}$ = 342 Hz). Anal. calcd. for $C_{19}H_{24}BNO_4$: C 66.88, H 7.09, B 3.17, N 4.11; found: C 66.81, H 7.15, B 3.28, N 3.95. Single crystals suitable for X-ray crystallography were obtained by very slow crystallization from absolute ethanol.

4,5-Dimethyl-2,2-diphenyl-1-oxa-3-azonia-2-borata-3-cyclohexen-3-ol (11*c*)

4-Hydroxy-3-methyl-2-butanonoxime (15) (0.59 g, 5 mmol) and oxybis(diphenylborane) (0.87 g, 2.5 mmol) are reacted as described for **5*a***. Instead of petroleum ether, diethyl ether is added to initiate the crystallization. Yield: 0.85 g (58%) of colorless crystals[6], mp 151°C (from ethanol–ether). IR (KBr, cm^{-1}): 2 691 (broad, O-H), 1 638 (C=N). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.40 (d, J = 7 Hz, N=C-C-CH_3), 2.23 (s, N=C-CH_3), 2.40–3.00 (m, X of ABX system, N=C-CH), 3.47/3.90 (m/m, AB of ABX system, O-CH_2), 7.07 (s, broad, exchangeable, OH), 7.20–7.67 (m, $B(C_6H_5)_2$). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 6.6 ($w_{1/2}$ = 235 Hz). Anal. calcd. for $C_{17}H_{20}BNO_2$: C 72.62, H 7.17, B 3.84, N 4.98; found: C 72.66, H 7.16, B 3.87, N 4.85.

4,6,6-Trimethyl-2,2-diphenyl-1-oxa-3-azonia-2-borata-3-cyclohexen-3-ol (11*d*)

4-Hydroxy-4-methyl-2-pentanonoxime (20) (0.66 g, 5 mmol) and oxybis(diphenylborane) (0.87 g, 2.5 mmol) are reacted as described for **5*a***. Yield: 0.60 g (41%) of colorless crystals[6], mp 124°C (from ethanol). IR (KBr, cm^{-1}): 2 702 (broad, O-H), 1 650 (C=N). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.37 (s, $C(CH_3)_2$), 2.30 (s, N=C-CH_3), 2.50 (s, N=C-CH_2-C), 7.10–7.90 (m, 1 H exchangeable, OH and $B(C_6H_5)_2$). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 6.2 ($w_{1/2}$ = 128 Hz). Anal. calcd. for $C_{18}H_{22}BNO_2$: C 73.24, H 7.51, B 3.66, N 4.75; found: C 73.27, H 7.65, B 3.71, N 4.58.

(Methylimino)acetic acid *N*-oxide (16*a*)

Method A

Glyoxylic acid monohydrate (0.46 g, 5 mmol), dried $MgSO_4$ (0.60 g), *N*-methylhydroxylamine hydrochloride (0.42 g, 5 mmol), and triethylamine (0.51 g, 5 mmol) are refluxed in 50 mL of ether for 5 min. The solid residue is filtered off and extracted several times with boiling ether. The combined ether solutions are partially evaporated and, if necessary, cooled for crystallization. Yield: 0.12 g (24%) of colorless crystals, mp 78°C (from ether). IR (KBr, cm^{-1}): 2 600–2 000 ("curtain," O-H assoc.), 1 711 (C=O), 1 580 (C=N). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 3.93 (s, CH_3), 7.43 (s, N=CH), 14.67 (s, very broad, exchangeable, OH). Anal. calcd. for $C_3H_5NO_3$: C 34.96, H 4.89, N 13.59; found: C 34.72, H 4.87, N 13.32.

Method B

Large quantities (up to 40 mmol) can be prepared advantageously also by the procedure described in the literature (21) for **16*d*** (see below), which gives better yields, but requires more time.

(*tert*-Butylimino)acetic acid *N*-oxide (16*b*)

Method A, as described above for **16*a***, is applied for *N*-*tert*-butylhydroxylamine (0.45 g, 5 mmol), without triethylamine in *n*-hexane as the solvent. Yield: 0.58 g (68%) of colorless crystals, mp 62°C (from hexane). IR (KBr, cm^{-1}): 2 600–2 170 (curtain, O-H assoc.), 1 703 (C=O), C=N band not identified. ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.60 (s, $C(CH_3)_3$), 7.47 (s, N=CH), 14.63 (s, broad, exchangeable, OH). Anal. calcd. for $C_6H_{11}NO_3$: C 49.65, H 7.64, N 9.65; found: C 49.42, H 7.73, N 9.42.

(Cyclohexylimino)acetic acid *N*-oxide (16*c*)

Method A, as described above for **16*b***, is applied for *N*-cyclohexylhydroxylamine (0.58 g, 5 mmol). Yield: 0.46 g (54%) of colorless crystals, mp 87°C (from hexane). IR (KBr, cm^{-1}): 2 500–2 340 (curtain, OH assoc.), 1 727/1 699 (C=O), 1 609 (C=N). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.00–2.37 (m, $(CH_2)_5$), 3.90 (m, N=CH), 7.43 (s, N=CH), 14.77 (s, broad, exchangeable, OH). Anal. calcd. for $C_8H_{13}NO_3$: C 56.13, H 7.65, N 8.18; found: C 56.02, H 7.80, N 8.05.

(Benzylimino)acetic acid *N*-oxide (16*d*)

The compound was prepared as described in the literature (21), using *N*-benzylhydroxylamine hydrochloride and triethylamine in equimolar amounts.

4-Methyl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexen-6-one (17*a*)

Method A

16*a* (0.21 g, 2 mmol) in 5 mL of absolute ethanol and oxybis(diphenylborane) (0.35 g, 1 mmol) in 5 mL of absolute ethanol are mixed. Under stirring at room temperature crystallization commences. After complete precipitation, the crystals are washed with 3 × 5 mL of warm ether. Yield: 0.40 g (75%) of colorless crystals[6], mp 114°C.[14] IR (KBr, cm^{-1}): 1 719/1 705 (C=O), 1 602 (C=N/C=C). ^1H NMR (90 MHz, DMSO-d_6–TMS) δ (ppm): 3.97 (s, CH_3), 7.00–8.00 (m, $B(C_6H_5)_2$), 8.53 (s, N=CH). A ^{11}B NMR spectrum could not be obtained because of poor solubility. Anal. calcd. for $C_{15}H_{14}BNO_3$: C 67.45, H 5.28, B 4.05, N 5.24; found: C 67.26, H 5.26, B 4.06, N 5.03.

Method B

Glyoxylic acid monohydrate (0.46 g, 5 mmol) and oxybis(diphenylborane) (0.87 g, 2.5 mmol) are dissolved in 5 mL of absolute ethanol under stirring at room temperature for 5 min. A solution of *N*-methylhydroxylamine hydrochloride (0.42 g, 5 mmol) and triethylamine (0.51 g, 5 mmol) in 5–10 mL of ethanol is added and stirred briefly for homogenization. Yield: 1.00 g (75%) of colorless crystals as described for method A.

[14]The usually analytical pure compound rearranges under thermal stress in solution[5]; therefore, recrystallization was not possible.

© 2000 NRC Canada

4-*tert*-Butyl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexen-6-one (17*b*)

16*b* (0.58 g, 4 mmol) and oxybis(diphenylborane) (0.70 g, 2 mmol) are reacted as described for **17*a*** (method A). Yield: 0.95 g, (77%) of colorless crystals[6], mp 132°C[14]. IR (KBr, cm^{-1}): 1 703 (C=O), 1 605 (C=N/C=C). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 1.47 (s, $C(CH_3)_3$), 7.00 – 7.60 (m, $B(C_6H_5)_2$), 7.70 (s, N=CH). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 10.5 ($w_{1/2}$ = 300 Hz), 30.0, ratio of peak areas 40:1.[15] Anal. calcd. for $C_{18}H_{20}BNO_3$: C 69.93, H 6.52, B 3.50, N 4.53; found: C 69.93, H 6.50, B 3.60, N 4.36. The compound is also available by a three component reaction of equimolar amounts of glyoxylic acid, *N*-*tert*-butylhydroxylamine, and diphenylborinic acid (method B as described for **17*a***, omitting triethylamine).

4-Cyclohexyl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexen-6-one (17*c*)

16*c* (0.34 g, 2 mmol) and oxybis(diphenylborane) (0.35 g, 1 mmol) are reacted as described for **17*a*** (method A). Yield: 0.21 g, (32%) of colorless crystals[6], mp 121°C[14]. IR (KBr, cm^{-1}): 1 706 (C=O), 1 603 (C=N/C=C). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.80–2.33 (m, $(CH_2)_5$), 3.73 (m, N-CH), 7.00–7.67 (m, $B(C_6H_5)_2$ and N=CH). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 10.3 ($w_{1/2}$ = 385 Hz), 30.1, ratio of peak areas 40:1[15]. Anal. calcd. for $C_{20}H_{22}BNO_3$: C 71.66, H 6.62, B 3.23, N 4.18; found: C 71.69, H 6.64, B 3.35, N 4.00. The compound is also available by a three component reaction of equimolar amounts of glyoxylic acid, *N*-cyclohexylhydroxylamine, and diphenylborinic acid (method B as described for **17*a***, omitting triethylamine).

4-Benzyl-2,2-diphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexen-6-one (17*d*)

16*d* (0.18 g, 1 mmol) and oxybis(diphenylborane) (0.17 g, 0.5 mmol) are reacted analogous as described for **17*a*** (method A). Yield: 0.16 g, (47%) of colorless crystals[6], mp 199°C[13]. IR (KBr, cm^{-1}): 1 719 (C=O), 1 615 (C=N/C=C). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 4.87 (s, N-CH_2), 6.67–7.73 (m, aromatic H and N=CH). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ: C 73.50, H 5.29, B 3.15, N 4.08; found: C 73.20, H 5.39, B 3.16, N 4.12. The compound is also available by a three component reaction of equimolar amounts of glyoxylic acid, *N*-benzylhydroxylamine (hydrochloride + triethylamine), and diphenylborinic acid (method B as described for **17*a***).

4-Benzyl-2,2-di(4′-chlorophenyl)-1,3-dioxa-4-azonia-2-borata-4-cyclohexen-6-one (17*e*)

16*d* (0.36 g, 2 mmol) and di(4-chlorophenyl)borinic acid (11) (0.50 g, 2 mmol) are reacted as described for **17*a*** (method A). Yield: 0.45 g, (55%) of colorless crystals[6], mp 113°C[14]. IR (KBr, cm^{-1}): 1 709 (C=O), 1 616 (C=N). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 4.93/5.13 (d/d, J = 15 Hz, AB system, N-CH_2), 6.67–8.00 (m, 13 aromatic H and N-CH). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 11.6 ($w_{1/2}$ = 684 Hz), 31.3, ratio of peak areas 50:1.[15] Anal. calcd. for $C_{21}H_{16}BCl_2NO_3$: C 61.21, H 3.91, B 2.62, N 3.40; found: C 61.13, H 3.85, B 2.90, N 3.30. The compound is also available by a three component reaction of glyoxylic acid, *N*-benzylhydroxylamine (hydrochloride + triethylamine), and di(4-chlorophenyl)borinic acid (method B as described for **17*a***).

4-Methyl-2,2,5-triphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexen-6-one (17*f*)

Phenylglyoxylic acid (0.75 g, 5 mmol) and oxybis(diphenylborane) (0.87 g, 2.5 mmol) are dissolved in 5 mL of absolute ethanol under stirring. After addition of a solution of *N*-methylhydroxylamine hydrochloride (0.42 g, 5 mmol) and triethylamine (0.51 g, 5 mmol) in 5 mL of ethanol and short heating, crystallization of the analytically pure product starts, at room temperature, eventually after cooling. Yield: 1.52 g, (89%) of colorless crystals[6], mp 132°C (from ethanol). IR (KBr, cm^{-1}): 1 711 (C=O), 1 594 (C=N/C=C). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 3.60 (s, CH_3), 6.80–7.83 (m, 15 aromatic H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 10.2 ($w_{1/2}$ = 214 Hz). Anal. calcd. for $C_{21}H_{18}BNO_3$: C 73.50, H 5.29, B 3.15, N 4.08; found: C 73.45, H 5.36, B 3.33, N 3.90.

2,2,5-Triphenyl-4-propyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexen-6-one (17*g*)

Phenylglyoxylic acid (0.75 g, 5 mmol), oxybis(diphenylborane) (0.87 g, 2.5 mmol), *N*-propylhydroxylamine hydrochloride (0.56 g, 5 mmol), and triethylamine (0.51 g, 5 mmol) are reacted as described for **17*f***. Yield: 0.66 g, (36%) of colorless crystals[6], mp 117°C (from ethanol). IR (KBr, cm^{-1}): 1 717 (C=O), 1 594 (C=N/C=C). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.80 (t, J = 7 Hz, CH_3), 1.67–2.17 (m, N-C-CH_2), 3.70 (t, J = 7 Hz, N-CH_2), 6.80–7.73 (m, 15 aromatic H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 11.1 ($w_{1/2}$ = 257 Hz). Anal. calcd. for $C_{23}H_{22}BNO_3$: C 74.41, H 5.97, B 2.91, N 3.77; found: C 74.33, H 5.97, B 2.96, N 3.80.

4-Cyclohexyl-2,2,5-triphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexen-6-one (17*h*)

Phenylglyoxylic acid (0.75 g, 5 mmol), oxybis(diphenylborane) (0.87 g, 2.5 mmol), and *N*-cyclohexylhydroxylamine (0.58 g, 5 mmol) are reacted as described for **17*f***, omitting triethylamine. Yield: 1.34 g, (65%) of colorless crystals[6], mp 139°C (from ethanol). IR (KBr, cm^{-1}): 1 719 (C=O), 1 586 (C=N/C=C). ^1H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.83–2.67 (m, $(CH_2)_5$), 3.73 (m, N-CH), 6.70–7.87 (m, 15 aromatic H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 9.2 ($w_{1/2}$ = 342 Hz). Anal. calcd. for $C_{26}H_{26}BNO_3$: C 75.93, H 6.37, B 2.63, N 3.41; found: C 75.82, H 6.36, B 2.57, N 3.27.

4-Benzyl-2,2,5-triphenyl-1,3-dioxa-4-azonia-2-borata-4-cyclohexen-6-one (17*i*)

Phenylglyoxylic acid (0.75 g, 5 mmol), oxybis(diphenylborane) (0.87 g, 2.5 mmol), *N*-benzyhlhydroxylamine hydrochloride (0.80 g, 5 mmol), and triethylamine (0.51 g, 5 mmol) are reacted as described for **17*f***. Yield: 1.31 g, (63%) of colorless crystals[6], mp 112°C (from ethanol). IR (KBr, cm^{-1}): 1 713 (C=O), 1 596 (C=N/C=C). ^1H NMR

[15]The signal with very small peak area originates from impurities caused by a thermally induced rearrangement reaction.[5]

(90 MHz, $CDCl_3$–TMS) δ (ppm): 4.90 (s, N-CH_2), 6.80–7.70 (m, 15 aromatic H). ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 11.5 ($w_{1/2}$ = 385 Hz). Anal. calcd. for $C_{27}H_{22}BNO_3$: C 77.35, H 5.29, B 2.58, N 3.34; found: C 77.36, H 5.33, B 2.63, N 3.17.

3-Hydroxy-2,2,4-triphenyl-1-oxa-3-azonia-2-borata-3-cyclopenten-5-one (19)

2-(Hydroxyimino)phenylacetic acid (22) (0.83 g, 5 mmol) is dissolved in 50 mL of refluxing $CHCl_3$. After the addition of oxybis(diphenylborane) (0.87 g, 2.5 mmol), dissolved in 2 mL of $CHCl_3$, the mixture is refluxed briefly. The solvent is distilled off until the volume is reduced to 10 mL. Crystallization is achieved after addition of small amount of petroleum ether and cooling to –18°C for 1 h. Yield: 1.16 g (70%) of colorless crystals[6], mp 181°C (from $CHCl_3$–petroleum ether). IR (KBr, cm^{-1}): 3 156–2 737 (curtain, O-H assoc.), 1 725 (C=O), 1 657 (C=N), 1597 (C=C). ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 7.23–7.73 (m, 13 aromatic H), 8.90 (d, J = 7 Hz, 2 aromatic H), signal for OH not detectable. ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 9.3 ($w_{1/2}$ = 300 Hz). Anal. calcd. for $C_{20}H_{16}BNO_3$: C 72.98, H 4.90, B 3.28, N 4.26; found: C 73.03, H 4.89, B 3.21, N 4.25. Single crystals suitable for X-ray crystallography were obtained by very slow crystallization from chloroform–petroleum ether (bp 30–70°C) using the liquid diffusion method (23).

X-ray crystallographic analyses of 5*d*, 9*a*, 11*b*, 19

Crystallographic data appear in Table 1. The final unit-cell parameters were obtained by least-squares based on 12 693, 12 078, 8 118, and 9 840 reflections with 2θ = 4–64° for **5*d***, **9*a***, **11*b***, and **19**, respectively. The data were processed,[16] corrected for Lorentz and polarization effects, and absorption (based on analysis of symmetry-equivalent data).

The structures were solved by direct methods, the coordinates of the atoms being determined from *E*-maps or from

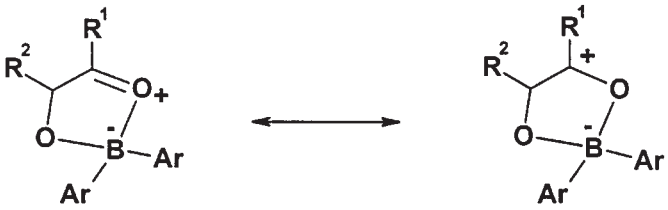
subsequent difference Fourier syntheses. The non-hydrogen atoms were refined with anisotropic thermal parameters, and the hydrogen atoms were refined with isotropic thermal parameters. No corrections for secondary extinction were necessary. Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from the *International Tables for X-Ray Crystallography*. For **9a**, the absolute configuration for the crystal used could not be determined from the small anomalous scattering effect. Selected bond lengths and angles are listed in Table 2. Complete tables of atomic coordinates and equivalent isotropic thermal parameters, bond lengths and angles, hydrogen atom parameters, anisotropic thermal parameters, torsion angles, intermolecular contacts, and least squares planes are included as supplementary material.[17]

Results and discussion



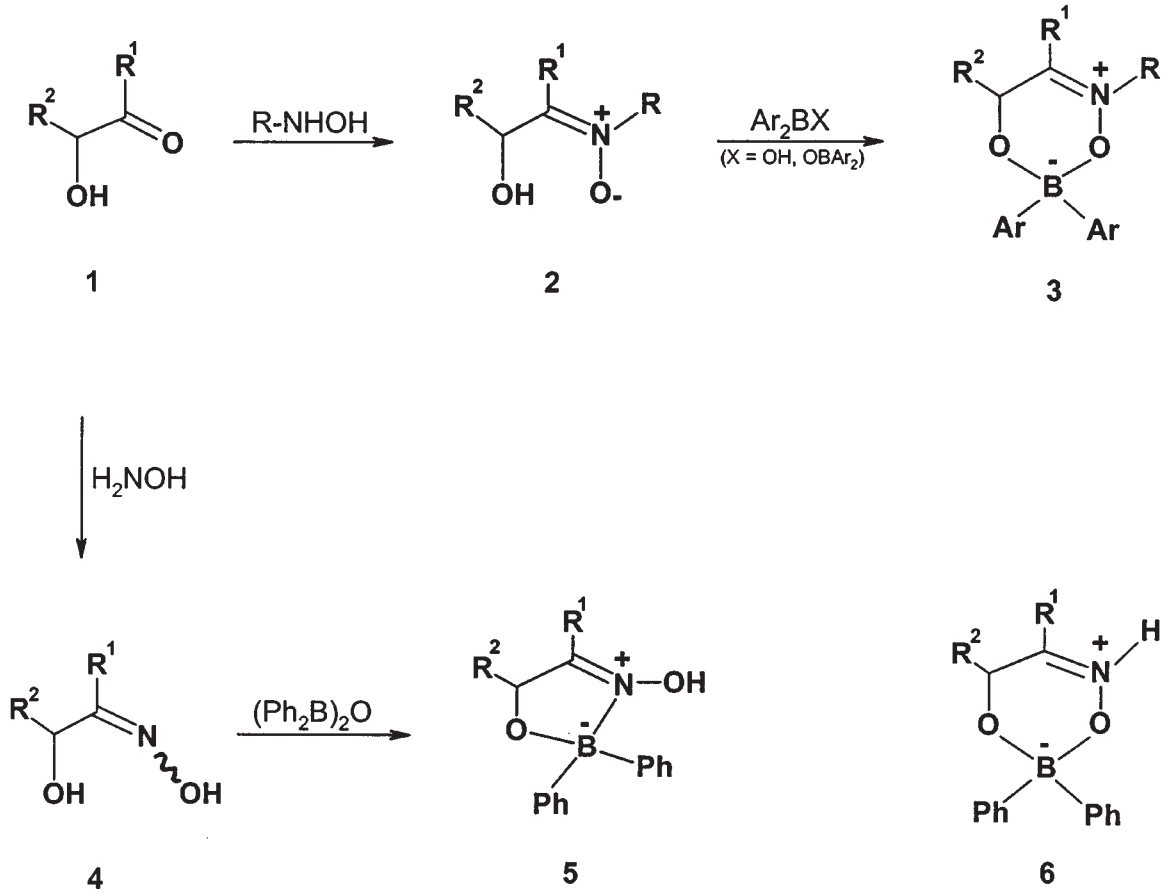
Nitrones 2

The *N*-alkylnitrones **2** which were required as intermediates for the synthesis of the six-membered boron chelates **3** could be prepared in the case of the aldonitrone species by condensation of *N*-alkylhydroxylamines with 2-hydroxycarbaldehydes **1** (R^1 = H) (9). The preparation of ketonitrones from 2-hydroxyketones (R^1 = alkyl) by condensation with *N*-alkylhydroxylamines appeared ineffective and led to some nitrone only in the case of **2*h***.

Since it has been recognized that the (*Z*)-configuration of aldonitrones is generally favored (24), it can be assumed that the aldonitrones **2** exist entirely in the (*Z*)-form which should be stabilized additionally by the intramolecular O-H···O bond in this case. The ready formation of **3**, described below, might corroborate this supposition.

Typical for the nitrones **2** are infrared spectra showing a C=N absorption band between 1 587 and 1 600 cm^{-1} and a broadened band of the associated O-H group at about 3 250 cm^{-1}. The ^1H NMR spectra of the aldonitrones **2** are characterized by the signals for the N=CH methine proton between 6.76 and 6.93 ppm and signals for an exchangeable OH proton which is present also in the spectrum of the ketonitrone **2*h***.

Scheme 1.



Nitrone complexes 3

Reaction of **2** with a diarylborinic acid or anhydride gave the diarylboron chelates **3** readily and in good yields. However, the preformation of the nitrone **2**, which is quite difficult with ketones, could be avoided by a three-component one-pot reaction of **1**, a diarylborinic acid, and an *N*-alkylhydroxylamine, which proved an advantage for the synthesis of ketonitrone derivatives applying the 2-hydroxyketones **1** (R^1 = alkyl). In the latter case, a preceding complex formation between the 2-hydroxyketone and the Lewis-acid boron compound (see Scheme 1)[18] might facilitate the nucleophilic attack of the hydroxylamine at the carbonyl carbon atom. Thus, only one of the ketonitrones (**2*h***) could be isolated in a satisfying yield and applied as an educt for the diphenylboron complex (**3*t***). All the other ketonitrone chelates **3** were prepared by the one-pot method without isolation of an intermediate **2**.

The infrared spectra of **3** are characterized by the disappearance of the stretching vibration of the O-H group of the free ligand **2**, and display an N=C band between 1 578 and 1 665 cm^{-1}, generally shifted to higher wave numbers

compared to the N=C bands of the corresponding educts **2**. In the ^{1}H NMR spectra of the aldonitrone derivatives (**3*a*–*l***), the N=CH methine proton shows a signal between 6 and 7 ppm. The ^{11}B NMR spectra of **3** indicate the tetracoordinate boron nucleus with signals between 3.6 and 9.2 ppm. In some of the spectra a second signal with very small peak area appears between 26.0 and 29.2 ppm, pointing to a trivalent boron atom in the trigonal arrangement of an arylboronate derivative (18). Small additional peaks were also observed in some of the ^{1}H NMR spectra and originate from impurities caused by a thermally induced rearrangement reaction (Scheme 2), leading to the isomeric arylboronates **3′**.[5] The isomerization can be retarded mostly by avoiding thermal stress during the preparation, recrystallization, and spectroscopy of **3**. The thermal stability of **3** depends on the substitution pattern. Thus the compounds **3*f*, *g*, *y*** can be recrystallized from the boiling solvent, and especially **3*z*–*cc*** show a high stability at all temperatures in various solvents.

Oxime complexes 5

Several 2-hydroxyketoximes **4** were reacted with diphenylborinic acid anhydride and gave readily crystalline compounds which show an elemental analysis consistent with both of the isomeric structures, **5** and **6**. An intact diphenylboron moiety is proved by the color reaction with

diphenylcarbazone (10). The infrared spectra, displaying a C=N absorption between 1 637 and 1 674 cm^{-1} and a broad band in the region of stretching vibrations of associated N-H/O-H groups (2 400–2 800 cm^{-1}), do not allow an unambiguous assignment to the five-membered ring system **5** with N-B coordination, or to the six-membered O-B-O chelate **6**, which is an *N*-unsubstituted derivative of **3**. From the ^1H NMR spectra, as well as from ^{11}B NMR spectra, no positive proof for one of the ring systems can be obtained. One exchangeable proton giving a ^1H signal about 12 ppm for acidic N-H or O-H, and a ^{11}B signal between 8.0 and 10.2 ppm, indicating the tetracoordinate boron nucleus (18), might characterize either of the structures **5** and **6**. For most of the metal complexes of 2-hydroxyoximes a five-membered O-*M*-N chelate structure is assumed (25), but evidence is presented also for six-membered O-*M*-O ring systems (26), even from the stereochemically defined (*E*)-benzoinoxime (α-benzoinoxime) as an educt (26*b*). The geometrical isomerism of the educt seems to be of minor significance, anyway, because *E*/*Z*-isomerization of oximes (inversion and (or) rotation) can take place easily, especially in the presence of an acid (27) or Lewis acid like a boron compound (28). Of the ketoximes **4** used in this work only α-benzoinoxime ((*E*)-**4**) (R^1 = R^2 = Ph), was stereochemically defined. An X-ray crystallographic analysis of **5*d*** proves the five-membered chelate ring structure presenting the oxime ligand in the (*E*)-conformation. Since the spectroscopic data of the other derivatives, **5*a*–*c***, are very similar, this structure should be applicable to all of the compounds **5**. To the best of our knowledge, **5*d*** is the first X-ray structurally characterized boron (or any other element) chelate of α-benzoinoxime.

The crystal structure of **5*d*** consists of discrete molecules (Fig. 1), linked by NO-H···O hydrogen bonds, the acceptor oxygen atom being the O(2) ring member:

O (1)···O (2) = 2.583(1), O(1)-H = 0.90(2),
H···O(2) = 1.71(2) Å, O(1)-H···O(2) = 162(2)°

© 2000 NRC Canada

Fig. 1. Views of the molecules of (*a*) ***5d***, (*b*) ***9a***, (*c*) ***11b***, and (*d*) **19**; 50% probability thermal ellipsoids are shown for the non-hydrogen atoms.

The C-C=N-B system in the five-membered ring in ***5d*** shows some deviation from exact planarity, torsion angle 9.6(2)°, and the ring conformation is best described as a half-chair, with B and O displaced on opposite sides of the C-C=N plane. A relatively narrow "bite" of the oxime ligand leads to a compressed O-B-N angle of 94.9(1)° (Table 2), thus distorting the tetrahedral grouping around the boron atom slightly. This angle is even smaller than the O-B-N angle between 98.2 and 99.9° in other five-membered COBNC rings derived from 2-aminoethanols and diarylborinic acids (29). The O-B, B-N, and N=C bond lengths are of the same order as those found in the diphenylboron chelate of

salicylaldoxime (cf. formula **13** below), which represents a six-membered analogue (30):

5*d*: 1.503, 1.613, and 1.289(2) Å, respectively.

13: 1.516, 1.609, and 1.284(2) Å, respectively.

The B—C (phenyl) bond lengths (1.604 and 1.612 Å) are about normal.

Nitrones 8

The 3-hydroxyaldehyde nitrones **8** were prepared by condensation of 3-hydroxy-2,2-dimethylpropanal with various *N*-alkylhydroxylamines to obtain bidentate ligands for the synthesis of the seven-membered boron chelate type **9**. Depending on the *N*-alkyl residue the nitrones **8** are high boil-

		R^1	R^2	Ar

	c	— $(CH_2)_4$ —		Ph
	d	Ph	Ph	Ph

ing liquids or crystalline substances under normal conditions. In the IR spectra the most characteristic absorptions are found in the 3 400–3 200 cm^{-1} region where stretching modes of hydrogen bonded O-H groups appear, and between 1 587 and 1 606 cm^{-1} where the C=N group of the nitrone function absorbs. The ^1H NMR spectra of **8** display some typical signals, common to all of the samples, such as the resonance of the N=CH methine proton between 6.53 and 6.60 ppm and a signal for the hydroxyl proton between 4.57 and 6.07 (in $CDCl_3$), as well as from the singlet of the 2,2-dimethyl grouping at about 1.23 ppm. As mentioned above for the aldonitrones **2**, it can be assumed that **8** exists in the (*Z*)-form and thus presents a suitable ligand for the diphenylborenium (Ph_2B^+) ion to form the chelate **9**.

Nitrone complexes 9

From the reaction of **8** with diphenylborinic acid anhydride the diphenylboron chelates **9** resulted as crystalline compounds in high yields, favored by larger *N*-alkyl substituents. The IR spectra of **9** show C=N absorptions be-

tween 1 636 and 1 664 cm^{-1}, a shift of 30–60 cm^{-1} to higher frequencies compared to the free ligand **8**. Similar observations have been made from the IR spectra of **2** and **3** and of other boron chelates and their nitrone ligands (31). In the ^1H NMR spectra of **9** the most significant signal is that of the N=CH methine proton between 6.73 and 6.93 ppm, shifted to lower field by 0.2–0.4 ppm compared to the ligand nitrone **8**. The ^{11}B NMR spectra of **9** show the expected signals of a tetravalent boron nucleus at about 10.5 ppm. A thermally induced 1,4-phenyl shift (from the diphenylboron group to the N=CH methine carbon), as observed from the spectra of **3**, obviously does not occur in **9**, even in boiling ethanol.

To prove the molecular structure, an X-ray crystallographic analysis of **9*a*** was carried out and confirmed the seven-membered ring structure derived from the (*Z*)-form of the nitrone ligand (Fig. 1). This is a new crystallographic example of a boron chelate with a stable seven-membered ring system. Similar chelate rings (**14**) containing a bidentate ligand with an *N*-oxide and a phenolate donor group have been described by X-ray crystallographic analyses in earlier work (17*c*, 32, 33). Two of these are derivatives of salicylaldehyde nitrones (**14**, X = Y = H, *R* = Me (32); X = NEt_2, Y = H, *R* = CH_2-C_6H_4-2-OH (17*c*)). Unlike the boron chelate rings of the salicylaldehyde nitrones **14**, which possess a somewhat distorted envelope (or sofa) conformation with the boron atom on the flap displaced by 0.8–1 Å from the mean plane formed by the remaining ring atoms, the seven-membered ring of **9*a*** has a distorted half-chair conformation (Fig. 1). The ring contains a planar segment, O(1)-N(1) = C(1)-C(2) of the nitrone moiety (torsion angle 0.1°), with the other three ring atoms considerably displaced from this plane (torsion angles as large as 95.5(2)°). This ring conformation places the B-phenyl groups quite far from the nitrone carbon atom C(1), the distance between the nearest boron-bound phenyl carbon atom C(7) and the nitrone carbon atom C (1) being 3.75 Å (with C(13)···C(1) = 4.40 Å). These distances are probably too long to facilitate the 1,4-migration of the phenyl group as observed in the diphenylboron chelate of *N*-methylsalicylaldonitrone (32). The higher thermal stability of the compounds **9** could be explained at least partially by that structural difference. As in other diphenylboron chelates with an *N*-oxide and an alcoholate or phenolate ligand (ref. 32 and refs. therein), the O—B bond between the nitrone oxygen atom and boron in **9*a*** (O(1)—B(1) = 1.593(2) Å) is longer than the O—B bond from the alcoholate (O(2)—B(1) = 1.464(2) Å). The mean O—B (1.528(2) Å) and C—B (1.619(2) Å) distances are similar to the average O—B and C—B bonds lengths in **14** (*R* = Me, X = Y = H) of 1.528 and 1.610 Å, respectively, (32), and the mean C—B:O—B bond length ratio of 1.059 for **9*a*** is only slightly larger than the value of 1.054 for **14** (*R* = Me, X = Y = H), indicating a minor increase of overall binding strength (34) of the ligand to the Ph_2B^+ nucleus in both of the seven-membered diphenylboron chelates. **9*a*** has no hydrogen-bond donating functional group, and the molecules in the crystal are linked by van der Waals forces, with a possibly significant C-H···O interaction: C···O = 3.235(2), C-H = 0.93(2), H···O = 2.33(2) Å, C-H···O = 153(2)°.

Oxime complexes 11

The stability of the nitrone chelates **9** led us to investigate diarylboron complexes of 3-hydroxyoxime which might have a six-membered ring structure **11** with N-B coordination or the seven-membered isomeric structure **12** corresponding to the nitrone O-B-O chelates **9**. The reaction of 3-hydroxyaldoximes (**10**, R^1 = H) and ketoximes (**10**, R^1 = alkyl)

(which were prepared according to the literature (15, 16, 20) without regard to geometrical isomerism) with a diarylborinic acid or anhydride gave crystalline compounds in quite good yields. The elemental analyses and the spectroscopic data confirm the 1:1 condensation of oxime and diarylborinic acid. In the IR spectra distinct C=N stretching modes at about 1 640 cm^{-1} and broad absorption bands between 2 700 and 2 400 cm^{-1} in the N-H/O-H region are characteristic but do not allow an unambiguous assignment to either **11** or **12**. The same holds for the ^1H NMR spectra, which give no specific indication of one of the two isomeric structures. The ^{11}B NMR spectra show the expected signals in the shift region of tetracoordinate boron nuclei between 4.0 and 9.9 ppm. An intact diphenylboron grouping was proved by the color reaction with diphenylcarbazone (10). Positive evidence of the molecular structure however, was furnished by an X-ray crystallographic analysis of **11*b*** (Fig. 1) which gave the best single crystals. The six-membered O-B-N chelate structure **11** based upon the (*E*)-form of the oxime ligand **10** corresponds to the structure of the salicylaldoximediphenylboron chelate **13** (30). Like **13** and also like **5*d*** (see above), the crystal structure of **11*b*** consists of discrete molecules (Fig. 1) linked by strong O-H···O hydrogen bonds:

O(1)···O(2) = 2.569(1), O (1)-H = 0.98(2),
H···O (2) = 1.59(2) Å; O(1)-H···O = 175(2)°

Compared to **13** and **5*d*** the hydrogen bond in **11*b*** is the shortest with the least bent angle:

	11*b*	**13**	**5*d***
O···O	2.569	2.737	2.583 Å
O-H···O	175	167	162°

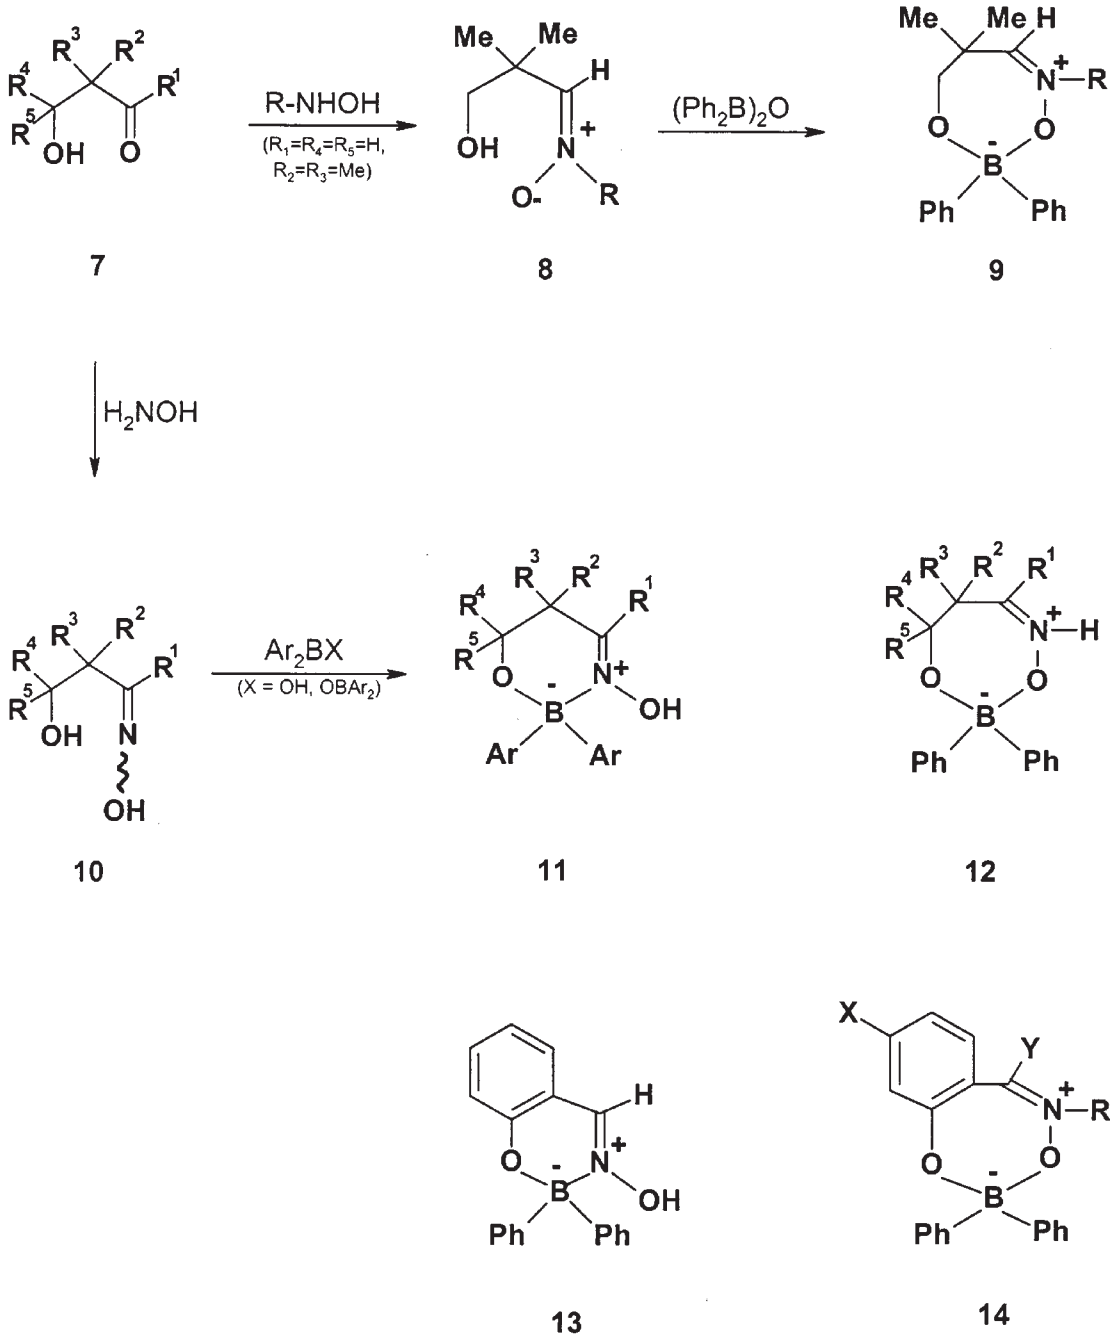
A half-chair conformation, with a nearly planar B(1)-N(1) = C(1)-C(2) segment (torsion angle = 0.9(2)°), and O(2) and C(3) displaced on opposite sides of the six-membered ring, characterizes the overall structure, as a result of the presence of the C=N double bond within the otherwise saturated ring skeleton of **11**. The O-B-N angle in **11*b*** (102.8(1)°, Table 2) is less compressed than the O-B-N angle in **5*d*** (94.9°), allowing a less distorted tetrahedral arrangement around the boron atom. Compared to **13** and also to **5*d***, the oxime C=N bond in **11*b*** (1.275(2) Å) is slightly shorter by about 0.01 Å, which is in accordance with a lengthened (by 0.01 Å) N—B bond.

Nitrones 16

As described in the literature (21), the aldonitrones **16** (R^1 = H) can be obtained by condensation of glyoxylic acid with an *N*-alkylhydroxlamine. The IR spectra of **16** show a

		R	R^1
16	***a***	CH_3	H
	b	$(CH_3)_3C$	H
	c	C_6H_{11}	H
	d	$PhCH_2$	H

broadened band of low intensity (curtain) in the region of associated O-H groups between 2 700 and 2 000 cm^{-1}, carboxyl-C=O stretching modes at about 1 700, and C=N vibrations at about 1 600 cm^{-1}, often hidden by aromatic C=C vibrations. In the ^1H NMR spectra, a typical N=CH methine proton signal between 7.43 and 8.13 ppm and a broad low field singlet (13–14 ppm) of the carboxyl-OH identify the nitrone and the carboxylic acid functions of **16**. It can be assumed that the aldonitrones **16** exist in the (*Z*)-form, stabilized additionally by an intramolecular O-H···O hydrogen bridge, as has been discussed above for the nitrones **2**.

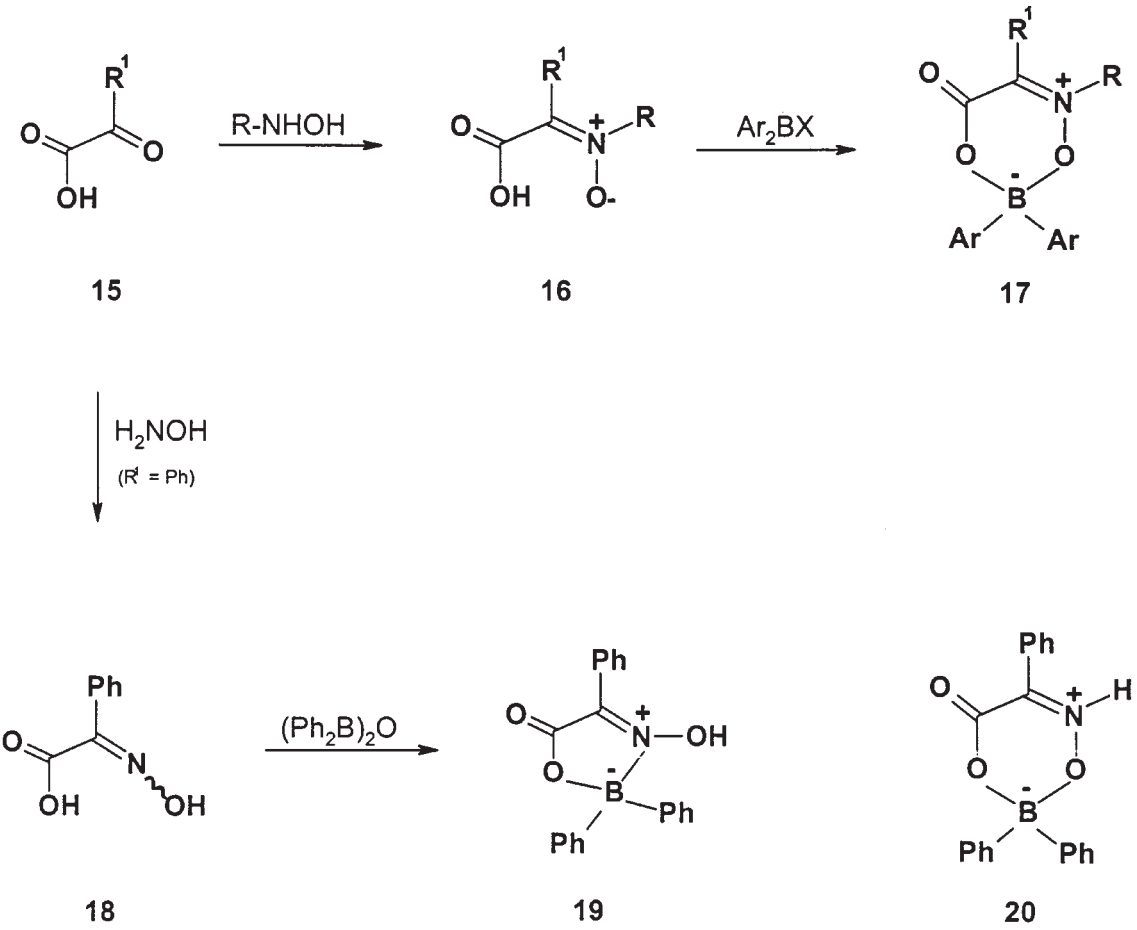


Nitrone complexes 17

Reaction of the aldonitrones **16** (R^1 = H) with a diarylborinic acid (or anhydride) resulted in the crystalline diarylboron chelates **17*a*–*e*** which can be isolated under avoidance of thermal stress leading to isomerization similar to that mentioned above for some type **3** nitrones.[5] For the synthesis of ketonitrone chelates **17**, the difficulties of preparing the nitrone of an α-ketocarbonic acid **16** could be avoided by a three-component one-pot reaction of **15** (R^1 = Ph), diarylborinic acid, and *N*-alkylhydroxylamine, with the advantage of a Lewis acid catalysis of the nitrone formation, as described above for the ketonitrone complexes **3**. The ketonitrone derivatives **17*f*–*i*** turned out to be thermally more stable, which suggests that they are less susceptible to an isomerization by 1,4-phenyl migration. In the IR spectra of the chelates **17** there is not much change as compared with the free ligands **16**, except for the absence of the O-H absorption. The disappearance of the OH signal is also the most significant change in the ^1H NMR spectra of the chelates **17** compared to the nitrone ligand **16**. In the ^{11}B NMR spectra of **17** the typical signals for tetracoordinate boron appear between 9.2 and 11.6 ppm. The compounds **17** are functionally related to the six-membered boron chelates of *N*-carboxymethylnitrones (4), with the difference of an *endo*cyclic nitrone-C=N group.

Oxime complex 19

To obtain at least one reaction product of an oxime of a 2-oxocarbonic acid and diphenylborinic acid, the phenylglyoxylic acid oxime **18** (22) was chosen. Because of the easy isomerization, even at room temperature in aqueous



© 2000 NRC Canada

solution (22*a*, *b*), the oxime was applied without separation of the *E*/*Z*-isomers. The high-melting crystalline product is obtained in good yield and has an elemental analysis corresponding to the isomeric molecular structures **19** and **20**. The IR spectrum shows the expected bands in the N-H/O-H region between 2 737 and 3 156 cm^{-1}, as well as the carboxylate C=O and the oxime C=N absorptions at 1 725 and 1 657 cm^{-1}, respectively. An ^{11}B NMR signal for tetracoordinate boron at 9.3 ppm and the blue color reaction with diphenylcarbazone indicate the diphenylboron–chelate character of the compound. The unambiguous discrimination between the five-membered ring **19** with N-B coordination, and the six-membered O-B-O chelate system **20** representing an *N*-unsubstituted derivative of **17**, was made possible by an X-ray crystallographic analysis. The X-ray analysis confirms the five-membered boron chelate structure **19** incorporating the (*E*)-form of the ligand **18**. The ring dimensions are similar to that of **5**, with the ring conformation being more near planar (B-N=C-C torsion angle = 2.7(2)°). As in **5*d***, the O-B-N angle in **19** is distinctly compressed (to 95.3(1)°). The ring C(2)-O(1) distance in **19** (1.311(2) Å, Fig. 1, Table 2), part of the carboxylate function, is shorter than the ring alcoholate-C(2)-O(2) distance in **5*d*** (1.427(2) Å), according to expectation. The crystal structure of **19** consists of discrete molecules linked by N-O-H···O=C hydrogen bonds:

O(2)···O(3) = 2.600(1), O(2)-H = 0.96(2),
H···O (3) = 1.76(2) Å; O-H···O = 144(2)°

To the best of our knowledge **19** is the first boron complex of a 2-(hydroxyimino)carboxylic acid reported on and structurally established. The coordination chemistry of 2-(hydroxyimino)carboxylic acids has not been a subject of extensive investigation until recently (35). Previous reviews (25) do not mention this species of ligand. However, a cobalt complex of phenylglyoxylate oxime is described by NMR data earlier (36). Structural details of 2-(hydroxyimino)propionate complexes of different metals have been determined by X-ray analyses (35). All of these complexes possess five-membered O-*M*-N chelate moieties with a near planar ring conformation like **19**.

The large number of compounds of type **3** with various substituents has been synthesized for a broader investigation of the thermal rearrangement reaction of these materials, and for the interest in new boron compounds with potentially herbicidal, insecticidal, and other biological effects (37).

New syntheses of dillapiol [4,5-dimethoxy-6-(2-propenyl)-1,3-benzodioxole], its 4-methylthio and other analogs

Sherry L. Majerus, Najma Alibhai, Sasmita Tripathy, and Tony Durst

Abstract: Three syntheses of the natural synergist dillapiol from the natural, commercially available sesamol as starting material, are described. A major difference between these is the order of introduction of the additional methoxy and allyl substituents. In one of the syntheses, a formyl group is introduced at C4 via an electrophilic aromatic substitution reaction and then converted into the methoxy group using a Baeyer–Villiger reaction and subsequent methylation; in the other two, a directed ortho-metalation, Baeyer–Villiger, methylation sequence was employed. Various intermediates along the synthetic route were used to generate more than 30 analogs, including the 4-thiomethyldillapiol, to investigate the structure activity relationships of the pesticide synergism of these compounds. Radio-labeled dillapiol, bearing ^{14}C at the C4 methoxy group was also prepared. Initial screening with mosquito larvae showed that most of the derivatives prepared in this study had signifacant synergistic activities in combination with the phototoxic larvicide α-therthiophene.

Key words: dillapiol, insecticide synergists, dillapiol analogs, 4-methylthiodillapiol.

Résumé : On décrit trois synthèses du dillapiol, un produit naturel de synergie, qui ont été réalisées à partir du sésamol, un produit naturel disponible commercialement. Ces trois ces synthèses diffèrent principalement par l'ordre d'introduction des substituants méthoxy et alkyles additionnels. Dans l'une de ces synthèses, le groupe formyle est introduit en C-4 par le biais d'une réaction de substitution aromatique électrophile et elle est ensuite transformée en groupe méthoxy à l'aide d'une réaction de Baeyer–Villiger et une réaction de méthylation subséquente; dans les deux autres, on fait appel à la séquence de réaction impliquant une métalation ortho dirigée, une réaction de Baeyer–Villiger et une méthylation. On a utilisé divers intermédiaires obtenus au cours de ces voies de synthèses pour générer plus de 30 analogues, y compris le 4-thiométhyldillapiol, afin d'en étudier les relations structure-activité de synergie de ces composés comme pesticide. On a aussi préparé du dillapiol radioactivement marqué par du ^{14}C dans le groupe méthoxy en C-4. Des évaluations initiales avec des larves de moustiques montrent que la plupart des dérivés préparés au cours de cette étude présentent des activités importantes de synergie lorsqu'on les utilise en combinaison avec l'α-therthiophéne, un larvicide phototoxique.

Mots clés : dillapiol, effet de synergie pour les insecticides, analogues de dillapiol, 4-méthylthiodillapiol.

Introduction

During the past few years we have been involved in a project aimed at developing natural insecticides (1). Part of this includes the use of the naturally occurring synergist dillapiol (**1**). Dillapiol is a member of a group of both natural and synthetic synergists known as polysubstrate mono-oxygenase inhibitors (PMSO) whose key structural unit is a benzene ring bearing a methylenedioxy unit (2). This unit binds strongly to the heme portion of the cytochrome P-450 thereby inhibiting the oxidation of various other substrate such as insecticides and delaying their rate of elimination from the insects. Examples of natural lignans with known synergistic activity, in addition to the dillapiol, are myristicin (**2**), safrole (**3**), and sessamin (**4**). Piperonyl butoxide (**5**) the commonly used commercial synergist for pyrethroids and carbamates, is also known to inhibit PSMOs.

Dillapiol is a monolignan and a major constituent of the essential oils of a number of plants, including Indian dill (*Antheum graveolus*) (3), and *Piper aduncum*, (4), a species in the Piperaceae family. The latter grows as a small shrub in many tropical areas such as Central America, the West Indies, and Southeast Asia. The development of dillapiol for commercial purposes requires either an inexpensive reliable natural source or a viable synthetic source. Additionally for registration purposes both the toxicity to nontarget species and pharmacokinetics including the nature of the metabolites need to be known. The latter studies can be carried out best with isotopically labeled material.

Three syntheses of dillapiol have previously been reported. 3,4,5-Tri-methoxyacetophenone (**5**), 2-hydroxy-3-methoxybenzaldehyde (*o*-vanillin) (**6**), and 1,2,3-trimethoxybenzene (**7**) were used as starting materials. These syntheses required

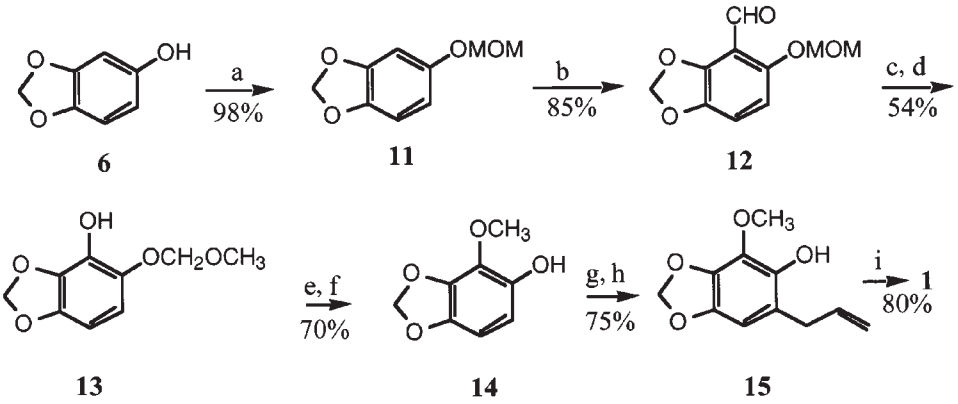
Scheme 1. Reagents: (*a*) K_2CO_3–CH_2=$CHCH_2Br$; (*b*) *N*,*N*-dimethylaniline (180°C); (*c*) $(CH_2O)n$–$SnCl_4$–Bu_3N; (*d*) CH_3I–K_2CO_3; (*e*) MCPBA–$CHCl_3$ (18 h, 0°C); (*f*) LiOH–THF–H_2O; (*g*) CH_3I–K_2CO_3–acetone.

5–7 steps and occurred in 2, 10, and 6% yield, respectively. None of the three syntheses is efficient or amenable to the introduction of isotopic carbon in the form of the relative inexpensive methyl iodide. We therefore decided to investigate several new syntheses which would be not only more efficient and enable us to introduce the labeled CH_3I in the last synthetic step, but also enable us to generate a family of derivatives to initiate a structure–activity relationship study. Finally, access to various intermediates is expected to help in the identification of metabolites.

Discussion of results

Three syntheses have been completed starting with sesamol (**6**). These are shown in Schemes 1–3. The structure of the intermediates generated in each sequence were determined mainly by ^{1}H NMR. The assignments were supported by ^{13}C NMR, IR, and HRMS data. These are given in the experimental section.

In the first synthesis, Scheme 1, sesamol (**6**)[2] was converted to the *ortho*-allylated phenol **7** in 81% overall yield via *O*-allylation, followed by a Claisen rearrangement. Introduction of the formyl group into the 4 position in **7** was accomplished by treatment with formaldehyde, $SnCl_4$, and tributylamine (8) to afford **8** in 60% isolated yield. Replacement of tributylamine by other tertiary amines such as triethyl- or trioctylamine either reduces or did not improve the yield of **8**. The variation of other reaction parameters such as temperature and reaction time also did not result in yield improvements.



This compound was quantitatively methylated to **9** in preparation for the Baeyer–Villiger and subsequent hydrolysis of the formate ester to form **10**. The conversion of **9** to **10** was carried out using 1 equiv. of MCPBA in $CHCl_3$ at 0°C for 18 h and afforded the formyl intermediate in 71% isolated yield, saponification of which gave **10.** Under these conditions competition by the alkene moiety for the peracid to give an epoxide was minor; at room temperature the rates of desired Baeyer–Villiger and the epoxidation were quite comparable. Finally, methylation of **10** with CH_3I–K_2CO_3 in acetone afforded pure dillapiol. Replacement of cold methyl iodide with carbon-14 labeled material afforded radiolabeled dillapiol, suitable for metabolism studies.

The overall yield of dillapiol from sesamol via Scheme 1, based on the isolated yields of each intermediate, is more than 21%. The major shortcomings of this route are the rather stringent conditions required for the introduction of the formyl group and the problem of the competing

[2] The numbering used throughout this paper is based on the IUPAC numbering of the 1,3-benzodioxole ring system. See structure **6**, Scheme 1.

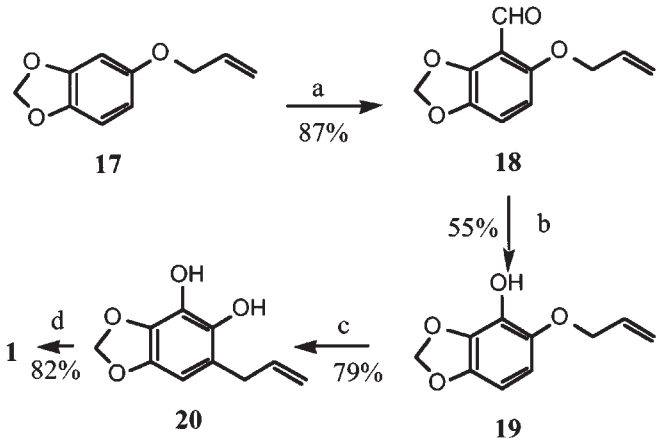
Scheme 2. Reagents: (*a*) MOM-Cl–*n*BuLi; (*b*) *n*BuLi, THF, (–78°C), then DMF; (*c*) MCPBA; (*d*) 10% KOH; (*e*) K_2CO_3 and CH_3I; (*f*) CH_3CO_2H, NaI; (*g*) K_2CO_3, CH_2=$CHCH_2Br$; (*h*) *N*,*N*-dimethylaniline (180°C); (*i*) K_2CO_3 and CH_3I.

epoxidation of the terminal double bond during the Baeyer–Villiger reaction of **9**. These difficulties became more severe on attempted scale-up.

Considerable effort was expended to avoid the sensitive reactions and shorten the synthesis by going directly from **7** to the resorcinol **20** and hence to dillapiol. Direct *o*-hydroxylation of **7** using H_2O_2–$AlCl_3$ according to Kurz and Johnson (9) or by use of oxygen and copper metal in the presence of $CuCl_2$ as developed by Capdevielle and Maumy (10) was unsuccessful and gave mainly recovered **7**.



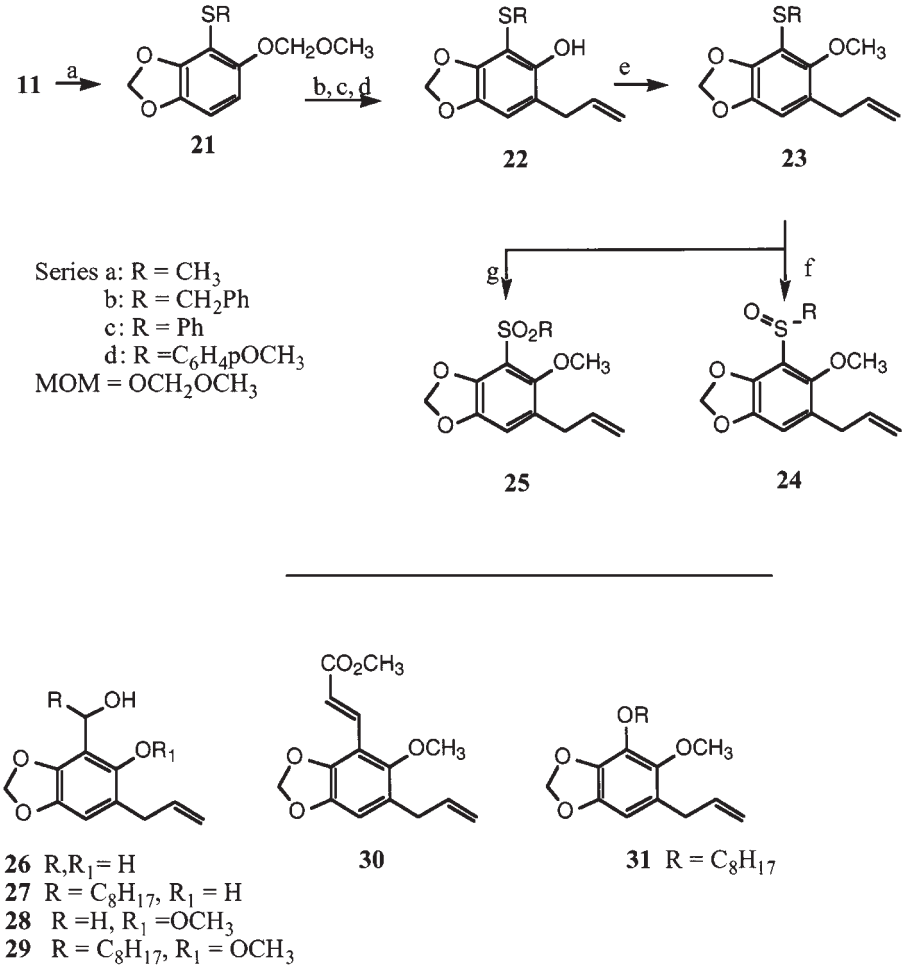
In the second synthesis, Scheme 2, the MOM-protected sesamol **11** was *o*-metallated (11) and treated with DMF to produce the aldehyde **12** in 85% yield. The protection of phenol as a THP derivative, thus avoiding the rather expensive MOM-chloride, was not possible since reaction of **6** with dihydopyran in the presence of acid resulted in the introduction of the THP unit at C6 via an electrophile aromatic substitution to afford **16** rather than the desired phenol protection.

Baeyer–Villiger oxidation followed by basic hydrolysis afforded phenol **13** which was methylated to give **14**. Removal of the MOM group set the stage for alkylation and subsequent Claisen rearrangement to afford phenol **15**, methylation of which gave dillapiol **1**. The overall yield of dillapiol via Scheme 2 was 19%.

After this synthesis was completed we realized that one might be able to avoid the protection–deprotection sequence if *ortho*-directed metallation and subsequent introduction of the formyl group could be carried out on the allyl ether **17** to give **18**. The conversion of **18** to dillapiol would require first a Baeyer–Villiger reaction and hydrolysis to the resorcinol **19** and then double methylation to dillapiol. Such a sequence would save three steps from the synthesis shown in Scheme 2.

We were concerned that **17** would undergo a 1,2-Wittig rearrangement rather than the directed *ortho*-metallation. Fortunately, this fear was unfounded and reaction of **17** with 1 equiv. of *n*Buli followed addition of DMF gave **18** in 87% isolated yield. Conversion to **19** was successful upon stirring with MCPBA at 0°C for 24 h. The reduced nucleophilicity of the double bond in **18** relative to **9** allows the Baeyer–Villiger reaction to proceed without competition from the epoxidation of the allyl ether. The intermediate formate ester was hydrolyzed to **19** without purification. Claisen rearrangement of **19** at 190°C afforded the resorcinol **20** which was methylated to dillapiol. The overall yield of dillaiol from sesamol via Scheme 3 is 31%.

Scheme 3. Reagents: (*a*) *n*BuLi, THF, (–78°C), then DMF; (*b*) MCPBA (25°C), then KOH; (*c*) *N*,*N*-dimethylaniline (180°C); (*d*) CH_3I, K_2CO_3, acetone.



Synthesis of dillapiol analogues

Several of the intermediates in Schemes 1 and 2 were suitable for the preparation of dillapiol analogues. These compounds have been evaluated for their ability to synergize the insecticidal property of α-terthienyl when determined in the presence of light (12). For example, *ortho*-metalation of the MOM-protected sesamol **11**, followed by treatment with dimethyl disulfide afforded the *S*-methyl derivative **21** in 91% yield. This compound was converted via **22a** into the 3-thiomethyl analog of dillapiol **23a** in four steps in 48% overall yield. Oxidation afforded the sulfoxide and sulfone analogs **24a** and **25a**, respectively (Scheme 4). A number of other sulfide, sulfoxide, and sulfone analogs were also prepared in a similar manner simply by replacing dimethyl disulfide with other disulfides (Scheme 4). Surprisingly, reaction of the *ortho*-lithiated allyl ether with dimethyl disulfide was not nearly as efficient as reaction with DMF and afforded only about 55% of the desired product. In addition, a significant amount of a by-product which was difficult to separate from the desired product was obtained. The

Scheme 4. Reagents: (*a*) *n*BuLi, THF, (–78°C), then RSSR; (*b*) Hcl–MeOH–NaI; (*c*) allyl bromide – K_2CO_3 – acetone; (*d*) *N*,*N*-dimethylaniline (180°C); (*e*) CH_3I–K_2CO_3–acetone; (*f*) MCPBA (1.1 equiv.); (*g*) MCPBA (2.2 equiv.).

by-product has not been identified and this route to sulfur analogues of dillapiol was not pursued further.

The aldehydes **8** and **9** served as a source of a number of derivatives. Thus, reduction of **8** with $NaBH_4$, or reaction with *n*-octylmagnesium iodide, gave the derivatives **26** and **27**, respectively.

Similarly, the methoxyaldehyde **9** was reduced to **28**, or converted to **29** upon addition of *n*-octylmagnesium bromide. Reaction of **9** with methyl (triphenylphosphoranylidene) acetate resulted in formation of the unsaturated ester **30**. The ^{1}H NMR of both **27** and **29** show nonequivalence of each of the methylene hydrogens both α and β to the chiral benzylic center. The β methylene hydrogen nonequivalence is somewhat surprising and may be due to a combination of both steric crowding and intramolecular hydrogen bonding resulting in a preferred conformation in which each of these sets of geminal hydrogens continue to show nonequivalence.

The use of the phenol **10** allowed us to generate ethers such as **31** and thereby test how increased lipophilicity relative to dillapiol affects the synergism of these compounds.

Biological results

Detailed SAR studies of the compounds described in this paper and a number of other analogs as synergists for the light α-terthienyl (α-T) is being published elsewhere (12). Qualitatively, only a few derivatives showed activity comparable to or greater than dillapiol. The most active derivative was the cinnamate ester **30** with a synergism factor 30% higher than dillapiol. In the sulfur series the sulfides showed synergism effects of approximately 1.1–1.3, relative to dillapiol equals. In contrast the corresponding sulfoxides and sulfones had effects which were approximately 40–60% of that observed for dillapiol.

Experimental

General comments

Unless stated otherwise, ^{1}H NMR were obtained at 200 or 500 MHz, and ^{13}C NMR spectra at 125 MHz. Solvents used in reactions were distilled prior to use. BuLi was purchased from Aldrich as a hexane solution and titrated [diphenylacetic acid] prior to use. Usual work-up refers to partitioning of the reaction mixture between an organic solvent such as ether, ethyl acetate, or dichloromethane and water or 5% NH_4Cl solution, drying of the organic phase with anhydrous $MgSO_4$, and evaporating the solvents at reduced pressure. Yields, unless indicated otherwise, refer to chromatograpically pure fractions.

© 2000 NRC Canada

5-Hydroxy-6-(2-propenyl)-1,3-benzodioxole (7)

This compound was prepared in 81% overall yield following the procedure of Grubbs et al. (13). Melting point 74–76°C, lit. (13) mp 74–76°C.

4-Formyl-5-hydroxy-6-(2-propenyl)-1,3-benzodioxole (8)

Paraformaldehyde (0.56 g, 18.5 mmol) was added to toluene (5.6 mL) containing 1.5 g (8.4 mmol) of **7**, 0.1 mL (0.84 mmol) of tin tetrachloride, and 0.8 mL (3.37 mmol) of tri-*n*-butylamine. The resulting yellow solution was heated 8 h at 100°C, then cooled, acidified with 2 N HCl to pH 2, and extracted with ether. Purification by silica gel chromatography (1:1, hexane :CH_2Cl_2) afforded 1.05 g (60%) of **8** as a bright yellow solid, mp 68–70°C. IR (cm^{-1}): 1658, 3215. ^1H NMR δ: 3.27–3.29 (m, 2H), 5.03–5.07 (m, 2H), 5.86–5.94 (m, 1H), 6.00 (s, 2H), 6.87 (s, 1H), 10.09 (s, 1H), 10.65 (s, 1H). ^{13}C NMR δ: 32.8, 102.5, 106.7, 116.0, 117.6, 119.0, 136.1, 140.1, 148.5, 152.3, 191.3. HRMS calcd. for $C_{11}H_{10}O_4$: 206.0579; found: 206.0568.

4-Formyl-5-methoxy-6-(2-propenyl)-1,3-benzodioxole (9)

Potassium carbonate (1.31 g, 9.45 mmol) and methyl iodide (3.92 mL, 63.0 mmol) were added sequentially to a solution of aldehyde **8** (1.30 g, 6.30 mmol) in acetone (10 mL). The resulting solution was allowed to stir at rt for 48 h, after which time the solvent was evaporated under reduced pressure. The remaining K_2CO_3 was dissolved in water and the aqueous phase extracted with ether (3 × 15 mL). Chromatography (5:1, hexane:EtOAc) of the crude product gave 1.35 g (97%) of **9** as a pale yellow solid, mp 101–102°C. ^1H NMR δ: 3.32 (dt, 2H, J = 6.4, 1.5 Hz), 3.77 (s, 3H), 5.03–5.08 (m, 2H), 5.86–5.91 (m, 1H), 6.05 (s, 2H), 6.83 (s, 1H), 10.23 (s, 1H). ^{13}C NMR δ: 33.0, 64.1, 102.9, 114.2, 114.7, 116.4, 125.7, 136.5, 144.9, 146.9, 153.6, 188.1. IR (cm^{-1}): 1689. HRMS calcd. for $C_{12}H_{12}O_4$: 220.0736; found: 220.0754.

4-Hydroxy-5-methoxy-6-(2-propenyl)-1,3-benzodioxole (10)

To a cooled (0°C) solution of aldehyde **9** (210 mg, 0.95 mmol) in dry $CHCl_3$ (6 mL) was added in one portion MCPBA (0.30 g, 0.95 mmol, 55%). After 18 h, the reaction mixture was allowed to reach rt and washed with sodium sulfite (sat., 2 × 10 mL), sodium bicarbonate (sat., 1 × 10 mL), and water (1 × 10 mL). The extract was dried over Na_2SO_4, filtered and evaporated to dryness. The resulting oily residue was purified by flash chromatography (3:1, Hex:EtOAc) to give the formyl derivative of **10** as a colorless oil (160 mg, 71%). IR (cm^{-1}): 1759. ^1H NMR δ: 3.32 (d, 2H, J = 6.5 Hz), 3.69 (s, 3H), 5.03–5.06 (m, 2H), 5.86–5.93 (m, 1H), 5.94 (s, 2H), 6.56 (s, 1H), 8.26 (s, 1H). ^{13}C NMR δ: 33.6, 61.8, 102.3, 107.0, 116.1, 126.3, 126.8, 136.8, 144.6, 144.8, 157.9. HRMS calcd. for $C_{12}H_{12}O_5$: 236.0685; found: 236.0690.

To a solution of the above formyl derivative (250 mg, 1.06 mmol) in THF (9 mL) was added 1 mL of a 3 N NaOH solution. The resulting homogeneous solution was stirred at rt for 1 h and diluted with brine. Usual work-up gave **10** (180 mg, 82%) as a pale yellow solid, mp 61–63°C. IR (cm^{-1}): 3523. ^1H NMR δ: 3.31 (dt, 2H, J = 6.5, 1.4 Hz), 3.73 (s, 3H), 5.03–5.07 (m, 2H), 5.50 (s, 1H), 5.87–5.93 (m, 1H), 5.90 (s, 2H), 6.25 (s, 1H). ^{13}C NMR δ: 33.6, 61.8, 101.0, 101.7, 115.9, 125.2, 132.7, 133.5, 137.0, 141.1, 144.9. HRMS calcd. for $C_{11}H_{12}O_4$: 208.0736; found: 208.0740.

4,5-Dimethoxy-6-(2-propenyl)-1,3-benzodioxole)(dillapiol) (1)

A mixture of **10** (100 mg, 0.48 mmol), CH_3I (0.28 mL), and K_2CO_3 (0.1 g) was stirred at rt for 72 h. The solvent was evaporated. Usual work-up afforded, after chromatography (5:1, hexane:EtOAc), 80 mg (78%) of dillapiol. The physical and spectroscopic properties were identical to those of the commercial material.

5-(Methoxymethoxy)-1,3-benzodioxole (11)

To a solution of sesamol (5.0 g, 36.2 mmol) in 20 mL of dry THF at 0°C was added 1 equiv. of BuLi (16.5 mL, 2.2 M). The reaction mixture was stirred for 30 min and then 1.5 equiv. of chloromethyl methyl ether (4.4 g, 4.1 mL) was added. The resulting mixture was stirred at rt for 24 h and then quenched with 10 mL of saturated NH_4Cl. The usual work-up gave 6.5 g (98%) of **11** as a colorless liquid. The product was used as such. EI–MS (m/z, %): 182 ($M^{+\cdot}$, 100), 152 (75), 137 (30). ^1H NMR δ: 3.47 (s, 3H), 5.08 (s, 2H), 5.91 (s, 2H), 6.49 (dd, 1H, J = 8.4 Hz, 2.4 Hz), 6.62 (d, 1H, J = 2.2 Hz), 6.70 (d, 1H, J = 8.4 Hz). ^{13}C NMR δ: 55.9, 95.5, 99.7, 101.2, 108.0, 108.4, 142.5, 148.1, 152.5. HRMS calcd. for $C_9H_{10}O_4$: 182.0579; found: 182.05830.

4-Formyl-5-(methoxymethoxy)-1,3-benzodioxole (12)

BuLi (12.5 mL, 2.2 M) was added to a solution of 5.0 g (27.5 mmol) of **11** in dry THF (20 mL) at 0°C. The reaction mixture was stirred for 30 min and 1.5 equiv. of DMF (3.00 g, 3.18 mL) was added. The resulting mixture was stirred at room temperature for 4 h and quenched with 10 mL of NH_4Cl solution. Work-up gave the crude product as an orange powder. Purification by flash column chromatography (3:1, hexane:ethyl acetate) gave **12** as pale yellow crystals (4.9 g, 85%), mp 85–87°C. EI–MS (m/z, %): 210 ($M^{+\cdot}$, 92), 178 (53), 164 (82). IR (cm^{-1}): 1687. ^1H NMR δ: 3.48 (s, 3H), 5.17 (s, 2H), 6.09 (s, 2H), 6.58 (d, 1H, J = 8.6 Hz), 6.86 (d, 1H, J = 8.6 Hz), 10.35 (s, 1H). ^{13}C NMR δ: 56.4, 95.7, 102.9, 106.4, 111.7, 113.1, 143.4, 148.1, 153.6, 188.0. HRMS calcd. for $C_{10}H_{10}O_5$: 210.0528; found: 210.05317.

4-Hydroxy-5-(methoxymethoxy)-1,3-benzodioxole (13)

MCPBA (5.30 g, 30.7 mmol) was added in one portion to a solution of aldehyde **12** (3.00 g, 14. 3 mmol) in dry $CHCl_3$ (25 mL) at 0°C. The reaction mixture was warmed up to rt and stirred for 24 h, washed with sodium sulfite solution (sat., 2 × 15 mL), sodium bicarbonate (sat., 2 × 20 mL), and water (2 × 20 mL). The extract was dried over anhyd. $MgSO_4$, filtered, and evaporated to dryness. The resulting oily residue was purified by flash column chromatography (5:1, hexane:ethyl acetate) affording the expected formate ester as a pale yellow liquid (2.76 g, 91%). EI–MS (m/z, %): 226 ($M^{+\cdot}$, 6), 45 (100). IR (cm^{-1}): 1752. ^1H NMR δ: 3.45 (s, 3H), 5.06 (s, 2H), 5.96 (s, 2H), 6.64 (d, 1H, J = 8.6 Hz), 6.62 (d, 1H, J = 8.6 Hz), 8.24 (s, 1H). ^{13}C NMR δ: 56.2, 96.2, 102.3, 105.5, 108.5, 124.1, 139.8, 143.9, 144.6, 157.7. HRMS calcd. for $C_{11}H_{10}O_6$: 226.077; found: 226.04806.

© 2000 NRC Canada

To the above compound (20 mg, 0.94 mmol) in 5 mL of THF was added 25% NaOH solution (2 mL). The reaction mixture was stirred for 4 h at rt and extracted with water (4 × 5 mL). The resulting oily residue, obtained after usual work-up was purified using flash chromatography (9:1, hexane:ethyl acetate). Phenol **13** was obtained as a pale yellow liquid, (11 mg, 59%). EI–MS (*m*/*z*, %): 198 ($M^{+\cdot}$, 100), 166 (29), 153 (33). IR (cm^{-1}): 3540. ^1H NMR δ: 3.51 (s, 3H), 5.07 (s, 2H), 5.92 (s, 1H), 6.20 (s, 1H), 6.30 (d, 1H, *J* = 8.4 Hz), 6.54 (d, 1H, *J* = 8.4 Hz, the OH proton was not located). ^{13}C NMR δ: 56.5, 97.6, 99.2, 101.7, 109.4, 132.3, 134.5, 141.5, 144.5. HRMS calcd. for $C_9H_{10}O_5$: 198.0528; found: 198.05296.

5-Hydroxy-4-methoxy-1,3-benzodioxole (14)

Phenol **13** (4.9 g, 24.7 mmol) was *O*-methylated following the procedure for formation of **9**. The yield of 4-methoxy-5-methoxymethyl-1,3-benzodioxole, a pale yellow liquid, was 5.05 g, (96%). EI–MS (*m*/*z*, %): 212 ($M^{+\cdot}$, 100), 182 (89), 167 (69). ^1H NMR δ: 3.49 (s, 3H), 3.99 (s, 3H), 5.08 (s, 2H), 5.88 (s, 2H), 6.41 (d, 1H, *J* = 8.4 Hz), 6.57 (d, 1H, *J* = 8.6 Hz). ^{13}C NMR δ: 56.1, 60.1, 96.6, 101.2, 101.4, 110.1, 135.4, 137.7, 144.1, 144.2. HRMS calcd. for $C_{10}H_{12}O_5$: 212.0685; found: 212.0709.

The above compound (4.86 g, 22.9 mmol) in acetone (15 mL) containing 5.15 g, (34.3 mmol) of NaI was stirred for 30 min. 3 N Methanol HCl (40 mL) was added and the resulting reaction mixture stirred for 4 h. Most of the solvent was evaporated and the crude residue dissolved in water (10 mL). The aqueous phase was extracted with ether (3 × 15 mL) and the combined organic extracts were then washed with 10% NaOH solution (3 × 15 mL). The combined aqueous phase was acidified using conc. HCl and extracted with ether (3 × 20 mL). Further work-up afforded 2.81 g (73%) of **14** as pale orange crystals, mp 53–55°C. EI–MS (*m*/*z*, %): 168 (M^+, 100), 153 (76). IR (cm^{-1}): 3541. ^1H NMR δ: 4.02 (s, 3H), 5.43 (s, 1H), 5.87 (s, 2H), 6.39 (s, 2H). ^{13}C NMR δ: 59.9, 101.1, 101.8, 105.9, 131.4, 136.2, 142.1, 142.7. HRMS calcd. for $C_8H_8O_4$: 168.0422; found: 168.0408.

5-Hydroxy-4-methoxy-6-(2-propenyl)-1,3-benzodioxole (15)

A solution of **14** (2.55 g, 15.2 mmol), allyl bromide (2.0 mL, 23 mmol), and anhyd. K_2CO_3 (3.15 g, 23 mmol) in acetone (15 mL) was refluxed for 30 h. The solvent was removed under reduced pressure and the crude residue was dissolved in 20 mL water and 10 mL of 10% NaOH solution. Further work-up gave 5-*O*-allyl-4-methoxy-1,3-benzodioxole as a yellow liquid (2.72 g, 86%). EI–MS (*m*/*z*, %): 208 ($M^{+\cdot}$, 39), 167 (100). IR (cm^{-1}): 977, 929.; ^1H NMR δ: 3.97 (s, 3H), 4.47 (dt, 2H, *J* = 5.4 Hz, 1.4 Hz), 5.22 (ddt, 1H, *J* = 10.5 Hz, 1.6 Hz, 1.4 Hz), 5.35 (ddt, 1H, *J* = 17.3 Hz, 1.6 Hz, 1.6 Hz), 5.86 (s, 1H), 6.00–6.06 (m, 1H), 6.32 (d, 1H, *J* = 8.5 Hz), 6.38 (d, 1H, *J* = 8.5 Hz). ^{13}C NMR δ: 60.2, 71.2, 101.1, 101.2, 107.2, 117.5, 133.6, 134.9, 138.1, 143.4, 146.2. HRMS calcd. for $C_{11}H_{12}O_4$: 208.0736; found: 208.0755.

A solution of the above allyl ether (460 mg, 2.0 mmol) in 5 mL *N*,*N*-dimethylaniline was heated at 190°C for 2.5 h. The solution was cooled, diluted with 7 mL of ether, and washed several times with 10% NaOH solution. The alkaline extract was acidified with conc. HCl and extracted with ether (3 × 15 mL). The crude residue obtained after work-up was purified by flash column chromatography (9:1, hexane:ethyl acetate) to give **15** as pale yellowish liquid (400 mg, 87%). EI–MS (*m*/*z*,%): 208 ($M^{+\cdot}$, 100). IR (cm^{-1}): 926, 987. ^1H NMR δ: 3.30 (d, 2H, *J* = 6.6 Hz), 4.03 (s, 3H), 5.00–5.11 (m, 2H), 5.43 (s, 1H), 5.84 (s, 2H), 5.85–6.02 (m, 1H), 6.33 (s, 1H). ^{13}C NMR δ: 33.7, 59.9, 100.9, 102.8, 115.4, 117.5, 131.1, 143.2, 136.7, 139.9, 141.6. HRMS calcd. for $C_{11}H_{12}O_4$: 208.0736; found: 208.0731.

4,5-Dimethoxy-6-(2-propenyl)-1,3-benzodioxole (1)

The phenol **15** (140 mg, 0.70 mmol), K_2CO_3 (140 mg, 0.10 mmol), and 0.50 mL (0.8 mmol) of methyl iodide was reacted in 5 mL of acetone as with **9**. Work-up and chromatography gave 130 mg (80%) of **1**.

5-Allyloxy-4-formyl-1,3-benzodioxole (18)

To a solution of compound **17** (0.3 g, 1.68 mmol) in anhyd. THF (5 mL), *n*-BuLi (1.35 mL, 2.01 mmol, 1.5 molar solution in hexane) was added dropwise at 78°C. The resulting yellow solution was allowed to stir for 45 min and then *N*,*N*-dimethylformamide (0.26 mL, 3.37 mmol) was added. After 30 min, the reaction mixture was quenched with sat. NH_4Cl solution and extracted with ether. Flash column chromatography of the crude ether extracts using ethyl acetate:hexane (1:5) furnished the aldehyde **18** (302 mg, 87%) as a yellow solid, mp = 98–100°C. ^1H NMR: δ 4.52 (m, 2H), 5.25 – 5.34 (m, 2 H), 6.04 (s, 2H), 5.81–6.11 (m, 1H), 6.27 (d, 1H, *J* = 8.6 Hz), 6.83 (d, 1H, *J* = 8.5 Hz), 10.37 (s, 1H). ^{13}C NMR δ: 70.6, 103.5, 104.2, 111.7, 113.5, 118.5, 133.1, 143.2, 148.9 155.7, 188.8. HRMS calcd. for $C_{11}H_{10}O_4$: 206.0593; found: 206.0581.

5-Allyloxy-4-hydroxy-1,3-benzodioxole (19)

To a solution of aldehyde **18** (0.3 g, 1.45 mmol) in dry chloroform (5 mL) at 0°C, was added in one portion MCPBA (0.61 g, 1.74 mmol, 50%). The resulting mixture was stirred at 0°C for 24 h. The mixture was diluted with chloroform (20 mL) and was washed with sat. sodium sulfite (1 × 15 mL), sat. sodium bicarbonate solution (1 × 15 mL) and water (1 × 15 mL). The crude formate ester (0.25 g, 78%) was obtained as an oil and used for the next reaction without any further purification. ^1H NMR δ: 4.45 (m, 2H), 5.25 (m, 2 H), 5.96 (s, 2H), 5.95–6.01 (m, 1H), 6.34 (d, 1H, *J* = 8.5 Hz), 6.59 (d, 1H, *J* = 8.5 Hz), 8.24 (s, 1H). To a solution of the ester (0.25 g, 1.13 mmol) in THF (5 mL), was added 1 mL of a 3 N NaOH solution. The resulting homogeneous solution was stirred at rt for 1 h and was extracted with water (4 × 10 mL). The aqueous phase was then acidified with 2 N HCl and was extracted with CH_2Cl_2 (3 × 20 mL). Further work-up afforded an oily residue. Purification by silica gel flash column chromatography using ethyl acetate–hexane (1:5) as eluent gave **19** (0.15 g, 70%) as a yellow liquid. ^1H NMR δ: 4.48 (m, 2H), 5.32 (m, 2H), 5.92 (s, 2 H), 5.90–6.10 (m, 1 H), 6.30 (s, 2 H). ^{13}C NMR δ: 71.6, 99.3, 102.3, 105.3, 119.1, 132.2, 133.5, 137.1, 142.8, 144.0. HRMS calcd. for $C_{10}H_{10}O_4$:194.0593; found: 194.0602.

4,5-Dihydroxy-6-(2-propenyl)-1,3-benzodioxole (20)

A solution of **19** (0.15 g, 0.77 mmol) in *N*,*N*-dimethylaniline (2 mL) was heated at 190°C for 1 h and then was allowed to cool to rt The reaction mixture was extracted into ethyl acetate and was washed with 1 N HCl solution (3 × 10 mL), brine (2 × 10 mL), followed by water (10 mL). The crude rearranged product was purified via silica gel flash chromatography using ethyl acetate–hexane (3:7) as eluent to yield **20** (0.12 g, 79%) as a brown syrup. ^{1}H NMR δ: 3.31 (m, 2 H), 5.44 (m, 2H), 5.87 (s, 2H), 5.85–6.02 (m, 1H), 6.22 (s, 1H). ^{13}C NMR δ: 35.4, 101.82, 102.0, 116.7, 118.4, 129.6, 133.4, 137.1, 138.2, 142.6. HRMS calcd. for $C_{10}H_{10}O_4$: 194.0579; found 194.5965.

4,5-Dimethoxy-6-(2-propenyl)-1,3-benzodioxole (1)

To a solution of **20** (0.02 g, 0.103 mmol) in acetone (3 mL), was added sequentially potassium carbonate (28 mg, 0.21 mmol), and methyl iodide (0.10 mL, 0.206 mmol). The resulting reaction mixture was allowed to stirred at rt for 60 h. Solvent was removed under reduced pressure. The crude product obtained after the usual work-up was purified by silica gel flash column chromatography using ethyl acetate–hexane (1:5) as eluent to furnish the dillapiol (**1**) (18 mg, 82%) as a yellow liquid.

Reaction of 11 with disulfides

General procedure

*n*BuLi (1 equiv.) was added to 1 equiv. of **11** in THF at 0°C. After 30 min, 1.5 equiv. of disulfide was added and the solution was stirred for 1 h. Further work-up followed by silica gel chro-matography afforded the desired 4-thio derivatives.

4-Methylthio-5-methoxymethoxy-1,3-benzodioxole (21a)

This reaction was carried out starting with 5.0 g (27.5 mmol) of **11**. The yield of **21a**, a pale yellow liquid, was 5.70 g (91%). EI–MS (*m*/*z*, %): 228 (M^+, 100), 198 (63), 182 (17). ^{1}H NMR δ: 2.41 (s, 3H), 3.47 (s, 3H), 5.92 (s, 2H), 5.11 (s, 2H), 5.92 (s, 2H), 6.52 (d, 1H, *J* = 8.6 Hz), 6.59 (d, 1H, *J* = 8.6 Hz). ^{13}C NMR δ: 16.9, 56.1, 95.9, 101.2, 106.7, 107.8, 108.8, 142.3, 148.5, 151.7. HRMS calcd. for $C_{10}H_{12}O_4S$: 228.0456; found: 228.04679.

4-Phenylmethanethio-5-methoxymethoxy-1,3-benzodioxole (21b)

From 3.0 g, (16 mmol) of **11** and 5.35 g (22 mmol) of benzyl disulfide was obtained 2.37 g (58%) of **21b** as yellow oil. EI–MS (*m*/*z*, %): 304 (M^+, 29), 259 (18), 182 (26), 91 (100). ^{1}H NMR δ: 3.45 (s, 3H), 4.07 (s, 2H), 5.03 (s, 2H), 5.85 (s, 2H), 6.54 (d, 1H, *J* = 8.5 Hz), 6.63 (d, 1H, *J* = 8.5 Hz), 7.20 (s, 5H). ^{13}C NMR δ: 38.0, 56.1, 96.0, 101.2, 106.5, 107.4, 107.9, 126.9, 128.1, 128.8, 138.0, 142.2, 149.5, 152.5. HRMS calcd. for $C_{16}H_{16}O_4S$: 304.0792; found: 304.0758.

4-Phenylthio-5-methoxymethoxy-1,3-benzodioxole (21c)

Reaction of 1.50 g (8.0 mmol) of **11** (1.5 g, 8.0 mmol) and 1.80 g (8.0 mmol) of diphenyl disulfide gave 0.67 g (30%) of **21c** as white crystals, mp 67–69°C. EI–MS (*m*/*z*, %): 290 (M^+, 51), 260 (25), 91 (50). ^{1}H NMR δ: 3.33 (s, 3H), 5.05 (s, 2H), 5.93 (s, 2H), 6.63 (d, 1H, *J* = 8.5 Hz), 6.77 (d, 1H, *J* = 8.5 Hz), 7.08–7.20 (m, 5H). ^{13}C NMR δ: 56.1, 95.7, 101.6, 104.2, 1007.8 08.8, 125.5, 127.1, 128.7, 136.2, 142.5, 150.4, 152.7. HRMS calcd. for $C_{15}H_{14}O_4S$: 290.0613; found: 290.0600.

4-(4′-Methoxyphenylthio)-5-methoxymethoxy-1,3-benzodioxole (21d)

Reaction of 420 mg of **11** with 530 mg of *p*-methoxyphenyl disulfide gave 250 mg (40%) of **21d** as white crystals, mp 82–84°C. EI–MS (*m*/*z*, %): 320 (M^+, 8.6), 278 (46), 139 (100). ^{1}H NMR δ: 3.34 (s, 3H), 3.69 (s, 3H), 5.03 (s, 2H), 5.88 (s, 2H), 6.56 (d, 1H, *J* = 8.5 Hz), 6.68 (d, 1H, *J* = 8.5 Hz), 6.74 (d, 2H, *J* = 8.9 Hz), 7.22 (d, 2H, *J* = 8.9 Hz). ^{13}C NMR δ: 55.0, 55.9, 95.7, 101.4, 106.3, 107.7, 108.1, 114.2, 126.2, 130.7, 142.3, 149.8, 152.3, 158.3. HRMS calcd. for $C_{16}H_{16}O_5S$: 320.0718; found: 320.0706.

Removal of the MOM group

General procedure

Each MOM derivative **21** was dissolved in a mixture of acetone and 3 N methanolic HCl containing NaI. The mixture was stirred for about 4 h and most of the solvent was removed under reduced pressure. The residue was partitioned between ether and 10% NaOH solution. The basic extracts were acidified and reextracted with ether. The crude products obtained after further work-up were purified by recrystallization or chromatography.

5-Hydroxy-4-methylthio-1,3-benzodioxole

From 4.0 g of **21a** and 3.94 g of NaI in 15 mL of acetone and 40 mL of 3 N methanolic HCl was obtained 2.65 g (80%) of the title compound as a white powder, mp 51–53°C. EI–MS (*m*/*z*, %): 184 (M^+, 100), 169 (30). IR (cm^{-1}): 3428. ^{1}H NMR δ: 2.31 (s, 3H), 5.98 (s, 2H), 6.22 (s, 1H), 6.42 (d, 1H, *J* = 8.4 Hz), 6.69 (d, 1H, *J* = 8.4 Hz). ^{13}C NMR δ: 18.0, 101.6, 103.4, 105.4, 109.4, 140.7, 149.3, 151.2. HRMS calcd. for $C_8H_8O_3S$: 184.0194; found: 184.0163.

5-Hydroxy-4-phenylmethanethio-1,3-benzodioxole

Reaction of 2.51 g of **21b** with 1.86 g of NaI in 50 mL of acetone–methanol–conc. HCl (1:3:1) for 1 h afforded 1.68 g (91%) of the deprotected phenol as a yellowish oil. EI–MS (*m*/*z*, %): 260 (M^+, 36), 169 (8.2), 91 (100). IR (cm^{-1}): 3434. ^{1}H NMR δ: 3.87 (s, 2H), 5.85 (s, 2H), 6.03 (s, 1H), 6.35 (d, 1H, *J* = 8.4 Hz), 6.68 (d, 1H, *J* = 8.4 Hz), 7.10–7.25 (m, 5H). ^{13}C NMR δ: 39.3, 101.0, 101.5, 105.3, 109.8, 127.4, 128.4, 128.7, 137.2, 140.4, 149.8, 151.7. HRMS calcd. for $C_{14}H_{12}O_3S$: 260.0510; found: 260.0512.

5-Hydroxy-4-phenylthio-1,3-benzodioxole

Compound **21c** (670 mg, 2.3 mmol), 5.2 g of NaI in 10 mL of acetone and 8 mL of 3 N methanolic HCl was stirred for 1 h. The yield of the title compound, a white powder, mp 119–122°C, was >99%. EI–MS (*m*/*z*, %): 246 (M^+, 100), 162 (23), 140 (49). IR (cm^{-1}): 3441. ^{1}H NMR δ: 5.96 (s, 2H), 6.18 (s, 1H), 6.52 (d, 1H, *J* = 8.5 Hz), 6.81 (d, 1H, *J* = 8.6 Hz), 7.12–7.26 (m, 5H). ^{13}C NMR δ (ppm): 99.5, 101.9, 105.9, 110.8, 126.5, 127.0, 129.3, 134.2, 141.0,

© 2000 NRC Canada

150.1, 151.9. HRMS calcd. for $C_{13}H_{10}O_3S$: 246.0351; found: 246.0334.

5-Hydroxy-4-(4′-methoxyphenylthio)-1,3-benzodioxole

Compound **21d** (250 mg, 0.78 mmol) in acetone (10 mL) and 8 mL of 3 N methanolic HCl containing 180 mg NaI was stirred for 2 h. The yield of the above phenol (mp 82–83°C) was 180 mg (83%). EI–MS (*m*/*z*, %): 276 (M^+,100), 162 (18), 140 (44). IR (cm^{-1}): 3443. ^1H NMR δ: 3.74 (s, 3H), 5.94 (s, 2H), 6.31 (s, 1H), 6.47 (d, 1H, *J* = 8.5 Hz), 6.75 (d, 1H, *J* = 8.4 Hz), 6.79 (d, 1H, *J* = 6.9 Hz), 7.20 (d, 1H, *J* = 7.6 Hz). ^{13}C NMR δ: 55.3, 101.5, 101.7, 105.8, 110.4, 114.9, 124.5, 130.4, 140.9, 149.8, 151.6, 159.0. HRMS calcd. for $C_{14}H_{12}O_4S$: 276.0456; found: 276.0466.

Allylation of the 4-thio-5-hydroxy derivatives

General procedure

The above phenols were dissolved in acetone containing about 10–20% excess of anhydrous potassium carbonate. The mixture was refluxed for up to 24 h. The solvent was evaporated under reduced pressure and the residue was partitioned between ether and 10% NaOH solution. Further processing of the ether phase gave the desired product.

5-Allyoxy-4-methylthio-1,3-benzodioxole

From 1.89 g of 5-hydroxy derivative, series **a**, 2.13 g of potassium carbonate and 0.90 mL of allyl bromide in 15 mL acetone was obtained after 23 h of reflux, 2.03 g (88%) of the desired product as a clear liquid. EI–MS (*m*/*z*, %): 224.1 ($M^{+\cdot}$, 100), 184 (13), 137 (98). ^1H NMR δ: 2.46 (s, 1H), 4.53 (dt, 2H, *J* = 5.1 Hz, 1.4 Hz), 5.28 (dd, 1H, *J* = 10.5 Hz, 1.5 Hz), 5.44 (dd, 1H, *J* = 17.0 Hz, 1.6 Hz), 5.97 (s, 2H), 6.00–6.09 (m, 1H), 6.31 (d, 1H, *J* = 8.5 Hz), 6.63 (d, 1H, *J* = 8.5 Hz). ^{13}C NMR δ: 16.9, 70.3, 101.2, 104.5, 106.4, 117.4, 133.1, 133.8, 141.5, 148.7, 153.3. HRMS calcd. for $C_{11}H_{12}O_3S$: 224.0507; found: 224.0533.

5-Allyoxy-4-phenylmethanethio,3-benzodioxole

A solution of the 5-phenol, series **b** (1.68 g, 6.5 mmol), anhyd. K_2CO_3 (1.10 g, 8.0 mmol and 0.63 mL of allyl bromide in 15 mL of acetone when refluxed for 23 h, yielded 1.39 g (83%) of the desired allyl ether as a clear oil. EI–MS (*m*/*z*, %): 300 (M^+, 30), 259 (38), 91 (100). IR (cm^{-1}): 953, 995. ^1H NMR δ: 4.09 (s, 2H), 4.46 (d, 2H, *J* = 5.1 Hz), 5.27 (dd, 1H, *J* = 10.5 Hz, 1.5 Hz), 5.43 (dd, 1H, *J* = 15.6 Hz, 1.6 Hz), 5.84 (s, 2H), 5.95–6.11 (m, 1H), 6.30 (d, 1H, *J* = 8.4 Hz), 6.62 (d, 1H, *J* = 9.2 Hz), 7.21 (s, 5H). ^{13}C NMR δ: 37.9, 70.3, 101.1, 104.6, 105.5, 107.1, 117.3, 126.8, 128.1, 128.8, 133.1, 138.0, 141.3, 149.7, 153.9. HRMS calcd. for $C_{17}H_{16}O_3S$: 300.0821; found: 300.0820.

5-Allyoxy-4-phenylthio-1,3-benzodioxole

A mixture of phenol, series **c** (1.62 g, 6.6 mmol), anhyd. K_2CO3 (1.10 g, 8.0 mmol), and 0.63 mL of allyl bromide when refluxed for 23 h in acetone (15 mL) gave 1.25 g (84%) of the expected allyl ether. EI–MS (*m*/*z*, %): 268 ($M^{+\cdot}$, 52), 245 (52), 91 (100). IR (cm^{-1}): 943, 996. ^1H NMR δ: 4.44 (dt, 2H, *J* = 5.0 Hz, 1.6 Hz), 5.15 (ddt, 1H, *J* = 10.5 Hz, 1.6 Hz, 1.5 Hz), 5.25 (ddt, 1H, *J* = 17.0 Hz, 1.7 Hz, 1.6 Hz), 5.76–5.95 (m, 1H), 5.93 (s, 2H), 6.35 (d, 1H, *J* = 8.5 Hz), 6.75 (d, 1H, *J* = 8.5 Hz), 7.07–7.22 (m, 5H). ^{13}C NMR δ: 70.3, 101.6, 103.5, 104.9, 108.4, 117.2, 125.4, 127.3, 128.6, 132.8, 136.2, 141.7, 150.5, 145. HRMS calcd. for $C_{16}H_{14}O_3S$: 286.0664; found: 286.0649.

5-Allyoxy-4-(4′-methoxyphenylthio)-1,3-benzodioxole

Reaction of the phenol, series **d** (1.10 g, 4.0 mmol), anhyd. K_2CO_3 (0.83 g, 6.0 mmol) and 0.41 mL of allyl bromide in acetone (15 mL) at reflux for 23 h gave 0.96 g (76%) of the expected product as a clear oil. EI–MS (*m*/*z*, %): 316 ($M^{+\cdot}$, 32), 275 (30), 149 (100). IR (cm^{-1}): 931, 953. ^1H NMR δ: 3.72 (s, 3H), 4.43 (dt, 2H, *J* = 5.1 Hz, 1.5 Hz), 5.18 (ddt, 1H, *J* = 12 Hz, 1.6 Hz, 1.5 Hz), 5.31 (ddt, 1H, *J* = 18 Hz, 1.7 Hz, 1.6 Hz), 5.90 (s, 2H), 5.83–5.97 (m, 1H), 6.30 (d, 1H, *J* = 8.5 Hz), 6.67 (d, 1H, *J* = 8.5 Hz), 6.75 (d, 2H, *J* = 9.0 Hz), 7.26 (d, 2H, *J* = 9.0 Hz). ^{13}C NMR δ: 55.1, 70.3, 101.4, 104.8, 105.6, 107.8, 114.2, 117.2, 126.3, 131.0, 132.9, 141.6, 149.9, 153.7, 158.4. HRMS calcd. for $C_{17}H_{16}O_4S$: 316.0770; found: 316.0766.

Claisen rearrangement of the 5-allyl ethers

General procedure

The 5-allyl ethers obtained as described above were dissolved in a small quantity of *N*,*N*-dimethylaniline and heated to 190°C for 1–3 h. The cooled reaction mixture was diluted with ether and extracted with 10% NaOH solution. The combined basic extracts were acidified and extracted with ether. Further work-up and purification yielded the desired Claisen rearrangement products.

5-Hydroxy-4-methylthio-6-(2-propenyl)-1,3-benzodioxole (22a)

Allyl ether, series **a** (1.0 g, 4.0 mmol) when heated in 5 mL of *N*,*N*-dimethylaniline (5 mL) at 190°C for 2.5 h, gave 0.87 g (87%)of **22a** as a colourless liquid. EI–MS (*m*/*z*, %): 224 ($M^{+\cdot}$, 100), 197 (9), 176 (18). IR (cm^{-1}): 927, 953, 3425. ^1H NMR δ (ppm): 2.31 (s, 3H), 3.32 (dt, 2H, *J* = 6.8 Hz, 1.4 Hz), 5.01–5.11 (m, 2H), 5.95 (s, 2H), 5.88–6.02 (m, 1H), 6.40 (s, 1H), 6.62 (s, 1H).^{13}C NMR δ: 18.0, 34.4, 101.3, 102.9, 110.4, 115.5, 117.1, 136.6, 140.3, 147.5, 148.2. HRMS calcd. for $C_{11}H_{12}O_3S$: 224.0507; found: 224.0493.

5-Hydroxy-4-phenylmethanethio-6-(2-propenyl)-1,3-benzodioxole (22b)

Allyl ether, series **b** (4.30 g, 14.0 mmol) when treated as above gave 0.42 g (98%) of **22b** as a colourless oil. EI–MS (*m*/*z*, %): 300 (M^+, 48), 224 (91), 209 (28), 176 (48). IR (cm^{-1}): 954, 997, 1638, 3429. ^1H NMR δ: 3.25 (d, 2H, *J* = 6.4 Hz), 3.87 (s, 2H), 4.93–5.04 (m, 2H), 5.82–5.96 (m, 1H), 5.83 (s, 2H), 6.18 (s, 1H), 6.61 (s, 1H), 7.08–7.25 (m, 5H). ^{13}C NMR δ: 34.4, 39.4, 100.6, 101.2, 10.9, 115.3, 116.9, 127.4, 128.5, 128.7, 136.6, 137.2, 140.1, 148.0, 148.8. HRMS calcd. for $C_{17}H_{16}O_3S$: 300.0821; found: 300.08240.

5-Hydroxy-4-phenylthio-6-(2-propenyl)-1,3-benzodioxole (22c)

From 1.5 g of allyl ether, series **c**, was obtained 550 mg (37%) of **22c** as a pale yellow oil. EI–MS (*m*/*z*, %): 286 (M^+, 100), 162 (8). IR (cm^{-1}): 953, 997, 1638, 3443. ^1H NMR δ: 3.35 (dt, 2H, *J* = 6.4 Hz, 1.4 Hz), 5.05–5.09

© 2000 NRC Canada

(m, 2H), 5.92 (s, 2H), 5.93–5.99 (m, 1H), 6.31 (s, 1H), 6.73 (s, 1H), 7.13–7.23 (m, 5H). ^{13}C NMR δ: 34.4, 99.0, 101.5, 111.9, 115.7, 117.6, 126.5, 127.0, 129.3, 134.3, 136.5, 40.6, 148.3, 148.9. HRMS calcd. for $C_{16}H_{14}O_3S$: 286.0664; found: 286.0641.

5-Hydroxy-4-(4′-methoxyphenylthio)-6-(2-propenyl)-1,3-benzodioxole (22d)

The allyl ether from series **d** (310 mg, 0.9 mmol) when heated for 2.5 h in 3 mL of *N*,*N*-dimethylaniline gave 0.29 g (97%) of **22d** as pale yellow oil. EI–MS (*m*/*z*, %): 316 (M^+, 100), 208 (22), 180 (47). IR (cm^{-1}): 949, 995, 1638, 3440. ^{1}H NMR δ: 3.32 (d, 2H, *J* = 6.5 Hz), 3.74 (s, 3H), 5.02 (s, 1H), 5.05 (d, 2H, *J* = 6 Hz), 5.91 (s, 2H), 5.89–5.97 (m, 1H), 6.42 (s, 3H), 6.67 (s, 1H), 6.78 (d, 2H, *J* = 8.7 Hz), 7.19 (d, 2H, *J* = 8.7 Hz). ^{13}C NMR δ: 34.5, 55.4, 101.1, 101.5, 111.5, 114.9, 115.6, 117.5, 124.7, 130.4, 136.6, 140.6, 148.0, 148.7, 159.0. HRMS calcd. for $C_{17}H_{16}O4S$: 316.0770; found: 316.0749.

Methylation of phenols (22)

These reactions were carried out in the same manner as the conversion **8** to **9**.

5-Methoxy-4-methylthio-6-(2-propenyl)-1,3-benzodioxole (23a)

Phenol **22a** (400 mg, 1.8 mmol), was converted in 87% yield (372 mg) to **23a**. EI–MS (*m*/*z*, %): 238 (M^+,100), 223 (13), 176 (41). IR (cm^{-1}): 949, 996. ^{1}H NMR δ: 2.45 (s, 3H), 3.30 (dt, 2H, *J* = 6.5 Hz, 1.4 Hz), 3.75 (s, 3H), 5.01–5.05 (m, 2H), 5.93 (s, 2H), 5.84–5.92 (m, 1H), 6.53 (s, 1H). ^{13}C NMR δ: 16.9, 34.0, 61.4, 101.3, 108.2, 112.3, 115.7, 125.8, 137.1, 143.4, 146.8, 151.8. HRMS calcd. for $C_{12}H_{14}O_3S$: 238.0664; found: 238.0682.

5-Methoxy-4-phenylmethanethio-6-(2-propenyl)-1,3-benzodioxole (23b)

Phenol **22b** (420 mg, 1.4 mmol) was converted into 0.420 mg (96%) of **23b**. EI–MS (*m*/*z*, %): 314 ($M^{+\cdot}$, 72), 223 (11), 91 (100). IR (cm^{-1}): 950, 994, 1638. ^{1}H NMR δ: 3.30 (dt, 2H, *J* = 6.4 Hz, 1.5 Hz), 3.65 (s, 3H), 4.12 (s, 2H), 4.96–5.07 (m, 2H), 5.88 (s, 2H), 5.83–5.95 (m, 1H), 6.55 (s, 1H), 7.17–7.24 (m, 5H). ^{13}C NMR δ: 34.0, 37.9, 61.6, 101.3, 108.9, 109.9, 115.7, 125.7, 127.0, 128.3, 128.9, 137.2, 138.0, 43.2, 147.6, 152.5. HRMS calcd. for $C_{18}H_{18}O_3S$: 314.0977; found: 314.0953.

5-Methoxy-4-phenylthio-6-(2-propenyl)-1,3-benzodioxole (23c)

The title compound **23c** was obtained as a yellowish oil in 87% yield starting with 550 mg of **22c**. EI–MS (*m*/*z*, %): 300 ($M^{+\cdot}$, 100), 176 (48), 162 (15). IR (cm^{-1}): 948, 995, 1639. ^{1}H NMR δ: 3.35 (dt, 2H, *J* = 6.4 Hz, 1.4 Hz), 3.73 (s, 3H), 5.02–5.11 (m, 2H), 5.91 (s, 2H), 5.86–6.05 (m, 1H), 6.71 (s, 1H), 7.10–7.22 (m, 5H). ^{13}C NMR δ: 34.2, 62.2, 101.6, 107.6, 110.4, 116.0, 125.6, 126.2, 127.1, 128.9, 136.2, 137.1, 143.7, 148.6, 153.2. HRMS calcd. for $C_{17}H_{16}O_3S$: 300.0821; found: 300.0802.

5-Methoxy-4-(4′-methoxyphenylthio)-6-(2-propenyl)-1,3-benzodioxole (23d)

Phenol **22d** (170 mg) was converted in 96% yield into **23d** as a pale yellow oil. EI–MS (*m*/*z*, %): 330 ($M^{+\cdot}$, 100), 176 (21), 121 (68). IR (cm^{-1}): 949, 995, 1638. ^{1}H NMR δ: 3.34 (dt, 2H, *J* = 6.5 Hz, 1.5 Hz), 3.73 (s, 3H), 3.75 (s, 3H), 5.03–5.07 (m, 2H), 5.87 (s, 2H), 5.88–5.94 (m, 1H), 6.63 (s, 1H), 6.77 (d, 2H, *J* = 8.9 Hz), 7.24 (d, 2H, *J* = 8.9 Hz). ^{13}C NMR δ: 34.1, 55.2, 62.0, 101.5, 109.7, 109.8, 114.5, 115.9, 126.0, 126.3, 130.7, 137.1, 143.6, 148.1, 152.7, 158.5. HRMS calcd. for $C_{18}H_{18}O_4S$: 330.0926; found: 330.0942.

Oxidation of the sulfides (23) to sulfoxides (24) and sulfones (25)

General procedures

For the oxidation to the sulfoxides, a solution of the sulfide in ethyl acetate was cooled to approx. –40°C and 1.2 equiv. of MCPBA was added. The reaction mixture was allowed to warm to rt and stirred for 24 h. Work-up consisted of washing first with sat. sodium bisulfite solution, then with sat. sodium bicarbonate, and finally with water. The organic soluble product was purified by column chromatography.

The oxidation to sulfones was carried out with 3–4 equiv. of MCPBA in ethyl acetate at rt for 24 h. The work-up of the reaction mixture was similar to that of the sulfoxides.

5-Methoxy-4-methylsulfinyl-6-(2-propenyl)-1,3-benzodioxole (24a)

Sulfide **23a** (100 mg, 0.42 mmol) was reacted with 0.5 mmol of MCPBA in 6 mL of ethyl acetate to afford 67 mg (63%) of **24a** as a pale yellowish liquid. EI–MS (*m*/*z*, %): 254 ($M^{+\cdot}$, 83), 237 (100). IR (cm^{-1}): 942, 994, 1050. ^{1}H NMR δ: 3.01 (s, 3H), 3.16 (dd, 2H, *J* = 6.4 Hz, 1.5 Hz), 3.78 (s, 3H), 5.03–5.09 (m, 2H), 5.84–5.89 (m, 1H), 6.06 (s, 2H), 6.74 (s, 1H). ^{13}C NMR δ: 33.1, 39.7, 63.4, 102.7, 112.3, 116.5, 120.8, 126.1, 136.3, 145.0, 145.5, 149.1. HRMS calcd. for $C_{12}H_{14}O_4S$: 254.0613; found: 254.0607.

5-Methoxy-4-methylsulfonyl-6-(2-propenyl)-1,3-benzodioxole (25a)

Oxidation of 50 mg, (0.21 mmol) of sulfide **23a** afforded 45 mg (80%) of sulfone **25a** as a pale yellow solid. EI–MS (*m*/*z*, %): 270 ($M^{+\cdot}$, 100). IR (cm^{-1}): 950, 993, 1136, 1316. ^{1}H NMR δ: 3.26 (s, 3H), 3.54 (d, 2H, *J* = 6.5 Hz), 3.84 (s, 3H), 5.06–5.13 (m, 2H), 5.84–5.92 (m, 1H), 6.05 (s, 2H), 6.83 (s, 1H). ^{13}C NMR δ: 32.1, 44.8, 63.8, 102.8, 113.9, 117.0, 118.1, 127.0, 135.9, 145.0, 145.2, 149.2. HRMS calcd. for $C_{12}H_{14}O_5S$: 270.0562; found: 270.0541.

5-Methoxy-4-phenylmethanesulfinyl-6-(2-propenyl)-1,3-benzodioxole (24b)

From 110 mg, (0.4 mmol) of **23b** was obtained 70 mg (61%) of sulfoxide **24b** as a yellowish oil. EI–MS (*m*/*z*, %): 330 ($M^{+\cdot}$, 21), 283 (47), 91 (100). IR (cm^{-1}): 951, 992, 1049, 1071. ^{1}H NMR (500 MHz) δ: 3.24 (d, 2H, *J* = 6.3 Hz), 3.56 (s, 3H), 4.34 (d, 1H, *J* = 12.5 Hz), 4.45 (d, 1H, *J* = 12.5 Hz), 5.00–5.06 (m, 2H), 5.82 (d, 1H, *J* = 1.34), 5.90 (d, 1H, *J* = 1.4 Hz), 5.81–5.87 (m, 1H), 6.67 (s, 1H), 7.10–7.24 (m, 5H). ^{13}C NMR δ: 33.0, 59.2, 63.0, 102.6, 112.3, 116.3, 118.6,

© 2000 NRC Canada

125.8, 128.1, 128.4, 130.2, 130.3, 136.4, 145.2, 145.8, 149.4. HRMS calcd. for $C_{18}H_{18}O_4S$: 330.0926; found: 330.0910.

5-Methoxy-4-phenylmethanesulfonyl-6-(2-propenyl)-1,3-benzodioxole (25b)

Oxidation of 80 mg (0.25 mmol) of sulfide **23b** in 6 mL of ethyl acetate gave 40 mg (45%) of sulfone **25b** as a white solid, mp 133–136°C. EI–MS (*m*/*z*, %): 346 ($M^{+\cdot}$, 34), 139 (16), 91 (100). IR (cm^{-1}): 1149, 1320. ^1H NMR δ: 3.35 (d, 2H, *J* = 6.4 Hz), 3.88 (s, 3H), 4.57 (s, 2H), 5.05–5.15 (m, 2H), 5.82 (s, 2H), 5.88–5.93 (m, 1H), 6.77 (s, 1H), 7.20–7.24 (m, 5H). ^{13}C NMR δ: 33.2, 62.2, 63.9, 102.6, 114.1, 116.8, 126.7, 128.1, 128.3, 128.5, 130.9, 133.9, 144.9, 146.3, 1494. HRMS calcd. for $C_{18}H_{18}O_5S$: 346.0875; found: 346.0852.

5-Methoxy-4-lphenylsulfinyl-6-(2-propenyl)-1,3-benzodioxole (24c)

Sulfide **23c** (100 mg, 0.30 mmol) was oxidized to sulfoxide **24c**, mp 83–87°C, in 76% yield. EI–MS (*m*/*z*, %): 316 ($M^{+\cdot}$, 39), 299 (100), 190 (59). IR (cm^{-1}): 948, 994, 1054,1639. ^1H NMR δ: 3.29 (d, 2H, *J* = 6.4 Hz), 3.85 (s, 3H), 5.00–5.07 (m, 2H), 5.82 (s, 1H), 5.82–5.88 (m, 1H), 5.97 (s, 1H), 6.68 (s, 1H), 7.24–7.71 (m, 5H). ^{13}C NMR δ: 33.0, 63.2, 102.6, 112.4, 116.5, 124.3, 125.8, 128.8, 130.3, 136.2, 143.8, 145.4. HRMS calcd. for $C_{17}H_{16}O_4S$: 316.0770; found: 316.0766.

5-Methoxy-4-phenylsulfonyl-6-(2-propenyl)-1,3-benzodioxole (25c)

Oxidation of 90 mg (0.21 mmol) of sulfide **23c** in ethyl acetate (6 mL) with 2 equiv. of MCPBA for 24 h provided the sulfone **25c** as a white solid, mp 86–88°C, in 71% yield. EI–MS (*m*/*z*, %): 332 ($M^{+\cdot}$, 100), 176 (34). IR (cm^{-1}): 992, 953, 1148, 1319. ^1H NMR δ: 3.23 (dt, 2H, *J* = 6.4 Hz, 1.5 Hz), 3.80 (s, 3H), 5.03–5.07 (m, 2H), 5.77–5.82 (m, 1H), 6.08 (s, 2H), 6.78 (s, 1H), 7.41–7.57 (m, 5H). ^{13}C NMR δ: 33.0, 63.6, 102.8, 114.0, 116.9, 118.7, 126.9, 127.5, 128.7, 133.2, 136.0, 142.6, 145.0, 145.4, 149.3. HRMS calcd. for $C_{17}H_{16}O_5S$: 332.0719; found: 332.0699.

5-Methoxy-4-(4′-methoxyphenylsulfinyl)-6-(2-propenyl)-1,3-benzodioxole (24d)

Sulfide **23d** (140 mg) was oxidized to give 100 mg (68%) of sulfoxide **25c** as a pale yellow oil. EI–MS (*m*/*z*, %): 330 ($M^{+\cdot}$, 60), 190 (28), 121 (100). IR (cm^{-1}): 949, 993,1044,1639. ^1H NMR δ: 3.27 (dt, 2H, *J* = 6.4 Hz, 1.4 Hz), 3.77 (s, 3H), 3.82 (s, 3H), 4.99–5.06 (m, 2H), 5.81–5.84 (m, 1H), 5.87 (s, 1H), 5.98 (s, 1H), 6.66 (s, 1H), 6.92 (d, 2H, *J* = 8.9 Hz), 7.64 (d, 2H, *J* = 8.9 Hz). ^{13}C NMR δ: 33.1, 55.4, 63.2, 102.6, 112.1, 114.4, 116.5, 122.1, 125.9, 126.4, 135.4, 136.4, 144.7, 145.5, 149.2, 161.5. HRMS calcd. for $C_{18}H_{18}O_5S$: 346.0875; found: 346.0875.

5-Methoxy-4-(4′-methoxyphenylsulfonyl)-6-(2-propenyl)-1,3-benzodioxole (25d)

Sulfide **23d** (90 mg) was oxidized to sulfone **25d**, mp 82–85°C, in 71% yield. EI–MS (*m*/*z*, %): 362 ($M^{+\cdot}$, 38), 300 (100), 176 (52). IR (cm^{-1}): 953, 992, 1145, 1315. ^1H NMR δ: 3.22 (dt, 2H, *J* = 6.4 Hz, 1.4 Hz), 3.80 (s, 3H), 3.81 (s, 3H), 4.99–5.07 (m, 2H), 5.75–5.83 (m, 1H), 6.05 (s, 2H), 6.92 (s, 1H), 6.84 (d, 2H, *J* = 8.9 Hz), 7.93 (d, 2H, *J* = 8.9 Hz). ^{13}C NMR δ: 33.1, 55.5, 63.6, 102.7, 113.7, 113.9, 116.9, 126.9, 129.8, 134.4, 136.0, 144.9, 145.1, 149.2, 163.4. HRMS calcd. for $C_{18}H_{18}O_6S$: 362.0824; found: 362.0821.

5-Hydroxy-4-hydroxymethyl-6-(2-propenyl)-1,3-benzodioxole (26)

To a solution of the aldehyde **8** (238 mg, 1.15 mmol) in 2.5 mL of ethanol was added 44 mg of sodium borohydride. The solution was stirred for 40 min, diluted with 2 mL of water, and then acidified with 2 N HCl. Work-up afforded 256 mg of crude product which was purified by chromatography to yield 198 mg (83%) of **26** as a white solid, mp 82–84°C. EI–MS (*m*/*z*, %): 208 ($M^{+\cdot}$, 26), 190 (100), 189 (50). IR (cm^{-1}): 3404, 3587. ^1H NMR δ: 2.55 (s, 1H), 3.28 (dt, *J* = 6.5, 1.4 Hz), 4.81 (s, 2H), 5.05–5.10 (m, 2H), 5.83 (s, 2H), 5.91–5.96 (m, 1H), 6.53 (s, 1H), 6.85 (s, 1H). ^{13}C NMR δ: 34.2, 57.8, 101.0, 108.9, 115.7, 118.3, 136.9, 140.4, 143.3, 148.8. HRMS calcd. for $C_{11}H_{12}O_4$: 208.0736; found: 208.0736.

5-Hydroxy-4-(1-hydroxyoctyl)-6-(2-propenyl)-1,3-benzodioxole (27)

A solution of 300 mg (1.45 mmol) of aldehyde **8** in 2 mL of ether was added to a freshly prepared solution (approx. 3 mmol) of *n*-octylmagnesium bromide in 3 mL of ether. The reaction mixture was refluxed for 45 min and quenched with sat. NH_4Cl solution. Work-up afforded 108 mg (25%) of **27**, mp 91–93°C. EI–MS: (*m*/*z*, %): 320 ($M^{+\cdot}$-H_2O, 100), 191 (53). IR (cm^{-1}): 3372, 3586. ^1H NMR δ: 0.86 (t, 3H, *J* = 6.7 Hz), 1.24–1.33 (m, 11H), 1.41–1.46 (m, 1H), 1.75–1.81 (m, 1H), 1.85–1.91 (m, 1H), 2.54 (s, 1H), 3.23–3.33 (m, 2H), 5.02–5.07 (m, 3H), 5.79 (d, 1H, *J*= 1.3 Hz), 5.83 (d, 1H, *J* = 1.4 Hz), 5.91–5.99 (m, 1H), 6.52 (s, 1H), 7.65 (d, 1H, *J* = 4.5 Hz). ^{13}C NMR δ: 14.1, 22.6, 25.5, 29.2, 29.3, 29.5, 31.8, 33.9, 36.6, 70.4, 100.8, 108.4, 111.4, 115.4, 119.0, 137.1, 139.8, 142.6, 147.8. HRMS calcd. for $C_{19}H_{28}O_4$: 320.1998; found: 320.1998.

4-Hydroxymethyl-5-methoxy-6-(2-propenyl)-1,3-benzodioxole (28)

The aldehyde **9** (350 mg) was reduced with $NaBH_4$ following the procedure for **8** to give **28** as an oil in 75% purified yield. IR (cm^{-1}): 3598. ^1H NMR δ: 2.45 (s, 1H), 3.30 (dt, 2H, *J* = 6.5, 1.4 Hz), 3.72 (s, 3H), 4.68 (s, 2H). ^{13}C NMR δ: 33.6, 55.7, 62.5, 101.4, 108.9, 115.9, 116.4, 125.4, 137.2, 143.7, 144.7, 150. EI–MS (*m*/*z*, %): 222 ($M^{+\cdot}$, 100). HRMS calcd. for $C_{12}H_{14}O_4$: 222.0892; found: 222.0906.

4-(1-Hydroxyoctyl)-5-methoxy-6-(2-propenyl)-1,3-benzodioxole (29)

This compound was prepared in 68% yield in a manner similar to the preparation of **27**. The yield of **29**, a clear yellowish oil, was 65%. EI–MS (*m*/*z*, %): 334 ($M^{+\cdot}$, 5), 316 (100), 190 (42), 43 (75). IR (cm^{-1}): 3588. ^1H NMR δ: 0.84–0.87 (m, 3H), 1.24–1.30 (m, 11H), 1.45–1.50 (m, 1H), 1.76–1.78 (m, 1H), 1.90–1.91 (m, 1H), 3.31 (dd, 2H, *J* = 6.4, 1.0 Hz), 3.70 (s, 3H), 4.88 (s, 1H), 5.02–5.06 (m, 2H), 5.87–5.93 (m, 1H), 5.91 (s, 2H), 6.56 (s, 1H). ^{13}C NMR δ: 14.1,

© 2000 NRC Canada

22.6, 26.1, 29.2, 29.5, 29.7, 31.9, 33.7, 37.6, 62.5, 68.3, 101.3, 108.4, 115.9, 120.8, 125.5, 137.2, 143.6, 143.9, 149.7. HRMS calcd. for $C_{20}H_{30}O_4$: 334.2145; found: 334.2157.

Cinnamate ester (30)

Methyl (triphenylphosphoranylidene)acetate (0.16 g, 0.47 mmol) was added to a solution of aldehyde **24** (85.5 mg, 0.39 mmol) in toluene (2 mL) and the mixture was refluxed for 22 h. After this time, the mixture was cooled to rt and the solvent was removed under vacuum. Purification by flash chromatography (5:1, hexane–ethyl acetate) afforded the desired product **30** as a pale yellow solid, mp 76–78°C, (98.4 mg, 91%). EI–MS (*m*/*z*, %): 276 ($M^{+\cdot}$, 100), 245 (41). IR (cm^{-1}): 1713 ^{1}H NMR δ: 3.32 (dt, 2H, *J* = 6,5, 1.4 Hz), 3.69 (s, 3H), 3.79 (s, 3H), 5.03–5.07 (m, 2H), 5.87–5.93 (m, 1H), 6.00 (s, 2H), 6.66 (s, 1H), 6.78 (d, 1H, *J* = 16.3 Hz), 7.81 (d, 1H, *J* = 16.3 Hz). ^{13}C NMR δ: 33.6, 51.6, 62.7, 101.8, 110.7, 112.3, 116.0, 121.8, 125.5, 135.0, 137.0, 143.9, 145.6, 151.2, 167.9. HRMS calcd. for $C_{15}H_{16}O_5$: 276.0998; found: 276.0999.

5-Methoxy-4-octyloxy-6-(2-propenyl)-1,3-benzodioxide (31)

A solution of phenol **10** (88 mg), K_2CO_3 (90 mg), and octyl bromide (0.09 mL) in 6 mL of acetone was refluxed for 64 h. The acetone was evaporated and the residue partitioned between water and ether. The yield of **31**, a yellow oil, was 60%. EI–MS (*m*/*z*, %): 320 ($M^{+\cdot}$, 64), 208 (74), 84 (62), 49 (100). ^{1}H NMR δ: 0.87 (t, 3H, *J* = 6.8 Hz), 1.24–1.32 (m, 8H), 1.42–1.45 (m,2H), 1.72–1.75 (m, 2H), 3.29 (dt, 2H), *J* = 6.6, 1.1 Hz), 3.75 (s, 3H), 4.16 (t, 2H, *J* = 6.7 Hz), 5.00–5.04 (m, 2H), 5.85 (s, 2H), 5.87–5.93 (m, 1H), 6.33 (s, 1H). ^{13}C NMR δ: 14.1, 22.6, 25.8, 29.2, 29.3, 30.1, 31.8, 34.0, 61.2, 72.6, 101.0, 102.7, 115.4, 126.0, 136.3, 136.9, 137.5, 144.4, 144.7. HRMS calcd. for $C_{19}H_{28}O_4$: 320.1988; found: 320.1984.

Acknowledgements

Funding was provided by Natural Sciences and Engineering Research Council of Canada (NSERC) (Strategic Program). S.L. Majerus was the recipient of an NSERC PGS A scholarship.
