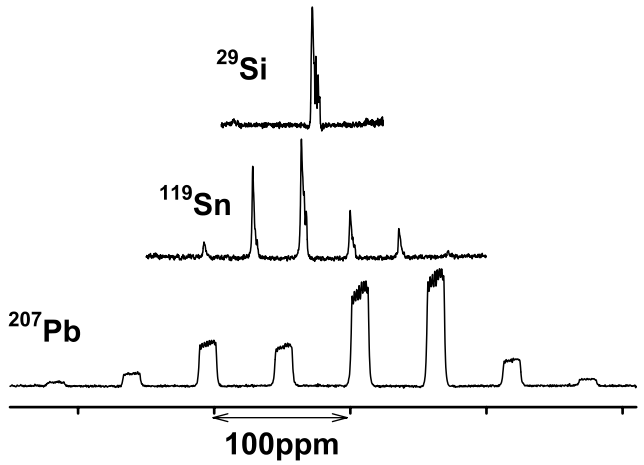
D' (Hz)[b]	–417(4)	–606(3)	314(4)
ΔJ (Hz)[c]	–1580(20)	–2690(30)	950(10)

[a]From ref. 14. The frequencies are ±0.05 MHz.
[b]Calculated from the M–Co bond lengths given in Table 2, errors calculated using $\pm 5\sigma$.
[c]Standard deviation propagated from *d*.

Fig. 4. CP MAS NMR spectra of **I–III** at 7.05 T. The three spectra were plotted on the same horizontal axis (in ppm) to illustrate the increase in span on going from ^{29}Si to ^{207}Pb. For the chemical shifts, see Table 4.



and the second-order quadupolar-dipolar splitting (*d*) given by $3\chi D'/10\nu_s$, can be obtained.

The NMR data for **I–III**, are given in Table 4, and the full spectra of all of the compounds are given in Fig. 4. In all cases, only a single chemical shift was observed, which is consistent with the crystal structures. In the case of the triphenylsilyl complex, the spectrum has only a centreband at the spinning speeds used. The ($\delta_{11}-\delta_{33}$) span of the spectrum is therefore very small, as was observed previously for the triphenylsilyl(pentacarbonyl)manganese(I) complex (25). The centreband should exhibit eight lines, but the downfield lines overlap, which is characteristic of a d/J ratio that is close to, or greater than, one. Since the lines overlap in the downfield region, the sign of *d* is positive.

The ^{119}Sn CP MAS spectrum of the triphenyltin complex has a much larger span and the components of the chemical shift tensor could be calculated, using the Herzfeld–Berger method, from the relative intensities of the spinning sidebands (28, 43). The span of the spectrum (133 ppm) is smaller than the values reported (25) for $Ph_3SnMn(CO)_5$ (187–209 ppm) and for the less-symmetrical diaryl complexes (44, 45). The centreband shows an overlap of the downfield lines, characteristic of a d/J ratio close to one.

Since ^{207}Pb spectra usually show a very wide range of chemical shifts, it is surprising that the span of the triphenyl lead complex is only 280 ppm. This value is similar to those obtained for the triphenylplumbyl(pentacarbonyl)manganese(I) complex (25), where the spans ranged from 268 to 329 ppm. It is notable that both the lead–cobalt and the lead–manganese complexes have smaller spans than the more symmetrical hexaorganyldiplumbanes, which have spans ranging from 484 to 996 ppm (46). Comparison of the spans for the tin and lead complexes showed the expected increase as the size of the valence *p*-electron radius ($\langle r^{-3}\rangle_{np}$) increases. According to the expression for paramagnetic shielding suggested by Ramsey (47–49), the ratio of the spans should correlate well with the $\langle r^{-3}\rangle_{6p}/\langle r^{-3}\rangle_{5p}$ ratio of 1.4 previously reported (50). The span of the lead complex is 2.1 times greater than that of the tin complex. Our results are not inconsistent with the greater-than-expected chemical shielding range of ^{207}Pb previously obtained (51) from a plot of $\delta(^{207}Pb)$ vs. $\delta(^{119}Sn)$ isotropic chemical shifts, where a slope of 3.0 was obtained. Unexpectedly large chemical shielding ranges for heavy nuclei have been previously discussed (52).

The spectrum of **III** is quite different from the spectra of **I** and **II**, showing an almost symmetric octet. The lines of the octet are almost evenly spaced, which is indicative of a small *d* value. The quadrupolar–dipolar shift term is small because the effective D' is small. Since the value χ for **III** was determined (110.82 MHz), D' can be obtained using eq. [1], and because the direct dipolar coupling constants can be calculated from the measured bond lengths, ΔJ can be extracted from eq. [2].

The differences between the isotropic solid and solution chemical shifts are greatest for the lead complex and smallest for silicon. This trend can be attributed to the larger range of observed chemical shifts for ^{207}Pb and ^{119}Sn rather than structural differences between the three complexes.

Very few instances of direct measurement of the spin–spin couplings of *I*–Co spin pairs have been reported. The compounds most frequently studied are highly symmetric with octahedral or tetrahedral symmetry, e.g., $Na[Co(CO)_4]$ (53) and $Na_3[Co(CN)_6]$ (54). Coupling between ^{59}Co and ^{13}C and ^{31}P has been indirectly measured by T_1 relaxation measurements in solution (55, 56) and in the solid state (57). The one-bond coupling constants to cobalt reported here are rare because these complexes have large quadrupole coupling constants, and are less symmetrical than the complexes previously reported.

The contributions to the spin–spin coupling constant arise from the diamagnetic spin-orbit (DSO), paramagnetic spin-orbit (PSO), spin-dipolar term (SD), Fermi contact (FC), and a spin-dipolar – Fermi contact (SD–FC) cross term. The DSO and PSO contributions are usually small, have opposite signs to each other, and tend to cancel, leaving the latter major terms (58). To compare the spin–spin coupling constants of different nuclei, the reduced coupling con-

© 2002 NRC Canada

stants ($K_{I,J} = 4\pi^2 J_{I,J}/(h\gamma_I\gamma_J)$) are used. For the FC term, $K_{I,J}$ is proportional to the product of the *s*-electron densities at the nuclei and the *s*-character of the hybrid orbitals used to form the bond, all divided by an average excitation energy (ΔE) (59, 60). Using the *s*-electron densities given by Pyykkö and Weisenfeld (61), with a non-relativistic value for silicon and relativistic values for the heavier elements, a plot of the reduced coupling constants against the *s*-electron densities ($|\psi(0)|^2$) for the silicon, tin, and lead nuclei showed a linear relationship, passing through the origin, for the triphenyl complexes with manganese pentacarbonyl (25). In the present series of compounds, the reduced coupling constants for the tin and lead complexes also showed a linear dependence extrapolating to the origin, but the silicon value was too high (Table 4). This, combined with the large ΔJ values for all complexes, suggests that, in addition to the FC term, there are appreciable anisotropic contributions to the *J* tensor most probably from the SD–FC term. Large ΔJ values were also observed for the manganese pentacarbonyl complexes (25) and for other heavy-atom cases, such as ^{199}Hg–^{31}P coupling (62–65). Theoretical calculations of ΔJ have been limited to light-atom systems, but even in the case of ^{13}C–^{13}C coupling in benzene, ethane, ethene, and ethyne (66, 67) there is appreciable anisotropy, but the FC term is still the major contribution.

Experimental

General

All reactants were used as received from Aldrich or Strem [$Co_2(CO)_8$]. With the exception of THF (which was dried over sodium with benzophenone indicator), solvents were not dried before use,. All reactions were performed under nitrogen with subsequent work-up under air.

IR spectra were measured (100 scans) in either CH_2Cl_2 or hexanes solutions between KBr plates on a Bruker IFS-48 FT-IR spectrometer at 1.0 cm^{-1} resolution. Raman spectra were recorded (100 scans) on a Bruker IFS-88 FT-Raman spectrometer with samples contained in a metal cup at 4.0 cm^{-1} resolution. Solution-state ^{13}C, ^{29}Si, and ^{119}Sn proton-decoupled NMR spectra were measured in $CDCl_3$ solutions at room temperature (21°C), on a Varian XL-400 spectrometer operating at a field strength of 9.40 T. The ^{207}Pb spectrum was measured on a JEOL 270 MHz spectrometer operating at 6.34 T. Solid-state proton-decoupled CP MAS spectra were obtained on a Chemagnetics CMX-300 spectrometer operating at 59.52 MHz (^{29}Si), 111.73 MHz (^{119}Sn), and 63.10 MHz (^{207}Pb). Experimental conditions **I**: contact time 2 ms; pulse delay 750 s; 128 transients. **II**: contact time 2 ms; pulse delay 20 s; 700 transients. **III**: contact time 2 ms; pulse delay 3 s; 18644 transients. Chemical shifts were externally referenced to tetramethylsilane (^{29}Si), tetramethyltin (^{119}Sn), and tetramethyllead (^{207}Pb), respectively. Powdered samples were contained in 7.5-mm diameter zirconia pencil-type rotors. FIDs on the CMX-300 were zero-filled to 8K data points. Spinning rates ranging from 2–4 kHz were used to identify isotropic chemical shifts. The chemical shifts of ^{207}Pb resonances can be temperature-dependent, but the centre band position did not vary with spinning speed and, therefore, no heating effects occurred. The resonance lines in all sidebands were fitted with Lorentzian line shapes using the program Peakfit (Jandel Scientific) and the errors given are from the averages of the fitted parameters. Calculation of the chemical shift tensors were performed with the aid of a computational package developed by Eichele and Wasylishen (28).

$Ph_3SiCo(CO)_4$ (I)

Compound **I** was synthesized using the reaction first described by Chalk and Harrod (3) and later improved by McIndoe and Nicholson (26). $Co_2(CO)_8$ (2.38 g, 6.95 mmol) and Ph_3SiH (6.79 g, 6.95 mmol) were reacted in hexanes (30 mL) at room temperature for 90 min. After cooling to 0°C (ice bath), an off-white solid was precipitated. The solid was isolated by Buchner filtration and washed with cold hexanes. Recrystallization from hot hexanes yielded clear crystals of the desired compound (3.71 g, 62%); mp 138–140°C (lit. (1) 135–140°C). IR ν_{CO} (hexanes, cm^{-1}): 2093 (m), 2033 (m), 2005 (s); (CH_2Cl_2, cm^{-1}): 2094 (s), 2033 (m), 1993 (s). ^{13}C NMR δ: 198.7 (s, CO), 138.2 (s, ipso), 135.4 and 127.9 (s, *ortho* and *meta*), 129.6 (s, *para*). The IR and ^{13}C NMR spectra were in agreement with previously published results (26).

$Ph_3SnCo(CO)_4$ (II)

Compound **II** was synthesized according to the method described by Darensbourg (6). $Co_2(CO)_8$ (4.00 g, 11.7 mmol) was dissolved in methanol and the solution was gently warmed to 50°C and stirred until the pink colour of $[Co^{2+}][Co(CO)_4^-]_2$ was observed and gas evolution ceased. The reaction mixture was then cooled to 0°C (ice bath) and a methanolic solution of Ph_3SnCl (4.20 g, 10.9 mmol) was added. The reaction mixture was stirred for 1 h at room temperature and then cooled to 0°C, which resulted in the precipitation of a white solid. The solid was isolated, washed with cold methanol, and then dried by vacuum filtration. Recrystallization from hot hexanes yielded large yellow crystals (3.97 g, 70%); mp 118–121°C (lit. (5) 119–121°C). IR ν_{CO} (hexanes, cm^{-1}): 2087 (m), 2026 (m), 1997 (s); (CH_2Cl_2, cm^{-1}): 2088 (s), 2026 (m), 1994 (s). ^{13}C NMR δ: 198.8 (s, CO), 140.2 (ipso, $^1J_{^{119}Sn,C}$ = 459, $^1J_{^{117}Sn,C}$ = 439 Hz), 128.8 (*meta*, $^3J_{Sn,C}$ = 53.4 Hz), 136.16 (*ortho*, $^2J_{Sn,C}$ = 41.2 Hz), 129.4 (*para*, $^4J_{Sn,C}$ = 12.2 Hz).

$Ph_3PbCo(CO)_4$ (III)

Compound **III** was synthesized in an analogous manner to complex **II** from $Co_2(CO)_8$ (4.00 g, 8.19 mmol) and Ph_3PbCl (5.07 g, 10.7 mmol), as described by Patmore and Graham (5). Upon recrystallization from hexanes, light-yellow block-shaped crystals were obtained (4.69 g, 72% yield); mp 102°C (lit. (6) 100–102°C). IR ν_{CO} (hexanes, cm^{-1}): 2079 (s), 2020 (m), 1993 (s); (CH_2Cl_2, cm^{-1}): 2082 (s), 2020 (m), 1994 (s). ^{13}C NMR δ: 199.4 (s, CO), 152.9 (ipso, $^1J_{Pb,C}$ = 314 Hz), 129.8 (*meta*, $^3J_{Pb,C}$ = 80.5 Hz), 136.5 (*ortho*, $^2J_{Pb,C}$ = 72.1 Hz), 128.9 (*para*, $^4J_{Pb,C}$ = 19.2 Hz).

X-ray crystallography

All complexes were recrystallized by dissolving in boiling hexanes and then cooling to –30°C, where, after several days, X-ray quality crystals were obtained. Details of the crystal data and structure refinements are given in Table 1.

© 2002 NRC Canada

Data for **I** and **III** were processed using a locally modified version of the NRC-2 program (29) and data for **II** was processed by SAINT (30).[2] All structures were solved by direct methods using SHELXS-97 (31) and refined using SHELXL-96 (32). Non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were included in calculated positions. Scattering factors were from the usual sources (33). **I** was run at low temperature (220 K) because it was prone to decomposition under X-rays at room temperature.

Acknowledgments

This work was supported by grants from the Natural Sciences and Engineering Research Council of Canada (NSERC) and Fonds pour la formation de chercheurs et l'aide à la recherche (Québec) (FCAR).We thank Dr. A.-M. Lebuis for assistance in examining the crystal structures and Professor R.E. Wasylishen for the HBA program.

Syntheses and X-ray structures of boraamidinate complexes of lithium, phosphorus, and tellurium

Tristram Chivers, Chantall Fedorchuk, Gabriele Schatte, and Justin K. Brask

Abstract: The dilithiated boraamidinate complexes $\{Li_2[RB(N\text{-}t\text{-}Bu)_2]\}_2$ (**1a**, R = Ph; **1b**, R = *t*-Bu), prepared by the reaction of $B[N(H)\text{-}t\text{-}Bu]_3$ with three equivalents of LiR, are shown by X-ray crystallography to have dimeric structures consisting of a distorted Li_4N_4 cube capped on two opposite faces by RB units. Reactions of **1a** with $TeCl_4$ or PX_3 (X = Cl, Br) yielded complexes $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2TeCl_2$ (**2**) and $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2PX$ (**4a**, X = Cl; **4b**, X = Br), respectively. The structures of **2** and **4b** were determined by X-ray crystallography. In the solid state, complex **2** forms a dimer with weak Te···Cl contacts (3.2411(6) Å). Complex **4b** is monomeric with a P—Br bond length of 2.3047(11) Å. The reactions of **2** and **4a** with the appropriate amounts of Li[N(H)-*t*-Bu] produce the monomeric tellurium imide $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2Te{=}N\text{-}t\text{-}Bu$ and the amido derivative $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2PN(H)\text{-}t\text{-}Bu$ (**4c**), respectively. The X-ray structure of **4c** was determined. Deprotonation of **4c** with *n*-BuLi produces the dimeric monolithium derivative $\{Li[PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2PN\text{-}t\text{-}Bu]\}_2$ (**5**), which was shown by X-ray crystallography to have a centrosymmetric structure with a central transoid Li_2N_2 ring.

Key words: boraamidinates, lithium, tellurium, phosphorus, X-ray structures.

Résumé : Faisant appel à la diffraction des rayons X, on a montré que les structures des complexes boraamidinates dilithiés $\{Li_2[RB(N\text{-}t\text{-}Bu)_2]\}_2$ (**1a**, R = Ph; **1b**, R = *t*-Bu) préparés par réaction du $B[N(H)\text{-}t\text{-}Bu]_3$ avec trois équivalents de LiR sont des dimères formés d'un cube Li_4N_4 déformé et portant des unités RB sur deux faces opposées. Les réactions de métathèse du composé **1a** avec le $TeCl_4$ ou le PX_3 (X = Cl, Br) fournissent respectivement les complexes $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2TeCl_2$ (**2**) et $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2PX$ (**4a**, X Cl; **4b**, X = Br). Les structures des composés **2** et **4b** ont été déterminées par diffraction des rayons X. Le complexe **2** forme un dimère avec de faibles contacts Te···Cl (3,2411(6) Å) à l'état solide. Le complexe **4b** est un monomère dans lequel la longueur de la liaison P—Br est de 2,3047(11) Å. Les réactions des composés **2** et **4a** avec des quantités appropriées de Li[N(H)N-*t*-Bu)] conduisent à la formation respectivement de l'imide de tellure monomère $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2Te{=}N\text{-}t\text{-}Bu$ et du dérivé amido $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2PN(H)\text{-}t\text{-}Bu$ (**4c**). On a déterminé la structure du composé **4c** par diffraction des rayons X. La déprotonation du composé **4c** à l'aide de *n*-BuLi conduit à la formation du dérivé monolithié dimère $\{Li[PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2PN\text{-}t\text{-}Bu]\}_2$ (**5**) dont structure, telle que déterminé par diffraction des rayons X, est centrosymétrique avec un cycle central Li_2N_2 transoïde.

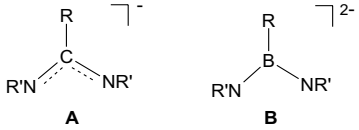
Mots clés : boraamidates, lithium, tellure, phosphore, structures par diffraction des rayons X.

[Traduit par la Rédaction]

Introduction

Amidinate ligands $(RC(NR')_2]^-$ (**A**) have been investigated extensively as ligands for *p*- and *d*-block metals (1). Recent studies have focused on the application of aluminum (2) and early transition-metal (3) complexes as catalysts for alkene polymerization. By contrast, the isoelectronic boraamidinate dianions $(RB(NR')_2]^{2-}$ (**B**) have received restricted attention. The known complexes of **B** are limited almost exclusively to elements from groups 4, 14, or 16 (4).

The most straightforward route to such complexes involves metathesis between a halide and the reagent $\{Li_2[PhB(N\text{-}t\text{-}Bu)_2]\}_2$, prepared in situ by dilithiation of $PhB[N(H)\text{-}t\text{-}Bu]_2$ with *n*-BuLi (5). This method has been used for the synthesis of complexes of the type $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2ML_n$ (where ML_n = Pb(II) (5), $ZrCp_2$ (6), and $SnMe_2$ (6)) as well as the spirocyclic compounds $[PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2]_2M$ (where M = Ge, Sn, Ti, or Zr (6), Te (7)). The fluorinated compound $C_6F_5B(\mu\text{-}N\text{-}t\text{-}Bu)_2SnMe_2$ has been obtained in a similar manner (8). Less direct methods have been employed for the synthesis of the following boraamidinates: $[MeB(\mu\text{-}NSiMe_3)_2Sn]_2$ (9), *t*-$BuB(\mu\text{-}N\text{-}t\text{-}Bu)_2P(N\text{-}t\text{-}Bu)\text{-}t\text{-}Bu$ (10), $RB(\mu\text{-}NR')_2S$ (R = alkyl, aryl, C_6F_5; R′ = *t*-Bu or $SiMe_3$) (11), $MeB[\mu\text{-}N(2,6\text{-}Me_2CH)_2C_6H_3]_2SiMe_2$ (12), $MesB(\mu\text{-}N\text{-}t\text{-}Bu)_2Si(SiMe_3)(Mes)$ (13), and $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2TeN\text{-}t\text{-}Bu$ (14).



More recently, we have reported an alternative and potentially more versatile route to boraamidinates that involves the reaction of $B(NH\text{-}t\text{-}Bu)_3$ with three equivalents of an

alkyl-lithium reagent (15). The dilithium salts $\{Li_2[RB(N\text{-}t\text{-}Bu)_2]\}_x$ obtained in this way form either dimeric (R = *n*-Bu; *x* = 2, **1c**) or trimeric (R = Me; *x* = 3) clusters (15). In this article we describe (*i*) the synthesis and X-ray structures of $\{Li_2[RB(N\text{-}t\text{-}Bu)_2]\}_2$ (R = Ph, *t*-Bu); (*ii*) the preparation and X-ray structure of $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2TeCl_2$ and a new route to the monomeric tellurium imide $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2TeN\text{-}t\text{-}Bu$; and (*iii*) the preparation, spectroscopic characterization, and X-ray structure (X = Br) of the P(III) boraamidinates $PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2PX$ (X = Cl, Br, N(H)-*t*-Bu), and the dimeric lithium derivative $\{Li[PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2PN\text{-}t\text{-}Bu]\}_2$.

Experimental

Reagents and general procedures

The compounds $PhBCl_2$ (Aldrich, 97%), PCl_3 (Aldrich, 98%), PBr_3 (Aldrich, 99.99+%), and $TeCl_4$ (Alfa Aesar, 99.9%) were used as received. Li[N(H)-*t*-Bu] was prepared by the addition of *n*-BuLi (2.5 M solution in hexanes, 200 mL, 0.5 mol; Aldrich) to a solution of anhydrous *t*-$BuNH_2$ (65 mL, 0.609 mol; Aldrich, 98%) in *n*-hexane (170 mL) at –10°C and its purity was checked by ^{1}H NMR spectroscopy (δ in C_7D_8, 1.37 (*t*-Bu) and in THF-d_8, 1.07 (*t*-Bu), –1.55 (NH)). The compound $\{Li_2[n\text{-}BuB(N\text{-}t\text{-}Bu)_2]\}_2$ (**1c**) (15) was obtained in 70% yield from the reaction of B[N(H)-*t*-Bu]$_3$ (16) with three equivalents of *n*-BuLi. Solvents were dried with appropriate drying agents and distilled onto molecular sieves before use. All reactions and the manipulation of moisture-sensitive products were carried out under an atmosphere of argon or under vacuum. All glassware was carefully dried prior to use.

Instrumentation

^{1}H NMR spectra were recorded on Bruker AC 200 and DRX 400 spectrometers, and chemical shifts are reported relative to Me_4Si in $CDCl_3$. ^{13}C, ^{11}B, ^{31}P, ^{125}Te, and ^{7}Li NMR spectra were measured at 23°C in C_6D_6, $CDCl_3$, or C_4D_8O on a Bruker DRX 400 spectrometer using a 5-mm broadband probe operating at 100.613, 128.377, 161.975, 126.429, and 155.505 MHz, respectively. The samples were externally referenced to $BF_3{\cdot}Et_2O$ in C_6D_6, H_3PO_4 in D_2O, K_2TeO_3 in D_2O (referenced to Me_2Te), and 1.0 M LiCl in D_2O, respectively. Line-broadening parameters, used in the exponential multiplication of the free induction decays, were 50–0.5 Hz. Chemical shifts with a positive sign are correlated with shifts to high frequencies (downfield) of the reference compound. EPR spectra were recorded at 20°C on a Buker EMX 10/12 EPR spectrometer equipped with a microwave X-Band bridge (9.1–9.9 GHz), a 10-inch magnet, and a 12-kW power supply ER083CS. Samples of **1a** and **1c** were loaded into a 4-mm glass tube in a glovebox and dissolved in oxygen-free toluene. After brief exposure of these solutions to dry air, the EPR spectra were recorded. Mass spectra were obtained with a VG Micromass spectrometer VG7070 (70 eV). Infrared spectra were obtained as Nujol mulls between KBr plates on a Nicolet Nexus 470 FT-IR spectrometer in the range of 4000–350 cm^{-1}. Elemental analyses were provided by the Analytical Services Laboratory of the Department of Chemistry, University of Calgary.

Preparation of $\{Li_2[PhB(N\text{-}t\text{-}Bu)_2]\}_2$ (1a)

From B[N(H)-t-Bu]$_3$ and 3 equivalents of LiPh

A solution of LiPh in cyclohexane–ether (1.8 M, 3.70 mL, 6.67 mmol) was added slowly to a solution of B[N(H)-*t*-Bu]$_3$ (0.50 g, 2.22 mmol) in Et_2O (50 mL) at 23°C and the mixture was stirred for 18 h. Concentration by removal of solvent in vacuo, and subsequent cooling (0°C for 18 h) of the resulting yellow solution (~20 mL) yielded colourless hexagonal blocks of $\{Li_2[PhB(N\text{-}t\text{-}Bu)_2]\}_2$ (0.82 g, 1.69 mmol, 76%); mp. 158–160°C (dec.). ^{1}H NMR (C_6D_6) δ: 7.38–7.18 (m, 5H, C_6H_5), 1.09 (s, 18H, C_4H_9). ^{13}C NMR (C_6D_6) δ: 133.85, 126.41, 125.12 (C_6H_5), 51.52 (CMe_3), 35.33 (CMe_3). ^{11}B NMR (C_6D_6) δ: 35.4 (br). ^{7}Li NMR (C_6D_6) δ: +2.24 (s). Anal. calcd. for $C_{28}H_{46}B_2Li_4N_4$: C 68.90, H 9.50, N 11.48; found: C 67.76, H 9.50, N 10.47.

A 1-mL aliquot of the initial Et_2O reaction mixture was pumped to dryness in vacuo and taken up in C_6D_6. The ^{1}H and ^{7}Li NMR spectra indicated the presence of Li[N(H)-*t*-Bu]: ^{1}H NMR δ: 1.36 (s, C_4H_9), cf. lit.: 1.37 (17). ^{7}Li NMR δ: 0.14 (s).

From PhB[N(H)-t-Bu]$_2$ and two equivalents of n-BuLi

PhB[N(H)-*t*-Bu]$_2$ is obtained by adding a solution of $PhBCl_2$ (2.000 g, 64 mL, 12.54 mmol) in *n*-hexane (20 mL) to a slurry of Li[N(H)-*t*-Bu] (3.900 g, 49.32 mmol)[2] in *n*-hexane (30 mL) at –20°C. The reaction mixture was stirred for 4 h at 23°C and then filtered twice using a glass-sintered frit (8 μm) and then a PTFE filter disk (Acrodisc syringe filter; diameter: 25 mm; pore size: 0.45 μm). The volatile materials were removed under vacuum to give PhB[N(H)-*t*-Bu]$_2$ as a golden yellow oil (2.600 g, 11.20 mmol, 89%). IR (cm^{-1}): 3429 (NH). ^{1}H NMR (C_6D_6) δ: 7.54–7.17 (m, 5H, C_6H_5), 2.80 (br s, 2H, N*H*), 1.12 (s, 18H, C_4H_9). ^{13}C NMR (C_6D_6) δ: 133.12, 127.81, 127.61 (C_6H_5), 49.32 (CMe_3), 33.63 (CMe_3). ^{11}B NMR (C_6D_6) δ: 29.6.

The product was dissolved in *n*-hexane (20 mL) and the solution was cooled to –10°C. Then *n*-BuLi in hexane (2.5 M, 9 mL, 22.20 mmol) was added, and the reaction mixture was heated at reflux for 17 h. The white precipitate of **1a** was allowed to settle and the yellow solution was removed via a cannula and discarded. The product was washed twice with *n*-hexane (~5 mL) at 0°C giving **1a** (2.220 g, 4.55 mmol, 81%). The ^{1}H, ^{13}C, and ^{11}B NMR spectral parameters were in good agreement with those obtained for **1a** prepared by method A.

An increase in the scale of the reaction of $PhBCl_2$ with Li[N(H)-*t*-Bu] by a factor of two results in lower yields (60–80%) of PhB[N(H)-*t*-Bu]$_2$.

Preparation of $\{Li_2[t\text{-}BuB(N\text{-}t\text{-}Bu)_2]\}_2$ (1b)

tert-Butyllithium (3.30 mL, 5.61 mmol) was added slowly to a solution of B[N(H)-*t*-Bu]$_3$ (0.425 g, 1.87 mmol) in *n*-pentane (10 mL) at 23°C and stirred for 2.5 h. Concentration by removal of solvent in vacuo and subsequent cooling (0°C

[2] It is necessary to use an excess of Li[N(H)-*t*-Bu] to optimize the yield of PhB[N(H)-*t*-Bu]$_2$. Unreacted Li[N(H)-*t*-Bu] is readily removed by filtration.

© 2002 NRC Canada

for 3 h) of the resulting solution (~2 mL) yielded colourless rods of **1b** (0.342 g, 0.76 mmol, 81%). ^{1}H NMR (C_6D_6) δ: 1.48 (s, 9H, BC_4H_9), 1.38 (s, 18H, NC_4H_9). ^{7}Li NMR (C_6D_6) δ: –0.55 (s). ^{11}B NMR (C_6D_6) δ: 35.1 (s). Anal. calcd. for $C_{12}H_{27}BLi_2N_2$: C 64.33, H 12.15, N, 12.50; found: C 64.70, H 11.32, N 12.58.

Preparation of PhB(μ-N-*t*-Bu)$_2$TeCl$_2$ (2)

The addition of a colourless solution of **1a** (1.000 g, 2.049 mmol) in toluene (10 mL) to a yellow solution of $TeCl_4$ (1.104 g, 4.098 mmol) in toluene (15 mL) at –78°C produced a dark red solution, which became black upon warming to 23°C. After 1 h, the volatiles were removed under vacuum and the solid black residue was extracted with acetonitrile (2 × 10 mL). Elemental tellurium (50 mg) was separated by filtration through an Acrodisc syringe filter (PTFE membrane, pore size 0.45 μm) to give an orange solution. Removal of solvent under vacuum produced PhB(μ-N-*t*-Bu)$_2$TeCl$_2$ (1.604 g, 3.742 mmol, 91%) as an orange-yellow solid; mp 110–114°C dec. ^{1}H NMR (C_6D_6) δ: 7.51–7.16 (m, 5H, C_6H_5), 1.22 (s, 18H, C_4H_9); ($CDCl_3$) δ: 7.60–7.38 (m), 1.29 (s). ^{13}C NMR (C_6D_6) δ: 131.08, 129.75, 128.49 (C_6H_5), 55.76 (CMe_3), 33.70 (CMe_3). ^{11}B NMR (C_6D_6) δ: 43.5; ($CDCl_3$) δ: 43.3. ^{125}Te NMR ($CDCl_3$) δ: 1677.1; (C_6D_6) δ: 1673.9. Anal. calcd. for $C_{14}H_{23}BCl_2N_2Te$: C 39.23, H 5.41, N 6.53; found: C 37.42, H 5.35, N 6.05.

Preparation of PhB(μ-N-*t*-Bu)$_2$TeN-*t*-Bu (3)

A slurry of Li[N(H)-*t*-Bu] (0.222 g, 2.800 mmol) in *n*-hexane (15 mL) was added to a yellow-orange solution of **2** (0.600 g, 1.400 mmol) in *n*-hexane (20 mL) cooled to –78°C. The reaction mixture was allowed to reach room temperature after 15 min, whereupon an orange solution containing a white solid (LiCl) was obtained. The mixture was stirred for 18 h, after which time the colour of the solution had changed to dark orange. The solution was filtered and the volatile materials were removed under vacuum to give a sticky red solid. Et_2O (5 mL) was added and at –60°C PhB(μ-N-*t*-Bu)$_2$TeN-*t*-Bu (**3**) crystallized from this solution. The red supernatant was removed via cannula, and the remaining yellow-brown solid was washed with Et_2O (2 × 5 mL) at –60°C to give **3** (0.233 g, 0.543 mmol, 39%). The final product was LiCl-free (^{7}Li NMR). ^{1}H NMR (C_6D_6) δ: 7.50–7.10 (m, 5H, C_6H_5), 1.71 (s, 9H, C_4H_9), 1.11 (s, 18H, C_4H_9); cf. lit. (14) δ: 7.6–7.2, 1.70, 1.11 (in C_6D_6). ^{13}C NMR (THF-d_8) δ: 132.03, 128.15, 128.00 (C_6H_5), 64.71 (CMe_3), 53.91 (CMe_3), 34.85 (CMe_3), 34.48 (CMe_3). ^{11}B NMR (THF-d_8) δ: 33.4 (br). ^{125}Te NMR (THF-d_8) δ: 1491.5 (s).

Preparation of PhB(μ-N-*t*-Bu)$_2$PCl (4a)

A colourless solution of **1a** (2.000 g, 4.098 mmol) in THF (15 mL) was added to a solution of PCl_3 (0.72 mL, 1.125 g, 8.195 mmol) in toluene (15 mL) at –78°C. The reaction mixture was allowed to reach room temperature after 0.5 h, whereupon a pale yellow solution containing a white solid (LiCl) was obtained. After 4 h, the reaction mixture was filtered through a PTFE filter disk (0.45 μm). The volatile materials were removed under vacuum to give a white solid. After addition of Et_2O (5 mL), the solution was filtered to remove LiCl. Further purification was achieved by sublimation at 100°C (10^{-3} torr) to give **4a** (2.028 g, 6.848 mmol, 84%) as a white solid; mp 104°C. ^{1}H NMR (C_6D_6) δ: 7.4–7.0 (m, 5H, C_6H_5), 1.15 (d, $^4J_{H,P}$ = 1.20 Hz, 18H, C_4H_9); (THF-d_8) δ: 7.44–7.30 and 7.13–7.08 (m, 5H, C_6H_5), 1.16 (d, $^4J_{H,P}$ = 0.96 Hz, 18H C_4H_9). ^{13}C NMR (THF-d_8) δ: 131.93, 129.54, 128.65 (3s, C_6H_5), 52.77 (d, $^2J_{C,P}$ = 6.10 Hz, CMe_3), 32.28 (d, $^3J_{C,P}$ = 6.90 Hz, CMe_3). ^{11}B NMR (THF-d_8) δ: 35.4 (s). ^{31}P NMR (THF-d_8) δ: 181.2 (s). MS *m*/*z*: 281 ([M – Me]$^+$), 225 ([M – N-*t*-Bu]$^+$). Anal. calcd. for $C_{14}H_{23}BClN_2P$: C 56.69, H 7.82, N 9.44; found: C 56.13, H 7.34, N 9.28.

Preparation of PhB(μ-N-*t*-Bu)$_2$PBr (4b)

A colourless solution of **1a** (0.500 g, 1.024 mmol) in THF (15 mL) was added to a solution of PBr_3 (0.195 mL, 0.555 g, 2.049 mmol) in toluene (10 mL) at –40°C. After 5 min, the reaction mixture was allowed to reach room temperature, whereupon a pale yellow solution containing a yellow-orange solid (LiBr) was obtained. The reaction mixture was filtered through a PTFE filter disk after 3.5 h. The volatile materials were removed under vacuum to give a pale sticky yellow solid. *n*-Hexane (~10 mL) was added and the cloudy solution was transferred into another Schlenk vessel leaving a microcrystalline yellow solid (0.293 g) (mainly LiBr). After removal of the solvent from the decanted solution an off-white, slightly sticky solid was recovered. The solid was identified as [PhB(μ-N-*t*-Bu)$_2$]PBr (**4b**, 0.600 g, 1.764 mmol, 86%) by multinuclear NMR spectroscopy and single crystal X-ray structure analysis. Two 20-mg samples of **4b** were dissolved in Et_2O and in a mixture of Et_2O–*n*-pentane (1:1) (~3 mL) in test tubes and colourless prism-like crystals were obtained from both samples after four days at –19°C. ^{1}H NMR (C_6D_6) δ: 7.6–7.2 (m, 5H, C_6H_5), 1.22 (d, $^4J_{H,P}$ = 1.00 Hz, 18H, C_4H_9); (THF-d_8) δ: 7.44 (m, 2H, C_6H_5), 7.34 (m, 3H, C_6H_5), 1.19 (d, $^4J_{H,P}$ = 1.12 Hz, 18H, C_4H_9). ^{13}C NMR (THF-d_8) δ: 131.88, 129.76, 128.62 (3s, C_6H_5), 53.21 (d, $^2J_{C,P}$ = 5.84 Hz, CMe_3), 32.07 (d, $^3J_{C,P}$ = 6.65 Hz, CMe_3). ^{11}B NMR (THF-d_8) δ: 34.5 (s). ^{31}P NMR (THF-d_8) δ: 199.5 (s). MS *m*/*z*: 340 (M$^+$), 325 ([M – Me]$^+$), 261 ([M – N-*t*-Bu]$^+$). Anal. calcd. for $C_{14}H_{23}BBrN_2P$: C 49.30, H 6.80, N 8.21; found: C 48.57, H 8.63, N 7.81.

Preparation of PhB(μ-N-*t*-Bu)$_2$P[N(H)-*t*-Bu] (4c)

A colourless solution of Li[N(H)-*t*-Bu] (0.133 g, 1.688 mmol) in THF (10 mL) was added to a solution of **4a** (0.500 g, 1.688 mmol) in THF (15 mL) at –20°C. The reaction mixture was allowed to reach room temperature after 10 min. The volatile materials were removed under vacuum after 4 h to give a white solid. *n*-Hexane (10 mL) was added and the resulting solution was filtered through a PTFE filter disk to remove LiCl. The solvent was removed under vacuum to give **4c** as a white solid (0.454 g, 1.362 mmol, 81%); mp 60°C. IR (cm^{-1}): 3347 (NH). ^{1}H NMR (C_7D_8) δ: 7.5–7.0 (m, 5H, C_6H_5), 2.37 (s, 1H, N*H*), 1.90 (d, $^4J_{H,P}$ = 0.90 Hz, 9H, C_4H_9), 1.25 (s, 18H, C_4H_9); (THF-d_8) δ: 7.36–7.30 and 7.27–7.20 (m, 5H, C_6H_5), 3.26 (d, $^2J_{H,P}$ = 6.0 Hz, 1H, N*H*), 1.31 (d, $^4J_{H,P}$ = 1.07 Hz, 9H, C_4H_9), 1.12 (s, 18H, C_4H_9). ^{13}C NMR (THF-d_8) δ: 132.09, 128.01, 127.96 (3s, C_6H_5), 51.74 (s, CMe_3), 51.67 (s, CMe_3), 33.27 (d, $^3J_{C,P}$ = 6.14 Hz, CMe_3), 33.03 (d, $^3J_{C,P}$ = 9.34 Hz, CMe_3). ^{11}B NMR (THF-d_8) δ: 32.66 (s). ^{31}P NMR (THF-d_8) δ: 94.02 (s). Anal.

Preparation of {Li[PhB(μ-N-*t*-Bu)$_2$N-*t*-Bu]}$_2$ (5)

A solution of *n*-BuLi (2.5 M, 0.60 mL, 1.50 mmol) in hexanes was added to a solution of **4c** (0.500 g, 1.50 mmol) in *n*-hexane (10 mL) at –78°C. After 2.5 h, the solvent was removed from the golden yellow solution under vacuum to give **5** as a white solid (0.443 g, 1.306 mmol, 87%); mp 151°C (dec.). The ^{1}H, ^{13}C, ^{7}Li, and ^{11}B NMR spectra of THF-d_8 solutions of this product at 23°C indicate the presence of two components (**5A** and **5B**) in the approximate molar ratio 3:1.

5A: ^{1}H NMR δ: 7.38–7.14 (m, 5H, C_6H_5), 1.24 (d, $^4J_{H,P}$ = 1.13 Hz, 9H, *exo*-C_4H_9), 1.13 (s, 18H, *endo*-C_4H_9). ^{13}C NMR δ: 127.59, 127.41, 127.21 (3s, C_6H_5), 53.09 (d, $^2J_{C,P}$ = 25.6 Hz, *exo*-*C*Me$_3$), 52.13 (d, $^2J_{C,P}$ = 7.7 Hz, *endo*-*C*Me$_3$), 36.47 (d, $^3J_{C,P}$ = 6.5 Hz, *exo*-C*Me*$_3$), 33.49 (d, $^3J_{C,P}$ = 6.5 Hz, *endo*-C*Me*$_3$). ^{7}Li NMR δ: 0.39 (s).[4] ^{11}B NMR δ: 31.68 (s). ^{31}P NMR δ: 129.89 (s).

5B: ^{1}H NMR δ: 7.38–7.14 (m, 5H, C_6H_5), 1.32 (s, 9H, *exo*-C_4H_9), 1.18 (s, 18H, *endo*-C_4H_9). ^{13}C NMR δ: 133.03, 132.49, 132.18 (3s, C_6H_5), 56.84 (d, $^2J_{C,P}$ = 18.7 Hz, *exo*-*C*Me$_3$), 51.58 (d, $^2J_{C,P}$ = 8.2 Hz, *endo*-*C*Me$_3$), 35.92 (d, $^3J_{C,P}$ = 10.9 Hz, *exo*-C*Me*$_3$), 33.38 (d, $^3J_{C,P}$ = 4.8 Hz, *endo*-C*Me*$_3$). ^{11}B NMR δ: 37.21 (s). ^{31}P NMR δ: 68.10 (s). X-ray quality crystals were obtained from a solution of this solid (0.040 g) in C_7D_8 after 5 days at –19°C in an NMR tube. Satisfactory CHN analyses could not be obtained because of the extremely moisture-sensitive crystalline samples of **5**.

X-ray analyses

Crystals suitable for X-ray diffraction were obtained from solutions of the desired compounds in *n*-pentane at 23°C (**1a**, **1b**), in $CDCl_3$ at 23°C (**2**), in Et_2O or Et_2O–*n*-pentane at –19°C (**4b**), in *n*-hexane at –19°C (**4c**), and in C_7D_8 at –19°C (**5**). Single crystals of **1a**, **1b**, **2, 4b**, **4c**, and **5** were coated with Paratone oil, mounted on thin glass fibres, and frozen in the cold nitrogen stream of the goniometer or on a CryoLoop (nylon fibre).

Measurements for **1a** and **1b** were made on a Bruker AXS SMART/Platform 1000 CCD (ω-scans) and on a Bruker AXS SMART/PY/RA/SMART 1000 CCD (ϕ- and ω-scans) diffractometer, respectively. The data were reduced with SAINT (18*a*), which corrects for Lorentz and polarization effects, and corrected for absorption with SADABS (18*b*).

X-ray data for **2**, **4b**, **4c**, and **5** were collected on a Nonius Kappa CCD 4-circle Kappa FR540C diffractometer using ϕ- and ω-scans. Data reduction was performed with the HKL, DENZO, and SCALEPACK (18*c*) software, which corrects for beam non-homogeneity, possible crystal decay, and *Lp* effects, respectively. A multiscan absorption correction was applied (SCALEPACK) (18*c*).

Relevant parameters for the data collections and crystallographic data for **1a**, **1b**, **2**, **4b**, **4c**, and **5** are summarized in Tables 1 and 2.[5]

All structures were solved using direct methods (**1a**, **1b**, **4b**: SHELXS-97 (19*a*); **4c**: SHELXS-97–2 (19*b*); **2**: SIR-92 (20*a*); **6**: SIR-97 (20*b*)) and refined by full-matrix least-squares methods on F^2 with SHELXL97–2 (19*b*). The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included at geometrically idealized positions (C—H and N—H bond distances 0.95 Å) and were not refined. The isotropic thermal parameters of the hydrogen atoms were fixed at 1.2 times that of the corresponding carbon or nitrogen atom.

Two of the carbon atoms (C(50) and C(53)) of the *t*-Bu group attached to B(1) in **1b** were disordered around the mirror plane with partial occupancy factors of 0.5 each, leading to two possible orientations of the disordered *t*-Bu group: C(52), C(50), C(51), C(53) and C(53)*, C(50)*, C(52), C(51) (*: *x*, *–y* + 1/2, *z*).

In **4b**, one of the carbon atoms (C(13), C(13′) of one of the *t*-Bu groups was disordered around the mirror plane with partial occupancy factors of 0.62(2) and 0.38(2), respectively. In **4c**, the hydrogen atom connected to N(3) was located from the Fourier difference map.

Results and discussion

Synthesis and X-ray structures of {Li$_2$[RB(N-*t*-Bu)$_2$]}$_2$ (1a, R = Ph; 1b, R = *t*-Bu)

In a preliminary communication (15), we reported that the dilithio boraamidinate complexes {Li$_2$[RB(N-*t*-Bu)$_2$]}$_x$ (R = *n*-Bu, *x* = 2 (**1c**); R = Me, *x* = 2,3) were obtained by treatment of B[N(H)-*t*-Bu]$_3$ with three equivalents of the appropriate organolithium reagent. In this transformation the alkyl-lithium reagent functions as a base to dilithiate B[N(H)-*t*-Bu]$_3$ and as a nucleophile to displace the third *t*-BuNH group with an alkyl substituent.[6] Here we have demonstrated that aryl-lithium reagents can also be used in this new synthesis of boraamidinates. Thus {Li$_2$[PhB(N-*t*-Bu)$_2$]}$_2$ (**1a**) is obtained in 76% yield via eq. [1]. The preferred synthesis of **1a**, however, is the dilithiation of PhB[N(H)-*t*-Bu]$_2$, for which an improved procedure is described in the *Experimental* section (eq. [2]). The overall yield of **1a** from $PhBCl_2$ is ~73%; it is not necessary to separate the product from Li[N(H)-*t*-Bu] (cf. eq. [1]).

[3] Slightly low CHN values were obtained for three different samples. The product was, however, spectroscopically pure (^{1}H, ^{13}C, and ^{31}P NMR spectra) and showed no resonance for LiCl in the ^{7}Li NMR spectrum.

[4] Two very weak resonances were also observed in the ^{7}Li NMR spectrum at δ 1.07 and 1.60, but neither of these resonances were sufficiently intense to be attributable to **5B**. It is possible that the ^{7}Li NMR resonance for **5B** is hidden under the resonance at δ 0.39 for **5A**.

[5] Supplementary material may be purchased from the Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, ON K1A 0S2, Canada. For information on obtaining material electronically go to http://www.nrc.ca/cisti/irm/unpub_e.shtml. Crystallographic information has also been deposited with the Cambridge Crystallographic Data Centre (CCDC Nos. 181868 (**1a**), 181864 (**1b**), 181865 (**2**), 181866 (**4b**), 181867 (**4c**), and 181863 (**5**)). Copies of the data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033; or deposit@ccdc.cam.ac.uk).

[6] A similar transformation has been reported by Nöth et al. (21) for the lithiation of MesP(NH-*t*-Bu)$_2$ with *n*-BuLi, which produces {*n*-BuP[N(Li)-*t*-Bu]$_2$}$_2$·(OEt$_2$)$_2$ via the nucleophilic substitution of the mesityl group at the phosphorus(III) centre by an *n*-butyl group.

Note: Symmetry transformations used to generate equivalent atoms ′: $-x + 1/2, y, -z$.

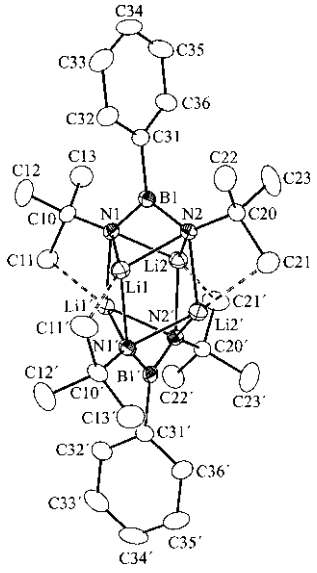
[1] $B[N(H)\text{-}t\text{-}Bu]_3 + 3LiPh \rightarrow 1/2\{Li_2[PhB(N\text{-}t\text{-}Bu)_2]\}_2 + Li[N(H)\text{-}t\text{-}Bu] + 2C_6H_6$

[2] $PhBCl_2 + 2LiN(H)\text{-}t\text{-}Bu \rightarrow PhB[N(H)\text{-}t\text{-}Bu]_2 + 2LiCl \xrightarrow{2n\text{-}BuLi} 1/2\{Li_2[PhB(N\text{-}t\text{-}Bu)_2]\}_2 + 2H\text{-}n\text{-}Bu$

We have also shown that the *tert*-butyl derivative $\{Li_2[t\text{-}BuB(N\text{-}t\text{-}Bu)_2]\}_2$ (**1b**) can be prepared in 81% yield by the reaction of $B[N(H)\text{-}t\text{-}Bu]_3$ with three equivalents of *t*-BuLi. It is interesting to compare this result with the related chemistry of transition-metal amides. The amido–niobium complex $[(THF)_2Li]_2[Nb(NMes)_3(NHMes)]$ (Mes = 2,4,6-$Me_3C_6H_2$) is lithiated by *t*-BuLi to give the tetrakisimidoniobate $(THF)_4Li_3[Nb(NMes)_4]$ (22*a*), whereas the reaction of the same complex with *n*-BuLi results in nucleophilic displacement of the amido ligand to give the alkyl–niobium complex $[[(THF)_2Li]_2n\text{-}BuNb(NMes)_3]$ (22*b*).

An intriguing observation, which was not reported in the earlier work (5, 6), is the appearance of persistent bright pink solutions when **1a**–**c** are exposed to air.[7] This transformation is reminiscent of the behaviour of solutions of the related dimeric clusters $\{Li_2[E(N\text{-}t\text{-}Bu)_3]\}_2$ (E = S, Se), which form deep blue (E = S) or green (E = Se) solutions upon air oxidation (23–25). These colours were attributed to the radicals $\{Li_3[E(N\text{-}t\text{-}Bu)_3]_2\}^{\bullet}$ on the basis of their EPR spectra, which consisted of a septet of decets with the appropriate relative intensities for the coupling of the unpaired electron with three nitrogen (^{14}N, 99.6%, $I = 1$) and three lithium

Fig. 1. ORTEP drawing of $\{Li_2[PhB(N\text{-}t\text{-}Bu)_2]\}_2$ (**1a**) (30% probability ellipsoids). Primed atoms are related by the symmetry transformation: $-x + 1/2, y, -z$.



(^7Li, 92.6%, $I = 3/2$) nuclei (24, 25). These neutral radicals are comprised of the radical anion $[E(N\text{-}t\text{-}Bu)_3]^{\bullet-}$ and the dianion $[E(N\text{-}t\text{-}Bu)_3]^{2-}$ bridged by three Li^+ ions. The pink solution of air-oxidized **1a** in toluene at 23°C exhibits a five-line EPR spectrum, but the hyperfine coupling with

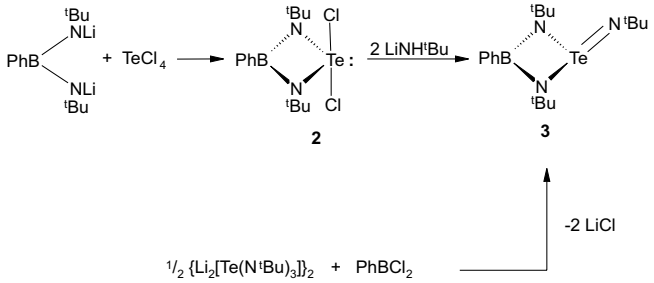
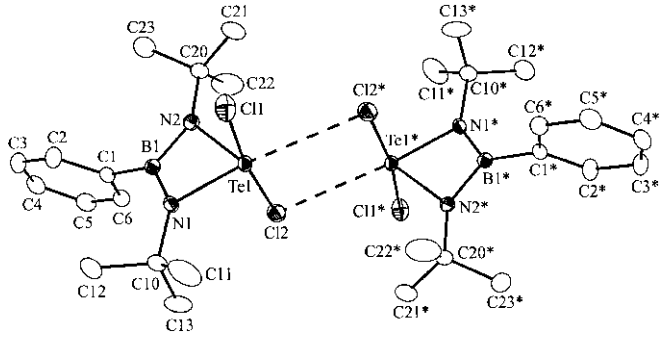
Scheme 1.



lithium centres is not resolved.[7] Consequently, we will not speculate on the identity of the radical species.

Because the structures of **1a** and **1b** were shown by X-ray crystallography to be similar, only the drawing of **1a** is shown (see Fig. 1). Pertinent structural parameters are compared in Table 3. The dimeric arrangement of **1a** and **1b** is similar to that previously reported for $\{Li_2[n\text{-BuB(N-}t\text{-Bu)}_2]\}_2$ (**1c**) (15); a detailed discussion here of the structures of **1a** and **1b** is therefore not warranted. All three structures consist of a distorted Li_4N_4 cube capped on two opposite faces by RB units, which are in a trigonal planar environment. Molecule **1b**, however, crystallizes in the space group $P2_1/m$ (cf. $P2_1/n$ for **1c**), imposing a mirror plane that bisects the cluster core at the atoms B(1), B(2), Li(2), Li(3), N(1), and N(2). Carbon atoms C(50) and C(53) of the *t*-Bu group attached to B(1) are disordered over two positions, each with site occupancy factors of 0.5. The replacement of the *n*-Bu groups attached to the boron atoms in **1c** with bulkier *t*-Bu groups results in lengthening of the B—N and B—C bonds (by ~0.02 and 0.05 Å, respectively) and contraction of the N-B-N angles (by ~3°). The weighted mean Li—N distance of 2.032 Å in **1b** is similar to that found for **1c** (2.037 Å), but the range of Li—N distances (1.976(4)–2.154(5) Å) is broader. The weighted mean distance of 2.226 Å for the agostic C–H···Li interactions in **1b** is significantly shorter (by ~0.2 Å) than that in **1c**, presumably as a result of the influence of the bulky *t*-Bu groups. Consistently, the mean C–H···Li contacts in **1a** (2.421 Å) are similar to the corresponding interaction exhibited by **1c** (2.440 Å).

Fig. 2. ORTEP drawing of $[PhB(\mu\text{-N-}t\text{-Bu})_2TeCl_2]_2$ (**2**) (30% probability ellipsoids). Starred atoms are related by the symmetry transformation: *–x, –y, –z*.



Phenylboraamidinate complexes of tellurium(IV)

We have shown earlier that a boraamidinate ligand stabilizes a monomeric tellurium imide in the complex $PhB(\mu\text{-N-}t\text{-Bu})_2Te{=}N\text{-}t\text{-Bu}$ (**3**) (14); however, the yield of this complex in the synthesis from $PhBCl_2$ and $\{Li_2[Te(N\text{-}t\text{-Bu})_3]\}_2$ was only 29%. Consequently, an alternative route to **3**, as depicted in Scheme 1, was investigated. The reaction of the monomer of **1a** with $TeCl_4$ in a 1:1 molar ratio produces $PhB(\mu\text{-N-}t\text{-Bu})_2TeCl_2$ (**2**) in 91% yield. The spirocyclic complex $[PhB(\mu\text{-N-}t\text{-Bu})_2]_2Te$ is obtained in 43% yield when a 2:1 stoichiometry is used for this reaction (7). Complex **2** was characterized by CHN analyses, multinuclear (^1H, ^{13}C, ^{11}B, and ^{125}Te) NMR spectroscopy,[8] and by an X-ray structural determination (vide infra). The subsequent reaction of **2** with two equivalents of Li[N(H)-*t*-Bu] produced **3** in ~40% yield. Although the improvement in the yield of **3** is modest, this new synthesis is preferable to the existing method using $\{Li_2[Te(N\text{-}t\text{-Bu})_3]\}_2$, (14) in view of the easier preparation of the reagents.

The structure of **2** was determined by X-ray crystallography (see Fig. 2). Selected bond lengths and bond angles are given in Table 4. Complex **2** forms a centrosymmetric dimer linked by weak Te···Cl interactions of 3.2411(6) Å (cf. sum of van der Waals radii for Te and Cl of 3.81 Å (27*a*) or 4.0 Å (27*b*)). Several bisamido or bisimido–tellurium dichloride complexes have been structurally characterized, including monomeric $[(Ph_3PN)_2TeCl_2$ (28), $(Ph_2CN)_2TeCl_2$ (29)],

[8] The ^{125}Te NMR resonance for **2** appears at δ 1677, which may be compared with the ^{125}Te chemical shifts of δ 1575 and 1693 observed for the inequivalent tellurium atoms in $t\text{-BuNTe}(\mu\text{-N-}t\text{-Bu})_2TeCl_2$ (26).

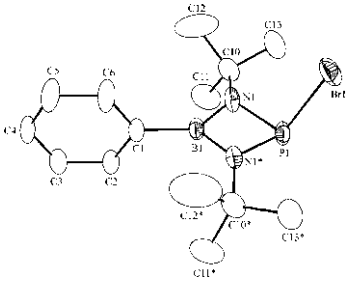
Fig. 3. ORTEP drawing of [PhB(μ-N-*t*-Bu)$_2$PBr] (**4b**) (30% probability ellipsoids).



dimeric [(Me$_3$PN)$_2$TeCl$_2$ (30), CF$_3$SNTeCl$_2$·THF (31)], or extended structures [{Cl$_2$Te(μ-N-*t*-Bu)$_2$TeCl$_2$}$_3$ (26), [(Me$_3$Si)$_2$N]$_2$TeCl$_2$ (32), MeN[PhBN(Me)]$_2$TeCl$_2$ (7), (Ph$_2$SN)$_2$TeCl$_2$ (29), and *t*-BuN(H)Sb(μ-N-*t*-Bu)$_2$TeCl$_2$ (33)[9]. The different degrees of oligomerization observed for closely related molecules suggest that packing considerations, influenced by subtle steric effects, are responsible for the presence (or absence) of association.

The boraamidinate ligand in **2** is symmetrically bonded to tellurium with equal B–N and Te–N bond lengths. The relevant bond angles (N(2)-Te(1)-N(1) = 69.33(7)°, Cl(2)*-Te(1)-N(1) = 168.06(2)°, Cl(2)*-Te(1)-N(2) = 108.97(2)°, Cl(1)-Te(1)-Cl(2) = 172.73(2)°) indicate that the tellurium atom in **2** is in a distorted pseudo-octahedral environment, with the lone pair occupying an octahedral site. The Te—N bond lengths (av 1.997 Å) can be compared with the values of 2.036 and 2.147 Å reported for the equatorial and axial bonds, respectively, in the spirocyclic compound [PhB(μ-N-*t*-Bu)$_2$]$_2$Te, which is a distorted trigonal bipyramid (7). The Te—Cl bond distances in **2** are significantly different (2.4356(6) and 2.6452(6) Å) as a result of the weak Te···Cl contacts, which are reflected by the non-linearity of the Cl-Te-Cl unit (172.73(2)°) and the Cl(2)-Te(1)···Cl(2)* bond angle (78.29(2)°) in the Te$_2$Cl$_2$ rectangle.

Phenylboraamidinate complexes of phosphorus(III)

We have also obtained boraamidinate complexes containing a phosphorus(III)–halogen bond in 85–95% yields by the reaction of **1a** with phosphorus trihalides (eq. [3]). The only previously reported P(III) complex is MeB(μ-N-*t*-Bu)$_2$PMe prepared by treatment of MeBBr$_2$ with (LiN-*t*-Bu)$_2$PMe (34). The complexes PhB(μ-N-*t*-Bu)$_2$PX (**4a**, X = Cl; **4b**, X = Br) were characterized by CHN analyses, multinuclear (^{1}H, ^{13}C, ^{11}B, and ^{31}P) NMR spectroscopy, mass spectrometry, and an X-ray structure determination of **4b**. The ^{1}H NMR spectra of **4a** or **4b** in C$_6$D$_6$ or THF-d_8 show resonances for the Ph and N-*t*-Bu groups with the appropriate intensities. The latter appears as a doublet owing to the four-bond ^{1}H–^{31}P coupling. ^{31}P NMR resonances are observed at δ 181 (**4a**) and 199 (**4b**) in THF-d_8 solution (cf. XP(μ-N-*t*-Bu)$_2$PX (δ 211, X = Cl; δ 224, X = Br)) (34). Surprisingly, the mass spectra of **4a** and **4b** show fragment ions corresponding to [M – Me]$^+$ and [M – N-*t*-Bu]$^+$ rather than [M – X]$^+$ implying a relatively strong covalent P–X (X = Cl, Br) bond. A molecular ion is observed for **4b**.

Table 5. Selected bond lengths (Å) and bond angles (deg) for **4b**.

Bond lengths (Å)		Bond angles (deg)	
Br(1)—P(1)	2.3047(11)	N(1)-P(1)-N(1)*	80.09(17)
P(1)—N(1)	1.688(3)	N(1)-P(1)-Br(1)	103.67(10)

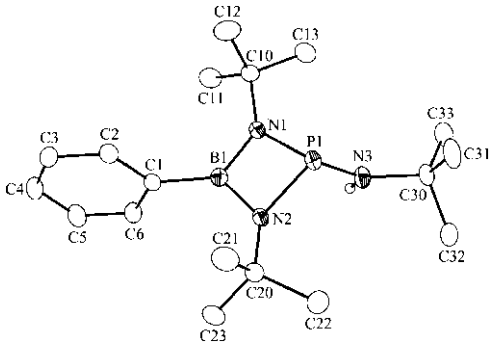
Fig. 4. ORTEP drawing of [PhB(μ-N-*t*-Bu)$_2$PN(H)-*t*-Bu] (**4c**) (30% probability ellipsoids).



[3] $$1/2\{Li_2[PhB(N\text{-}t\text{-}Bu)_2]\}_2 + PX_3 \rightarrow PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2PX \quad (X = Cl, Br)$$

The X-ray structure of **4b** is illustrated in Fig. 3 and selected bond lengths and bond angles are given in Table 5. The four-membered PNBN ring is slightly puckered (P(1)-N(1)-B(1)-N(1)* = 8.8(3)°) with symmetrically bridging N-*t*-Bu groups. The B–N bond lengths are in the typical range for phenylboraamidinate complexes (14) and the geometry at nitrogen is essentially planar. A search of the Cambridge Crystal Data Base revealed no structural information for cyclic P(III)–N compounds with exocyclic P–Br bonds. For example, the structure of the cyclodiphosph(III) azane BrP(μ-N-*t*-Bu)$_2$PBr is unknown (34). The P—N bond distance of 1.688(3) Å can be compared with values in the range 1.674(3)–1.689(9) Å for cyclodiphosph(III) azanes with Cl substituents attached to phosphorus (35, 36). The P—Br distance of 2.3047(11) Å is only slightly longer than the sum of the covalent radii for P and Br (2.24 Å) (27*b*), consistent with a strong covalent contribution to the P–Br bond.

The nucleophilic substitution reaction of **4a** with one equivalent of Li[N(H)-*t*-Bu] produced PhB(μ-N-*t*-Bu)$_2$PN(H)-*t*-Bu (**4c**) in ~80% yield. Amido derivative **4c** (see Table 6) was characterized by multinuclear (^{1}H, ^{13}C, ^{11}B, and ^{31}P) NMR and by X-ray crystallography (Fig. 4). The geometrical parameters of the phenylboraamidinate ligand in **4c** are similar to those discussed above for **4b**, although the four-membered ring is more puckered (torsion angle P(1)-N(1)-B(1)-N(2) = –12.50(13)°). The exocyclic P—N bond length of 1.6544(16) Å is ~0.1 Å shorter than

[9] The complex *t*-BuN(H)Sb(μ-N-*t*-Bu)$_2$TeCl$_2$ forms an extended structure involving weak Sb···Cl contacts rather than Te···Cl contacts (33).

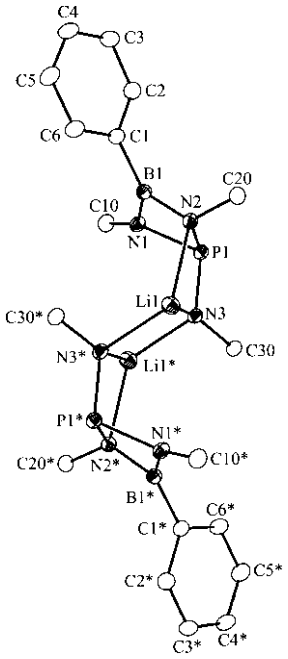
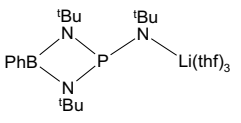
Fig. 5. ORTEP drawing of $\{Li[PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2PN\text{-}t\text{-}Bu]\}_2$ (**5**) (30% probability ellipsoids). Only the α-carbon atoms of *t*-Bu groups are shown. Starred atoms are related by the symmetry transformation: $-x + 2, -y, -z$.



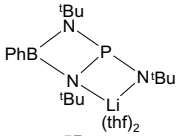
the mean endocyclic P–N bond distance and the geometry at N(3) is planar, suggesting a significant $p\pi$–$p\pi$ interaction between N(3) and P(1).

The reaction of **4c** with one equivalent of *n*-BuLi produced the monolithium derivative $\{Li[Ph(\mu\text{-}N\text{-}t\text{-}Bu)_2PN\text{-}t\text{-}Bu]\}_2$ (**5**), which was shown by X-ray crystallography to be a centrosymmetric dimer (Fig. 5). The monomeric units in **5** are formed by *N*,*N*′-chelation of the $[PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2N\text{-}t\text{-}Bu]^-$ anion to Li^+ through both the exocyclic and one of the endocyclic N atoms. As a result, one of the nitrogen atoms (N1) in the puckered PNBN ring (torsion angle P(1)-N(1)-B(1)-N(2) = 17.58(10)°) is three-coordinate, while the other (N2) is four-coordinate. As indicated in Table 7, this difference is reflected in an asymmetry in the B—N and P—N bond distances (1.4171(19) vs. 1.4762(19) Å and 1.7661(12) vs. 1.8114(12) Å, respectively). The relatively short P(1)—N(3) bond length (1.6403(12) Å) is comparable to the mean value of ~1.65 Å reported for the corresponding P—N bonds in $\{Li[P(N\text{-}t\text{-}Bu)_2]\}_4$ (37). The two monomeric units in **5** are linked by Li–N interactions to give a transoid ladder structure (38) with typical Li–N bond distances. The chelation of the $[PhB(\mu\text{-}N\text{-}t\text{-}Bu)_2PN\text{-}t\text{-}Bu]^-$ anion to Li^+ in **6** does not change the bond angles at the P(III) centre from those observed for **4c**.

The multinuclear (^1H, ^{13}C, ^7Li, ^{11}B, and ^{31}P) NMR data for **5** in THF-d_8 indicated the presence of two components, **5A** and **5B**, in solution in the approximate molar ratio 3:1. The relative intensities of the ^1H and ^{13}C NMR resonances for **5A** and **5B** both indicate C_6H_5, *endo*-*t*-Bu, and *exo*-*t*-Bu



5A



5B

© 2002 NRC Canada

groups in the ratio 1:2:1, consistent with the empirical formula Li[*t*-BuN(μ-N-*t*-Bu)$_2$BPh], in addition to a resonance for a three-coordinate boron atom. Both **5A** and **5B** exhibit singlets in the ^{31}P NMR spectra with chemical shifts of δ 129.9 and 68.1, respectively. It is well established that solvation of Li^+ centres in lithium derivatives of polyimido anions of *p*-block elements may lead to the disruption of polycyclic (cluster) structures or the stabilization of smaller aggregates (39). A pertinent example is the tetramer [Li{P(N-*t*-Bu)$_2$}]$_4$ (40), which forms the solvated dimer [(THF)Li{P(N-*t*-Bu)$_2$}]$_2$ in THF solution (41). Another, more dramatic, demonstration of this effect is the unraveling of the cyclic ladder structure of [Li$_2${C(N-*t*-Bu)$_3$}]$_2$ (42) upon solvation to give the open ladder [(THF)$_3$Li$_2${C(NPh)$_3$}]$_2$ (43). Although the imido (NR) groups are different in these two derivatives, the primary cause of the different structures is clearly the Li^+ centres. For **5**, in the presence of an excess of THF, the most likely solvated complexes are **5A** and **5B**. The former has equivalent endocyclic N-*t*-Bu environments, consistent with the ^{1}H NMR spectrum, while in **5B** this equivalence could arise as a result of exchange of the lithium centre between the two endocyclic nitrogen centres. Such fluxional processes in lithium derivatives of polyimido anions of *p*-block elements have low activation energies (39). The only significant change in the ^{31}P NMR spectrum over the temperature range 183–333 K was an adjustment of the relative amounts of **5A** and **5B** from 1.0:0.26 at 333 K to 1.0:0.65 at 183 K. In the ^{7}Li NMR spectrum, the singlet observed at δ 0.414 at 295 K was resolved into two resonances at δ 0.447 and –0.06 (1.0:0.57) at 233 K. In the ^{31}P NMR spectrum at 233 K the relative intensities of the two components were 1.0:0.61.

The origin of the difference of ~60 ppm in the ^{31}P NMR chemical shifts of **5A** and **5B** is not clear. Unfortunately, the NMR spectra of **5** in the non-coordinating solvent toluene are surprisingly complex and, consequently, do not shed further light on the solution species. The solid-state NMR spectrum of **5** show as a resonance at δ 113.35 with a shoulder at δ 111.28. The observation of a shoulder close to the main resonance is puzzling because **5** has an entrosymmetric structure. This may indicate the presence of a conformational isomer of **5** in the bulk sample that was used in the solid-state NMR experiment. For comparison, the solid-state ^{31}P NMR spectrum of **4c**, which is formed on hydrolysis of **5**, exhibits a singlet at δ 78.9.

In the light of recent work by Stahl et al. (42) on Ni(II) complexes of the mono-anion *cis*-[*t*-BuOP(μ-N-*t*-Bu)$_2$PN-*t*-Bu]$^-$, the ligand behaviour of [PhB(μ-N-*t*-Bu)$_2$PN-*t*-Bu]$^-$ towards transition metals offers the interesting possibility of the involvement of the P(III) centre in the coordination sphere.

Conclusions

Complexes **2**, **4a**, and **4b** are the first examples of boraamidinates-containing element–halide bonds, which provide an opportunity to explore the properties of the boraamidinate ligand via functionalization of the main-group element centre, e.g., in the formation of the monomeric tellurium imide **3** and the chelating P(III) monoanion **5**. An interesting feature of dilithiated boraamidinate complexes, which is not observed for the corresponding amidinates, is the formation of long-lived radicals upon oxidation. Detailed EPR studies will be necessary to characterize these radicals. This propensity for radical formation is likely to lead to interesting chemistry in future investigations of metal–halogen exchange reactions of lithium boraamidinates, especially for those metals which have two (or more) readily accessible oxidation states.

Acknowledgments

We thank the Natural Science and Engineering Research Council of Canada (NSERC) for financial support, Dr. R. McDonald (University of Alberta) for X-ray data collection of **1a** and **1b**, and Dr. M. Parvez for advice in the refinement of the X-ray structures.

Peptide model XXVIII: An exploratory ab initio and density functional study on the side-chain–backbone interaction in *N*-acetyl-L-cysteine-*N*-methylamide and *N*-formyl-L-cysteinamide in their γ_L-backbone conformations

M.A. Zamora, H.A. Baldoni, A.M. Rodriguez, R.D. Enriz, C.P. Sosa, A. Perczel, A. Kucsman, O. Farkas, E. Deretey, J.C. Vank, and I.G. Csizmadia

Abstract: A conformational and electronic study on the energetically preferred conformations (γ_L) of N- and C-protected L-cysteine (P-CONH-CH(CH_2SH)-CONH-Q, where P and Q may be H or Me) was carried out. After restraining the backbone (BB) conformation to its global minimum (γ_L or C_7^{eq}), all nine possible side-chain (SC) conformations were subjected to geometry optimization at the HF/3–21G and the B3LYP/6–31G(d,p) levels of theory. Seven of the nine side-chain conformers were located on the potential-energy surface. All conformers were subjected to an AIM (atoms in molecules) analysis. This study indicates that three of the seven optimized conformers exhibited either or both SC → BB- or BB → SC-type intramolecular hydrogen bonding. Five conformers, however, had distances between a proton and a heteroatom that suggested hydrogen bonding.

Key words: L-cysteine diamides, side-chain potential-energy surface, ab initio and DFT geometry optimization, AIM analysis, intramolecular hydrogen bonding.

Résumé : On a réalisé une étude conformationnelle et électronique des conformations énergétiquement privilégiée (γ_L) de la L-cystéine N- et C-protégée (P-CONH-CH(CH_2SH)-CONH-Q; P et Q peuvent être égaux à H ou à Me). Ainsi, en retreignant la conformation du squelette (BB) à son minimum global (γ_L ou C_7^{eq}), on a soumis les neuf conformations possibles pour la chaîne latérale (SC) à une optimisation de la géométrie aux niveaux HF/3–21G et B3LYP/6–31G(d,p) de la théorie. Sept des neuf conformères de la chaîne latérale se situent sur la surface d'énergie potentielle. Tous les conformères ont été soumis à une analyse par la méthode des atomes dans les molécules (AIM). Cette étude indique que trois des sept conformères optimisés présentent l'une ou l'autre ou les deux types de liaisons intramoléculaires SC → BB ou BB → SC. Toutefois, dans cinq des conformères les distances entre un proton et un hétéroatome suggèrent l'existence d'une liaison hydrogène.

Mots clés : diamides de la L-cystéine, surface d'énergie potentielle de la chaîne latérale, optimisation ab initio et DFT de la géométrie, méthode des atomes dans les molécules (AIM), liaison hydrogène intramoléculaire.

Introduction

Cysteine (Cys) is the sulfur analogue of serine (Ser). Both amino acid residues may conveniently be studied computationally in their N- and C-protected forms; Fig. 1 shows *N*-acetyl-L-Cys-*N*-methylamide (**I**) and *N*-formyl-L-Cys-amide (**II**). *N*-Formyl-L-Ser-amide (**III**) has already been studied extensively (1–5) as a continuation of a general investigation including Gly (6, 7), Ala (6–8), Val (9), and Phe (10–12).

In many ways the cysteine residue is similar to serine; one therefore expects the -CH_2-SH moiety of cysteine to be in-

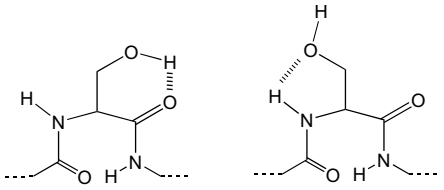
volved in intramolecular hydrogen bonding similar to that demonstrated in Fig. 2 for the -CH_2-OH group of serine.

Cysteine, a residue with a polar side chain, is often located on the surface of proteins, and thus is directly involved in various biochemical interactions. Cysteine can mediate structural changes, improve hydration of accessible area, or participate in intermolecular interactions. Thus, cysteine is frequently involved in a wide range of enzymatic reactions including those of cysteine proteases (13–15). In Scheme 1, a simplified mechanism of cysteine protease (HS-E-Im) is shown, where HS symbolizes the mercaptan side chain of a cysteine residue and Im denotes the imidazole moiety in the side chain of a histidine residue. The enzyme is not active at low pH due to protonation at Im, and it is also inactive at high pH due to deprotonation of the SH group. It is only active at neutral pH when internal proton transfer is possible from the SH group to Im.

A schematic mechanism for the hydrolysis of the peptide bond with the catalytic action of cysteine protease is shown in Scheme 2.

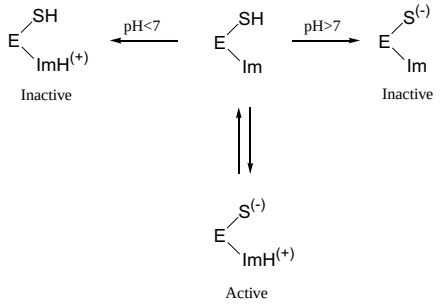
In addition to regular cysteine proteases, there are numerous other enzymes that contain free-sulfhydril groups. For example, there is a cysteine-containing enzyme called *transglutaminase*, which does not hydrolyze peptide bonds, but instead transfers an acyl group from one nitrogen to another. This field of study has recently been extensively reviewed (16). Vigorous theoretical investigations of this cysteine-containing pro-enzyme is currently being pursued by other research groups (17).

Fig. 2. A schematic representation of possible intramolecular hydrogen bonds for serine.



A **B**

Scheme 1.



The full conformational space of compound **I** was recently explored by ab initio RHF/3–21G computations (18). On the Ramachandran hypersurface of four independent variables $E = f(\phi, \psi, \chi_1, \chi_2)$ (Fig. 1), 47 conformers were located instead of the expected $3^4 = 81$ stable structures. The relative stabilities of the various conformers were analyzed in terms of side-chain–backbone interactions covering both hydrogen bonding and charge-transfer types. These results indicated that the γ_L-backbone conformation is the preferred form for this compound. In the present report, we have mainly focused our attention on the conformational intricacies of compound **I**, while restricting the backbone conformation to its global minimum (γ_L). A comparative study using different levels of theory of compounds **I–III** was also carried out.

Methods

Conformational analysis

IUPAC-IUB (19) recommended the use of $0° \rightarrow +180°$ in the clockwise direction for rotation and $0° \rightarrow -180°$ for counter-clockwise rotation (Scheme 3). For side-chain torsions, this implied the following range: $-180° \leq \chi_1 \leq 180°$ and $-180° \leq \chi_2 \leq 180°$. On the Ramachandran map, the $-180° \leq \phi \leq 180°$ and $-180° \leq \psi \leq 180°$ cut is indicated by the square drawn in broken lines (Fig. 3).

But for the graphical presentation of the side-chain conformational potential-energy surface (PES), we used the traditional cut ($0° \leq \chi_1 \leq 360°$ and $0° \leq \chi_2 \leq 360°$), similar to that previously suggested by Ramachandran and Sasisekharan (20).

Molecular computations

Initially, the nine side-chain conformations of cysteine in its γ_L-backbone conformation were determined using the topologically probable set of conformers as predicted by multidimensional conformational analysis (MDCA) (21–23).

Scheme 2.

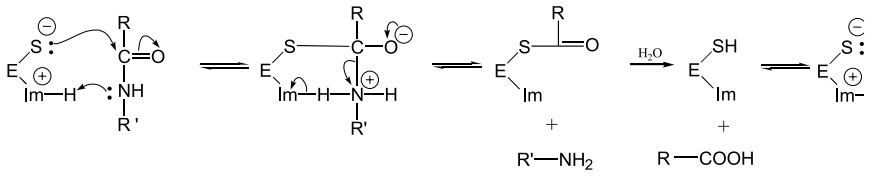

Table 1. Total energy values (Hartree) of the component molecules for isodesmic reactions.

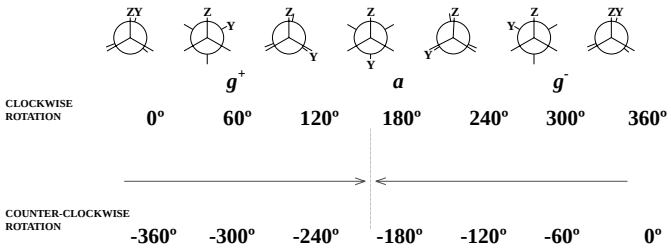
Molecular system	HF/3–21G			B3LYP/6–31G(d,p)		
P-CONH-CH_2-CONH-**Q**	P = Q = H		P = Q = Me	P = Q = H		P = Q = Me
γ_L	–373.6487900		–451.2942433	–377.9165567		–456.5553698
β_L	–373.6477487		–451.2931883	–377.9158533		–456.5536252
CH_3-**R**	R = CH_2-SH	R = CH_2-OH	R = H	R = CH_2-SH	R = CH_2-OH	R = H
	–474.3472547	–153.2226808	–39.976877	–478.0228756	–155.0462074	–40.5238417

Scheme 3.



To investigate the side-chain–backbone conformational interaction effects, calculations were performed on compounds **I** and **II** using the Gaussian 94 (24) program at the RHF/3–21G (25) level of theory. This lower level is suitable for the purpose of comparing the present results with those obtained for serine (1, 2), even though the current trend is to rely on larger basis sets at a higher level of theory (8, 26). For this reason, geometry optimizations were also carried out for compounds **I** and **II** at the B3LYP/6–31G(d,p) level of theory.

Stabilization energies

The stabilization energies were calculated with respect to γ_L- as well as to $\beta_L(C_5)$-backbone conformation of N- and C-protected glycine (9, 27) using the following isodesmic (same number of the same type of bonds) reaction, where P and Q may be H (**II**) or CH_3 (**I**) and R = CH_2-SH:

$$\underset{\text{reference conformation } \gamma_L \text{ or } \beta_L}{\text{P-CONH-CH}_2\text{-CONH-Q} + \text{CH}_3\text{-R}} \rightarrow \underset{\text{conformation X}}{\text{P-CONH-CHR-CONH-Q}} + \text{CH}_3\text{-H}$$

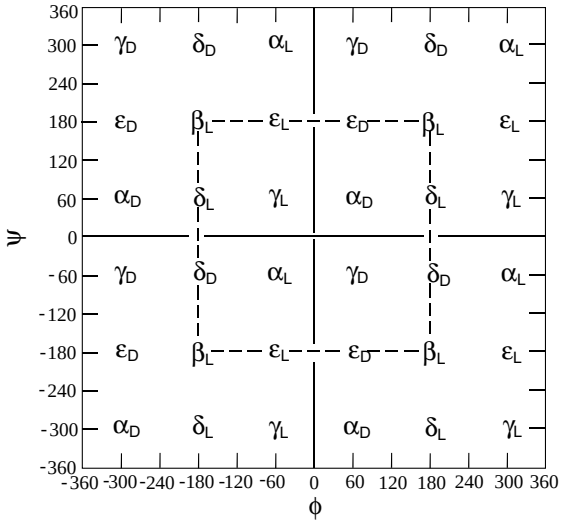
The stabilization energy may be calculated as follows:

$$\Delta E_{\text{stabil}} = \{E[\text{P-CONH-CHR-CONH-Q}]_X + E[\text{CH}_3\text{-H}]\} - \{E[\text{P-CONH-CH}_2\text{-CONH-Q}]_{\gamma_L \text{ or } \beta_L} + \text{CH}_3\text{-R}]\}$$

The energy values of the components are summarized in Table 1.

The results of the structure optimizations, namely, geometrical parameters, total energies, relative energies, and stabilization energies, are given in Tables 2–4. The total energies are given in Hartrees, and the relative energies and stabilization energies in kcal mol^{-1} (using the conversion factor: 1 Hartree = 627.5095 kcal mol^{-1}). The numbering system used for *N*-acetyl-L-cysteine-*N*-methyl amide (P = Q = Me) and *N*-formyl-L-cysteinamide (P = Q = H) is shown in Fig. 1.

Fig. 3. Topological representation of the Ramachandran map for an N- and C-protected amino acid P-CONH-CHR-CONH-Q (P and Q may be H or CH_3) showing two full cycles of rotation: $-360° \le \phi \le +360°$; $-360° \le \psi \le +360°$. The central box, denoted by broken line, represents the cut suggested by the IUPAC convention. The four quadrants denoted by solid lines are the conventional cuts. Most peptide residues exhibit nine unique conformations labeled as α_D (α_{LEFT}), ε_D, γ_D (C_7^{ax}), δ_L (β_2), β_L (C_5), δ_D (α'), γ_L (C_7^{eq}), ε_L, and α_L (α_{RIGHT}).



Topological analysis of electron density

The topology of the electron density was analyzed using AIM (atoms in molecules) (28). In this analysis, the gradient $[\nabla\rho(r)]$ and the Laplacian $[\nabla^2\rho(r)]$ play important roles. A critical point of the electron density along the line of two interacting atoms in a molecule is called the bond critical point (BCP), where $\nabla\rho(r) = 0$.

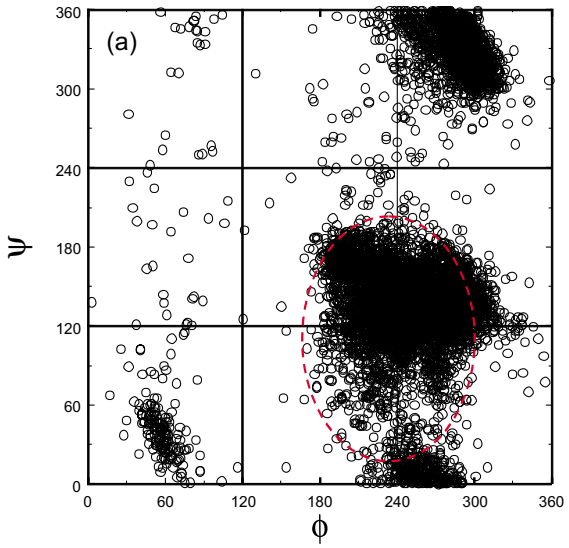
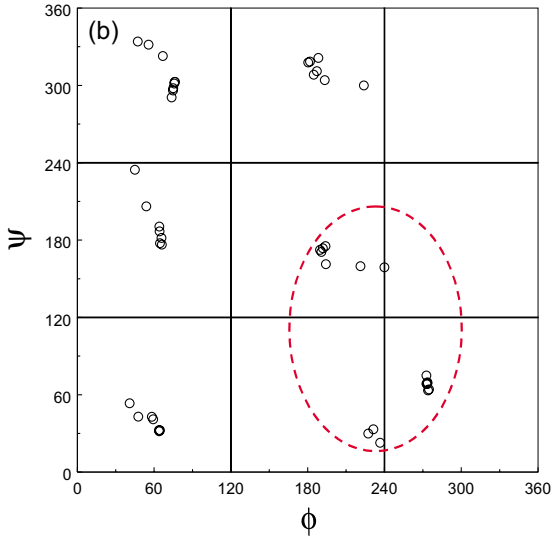
Fig. 4. (*a*) Backbone conformers of all 10122 Cys residues taken from 974 non-homologous proteins (31). Using their backbone-dihedral parameters, all of the above Cys residues were plotted on a [ϕ, ψ] map. (*b*) Locations of calculated ab initio RHF/3–21G MeCO-Cys-NHMe backbone conformers (18) on a [ϕ, ψ] map.





The bond path is made up of a pair of gradient paths, originating at a BCP and terminating at a neighbouring nuclei. The necessary condition for two atoms to be bonded to each other is that their nuclei must be linked by a bond path. The bond path is regarded as "a universal indicator of bonded interaction" (29). The method is widely used for proving the existence of hydrogen bonds (30).

Results and discussion

The comparison of structural parameters from experimental databases (X-ray and NMR) with the ab initio (RHF/3–21G) results is an excellent validation of the computed results. Thus, the comparison of relative energies and the relative probabilities of conformers using a non-homologous database is a possibility for this cross-validation. Let us truncate the backbone of a protein into building units, e.g., amino acid diamides. We will assume that the probability of conformers in proteins depends only on its relative energy. This is a model where several stabilizing factors are neglected, such as inter-residue interactions, long-range effects, and hydration. By acknowledging the limitations of this approach, it is possible to correlate the relative energy of a conformer and the relative probability of the same backbone structure in an ensemble of proteins with known X-ray and NMR structures.

Using a recent (February 2002) X-ray- and NMR-determined protein data set of non-homologous proteins

Fig. 5. The possible nine molecular conformations of MeCO-Cys-NHMe. The two conformations that are crossed over are not minima, the remaining seven were located during HF/3–21G optimization.

(31), a population-distribution map was generated (Fig. 4*a*). The backbone conformers of 10122 Cys residues, found in a total of 974 proteins, were plotted, showing ϕ vs. ψ values (Fig. 4*a*). The overall appearance of the Ramachandran surface is similar to other previously reported Ramachandran maps (Phe (12) and Ser (32)). Thus Cys shows an "average conformational character."

To perform a comparison between calculated and observed backbone conformers, an additional plot was made with the RHF/3–21G results (Fig. 4*b*). Comparing these data a promising overall similarity emerged. In the highly populated extended β-strand (β_L) and inverse γ-turn (γ_L) region, the location of the RHF/3–21G model structures and the largest probability of experimental- backbone conformers taken from the protein databases are similar (zone denoted with dotted lines in Fig. 4).

It should be noted that the seven γ_L conformers and the seven β_L conformers, together with the three δ_L conformers, are a subgroup formed by the most stable conformers of compound **I**. This low-energy region of the Ramachandran map (often quoted as the β region) is also the most dense area if X-ray- and NMR-determined main-chain probabilities are investigated. Such a correlation permit us to assume that if the diamide model is relevant to the description of main-chain folding of proteins, then the most stable conformers should have the lowest energy.

On the basis of the above results, in the present study we focused our attention on the conformational intricacies of the highly preferred backbone conformation of compounds **I** and **II**, this being the γ_L form.

Conformational study

The nine side-chain conformations, topologically predicted on the basis of MDCA, are depicted for compound **I** in Fig. 5. Two of the structures (g^+g^- and *aa*) are crossed out, since they were not found. On the basis of the $E = f(\chi_1, \chi_2)$ potential-energy surface (PES) generated for HCO-Ser-NH_2 (1), one may anticipate that these minima were eliminated due to a high-energy region or "mountain ridge" formed along the disrotatory diagonal axis. The other seven minima,

Fig. 9. Structures located on the side-chain PES of the γ_L-backbone conformations of N- and C-protected serine and cysteine. The stabilization energies (ΔE_{stabil}, kcal mol^{-1}) exerted by the side chain with respect to the glycine residue in its γ_L conformation are shown in brackets.

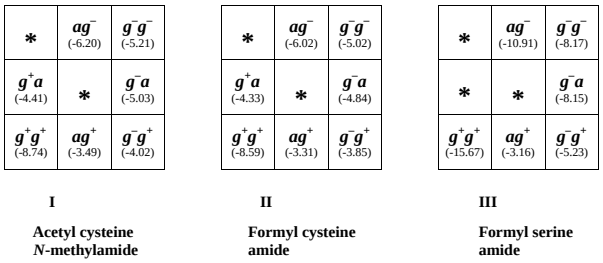

Fig. 10. Spectrum of conformational dependence of the side-chain stabilization energy on the γ_L-backbone conformation of protected Ser and Cys.

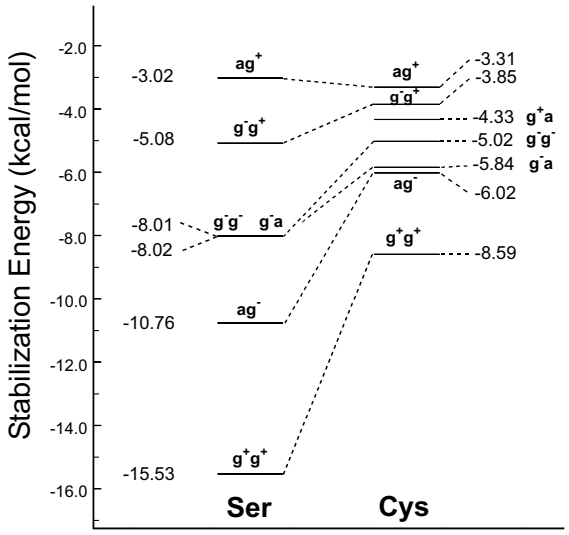


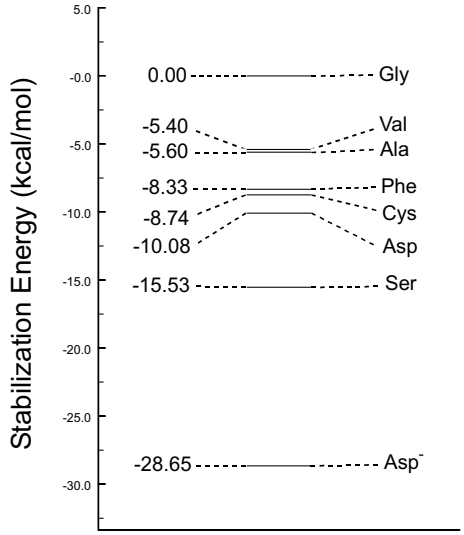
however, were successfully geometry optimized at the HF/3–21G level of theory (Table 2).

The structures of **I** and **II** were geometry optimized at the HF/3–21G level of theory and further optimized at the B3LYP/6–31G(d,p) level of theory (Tables 2 and 3). Their relative energy values are shown in a topological fashion in Fig. 6. For full comparison, HCO-Ser-CONH$_2$ (**III**) conformations were also evaluated at the B3LYP/6–31G(d,p) level of theory (Table 4).

The reliability of the HF/3–21G level of computations can be investigated here since we have results from HF/3–21G and B3LYP/6–31G(d,p) levels. The relative energies (ΔE_{rel}) of compounds **I**–**III**, computed at the two levels of theory, are compared in Fig. 7. Since the global minimum on the relative energy scale is, by definition, always zero, in order for the fitted line to pass over the origin, a $y = mx$ equation was fitted to the data points. While the slopes of the fitted lines are never unity, it is clear that the HF/3–21G results reproduce the trend quite well.

In addition to the relative stabilities, the accuracy of the key torsional angles (in the present case, ϕ, ψ, χ_1, χ_2, ω_0, and ω_1) is of great importance. The correlation of the above torsional angles computed at two levels of theory for compounds **I**–**III** are shown in Fig. 8. The least-square fit was of the type $y = mx + b$. For the cysteine and serine residues, m is not unity nor is b zero. The fitted lines, however, suggest a surprisingly good correlation.

Fig. 11. Relative side-chain stabilization energy values of various amino acids in the γ_L-backbone conformation.



Stabilization energies

Stabilization energies emerging from side-chain interaction with the backbone are traditionally calculated (7, 27) with respect to the global minimum, i.e, the γ_L conformation. It has been noted recently (33), however, that during the *cis*–*trans* isomerization process, the γ_L conformation may disappear for at least some of the amino acids. In other words, the γ_L conformer does not exist as a minimum-energy conformation on some of the *cis*-Ramachandran maps. For this reason, an alternative backbone conformation β_L was selected for calculating the stabilization energy (ΔE_{stabil}). The method of calculation, as outlined in the *Computational methods* section, is the same, but instead of the γ_L conformation of glycine, the β_L conformation is chosen as the reference conformation. Such a new standard may be important in the future, when an ab initio peptide database may include both *cis* and *trans* peptides. Nevertheless, the $\Delta E_{stabil}(\gamma_L)$ values are more practical if we wish to make comparisons with previously reported values.

Figure 9 compares $\Delta E_{stabil}(\gamma_L)$ values for compounds **I**–**III**. It is reassuring to see that the effect of the side-chain stabilization is not affected substantially if we change the protecting group from formyl to acetyl at the nitrogen end and from amide to methylamide at the carboxyl end.

The *N*-acetyl and *N*-methyl amide protecting groups of cysteine **I** are stabilized by the CH$_2$-SH side chain by ~0.16 kcal mol^{-1} more when compared with the same side chain stabilizing the *N*-formyl-cysteinamide (**II**) backbone. There are, however, marked differences when the oxygen is changed to sulfur in the side chain. Undoubtedly, such a change between serine and cysteine, as seen in Fig. 9, is also present in the relative energy values (ΔE_{rel}) presented in Fig. 6. The stabilization energy values are not only numerically different for Ser and Cys but they are also decreased

for Cys and increased for Ser, as seen in Fig. 10. When the global minima are compared, the side chain of Cys is stabilizing the backbone more than that of Phe but less than those of Asp and Ser. Such a "spectrum" of side-chain stabilization is presented in Fig. 11.

The size difference between O and S could play a major role in producing such remarkable energy differences. Additionally, since both make the same kinds of hydrogen bonds it is reasonable to assume that the Ser side chain is more favourably stabilizing than the Cys side chain because hydrogen bonds to and from oxygen atoms are stronger than sulfur atoms. This result is not surprising, since methanol is a liquid and methanethiol is a gas. This is in agreement with the ordering of the g^+g^+, g^+a, and ag^- conformations discussed in the next section.

Intramolecular interactions

The three types of intramolecular interactions, which may occur in the various conformers of cysteine, are shown in Fig. 12. The characteristic distances and angles, as well as the classification of interactions, are summarized in Table 5. Only the g^+a conformer has a heteroatomic distance that is short enough to suggest an O → S charge-transfer interaction.

In agreement with the data presented in Table 6, AIM analysis revealed that extensive side-chain–backbone intramolecular hydrogen-bonding-type interactions exists in three of the seven conformers. These were found to be g^+g^+, g^+a, and ag^-. Taking into account the distances and angles, however, we might consider that five of the seven γ_L conformations are stabilized by hydrogen bonding interactions (Table 5).

The g^+g^+ conformer has the greatest number of hydrogen bonds, so it is not surprising that it emerges as being the global minimum. In addition to the hydrogen bond, which is characteristic of the seven-member ring of the γ_L-backbone conformation, there are two additional hydrogen bonds corresponding to side-chain → backbone (C=O··H-S) and

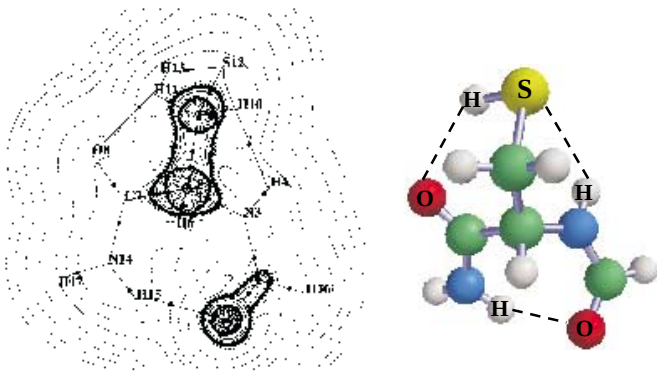

Fig. 14. The contour map of the Laplacian of the electron density for the (g^+a) conformation of HCO-Cys-NH_2 calculated at the B3LYP/6–31+G(d,p)//RHF/3–21G level of theory. Bond paths are denoted by lines, bond critical points (BCPs) are denoted by black dots, ring critical points (RCPs) are denoted by open triangles, and the nuclei are denoted by crosses.

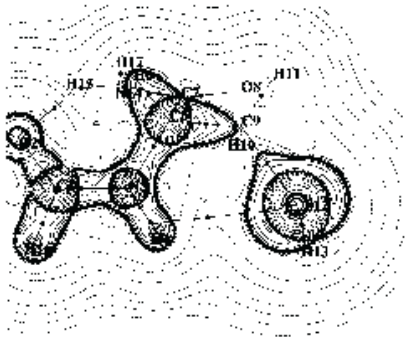

backbone→side-chain (N-H··S-H)-type hydrogen bonding (Fig. 13). The three ring-critical points, associated with the rings formed as the result of intramolecular hydrogen bonding are denoted by open triangles (Δ). The various BCPs are symbolized by solid dots (●).

Beyond the characteristic hydrogen bonding associated with the seven-member ring of the γ_L-backbone conformation, the g^+a conformer also exhibited an N-H··S-H-type hydrogen bonding. In Fig. 14, the ring-critical points are shown by open triangles (Δ) and the various BCPs are symbolized by solid dots (●).

Figure 15 shows the ag^- conformation, featuring a C=O··H-S hydrogen bond in addition to the hydrogen bond associated with the seven-member ring of the γ_L-backbone conformation.

In addition to these side-chain–backbone-type of hydrogen bonds, there exists the backbone—backbone C=O··H-N-type of hydrogen bond, typical in the seven-member ring of the γ_L conformer.

Conclusions

In summary, we found seven different conformations for the side chain of compounds **I** and **II** when the backbone is in γ_L form. These results suggest that the side-chain stabilization is not substantially affected if we change the protecting group from formyl to acetyl at the nitrogen end and from amide to methylamide at the carboxyl end. In contrast, noticeable differences were found when comparing the conformational intricacies of compounds **II** and **III**: only six different conformations were obtained for compound **III** and the order of preference is also different. DFT calculations proved that polar side chains are able to interact with a peptide backbone, eliminating some otherwise legitimate minima through unfavourable backbone and side-chain torsional-angle combinations. The comparative study between compounds **II** and **III** illustrates this point very well. On the basis of our results, we might assume that the strength of hydrogen bonding involved is responsible for the different conformational behavior obtained for these compounds. On the other hand, it is interesting to note that both levels of theory (HF/3–21G and B3LYP/6–31G(d,p)) displayed closely related results indicating that HF/3–21G calculations are satisfactory to use in exploratory conformational studies.

Ab initio and DFT conformational analysis of selected flavones: 5,7-dihydroxyflavone (chrysin) and 7,8-dihydroxyflavone

Ken S. Lau, Athena Mantas, Gregory A. Chass, Fernando H. Ferretti, Mario Estrada, Graziela Zamarbide, and Imre G. Csizmadia

Abstract: Ab initio and DFT conformational analysis was performed on the flavone derivatives chrysin (5,7-dihydroxyflavone; 2-phenyl-5,7-dihydroxy-4*H*-1-benzopyran-4-one) and 7,8-dihydroxyflavone (2-phenyl-7,8-dihydroxy-4*H*-1-benzopyran-4-one). The structural features required for optimal stabilization in each molecule were identified. It was discovered that sparsely placed hydroxyl groups, particularly with hydrogen bond-like interactions, resulted in lowering the potential energy minimum for the molecules. It was also noted that one of the factors capable of destroying co-planarity was steric interference between closely placed functional groups across the phenyl and the benzo-γ-pyrane ring. Studies performed on the radical forms of the flavonoids, however, showed that the unpaired electron is confined only to the benzo-γ-pyrane ring, and not delocalized across the phenyl ring.

Key words: flavonoid, flavone, chrysin, ab initio conformational analysis, anti-oxidant, free radical, 5,7-dihydroxyflavone, 7,8-dihydroxyflavone.

Résumé : On a effectué une analyse conformationnelle ab initio et « DFT » sur des dérivés de la flavone: la chrysine (5,7-dihydroxyflavone; 2-phényl-5,7-dihydroxy-4*H*-1-benzopyran-4-one) et la 7,8-dihydroxyflavone (2-phényl-7,8-dihydroxy-4*H*-1-benzopyran-4-one). On a identifié les caractéristiques de la structure qui sont nécessaires pour une stabilisation maximale de chaque molécule. On a découvert que les groupes hydroxyles parsemés, particulièrement ceux avec des interactions de type liaisons hydrogènes, conduisent à des abaissements du minimum de l'énergie potentielle pour les molécules. On a aussi noté que l'interférence stérique entre des groupes fonctionnels situés à proximité l'un de l'autre sur le noyau phényle et le cycle benzo-γ-pyrane est un facteur susceptible de détruire le caractère coplanaire. Toutefois, des études effectuées sur les formes radicalaires des flavonoïdes ont permis de montrer que l'électron célibataire est confiné uniquement sur le cycle benzo-γ-pyrane et qu'il ne se délocalise pas sur le noyau phényle.

Mots clés : flavonoïde, flavone, chrysine, analyse conformationnelle ab initio, antioxydant, radical libre, 5,7-dihydroxyflavone, 7,8-dihydroxyflavone.

Introduction

Aging is thought to be associated with various free radical reactions, a series of processes within the body collectively known as "oxidative stress." Generated as by-products of metabolism, free radicals are short-lived, but highly reactive intermediates. Because of the presence of at least one unpaired electron, free radicals will constantly seek to react with other molecules for stabilization. They will react with cellular structures, altering DNA and destroying membranes through lipid peroxidation (1–3). It is proposed that through these processes, age-related degenerative diseases like cancer are induced.

By supplementing a diet with molecules that act as scavengers of these free radicals (anti-oxidants) oxidative damage can be greatly reduced. Anti-oxidants are defined as "any substance that, when present at low concentrations compared with those of an oxidizable substrate, significantly delays or prevents the oxidation of that substrate" (4*a*). They are molecules with the ability to stabilize free radicals and render them harmless. There are various anti-oxidants under study today, some of which include L-ascorbic acid (vitamin C), α-tocopherol (vitamin E), β-carotene, lycopene, and coenzyme Q (4*b*). The molecules of interest in this paper, a class of compounds called flavonoids, also act as anti-oxidants.

Flavonoids are polyphenolic compounds found in many types of plants, occurring mainly as glycosides in fruits, vegetables, nuts, seeds, flowers, and bark (5, 6). The basic structure

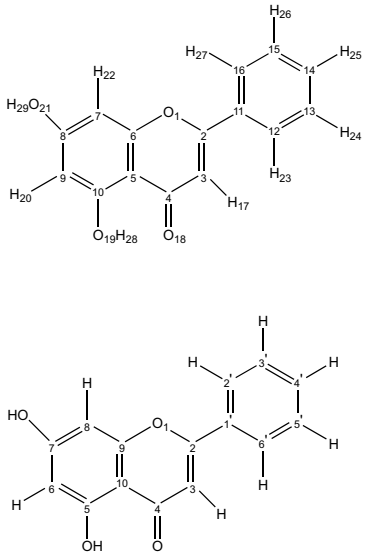
of these compounds resembles that of the parent flavone molecule, which consists of a phenyl group attached to a benzo-γ-pyrane ring (7) (Fig. 1). Because of their anti-aging effects, flavonoids and their derivatives are beginning to receive attention in commercial products, for example, anthocyanidin in ENOCH© grape extract. In 1936, the biological benefits of flavonoids were first introduced by Szent-Gyorgyi (8). These compounds were first thought to reduce arteriole hardening, which is an age-related ailment attributed to free radical oxidations within the body. Furthermore, a subclass of flavonoids called flavonols is the major polyphenolic anti-oxidant found in red wines (9). A statistical analysis performed on the population of France reports that people who consume red wine on a regular basis have a reduced risk of coronary heart diseases (5, 9). It is suggested that flavonols reduce coronary heart disease by preventing oxidation of low-density proteins by free radicals (9).

The exact mechanism of free radical scavenging remains elusive. Previous studies have shown that some structural properties in flavonoids are necessary for anti-oxidant activity. The radical scavenging flavonoids tend to have, on their benzo-γ-pyrane rings, a double bond between the 2,3-carbons, a carbonyl group at carbon 4, and a number of

Fig. 3. The structure of the two molecules used in this study, chrysin and 7,8-dihydroxflavone. The altered numbering system used in this study (above) and the standard IUPAC numbering system (below).



hydroxyl groups distributed among the three rings (5, 6, 9–11). Structural–activity relationships (SAR) of flavonoids are, however, often not consistent with real data. For example, the flavonoid catechin, lacking the C2–C3 double bond and the 4-keto functional group, is a very potent anti-oxidant (12). Furthermore, SARs do not give molecular explanations as to why these structural features are important.

It has been vaguely proposed that a flavonoid molecule neutralizes a free radical in vivo by donating a hydrogen atom to the free radical, forming a flavonoid radical itself (5). Eventually, the flavonoid radical will react with another free radical, thus terminating the reaction (5, 9). Although the exact mechanism remains elusive at this time, there is ample data to support a hydrogen transfer from the molecule to the free radical. In fact, other phenolic anti-oxidants such as quercetin, α-tocopherol, and curcumin are known to use similar mechanisms (13–16).

A recent study by Wright et al. (17) proposes that one of the main properties of a good phenolic anti-oxidant is low bond-dissociation enthalpy (BDE) of the hydrogen being abstracted. The term "chain-breaking anti-oxidant" is introduced because free radicals usually act by a chain-reaction mechanism. It is thought that anti-oxidants can prevent oxidative damage by reacting with free radicals more rapidly and readily than cellular structures do. The lower the BDE of the abstracted hydrogen, the faster it reacts with free radicals, thus preventing the chain reaction with cellular substrates (17). It is important, however, for the anti-oxidant radical to be stable enough, and not initiate any further aggressive reactions.

It has been proposed that the radical scavenging ability of an anti-oxidant is based on three basic properties: (*i*) the inability for the anti-oxidant to undergo auto-oxidation; (*ii*) the lipophilicity of the molecule to localize the main location for anti-oxidant reactions across membranes; and (*iii*) the ability to stabilize a lone electron once it is bound (10–13). It is obvious that flavonoids are mainly lipophilic as seen by their

[8]

benzo-γ-pyrane and phenyl structures. Consequently, the overall anti-oxidant properties of flavonoids are determined mostly by the two remaining properties. The optimal geometry required for lone-electron stabilization will be the main focus of this study.

The molecules under study in this paper are chrysin (5,7-dihydroxyflavone; 2-phenyl-5,7-dihydroxy-4*H*-1-benzopyran-4-one) and its structural isomer 7,8-dihydroxyflavone (2-phenyl-7,8-dihydroxy-4*H*-1-benzopyran-4-one) (see Fig. 3). Like its parent molecule flavone, chrysin is a mild anti-oxidant (20). It possesses hydroxyl groups at the 5 and 7 positions on the benzo-γ-pyrane ring, which slightly improves its anti-oxidant activity. A mechanism for free radical scavenging based on hydrogen transfer can be proposed for chrysin (Fig. 2). The degree of conjugation of the system is a good gauge for anti-oxidant strength, since it is important for the stabilization of the unpaired electron.

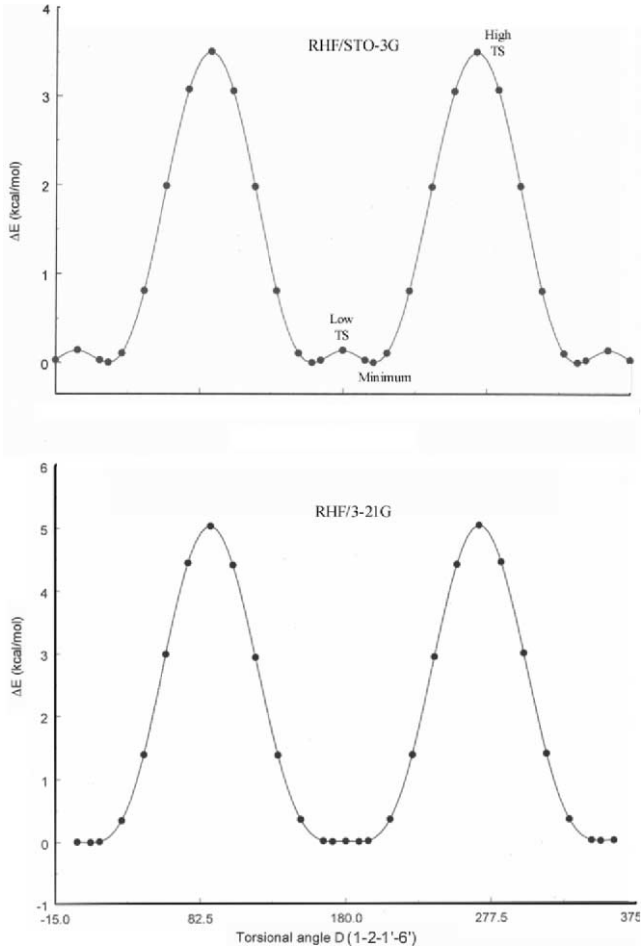
Fig. 6. Potential energy curve for phenyl-ring rotation of flavone (standard IUPAC numbering) computed at RHF/STO3-G (above) and RHF/3–21G (below) (24).



Aside from its radical scavenging ability, chrysin has also been investigated for its inhibition of benzo[*a*]pyrene carcinogenesis based on its activity on cytochrome P450-mediated detoxification (21). Furthermore, chrysin is a dietary supplement for bodybuilding because it is a competitive inhibitor of human aromatase, which actively converts testosterone into estrogen (22, 23). The effect of aromatase inhibition is to increase testosterone levels, which will stimulate muscle growth. The property of chrysin as an aromatase inhibitor can also be used to control breast cancer, because estrogen levels in females play a major role in carcinogenesis. Through mutational studies and computer modeling by Kao et al. (24), it has been suggested that chrysin binds to the active site of aromatase by mimicking the D and C rings of the androgen substrate with its A and C rings. Conformational analysis of these molecules will indicate the most effective conformation for optimal radical scavenging ability and other bioactivities of flavonoids and other polyphenolic compounds.

Computational methodology

The molecules of interest were geometrically optimized with the Gaussian 94 (25) and Guassian 98 (26) program packages. The calculations were initially performed on an Intel Celeron 433-MHz chip with 64 MB of RAM for the low-basis sets, and then on the NIH supercomputers for high-basis sets. Radical computations were also performed on diskless AMD K-7 1.33 GHz CPU, 128 MB PC-clusters at Velocel Communications Inc. (Toronto). The standard IUPAC numbering of flavonoids was altered, as shown in Fig. 3, for the purpose of constructing the input data as Z-matrices. This new numbering system will be referred to for the rest of the paper. For each molecule, four initial assumptions about their hydroxyl (OH) orientations were made and designated as [1]–[4] and [5]–[8], respectively (Figs. 4 and 5). These assumptions were made on the basis of the conjugated electron system of the benzo-γ-pyrane ring forming an essentially planar conformation. Thus, the hydroxyl groups are expected to lie in this plane. The four different orientations may represent four different local minima on the potential energy surface of the one molecule.

Each of the hydroxyl orientations of the three molecules were geometrically optimized using three levels of theory: RHF/3–21G, RHF/6–31G(d), and B3LYP/6–31G(d). The molecules were initially modeled based on a template of flavone, previously optimized at the RHF/3–21G level of theory (25). Furthermore, calculations were performed on the radical forms of a few selected conformations ([1], [6], [7]]) at the UHF/3–21G level of theory to study the free radical scavenging mechanism. In this study, a thermal correction was not applied to the calculations because the energies of the molecules were only used in relative terms.

Frequency calculations were performed after each optimization to ensure that the critical points were indeed minima. A scan of each orientation for each molecule was not performed but it was implied that the energy pattern of the phenyl group's rotation was analogous to that of flavone, whose scan was performed at both the RHF/STO-3G and RHF/3–21G level at 15° intervals (27).

phenyl group's symmetry, the minima (0 + α), (180 – α), (180 + α), and (360 – α), where α is the deviation from co-planarity, are identical. It is therefore sufficient to geometrically optimize one conformation from the above set of angles.

The torsional angles resulting from phenyl rotation (C12-C11-C2-O1 calculated as deviations from co-planarity (α)) for each hydroxyl orientation of chrysin (5,7-dihydroxyflavone) and 7,8-dihydroxyflavone (as calculated at RHF/3–21G, RHF/6–31G(d), and B3LYP/6–31G(d)) are summarized in Table 1. Aside from chrysin at orientation [3], the geometric data for the compounds seem to be consistent for all three basis sets.

Table 2 compares the relative energies of the orientations in their minimum energy conformations as calculated at RHF/3–21G, RHF/6–31G(d), and B3LYP/6–31G(d). The geometric data of the molecules are summarized graphically in Fig. 7, while the distances (as calculated at RHF/3–21G, RHF/6–31G(d), and B3LYP/6–31G(d)) between pseudo-hydrogen bonded atoms are summarized in Table 3. Table 4 summarizes the geometric conformations of the hydroxyl groups of each conformer in relation to their energies.

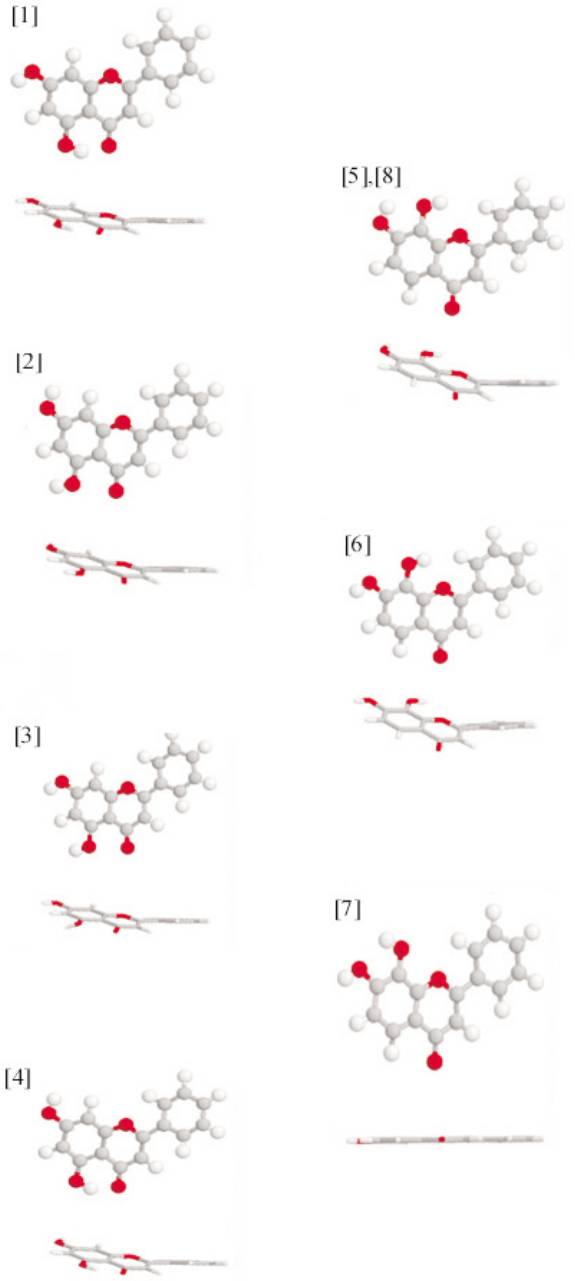
The geometric parameters for the two molecules in their different hydroxyl orientations were determined (not shown). Excluding all the C–H, O–H, C3–C4, C4–C5, C2–C11, C2–C3, and C4–O18 bonds, the bond lengths of all conformations fluctuate between 1.37 and 1.40 Å, indicating the strong double-bond characteristics of these bonds (a C—C double bond is typically 1.33 Å in length). For all conformations, the bond connecting the phenyl ring to the benzo-γ-pyrane ring (C2—C11) is in the range of 1.47–1.48 Å. Although this bond has fewer double-bond characteristics, its length is still shorter than a typical C—C single bond (1.54 Å). This data suggests the presence of a π-electron delocalization system in most parts of the molecules, contributing to conjugative stabilization. The conjugation between the phenyl ring and the benzo-γ-pyrane, however, is not as high as that of the rest of the molecule and, therefore, this section of the molecule can be seen as the weakest part of the delocalized system; the easiest portion to become unconjugated.

Trends for stabilization

The disparities in minimum energies are due to the different orientations of the hydroxyl subsituents, which results in different extensions of hydrogen bond-like interactions within the molecule (Table 3). It can easily be shown that the orientations with more hydrogen bond-like interactions

© 2002 NRC Canada

Fig. 7. Geometric conformations of chrysin [1]–[4] (left) and 7,8-dihydroxyflavone [5]–[8] (right).



have lower minimum energies than others, and hence, are more stable. For example, for chrysin, orientations [1] and [4] both possess a hydrogen bond-like interaction between O18 and H28 (Table 3), while the other conformers do not have such interactions. Consequently, these two orientations possess lower minimum energies than the others without the hydrogen bond-like interactions (Table 2). The same argument can be made for 7,8-dihydroxyflavone, where orientation [5] proves to be the most stable out of the four orientations (Table 2) because of the two hydrogen bond-like interactions between O1 and H28, and O22 and H29, which result in extra stabilization (Table 3), while other orientations have at most one such hydrogen bond.

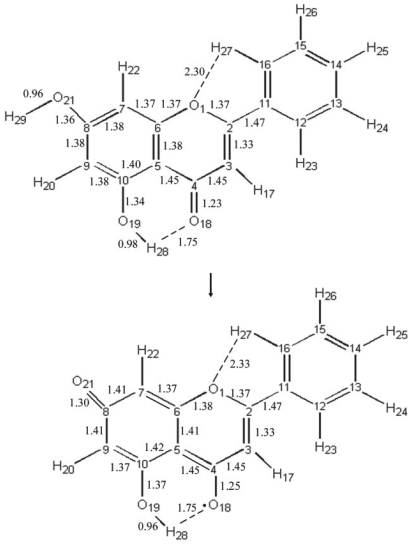

Fig. 8*b*. Spin densities of individual atoms and whole regions of chrysin radical orientation [1].

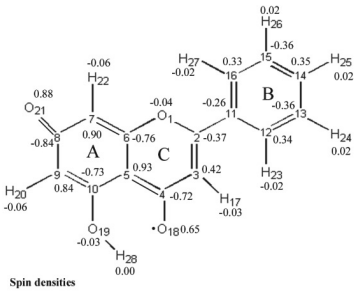

Chrysin (5,7-dihydroxyflavone)

The molecule chrysin gives peculiar results. In particular, there are discrepancies between the optimization results performed at the restricted Hartree–Fock level of theory and the density functional level of theory. This fact is especially emphasized for the phenyl dihedral angle of orientation [3] (Table 1). At the restricted Hartree–Fock level of theory, the molecule with respect to this dihedral angle is essentially coplanar. At the density functional level, the co-planarity disappears, and because the density function method of calculation is more robust, the data from this level of calculation are considered to be more reliable.

Based on the calculations performed at the density functional level, the four hydroxyl orientations of chrysin produce similar results, all having a phenyl torsional angle in the range of 17.8–19.3°. The conjugative stabilization across the phenyl ring does not appear strong, since the deviations from co-planarity of all the orientations are quite high. All the hydroxyl groups, however, remained in plane with the molecule as seen in Table 4, contributing to conjugative stabilization of the benzo-γ-pyrane ring.

7,8-Dihydroxyflavone

Examining the geometries and energies of each hydroxyl orientation of 7,8-dihydroxyflavone, it is evident that the optimized conformation of orientation [8] has migrated to that of [5]. The migration is the result of excessive steric hindrance between the two hydroxyl groups on C7 and C8 of orientation [8], which causes this orientation to become very unstable and not to exist as a minimum on the potential energy surface. The non-co-planar conformations of orientations [5] and [6] are most likely due to electron cloud repulsion and steric interference between H28 and H27. Additionally, the hydroxyl substituents in these orientations are not in plane with the molecule (Table 4), and although these conformers may have lower minimum energies than orientation [7], the conjugation systems within them are disturbed.

© 2002 NRC Canada

Fig. 10*a*. The change of bond lengths from the native form to radical form of 7,8-dihydroxyflavone orientation [6a]. Hydrogen 29 is abstracted in this case. Note the resonance structure (hence delocalization) available for the radical form.

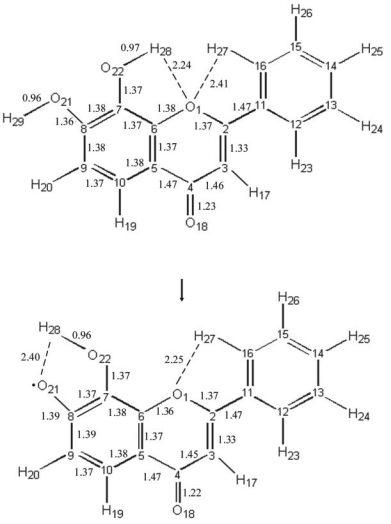

Fig. 10*b*. Spin densities of individual atoms and whole regions of 7,8-dihydroxyflavone radical orientation [6a].

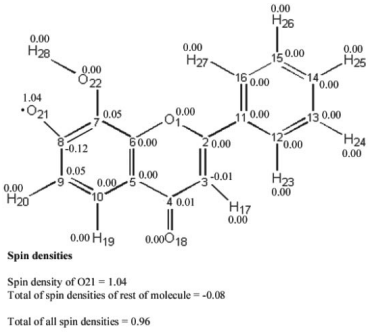

For orientation [7], co-planarity is achieved by three factors: lack of steric hindrance between H28 and H27, conjugative stabilization of the π-electron system, including planar hydroxyl groups (Table 4), and the electronic interaction between O1 and H27 (Table 3), which "locks" the molecule into a planar conformation. Although O1 and H27 are quite far apart (approximately 2.3 Å), and H27 is not highly polarized, some type of dipole-induced dipole interaction may still be established.

Vibrational frequencies

The vibrational frequencies of the molecules at their minimum conformations are performed at B3LYP/6–31G(d) (not shown). The absence of negative frequencies for all molecules except [7] shows that the conformations obtained are indeed minima on their potential energy surfaces. The lone negative frequency obtained for [7] is extremely small (~19.6 cm^{-1}) and is considered to be within convergence error. No further calculation for that molecule was carried out.

Studies on the radical forms of selected conformations

Because the bond dissociation enthalpy of H_2O is one of the strongest of all bonds (119 kcal mol^{-1}), it is obvious that

Fig. 11*a*. The change of bond lengths from the native form to radical form of 7,8-dihydroxyflavone orientation [7]. Hydrogen 28 is abstracted in this case. Note the resonance structure (hence delocalization) available for the radical form.

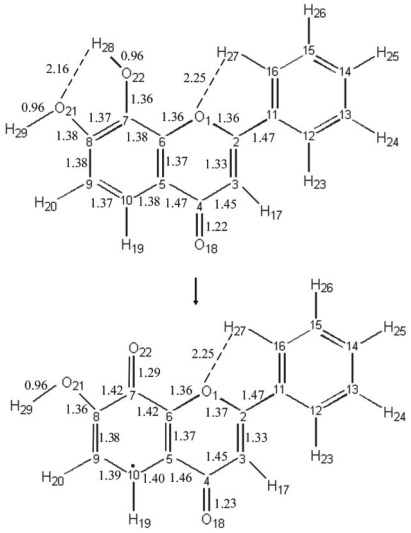

Fig. 11*b*. Spin densities of individual atoms and whole regions of 7,8-radical dihydroxyflavone orientation [7].

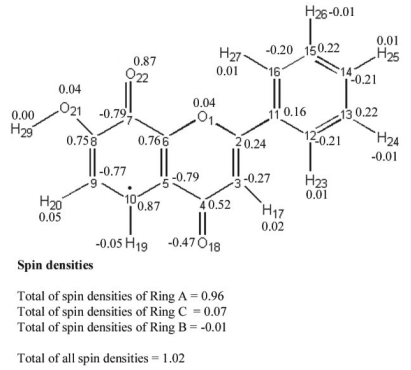

every organic molecule will react exothermically to •OH (17). Hence, the radical forms of the flavonoids are expected to be generated by hydrogen transfer in the presence of •OH:

$$\text{Native flavonoid} + {}^{\bullet}\text{OH} \rightarrow \text{Flavonoid radical} + H_2O$$

The radical forms of conformations [1], [6], and [7] are selected for further calculations because they are the most probable candidates for free radical scavenging by hydrogen transfer. The main determinants for their selections are the availability of a hydrogen atom, either H29 or H28 (on 7,8-dihydroxyflavone only), for abstraction, and the minimal amount of hydrogen bond-like interactions disturbed. For example, H28 of chrysin is not suitable for hydrogen extraction because the molecule attains maximum stabilization when H28 is interacting with O18, thereby making H28 inaccessible. Significant bond lengths and atom-by-atom spin densities resulting from these calculations are shown in Figs. 8–12.

The results obtained for the radical forms of molecules [1] and [6] are similar, since both molecules have H29 extracted from O21. The geometric parameters indicate that the lone

[1]	–867.87	0.00	Yes	16.81	(5OH) 0.16
7,8-Dihydroxyflavone					
[6]	–867.85	0.00	No	29.02	(8OH) 4.03
[6a]	–867.81	+25.10	Yes	0.03	(8OH) 0.02
[7]	–867.84	0.00	No	0.01	(7OH) 0.02
[7a]	–867.85	–6.28	Yes	0.00	(7OH) 0.02

[a]ΔE (kcal mol^{-1}) = 627.51 ($E_{TS} - E_{min}$) calculated using the lowest minimum energy as E_{min}.
[b]Note that there are four equivalent torsional angles that govern minimum energy conformations: (0 + α), (180 – α), (180 + α), and (360 – α).

Fig. 12*a*. The change of bond lengths from the native form to radical form of 7,8-dihydroxyflavone orientation [7a]. Hydrogen 28 is abstracted in this case. Note the resonance structure (hence delocalization) available for the radical form.

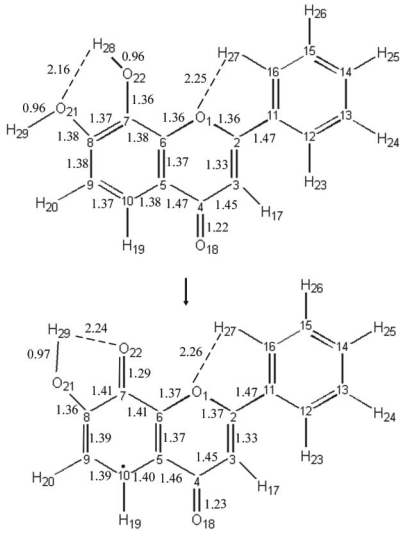

Fig. 12*b*. Spin densities of individual atoms and whole regions of 7,8-radical dihydroxyflavone orientation [7a].

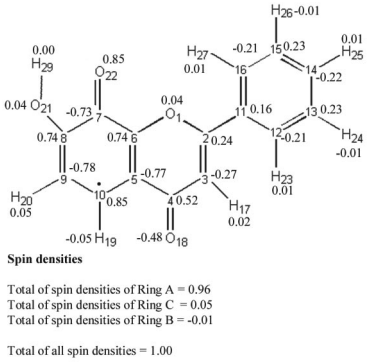

electrons of the radicals may not be localized to O21, and their conformations can adopt *para*-quinoidal structures through resonance (Figs. 8*a*, 9*a*). This conjecture is suggested by the alteration of bond lengths between the native forms of the molecules and their radical forms. The reduction in bond length of O21–C8 in the radical forms indicates that the bond is changing from a pure single bond to one with more double-bond characteristics. Furthermore, bonds O18–C4, C8–C7, C9–C8, C6–C5, and C10-C5 are all lengthened after hydrogen transfer, while bonds C7–C6 and C10–C9 remain unchanged. The significant lengthening of a bond indicates an increase in single-bond characteristics. In the resonance structures of the two molecules, the lone electron can be drawn to reside on O18. From a quantum mechanical standpoint, an electron is not considered to be a particle, but the possibility for electron movement suggests that the lone electron is delocalized across rings A and C. This fact is further reinforced by the spin densities of the molecules (Figs. 8*b*, 9*b*). While combining the spin densities of rings A and C yields a result of nearly 1, ring B has a total spin density of zero (within computational range of accuracy). This result suggests that the lone electron is shared by rings A and C, but not B. The participation of ring B in the delocalization system is therefore negligible. It can also be seen that the spin densities of the atoms in rings A and C are large (>0.5) except for O1, C2, and C3, suggesting the exclusion of these atoms from the delocalization system.

Another possible hydroxyl orientation for the 7,8-dihydroyflavone [6] radical is shown in Fig. 10*a*. This orientation occurs because the rotation barriers for hydroxyl groups in phenolic compounds are low (4 kcal mol^{-1}); the hydrogen atoms on any hydroxyl groups should therefore be free to rotate to their minimum conformations (17) — this hydroxyl orientation is labeled as [6a]. H28 of the hydroxyl group now forms a hydrogen bond with O21, the site where the radical is initially formed. Based on the radical's geometric parameters shown in Fig. 10*a*, a delocalized *para*-quinoidal structure is not observed because the geometry of the radical is nearly the same as its neutral form. The spin densities of radical [6a] also show that most of the charge contributed by the lone electron is localized to O21 (Fig. 10*b*), and not spread throughout the molecule. Furthermore, energy of radical [6a] is higher than that of radical [6] (Table 5; compare rows 2 and 3, column 3). The instability of this conformation suggests that a *para*-quinoidal structure is not formed because delocalization usually leads to stabilization and lower minimum energy. The phenomenon can be explained by the fact that a hydrogen bond formed between H28 and O21 will draw negative charges to O21 to

© 2002 NRC Canada

strengthen that interaction as much as possible. The lone electron will, therefore, stay at O21, which will prevent its movement to other sites. The instability of radical conformation [6a], as opposed to delocalized form [6], will prevent it from being the dominant radical species.

The results from the calculations of the molecule [7] radical are different, because in this case, the hydrogen (H28) is abstracted from O22 instead of O21. Again, the radical can adopt a *para*-quinoidal structure via resonance (Fig. 11*a*), and the geometry of the radical conformation confirms this fact. Bonds C8–C7, C7–C6, C10–C9, and C10–C5 are lengthened, while bonds C9–C8 and C6–C5 remain the same lengths. The longer bond lengths suggest increases in single-bond characteristics, while the shortening of bond O22–C7 suggests an increase in double-bond characteristics in that single bond. Although a slight increase in the bond length (by 0.01 Å) of O18–C4 is observed, it is small enough to be negligible. A delocalized system can be proposed for this radical conformation with the lone electron residing at C10 (Fig. 11*a*), and the spin densities also support the fact that the electron is only delocalized in ring A (Fig. 11*b*). In this particular orientation, rings B and C have small spin densities (<0.5), while ring A has a large spin density adding up to 1 (within computational range of accuracy), signifying that the unpaired electron resides mainly at ring A. The spin densities of C4 and O18 in [7] are much less than those in molecules [1] and [6], suggesting that these atoms in [7] do not participate in the delocalization system as much as those in [1] and [6].

Another possible hydroxyl orientation for the 7,8-dihydroyflavone [7] radical is shown in Fig. 12*a* and is labeled [7a]. The hydrogen of the hydroxyl group H29 now forms a hydrogen bond with O22. Indeed, because of the extra stabilization provided by the hydrogen bond, the minimum energy, compared with conformation [7], is lowered without this hydrogen bond interaction (Table 5; compare rows 4 and 5, column 3). In addition, the delocalized system of the *para*-quinoidal structure is not disturbed; the conformation [7a] therefore represents the most stable conformation for this radical species.

Conclusion

Conjugation contributes to the overall stabilization of the radical complex formed after scavenging. Hydroxyl groups will contribute to conjugative stabilization if placed in a non-sterically hindered way. Stabilization can also be achieved through intramolecular hydrogen bond-like interactions. Dihydroxyflavones, as weak anti-oxidants, possess strong conjugation systems across rings A and C, and perhaps much weaker ones across ring B. This fact is supported by the deviation of the phenyl ring from co-planarity from the rest of the molecule in both the radical and neutral forms. The lone electron of the radical forms of the flavones is also found to be mainly delocalized in rings A and C by spin densities.

Suggestions for further works

As noted by Wright et al. (17), the NDE of a phenolic anti-oxidant would indicate how fast it reacts with a free radical, giving a good indication of its anti-oxidant ability. The NDE of flavonoid anti-oxidants can be determined by calculating the enthalpy of the following reaction and comparing it to the phenol standard:

$$\text{Native flavonoid} \rightarrow \text{Flavonoid radical} + \text{H}^{\bullet}$$

Another logical improvement on this study is to perform the calculations at higher and more reliable levels of theory, especially on the 1-D scans. This improvement applies especially to chrysin at orientation [3], since a discrepancy is detected between the three basis sets. For this molecule, full 1-D scans should be performed at each of the basis sets to show how the energy pattern changes with the level of theory.

Other proven polyphenolic anti-oxidants (not necessarily flavonoids) should also be geometrically analyzed to determine other structural features for radical scavenging abilities. To support the idea of conjugation, the anti-oxidants chosen should possess many possible resonance structures. Furthermore, the molecules should be studied in their hydrated state, since flavonoids usually exist in aqueous environments in the body.

The synthesis of a carbohydrate-like dihydrooxazine and tetrahydrooxazine as putative inhibitors of glycoside hydrolases: A direct synthesis of isofagomine

Wayne M. Best, James M. Macdonald, Brian W. Skelton, Robert V. Stick, D. Matthew G. Tilbrook, and Allan H. White

Abstract: The treatment of benzyl 2,3-*O*-isopropylidene-β-L-xylopyranoside with *N*-hydroxyphthalimide under Mitsunobu conditions, followed by protecting-group interchange, gave benzyl 4-*O*-[(*tert*-butoxycarbonyl)amino]-2,3-*O*-isopropylidene-α-D-arabinoside. Mild acid hydrolysis and catalytic hydrogenolysis afforded 4-*O*-[(*tert*-butoxycarbonyl)amino]-D-arabinose that, upon heating in water, gave the dihydrooxazine [(4*R*,5*S*,6*R*)-5,6-dihydro-4,5-dihydroxy-6-hydroxymethyl-4*H*-1,2-oxazine] as a crystalline solid. A single-crystal structure determination of this solid showed it to exist in the $^5H_6$ conformation. Reduction of the dihydrooxazine gave the tetrahydrooxazine [(4*R*,5*S*,6*R*)-4,5-dihydroxy-6-hydroxymethyl-3,4,5,6-tetrahydro-2*H*-1,2-oxazine]. The dihydrooxazine was an effective inhibitor of two β-glucosidases (K_i = 27 and 35 μM). Benzyl 2,3-*O*-isopropylidene-β-L-xylopyranoside, via the derived imidazylate, was converted into a nitrile that, upon reduction and protecting-group manipulations, gave benzyl 4-*C*-aminomethyl-4-deoxy-α-D-arabinoside. Treatment of this amine with hydrogen and palladium-on-carbon gave isofagomine.

Key words: dihydrooxazine, tetrahydrooxazine, isofagomine, iminosugars, glycosidase inhibitors.

Résumé : Le traitement du 2,3-*O*-isopropylidène-β-L-xylopyranoside de benzyle par du *N*-hydroxyphtalimide dans des conditions de Mitsunobu, suivi d'un échange des groupes protecteurs, conduit à la formation du 4-*O*-[(*tert*-butoxycarbonyl)amino]-2,3-*O*-isopropylidène-α-D-arabinoside de benzyle. Soumis à une hydrolyse acide légère et une hydrogénolyse catalytique, celui-ci fournit alors le 4-*O*-[(*tert*-butoxycarbonyl)amino]-D-arabinose qui, par chauffage dans l'eau, livre la dihydrooxazine [(4*R*,5*S*,6*R*)-5,6-dihydro-4,5-dihydroxy-6-hydroxyméthyl-4*H*-1,2-oxazine] sous la forme de solide cristallin. Une détermination de structure sur un cristal unique montre qu'elle existe dans la conformation $^5H_6$. La réduction de la dihydrooxazine fournit la tétrahydrooxazine [(4*R*,5*S*,6*R*)-4,5-dihydroxy-6-hydroxyméthyl-3,4,5,6-tétrahydro-2*H*-1,2-oxazine]. La dihydrooxazine est un inhibiteur efficace de deux β-glucosidases (K_i = 27 et 35 μM). Le 2,3-*O*-isopropylidène-β-L-xylopyranoside de benzyle, par le biais de l'imidazylate qui en dérive, a été transformé en un nitrile qui, après réduction et des manipulations des groupes protecteurs, fournit le 4-*C*-aminométhyl-4-désoxy-α-D-arabinoside de benzyle. Le traitement de cette amine avec de l'hydrogène et du palladium sur du charbon conduit alors à l'isofagomine.

Mots clés : dihydrooxazine, tétrahydrooxazine, isofagomine, iminosucres, inhibiteurs de glycosidases.

[Traduit par la Rédaction]

Introduction

The making and breaking of the glycosidic linkage are events central to the survival of virtually all organisms. Both processes are mediated by enzymes, generally described as synthases or transferases for the former process and hydrolases for the latter. The study of the mechanism of action of glycoside hydrolases has received much attention in the last half century (1–3).

One way to study the action of an enzyme is to design molecules that will inhibit the normal catalytic process. In this regard, glycoside hydrolases are no exception and there exists a class of inhibitor, generally described as "imino sugars," that encompasses such well-known molecules as swainsonine, castanospermine, nojirimycin, deoxynojirimycin, and fagomine (4, 5). Bols (6) suggested, and subsequently synthesised, an unnatural aza sugar, isofagomine (**1**), which was shown to be a powerful inhibitor of some enzymes that hydrolyze β-D-glycosidic linkages with retention of configuration.

Some years ago, it occurred to us that tetrahydrooxazine **2** might better represent the natural substrate for the enzymes of interest (or, rather, conjugate acid **3** would better represent the transition state commonly implicated in the

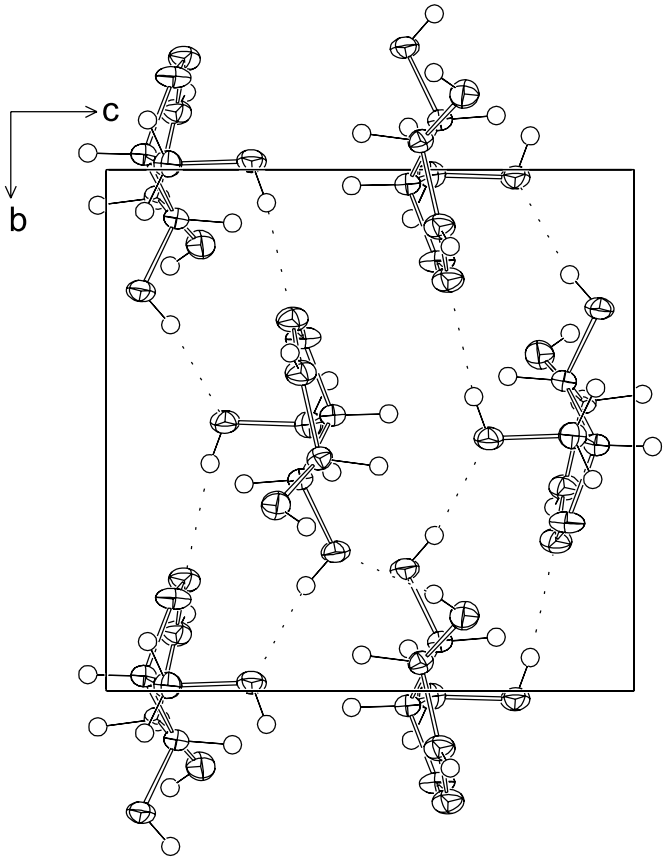
hydrolytic process (1–3)). We thus started a synthetic program that would furnish tetrahydrooxazine **2**, via dihydrooxazine **4**; subsequently, the synthetic route chosen also supplied isofagomine (**1**).

In 1999, during the course of our investigations, Bols and co-workers (7) published a synthesis of the racemic form of **2**, not unexpectedly involving the cycloaddition of a nitroso compound onto a diene. It was always our intention to produce the tetrahydrooxazine as one enantiomer and the success of the process, starting with L-xylose and outlined in Scheme 1, would ultimately depend upon the choice of protecting groups.

Results and discussion

In our initial investigations, D-xylose (in the early stages of our work, it was much cheaper to use this enantiomer) was converted into methyl β-D-xylopyranoside and then to methyl 2,3-*O*-isopropylidene-β-D-xylopyranoside (**5**). *N*-Hydroxyphthalimide (**6**) was seen as a suitable source of the required hydroxylamine residue. Thus, treatment of alcohol **5** with **6** under Mitsunobu conditions gave α-L-arabinoside **7**. Mild acid hydrolysis of **7** then gave diol **8** and a subsequent treatment with phenylhydrazine gave hydroxylamine **9**. Try as we might, hydroxylamine **9** could never be converted into any recognizable product under acidic conditions (there was never any evidence for the formation of the desired product, the enantiomer of the dihydrooxazine (**4**) [*ent*-(**4**)]).

Fig. 2. Unit cell contents, projected down *a*, showing hydrogen bonding.



The source of our problem seemed to reside with the choice of a methyl glycoside for the protection of the anomeric centre. The sequence from D-xylose was, therefore, mimicked in both the allyl and 2-trimethylsilylethyl series, resulting in α-L-arabinosides **10** and **11**. But conditions could not be found for the removal of either the allyl or 2-trimethylsilylethyl glycoside with concomitant formation of *ent*-(**4**).

In some desperation, a benzyl glycoside was considered and, subsequently, α-L-arabinoside **12** was synthesized. All attempts at the hydrogenolysis–hydrogenation of **12**, generally over palladium-on-carbon, failed to produce either *ent*-(**4**) or *ent*-(**2**).

Much discussion, heartache, and experimentation were to follow before we hit upon a successful twist for the synthesis of **2** and **4**. L-Xylose was converted into benzyl β-L-xylopyranoside (we now employ trichloroacetimidate methodology for the synthesis of the glycoside, rather than the earlier Koenigs–Knorr approach) and in turn into alcohol **13**. Normal Mitsunobu chemistry gave phthalimide **14**, and

subsequent manipulations gave hydroxylamine **15** and then presumably carbamate **16**. Mild acid hydrolysis of **16** gave diol **17** and subsequent catalytic hydrogenolysis gave hemiacetal **18**. Treatment of **18** in boiling water presumably liberated hydroxylamine **19**, which subsequently formed the desired and crystalline dihydrooxazine **4**! A single-crystal structure determination of **4** (Figs. 1 and 2, Table 1) showed it to exist in the $^5H_6$ conformation.

Dihydrooxazine **4** could be converted into desired tetrahydrooxazine **2** by treatment with sodium cyanoborohydride in acetic acid. Our synthetic material (**2**) shared all of the physical attributes as described by Bols (7), especially in terms of NMR chemical-shift predictions (both ^{1}H and ^{13}C), and possessed a negative value for the specific optical rotation.

Dihydrooxazine **4** acted as an efficient inhibitor of two β-glucosidases isolated from *Aspergillus niger* and *Clostridium saccharolyticium* — **4** had K_i values of 27 and 35 μM, respectively. Bols and co-workers (7) have previously reported an inhibition constant (60 μM) for (±)-(**2**) against almond β-glucosidase.

With the euphoria that comes with the successful conclusion to a long and protracted piece of work, we wondered if our process could be adapted to a synthesis of isofagomine (**1**). (All that was really required was to replace the oxygen of the hydroxylamine by a carbon, and the cyano group seemed a logical choice.) Thus, alcohol **13** was converted into imidazylate **20** (8) and a subsequent treatment with trimethylsilyl cyanide and tetrabutylammonium fluoride gave nitrile **21** (9), a far superior result to our efforts using potassium cyanide in dimethylformamide.

Nitrile **21** was then reduced, presumably to amine **22**, and the product isolated as carbamate **23**. Then, in virtually quantitative yields, mild acid hydrolysis of **23** gave diol **24**, and subsequent treatment with anhydrous acid presumably gave amine **25**. Hydrogenolysis–hydrogenation of **25** over palladium-on-carbon then gave isofagomine (**1**).

We have routinely used the synthesis described here to produce appreciable amounts of isofagomine — the lowest yielding step, the isopropylidenation of benzyl β-L-xylopyranoside, is encountered early on in the sequence and the

N(2)-C(3)-C(4)-C(5)	–19.3(2)	C(5)-C(6)-O(1)-N(2)	36.7(2)

Note: Hydrogen bonds: OH(4)··O(5) (x – 1/2, 1/2 – y, 2 – z) = 2.747(2), 2.03(2) Å; OH(5)··O(7) (2 – x, y – 1/2, 1.5 – z) = 2.737(2), 1.94(2) Å; OH(7)··N(2) (2 – x, y – 1/2, 1.5 – z) = 2.808(2), 2.05(3) Å.

whole process compares favourably with previously published syntheses (10–16). It is our immediate intention to produce glycosylated versions of isofagomine, such as **26**, and to see if our synthetic sequence can be adopted to produce 1-azafagomine (**27**) (17) and interesting nitrone **28**.

Experimental

General experimental procedures have been given previously (18). HCl in MeOH was generated by the addition of acetyl chloride to anhydrous MeOH.

Structure determination of 4

A full sphere of CCD area-detector diffractometer data was measured (Bruker AXS instrument; (ω–scans, $2\theta_{max}$ = 58°; monochromatic Mo Kα radiation, λ = 0.7107$_3$ Å; T = ~153 K) yielding 6405 total reflections, merging to 939 unique (R_{int} = 0.023), 897 with $F > 4\sigma(F)$ being used in the full matrix least squares refinement (C, N, and O thermal parameter forms anisotropic (x, y, z, U_{iso})$_H$ refined). "Friedel pair" data were not retained distinct, chirality being assigned from the chemistry. Conventional residuals R and R_w (weights: $\sigma^2(F) + 0.0004\,F^2)^{-1}$) on | F | at convergence were 0.028 and 0.039, respectively. Neutral-atom scattering factors were used within the context of the Xtal 3.6 program system (19).

Crystal data

$C_5H_9NO_4$, M = 197.1, orthorhombic, space group $P2_12_12_1$ (D_2^4, No. 19), a = 7.091(1), b = 8.847(1), c = 8.928(1) Å, V = 631.2 Å^3, $D_{calcd.}$ = 1.548 g cm^{-3}, Z = 4, μ_{Mo} = 1.3 cm^{-1} (no correction).

Methyl 2,3-*O*-isopropylidene-4-*O*-(*N*-phthalimido)-α-L-arabinoside (7)

Methyl 2,3-*O*-isopropylidene-β-D-xylopyranoside (20) (**5**) (2.80 g, 13.7 mmol), triphenylphosphine (4.10 g, 15.6 mmol), and *N*-hydroxyphthalimide (**6**) (2.50 g, 15.3 mmol) in THF (20 mL) were cooled (10°C) and treated with diisopropyl azodicarboxylate (3.60 mL, 18.3 mmol) for 3 days at rt. The mixture was then poured into $NaHCO_3$ solution and subjected to normal workup (EtOAc). Flash chromatography (EtOAc–petrol, containing 0.5% Et_3N, 2:3) gave the phthalimide (**7**) (3.10 g, 65%) as a colourless solid; mp 158–160°C; $[\alpha]_D$ +7.8 ($CHCl_3$). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.35, 1.40 (2s, CMe_2), 3.57 (s, OMe), 3.64 (dd, $J_{2,3}$ = 9.8, $J_{3,4}$ = 2.4 Hz, H3), 3.66 (dd, $J_{4,5}$ = 1.7, $J_{5,5}$ = 13.6 Hz, H5), 4.30 (dd, $J_{1,2}$ = 7.7 Hz, H2), 4.40 (dd, $J_{4,5}$ = 1.5 Hz, H5), 4.49 (d, H1), 5.04 (m, H4), 7.72–7.73, 7.79–7.81 (2m, 4H, Ar). ^{13}C NMR (125.8 MHz, $CDCl_3$) δ: 26.03, 26.52 (CMe_2), 56.50 (OMe), 65.49 (C5), 72.88, 77.63, 79.64 (C2,3,4), 104.29 (Cl), 111.00 (CMe_2), 123.45, 128.98, 134.42 (6C, Ar), 163.04 (2C, CO).

Methyl 4-*O*-(*N*-phthalimido)-α-L-arabinoside (8)

Phthalimide **7** (1.01 g) in MeOH (40 mL) was treated with hydrochloric acid (0.4 mL of 1 M) for 45 min. The mixture was then concentrated and the residue dissolved in warm $CHCl_3$, filtered and concentrated to give diol **8** (900 mg) as a colourless solid, a portion of which was recrystallized to give colourless needles; mp 205–206°C (EtOH); $[\alpha]_D$ –16.7 ($CHCl_3$). ^{1}H NMR (500 MHz, DMSO-d_6) δ: 3.39 (s, OMe), 3.58 (dd, $J_{4,5}$ = 1.8, $J_{5,5}$ = 12.7 Hz, H5), 3.64 (ddd, $J_{1,2}$ = 6.0, $J_{2,3}$ = 8.5, $J_{2,OH}$ = 4.5 Hz, H2), 3.68 (ddd, $J_{3,4}$ = 3.1, $J_{3,OH}$ = 5.4 Hz, H3), 4.08 (dd, $J_{4,5}$ = 3.8 Hz, H5), 4.11 (d, H1), 4.47–4.51 (m, H4), 4.89 (d, 3-OH), 5.26 (d, 2-OH), 7.86 (s, 4H, Ar). ^{13}C NMR (125.8 MHz, DMSO-d_6) δ: 55.76 (OMe), 61.52 (C5), 70.34, 71.36, 82.86 (C2,3,4), 104.00 (Cl), 123.19, 128.64, 134.71 (6C, Ar), 163.29 (2C, CO). Anal. calcd. for $C_{14}H_{15}NO_7$: C 54.4, H 4.9, N 4.5; found: C 54.4, H 5.0, N 4.5.

Methyl 4-*O*-amino-α-L-arabinoside (9)

Diol **8** (777 mg, 2.50 mmol) in EtOH (15 mL) was treated with phenylhydrazine (0.35 mL, 3.6 mmol) and the mixture stirred (45 min, rt), poured into water, and washed with EtOAc. The aqueous phase was concentrated and the residue triturated with EtOAc (which was discarded) to leave hydroxylamine derivative **9** (357 mg, 79%) as a colourless solid, a portion of which was recrystallized to give colourless needles; mp 144°C (EtOH); $[\alpha]_D$ +32.3 (MeOH). ^{1}H NMR (300 MHz, DMSO-d_6) δ: 3.25 (ddd, $J_{1,2}$ = 6.7, $J_{2,3}$ = 9.0, $J_{2,OH}$ = 4.8 Hz, H2), 3.28 (dd, $J_{4,5}$ = 1.5, $J_{5,5}$ = 12.3 Hz, H5), 3.34 (s, OMe), 3.41–3.46 (m, H3), 3.57–3.60 (m, H4), 3.97 (d, H1), 3.99 (dd, $J_{4,5}$ = 3.0 Hz, H5), 4.79 (br d, $J_{3,OH}$ = 5.4 Hz, 3-OH), 5.00 (br d, 2-OH), 6.00 (br s, NH_2). ^{13}C NMR (75.5 MHz, DMSO-d_6) δ: 55.7 (OMe), 61.5 (C5), 70.6, 71.7, 80.1 (C2,3,4), 104.4 (Cl). Anal. calcd. for $C_6H_{13}NO_5$: C 40.2, H 7.3, N 7.8; found: C 40.4, H 7.2, N 7.9.

Allyl 2,3-*O*-isopropylidene-β-D-xylopyranoside

HCl in MeOH (4 M, 60 μL) was added to allyl β-D-xylopyranoside (21) (2.9 g, 15 mmol) suspended in DMF (13 mL), the mixture cooled (0°C), and 2-methoxypropene (4.0 mL, 42 mmol) added. The mixture was stirred (1 h, rt) and normal work-up ($CHCl_3$) gave a colourless oil. Flash chromatography (EtOAc–petrol, containing 0.5% Et_3N, 1:4) gave allyl 3,4-*O*-isopropylidene-β-D-xyloside as a colourless

© 2002 NRC Canada

syrup (210 mg, 6%). A small sample was distilled (glass T-piece, 0.05 mm Hg, heating block 110–130°C); $[\alpha]_D$ –59 ($CHCl_3$). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.46, 1.47 (2s, CMe_2), 3.47–3.54 (m, H3,5), 3.57–3.59 (m, H5), 3.72 (m, H2), 4.11 (tdd, $J_{1',1'}$ = 11.8, $J_{1',2'}$ = 6.4, $J_{1',3'}$ = 1.2 Hz, H1′), 4.17 (dd, $J_{3,4}$ = 9.8, $J_{4,5}$ = 4.3 Hz, H4), 4.29 (d, $J_{1,2}$ = 6.9 Hz, H1), 4.35–4.39 (m, H1′), 5.22–5.25 (m, H3′), 5.31 (dq, $J_{2',3'}$ = 17.1, $J_{3',3'}$ = 1.3 Hz, H3′), 5.89–5.97 (m, H2′). ^{13}C NMR (125.8 MHz, $CDCl_3$) δ: 26.51, 26.73 (C*Me*$_2$), 64.63, 70.88 (C5,1′), 73.06, 73.61, 81.17 (C2,3,4), 103.64 (Cl), 112.44 (*C*Me$_2$), 118.31 (C3′), 133.44 (C2′). Further elution gave allyl 2,3-*O*-isopropylidene-β-D-xylopyranoside (2.7 g, 77%) as a colourless syrup; $[\alpha]_D$ –49 ($CHCl_3$). ^{1}H NMR (500 MHz, C_6D_6) δ: 1.32, 1.36 (2s, CMe_2), 2.40 (d, $J_{4,OH}$ = 2.6 Hz, OH), 3.07 (dd, $J_{4,5}$ = 7.6, $J_{5,5}$ = 11.9 Hz, H5), 3.46–3.53 (m, H2,3), 3.69–3.73 (m, H4), 3.85 (dd, $J_{4,5}$ = 5.3 Hz, H5), 3.92 (tdd, $J_{1',1'}$ = 13.1, $J_{1',2'}$ = 5.7, $J_{1',3'}$ = 1.5 Hz, H1′), 4.24 (tdd, $J_{1',2'}$ = 5.0, $J_{1',3'}$ = 1.6 Hz, H1′), 4.53 (d, $J_{1,2}$ = 6.8 Hz, H1), 4.99 (dq, $J_{2',3'}$ = 10.4, $J_{3',3'}$ = 1.5 Hz, H3′), 5.25 (dq, *J* = 1.7, 17.2 Hz, H3′), 5.81 (dddd, H2′). ^{13}C NMR (125.8 MHz, C_6D_6) δ: 26.76, 26.87 (C*Me*$_2$), 67.49, 69.38 (C5,1′), 69.60 (C4), 77.11, 81.63 (C2,3), 101.44 (C1), 111.19 (*C*Me$_2$), 116.74 (C3′), 134.50 (C2′).

Allyl 2,3-*O*-isopropylidene-4-*O*-(*N*-phthalimido)-α-L-arabinoside

Allyl 2,3-*O*-isopropylidene-β-D-xylopyranoside (2.3 g) was treated with **6** as previously for **5** to give, after flash chromatography (EtOAc–petrol, containing 0.5% Et_3N, 1:4 then 1:2) and trituration with diisopropyl ether, the title phthalimide (2.1 g, 56%) as a colourless solid; mp 148°C; $[\alpha]_D$ +0.5 ($CHCl_3$). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.35, 1.41 (2s, CMe_2), 3.63 (dd, $J_{3,4}$ = 2.4, $J_{2,3}$ = 9.9 Hz, H3), 3.66 (dd, $J_{4,5}$ = 1.9, $J_{5,5}$ = 13.6 Hz, H5), 4.19 (tdd, $J_{1',1'}$ = 12.6, $J_{1',2'}$ = 6.4, $J_{1',3'}$ = 1.3 Hz, H1′), 4.34 (dd, $J_{1,2}$ = 7.7 Hz, H2), 4.38–4.42 (m, H5,1′), 4.61 (d, H1), 5.04 (bq, *J* = 1.8 Hz, H4), 5.21 (dq, $J_{2',3'}$ = 10.3 Hz, H3′), 5.34 (dq, $J_{2',3'}$ = 17.2 Hz, H3′), 5.98 (dddd, $J_{1',2'}$ = 5.4 Hz, H2′), 7.71–7.74, 7.79–7.83 (2m, 4H, Ar). ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 26.02, 26.53 (C*Me*$_2$), 65.41, 69.53 (C5,1′), 72.88, 77.65, 79.59 (C2,3,4), 102.25 (Cl), 110.92 (*C*Me$_2$), 117.94 (C3′), 123.41, 128.96, 134.36 (6C, Ar), 133.66 (C2′), 163.00 (2C, CO).

Allyl 4-*O*-(*N*-phthalimido)-α-L-arabinoside

Allyl 2,3-*O*-isopropylidene-4-*O*-(*N*-phthalimido)-α-L-arabinoside (2.0 g) was treated with hydrochloric acid as previously for **7** to give the title diol (1.9 g) as a colourless solid, a small portion of which was recrystallized to give long, fine, colourless needles; mp 145°C (EtOAc–*i*-Pr_2O); $[\alpha]_D$ –7.3 (MeOH). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 3.69 (dd, $J_{4,5}$ = 1.7, $J_{5,5}$ = 13.0 Hz, H5), 3.78 (dd, $J_{2,3}$ = 9.1, $J_{3,4}$ = 3.4 Hz, H3), 3.90 (dd, $J_{1,2}$ = 6.7 Hz, H2), 4.15 (ddt, $J_{1',1'}$ = 12.7, $J_{1',2'}$ = 6.5, $J_{1',3'}$ = 1.2 Hz, H1′), 4.27–4.29 (m, H4), 4.35 (d, H1), 4.40 (ddt, $J_{1',2'}$ = 5.2, $J_{1',3'}$ = 1.4 Hz, H1′), 4.60 (dd, $J_{4,5}$ = 3.2 Hz, H5), 5.23 (dq, $J_{2',3'}$ = 10.4, $J_{3',3'}$ = 1.4 Hz, H3′), 5.34 (dq, $J_{2',3'}$ = 17.2 Hz, H3′), 5.96 (dddd, H2′), 7.78–7.80, 7.84–7.87 (2m, 4H, Ar). ^{13}C NMR (125.8 MHz, $CDCl_3$) δ: 63.77 (C5), 69.93 (C1′), 71.98, 72.22, 86.77 (C2,3,4), 101.68 (Cl), 118.11 (C3′), 124.01, 128.49, 134.96 (6C, Ar), 133.67 (C2′), 164.02 (2C, CO). Anal. calcd. for $C_{16}H_{17}NO_7 \cdot H_2O$: C 54.4, H 5.4, N 4.0; found: C 54.0, H 5.3, N 4.0.

Allyl 4-*O*-amino-α-L-arabinoside (10)

Allyl 4-*O*-(*N*-phthalimido)-α-L-arabinoside (1.6 g, 4.8 mmol) in $CHCl_3$ (60 mL) was treated with methylhydrazine (0.4 mL, 7.5 mmol) and the mixture stirred (2 h, rt), extracted with water, and the extracts filtered and concentrated. Recrystallization of the residue gave hydroxylamine derivative **10** (620 mg, 63%) as colourless plates; mp 120°C (EtOH); $[\alpha]_D$ +24.5 (MeOH). ^{1}H NMR (500 MHz, DMSO-d_6) δ: 3.24–3.28 (m, H2,5), 3.41–3.44 (m, H3), 3.56–3.57 (m, H4), 3.95–4.00 (m, H5,1′), 4.08 (d, $J_{1,2}$ = 6.8 Hz, H1), 4.17 (tdd, $J_{1',1'}$ = 13.4, $J_{1',2'}$ = 5.0, $J_{1',3'}$ = 1.6 Hz, H1′), 4.77 (d, $J_{3,OH}$ = 5.8 Hz, 3-OH), 4.98 (d, $J_{2,OH}$ = 4.9 Hz, 2-OH), 5.12 (dq, $J_{2',3'}$ = 10.5 Hz, H3′), 5.29 (dq, $J_{2',3'}$ = 17.3 Hz, H3′), 5.83–5.91 (m, H2′), 5.99 (br s, NH_2). ^{13}C NMR (125.8 MHz, DMSO-d_6) δ: 61.60, 68.65 (C5,1′), 70.94, 71.94, 80.15 (C2,3,4), 102.61 (Cl), 116.43 (C3′), 134.97 (C2′). Anal. calcd. for $C_8H_{15}NO_5$: C 46.8, H 7.4, N 6.8; found: C 46.6, H 7.4, N 6.8.

2′-Trimethylsilylethyl β-D-xylopyranoside

HgO (11.5 g, 54.0 mmol), $HgBr_2$ (1.16 g, 3.21 mmol), $CaSO_4$ (36 g), and 2-trimethylsilylethanol (8.0 mL, 56 mmol) in CH_2Cl_2 (75 mL) were stirred (5 min) before tri-*O*-acetyl-α-D-xylopyranosyl bromide (22) (18.3 g, 54.0 mmol) in CH_2Cl_2 (60 mL) was added dropwise. The mixture was stirred (2 days, rt), then filtered through silica with a pad of Celite on top, washing the filter residue with CH_2Cl_2. The combined filtrate and washings were washed with saturated KI solution and brine, then dried, and concentrated to give a yellow oil. Vacuum distillation (Kugelrohr, 30 mm Hg, 170°C) removed the excess 2-trimethylsilylethanol. The residue was dissolved in MeOH (150 mL) and treated with sodium (200 mg). After 2 h, the mixture was neutralized with resin (Dowex-50W, H^+ form), then filtered, washed with MeOH, and the combined filtrate and washings were concentrated to give a pale yellow solid. Recrystallization gave 2′-trimethylsilylethyl β-D-xylopyranoside (6.6 g, 49%) as white flakes; mp 126–128°C (CH_2Cl_2–*i*-Pr_2O); $[\alpha]_D$ –46.9 (MeOH). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.02 (s, $SiMe_3$), 0.91–1.11 (m, 2H, H2′), 3.27 (dd, $J_{4,5}$ = 8.9, $J_{5,5}$ = 11.8 Hz, H5), 3.38 (dd, $J_{1,2}$ = 6.9, $J_{2,3}$ = 8.4 Hz, H2), 3.52 (t, *J* = 8.4 Hz, H3), 3.57 (ddd, $J_{1',1'}$ = 11.4, $J_{1',2'}$ = 6.2, 9.8 Hz, H1′), 3.68 (dt, $J_{4,5}$ = 5.0 Hz, H4), 3.93 (ddd, $J_{1',2'}$ = 6.2, 9.7 Hz H1′), 3.95 (dd, H5), 4.29 (d, H1). ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: –1.44 ($SiMe_3$), 18.32 (C2′), 65.26, 67.32 (C5,1′), 69.62, 72.94, 76.04 (C2,3,4), 102.50 (C1). Anal. calcd. for $C_{10}H_{22}O_5Si$: C 48.0, H 8.9; found: C 48.1, H 8.6.

2′-Trimethylsilylethyl 2,3-*O*-isopropylidene-β-D-xylopyranoside

2′-Trimethylsilylethyl β-D-xylopyranoside (1.0 g) was treated with 2-methoxypropene as previously for allyl β-D-xylopyranoside to give a colourless oil (930 mg). Flash chromatography (EtOAc–petrol, containing 0.5% Et_3N, 1:4 then 3:7) gave the title alcohol (580 mg, 50%) as an unstable, colourless oil; $[\alpha]_D$ –43.4 ($CHCl_3$–1% pyridine). ^{1}H NMR (300 MHz, $CDCl_3$) δ: –0.02 (s, $SiMe_3$), 0.91–1.08 (m, 2H, H2′), 1.42, 1.43 (2s, CMe_2), 3.20 (dt, $J_{4,5}$ = 3.3, $J_{5,5}$ = 11.1 Hz, H5), 3.24 (br s, OH), 3.29 (dd, $J_{1,2}$ = 7.6, $J_{2,3}$ = 9.6 Hz, H2), 3.48 (t, $J_{3,4}$ = 9.4 Hz, H3), 3.60 (ddd, $J_{1',1'}$ = 11.3, $J_{1',2'}$ = 6.1, 9.5 Hz, H1′), 3.91 (ddd, $J_{1',2'}$ = 6.1, 9.5 Hz,

© 2002 NRC Canada

H1′), 3.97–4.05 (m, H4,5), 4.60 (d, H1). ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: –1.58 ($SiMe_3$), 18.12 (C2′), 26.47, 26.62 (C*Me*$_2$), 66.73, 67.11 (C5,1′), 68.94, 76.42, 81.04 (C2,3,4), 101.16 (Cl), 111.42 (*C*Me$_2$). Anal. calcd. for $C_{13}H_{26}O_5Si$: C 53.8, H 9.0; found: C 53.9, H 9.0.

2′-Trimethylsilylethyl 2,3-*O*-isopropylidene-4-*O*-(*N*-phthalimido)-α-L-arabinoside

2′-Trimethylsilylethyl 2,3-*O*-isopropylidene-β-D-xylopyranoside (383 mg, 1.30 mmol), triphenylphosphine (420 mg, 1.60 mmol), and **6** (260 mg, 1.60 mmol) in THF (12 mL) were treated with diethyl azodicarboxylate (0.31 mL, 1.6 mmol) for 3 days (rt). Air was bubbled through the mixture (2 h) before it was concentrated and the residue subjected to flash chromatography (EtOAc–petrol, containing 0.5% Et_3N, 1:9 then 1:4) to give the title phthalimide (442 mg, 77%) as an unstable colourless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.01 (s, $SiMe_3$), 0.99–1.13 (m, 2H, H2′), 1.34, 1.40 (2s, CMe_2), 3.60–3.73 (m, H3,5,1′), 4.01 (ddd, $J_{1',1'}$ = 10.9, $J_{1',2'}$ = 7.2, 9.4 Hz, H1′), 4.31 (dd, $J_{1,2}$ = 7.4, $J_{2,3}$ = 9.9 Hz, H2), 4.40 (dd, $J_{4,5}$ = 1.6, $J_{5,5}$ = 13.7 Hz, H5), 4.58 (d, H1), 5.03 (dd, $J_{3,4}$ = 3.8 Hz, H4), 7.70–8.81 (m, 4H, Ar). ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: –1.48 ($SiMe_3$), 18.17 (C2′), 26.06, 26.58 (C*Me*$_2$), 65.43, 66.65 (C5,1′), 73.03, 77.74, 79.74 (C2,3,4), 102.93 (Cl), 110.87 (*C*Me$_2$), 123.43, 128.99, 134.36 (6C, Ar), 163.05 (2C, CO).

2′-Trimethylsilylethyl 4-*O*-(*N*-phthalimido)-α-L-arabinoside

2′-Trimethylsilylethyl 2,3-*O*-isopropylidene-4-*O*-(*N*-phthalimido)-α-L-arabinoside (253 mg) in THF (8 mL) was treated with hydrochloric acid (2 mL of 1 M) for 2 days. The mixture was neutralized with resin (Amberlite IRA 400, OH^- form), then filtered, and concentrated to give the title diol (216 mg, 94%) as a colourless crystalline solid; mp 118–120°C; $[\alpha]_D$ –10.7 ($CHCl_3$). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.02 (s, $SiMe_3$), 0.92–1.12 (m, 2H, H2′), 2.64 (br s, 2-OH), 3.60 (ddd, $J_{1',1'}$ = 11.3, $J_{1',2'}$ = 6.1, 9.6 Hz, H1′), 3.68 (dd, $J_{4,5}$ = 1.6, $J_{5,5}$ = 13.0 Hz, H5), 3.76 (dd, $J_{2,3}$ = 9.5, $J_{3,4}$ = 3.2 Hz, H3), 3.84 (dd, $J_{1,2}$ = 6.6 Hz, H2), 4.00 (ddd, $J_{1',2'}$ = 6.6, 9.5 Hz, H1′), 4.10 (d, $J_{3,OH}$ = 3.2 Hz, 3-OH), 4.26 (dt, $J_{4,5}$ = 3.0 Hz, H4), 4.29 (d, H1), 4.61 (dd, H5), 7.76–7.87 (m, 4H, Ar). ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: –1.46 ($SiMe_3$), 18.17 (C2′), 63.91, 67.13 (C5,1′), 72.05, 72.30 (C2,3), 86.96 (C4), 102.29 (Cl), 123.96, 128.47, 134.89 (6C, Ar), 163.96 (2C, CO). Anal. calcd. for $C_{18}H_{25}NO_7Si$: C 54.7, H 6.4, N 3.5; found: C 54.7, H 6.4, N 3.5.

2′-Trimethylsilylethyl 4-*O*-amino-α-L-arabinoside (11)

2′-Trimethylsilylethyl 4-*O*-(*N*-phthalimido)-α-L-arabinoside (26 mg) in $CHCl_3$ (3 mL) was treated with methylhydrazine (0.15 mL). After 5 min, TLC showed that no starting material remained and the solution was applied to the top of a small silica-gel column. Elution with $CHCl_3$, then MeCN–$CHCl_3$ (2:3), gave a colourless solid. Recrystallization gave hydroxylamine derivative **11** (16 mg, 92%) as a colourless crystalline solid; mp 140–142°C ($CHCl_3$–petrol); $[\alpha]_D$ +14.2 (MeOH). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.17 (s, $SiMe_3$), 0.94–1.12 (m, 2H, H2′), 1.62 (br s, 4H, OH,NH_2), 3.43 (dd, $J_{4,5}$ = 1.2, $J_{5,5}$ = 13.2 Hz, H5), 3.56 (ddd, $J_{1',1'}$ = 11.6, $J_{1',2'}$ = 6.6, 9.6 Hz, H1′), 3.63 (dd, $J_{1,2}$ = 6.8, $J_{2,3}$ = 9.3 Hz, H2), 3.70 (dd, $J_{3,4}$ = 2.4 Hz, H3), 3.91–3.94 (m, H4), 3.97 (ddd, $J_{1',2'}$ = 6.1, 9.5 Hz, H1′), 4.19 (d, H1), 4.24 (dd, $J_{4,5}$ = 2.4 Hz, H5). ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: –1.47 ($SiMe_3$), 18.27 (C2′), 62.86, 67.19 (C5,1′), 72.28, 73.05 (C2,3,4), 102.59 (Cl). Anal. calcd. for $C_{10}H_{23}NO_5Si$: C 45.3, H 8.7, N 5.3; found: C 45.4, H 8.9, N 5.4.

Benzyl 2,3-*O*-isopropylidene-β-D-xylopyranoside

Benzyl β-D-xylopyranoside (23) (7.60 g) was treated as previously for allyl β-D-xylopyranoside to give, after flash chromatography (EtOAc–petrol, containing 0.5% Et_3N, 1:4), benzyl 3,4-*O*-isopropylidene-β-D-xyloside (620 mg, 7%) as a colourless solid, a small portion of which was recrystallized; mp 129–130°C (*i*-Pr_2O; lit. (24) 126°C); $[\alpha]_D$ –79 ($CHCl_3$, lit. (24) –87). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.46, 1.47 (2s, CMe_2), 2.52 (br s, OH), 3.49 (dd, $J_{2,3}$ = 9.6, $J_{3,4}$ = 9.0 Hz, H3), 3.54 (t, $J_{4,5} \approx J_{5,5}$ = 10.1 Hz, H5), 3.62 (ddd, $J_{4,5}$ = 4.3, 10.1 Hz, H4), 3.74 (ddd, $J_{1,2}$ = 6.8 Hz, H2), 4.20 (dd, H5), 4.35 (d, H1), 4.59, 4.92 (ABq, *J* = 11.5 Hz, PhCH_2), 7.31–7.37 (m, Ph). ^{13}C NMR (125.8 MHz, $CDCl_3$) δ: 26.54, 26.77 (C*Me*$_2$), 64.72 (C5), 71.80 (Ph*C*H_2), 73.16, 73.66, 81.17 (C2,3,4), 103.67 (Cl), 112.45 (*C*Me$_2$), 128.19, 128.24, 128.58, 136.76 (Ph). Further elution (EtOAc–petrol, containing 0.5% Et_3N, 1:2) gave benzyl 2,3-*O*-isopropylidene-β-D-xylopyranoside (5.26 g, 59%) as a somewhat unstable, colourless syrup; $[\alpha]_D$ –58.0 ($CHCl_3$, lit. (24) –54). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.45, 1.46 (2s, CMe_2), 2.22 (d, $J_{4,OH}$ = 3.8 Hz, OH), 3.28 (dd, $J_{4,5}$ = 7.7, $J_{5,5}$ = 11.7 Hz, H5), 3.43 (dd, $J_{1,2}$ = 7.4, $J_{2,3}$ = 9.6 Hz, H2), 3.53 (t, *J* = 9.2 Hz, H3), 4.04–4.08 (m, H4), 4.10 (dd, $J_{4,5}$ = 5.3 Hz, H5), 4.68, 4.89 (ABq, *J* = 11.7 Hz, PhCH_2), 4.74 (d, H1), 7.28–7.39 (m, Ph). ^{13}C NMR (125.8 MHz, $CDCl_3$) δ: 26.58, 26.77 (C*Me*$_2$), 67.26 (C5), 70.44 (Ph*C*H_2), 69.43, 76.56, 81.01 (C2,3,4), 100.77 (Cl), 111.71 (*C*Me$_2$), 127.90, 128.12, 128.43, 136.91 (Ph).

Benzyl 2,3-*O*-isopropylidene-4-*O*-(*N*-phthalimido)-α-L-arabinoside

Benzyl 2,3-*O*-isopropylidene-β-D-xylopyranoside (2.8 g) was treated with **6** as previously for **5** to give after flash chromatography (EtOAc–toluene, containing 0.5% Et_3N, 1:5) an oil. Trituration of this oil with *i*-Pr_2O then gave the title phthalimide (3.4 g, 80%) as a colourless solid, a small portion of which was recrystallized; mp 172–174°C (MeOH); $[\alpha]_D$ –19 ($CDCl_3$). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.35, 1.42 (2s, CMe_2), 3.63 (dd, $J_{2,3}$ = 9.9, $J_{3,4}$ = 2.4 Hz, H3), 3.67 (dd, $J_{4,5}$ = 1.9, $J_{5,5}$ = 13.6 Hz, H5), 4.39 (dd, $J_{1,2}$ = 7.7 Hz, H2), 4.43 (dd, $J_{4,5}$ = 1.6 Hz, H5), 4.66 (d, H1), 4.72, 4.97 (ABq, *J* = 11.8 Hz, PhCH_2), 5.05 (m, H4), 7.27–7.43, 7.72–7.75, 7.80–7.83 (3m, 9H, Ar). ^{13}C NMR (125.8 MHz, $CDCl_3$) δ: 26.08, 26.58 (C*Me*$_2$), 65.48 (C5), 70.09 (Ph*C*H_2), 73.00, 77.68, 79.65 (C2,3,4), 102.20 (Cl), 110.97 (*C*Me$_2$), 123.46, 127.76, 128.10, 128.35, 129.02, 134.40, 136.98 (12C, Ar), 163.05 (2C, CO). Anal. calcd. for $C_{23}H_{23}NO_7$: C 64.9, H 5.5, N 3.3; found: C 64.6, H 5.4, N 3.3.

Benzyl 4-*O*-(*N*-phthalimido)-α-L-arabinoside

Benzyl 2,3-*O*-isopropylidene-4-*O*-(*N*-phthalimido)-α-L-arabinoside (2.00 g) was treated with hydrochloric acid as previously for **7** to give the title diol (1.82 g) as a colourless solid, a small portion of which was recrystallized to give colourless micro-needles; mp 183°C (EtOH); $[\alpha]_D$ –20.0

© 2002 NRC Canada

($CHCl_3$). ^{1}H NMR (500 MHz, DMSO-d_6) δ: 3.61 (dd, $J_{4,5}$ = 1.7, $J_{5,5}$ = 12.6 Hz, H5), 3.70–3.75 (m, H2,3), 4.12 (dd, $J_{4,5}$ = 3.8 Hz, H5), 4.32 (d, $J_{1,2}$ = 5.8 Hz, H1), 4.50–4.52 (m, H4), 4.57, 4.80 (ABq, J = 12.2 Hz, PhCH_2), 4.93 (d, J = 5.1 Hz, OH), 5.32 (d, J = 4.4 Hz, OH), 7.28–7.43 (m, Ph), 7.86 (s, 4H, Ar). ^{13}C NMR (125.8 MHz, DMSO-d_6) δ: 61.60 (C5), 69.42 (Ph*C*H_2), 70.48, 71.35, 82.85 (C2,3,4), 102.25 (Cl), 123.21, 127.41, 127.61, 128.18, 128.66, 134.72, 138.01 (12C, Ar), 163.31 (2C, CO). Benzyl 4-*O*-amino-α-L-arabinoside (12)

Benzyl 4-*O*-(*N*-phthalimido)-α-L-arabinoside (1.60 g) was treated with methyl hydrazine, as previously for allyl 4-*O*-(*N*-phthalimido)-α-L-arabinoside, to give hydroxylamine derivative **12** (726 mg, 69%) as colourless plates; mp 155–156°C, $[\alpha]_{436}$ −4.0 (MeOH). ^{1}H NMR (500 MHz, DMSO-d_6) δ: 3.31 (dd, $J_{4,5}$ = 1.4, $J_{5,5}$ = 12.3 Hz, H5), 3.34 (ddd, $J_{1,2}$ = 6.7, $J_{2,3}$ = 8.8, $J_{2,OH}$ = 4.8 Hz, H2), 3.46–3.48 (m, H3), 3.60–3.62 (m, H4), 4.03 (dd, $J_{4,5}$ = 3.1 Hz, H5), 4.20 (d, H1), 4.53, 4.75 (ABq, J = 12.2 Hz, PhCH_2), 4.80 (br d, J = 6.2 Hz, 3-OH), 5.05 (d, 2-OH), 6.03 (br s, NH_2), 7.27–7.39 (m, Ph). ^{13}C NMR (125.8 MHz, DMSO-d_6) δ: 61.59 (C5), 69.39 (Ph*C*H_2), 70.98, 71.86, 80.10 (C2,3,4), 102.64 (Cl), 127.33, 127.57, 128.12, 138.10 (Ph). Anal. calcd. for $C_{12}H_{17}NO_5$: C 56.5, H 6.7, N 5.5; found: C 56.2, H 6.7, N 5.4.

Benzyl β-L-xylopyranoside

Tri-*O*-acetyl-L-xylopyranosyl trichloroacetimidate (25) (51.1 g, 120 mmol), benzyl alcohol (38 mL, 0.37 mol), and crushed molecular sieves (3 Å, 15 g) in CH_2Cl_2 (250 mL) were stirred (30 min, 0°C). $Et_2O{\cdot}BF_3$ (1 mL, 7.9 mmol) was added and the reaction was stirred (4 h). Pyridine (120 mL) and acetic anhydride (90 mL) were added and, after 2 h, the reaction was quenched upon the addition of MeOH (70 mL). After 1 h, the mixture was filtered (silica, washing with EtOAc) and the filtrate concentrated. The residue was subjected to normal work up (EtOAc), and rapid silica filtration (EtOAc–petrol, 1:9 then 1:3) afforded a colourless solid (44 g) that was taken up in MeOH and sodium (200 mg) added. After 3 h, the mixture was neutralized with resin (Dowex-50W, H^+ form), then filtered, washed with MeOH, and the combined filtrate and washings concentrated to give a colourless solid. Recrystallization of the solid gave benzyl-β-L-xylopyranoside (26.2 g, 90%) as colourless cubes; mp 112–114°C (EtOAc; lit. (23) 116–117°C).

Benzyl 2,3-*O*-isopropylidene-β-L-xylopyranoside (13)

Compound **13** was prepared as previously for the enantiomer, 60%; $[\alpha]_D$ +65.9 ($CHCl_3$).

Benzyl 2,3-*O*-isopropylidene-4-*O*-(*N*-phthalimido)-α-D-arabinoside (14)

Compound **14** was prepared as previously for the enantiomer, 68%; mp 177.5–179°C (MeOH); $[\alpha]_D$ +18.4 ($CHCl_3$).

Benzyl 4-*O*-amino-2,3-*O*-isopropylidene-α-D-arabinoside (15)

Alcohol **13** (3.23 g, 11.5 mmol), triphenylphosphine (3.93 g, 15.0 mmol), and **6** (2.45 g, 15.0 mmol) in THF (100 mL) were treated with diethyl azodicarboxylate (4.90 mL, 15.0 mmol) for 4 days at rt. The mixture was concentrated and flash chromatography (EtOAc–petrol, containing 0.5% Et_3N, 1:4 then 2:3) gave crude phthalimide **14** (4.62 g) as a pale yellow solid. This solid was dissolved in $CHCl_3$ and treated with $N_2H_4{\cdot}H_2O$ (2 mL, 30 min). The mixture was filtered and the residue washed with $CHCl_3$. The combined filtrate–washings were washed with H_2O and brine, then dried and concentrated to give a pale yellow oil which crystallized. Recrystallization gave hydroxylamine **15** as colourless cubes (1.2 g, 62%); mp 85–87°C (Et_2O–petrol); $[\alpha]_D$ +1.9 ($CHCl_3$). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.44, 1.48 (2s, CMe_2), 3.43 (dd, $J_{4,5}$ = 1.5, $J_{5,5}$ = 13.2 Hz, H5), 3.57 (dd, $J_{2,3}$ = 9.8, $J_{3,4}$ = 2.9 Hz, H3), 3.86 (dd, $J_{1,2}$ = 7.7 Hz, H2), 4.18–4.20 (m, H4), 4.32 (dd, $J_{4,5}$ = 1.8 Hz, H5), 4.61 (d, H1), 4.72, 4.97 (ABq, J = 11.8 Hz, PhCH_2), 5.65 (br s, NH_2), 7.27–7.41 (m, Ph). ^{13}C NMR (125.8 MHz, $CDCl_3$) δ: 26.51, 26.58 (C*Me*$_2$), 65.00 (C5), 70.17 (Ph*C*H_2), 73.47, 77.60, 78.36 (C2,3,4), 101.74 (Cl), 110.58 (*C*Me$_2$), 127.77, 128.07, 128.34, 136.94 (Ph). Anal. calcd. for $C_{23}H_{23}NO_7$: C 61.0, H 7.2, N 4.7; found: C 61.2, H 7.1, N 4.6.

Benzyl 4-*O*-[(*tert*-butoxycarbonyl)amino]-α-D-arabinoside (17)

Hydroxylamine **15** (1.12 g, 3.80 mmol) in $CHCl_3$ (70 mL) was treated with triethylamine (1.0 mL) and di-*tert*-butyl dicarbonate (1.24 g, 5.69 mmol). The mixture was heated at reflux overnight and then concentrated. The residue was dissolved in MeOH–$CHCl_3$ (50 mL, 1:1), treated with pyridinium *p*-toluenesulfonate (70 mg) and heated under reflux (1 h), then allowed to cool. The mixture was treated with resin (Amberlite IRA 400, OH^- form), filtered, and then concentrated, co-evaporating with toluene, to afford diol **17** (984 mg, 73%) as a colourless crystalline solid. A small portion was recrystallized to give colourless microcrystals; mp 158–160°C (EtOAc–petrol); $[\alpha]_D$ +5.8, $[\alpha]_{365}$ +35.8 (MeOH). ^{1}H NMR. (500 MHz, $CDCl_3$) δ: 1.46 (s, CMe_3), 3.45 (d, $J_{5,5}$ = 12.5 Hz, H5), 3.67 (dd, $J_{3,4}$ = 3.7, $J_{2,3}$ = 9.2 Hz, H3), 3.71 (dd, $J_{1,2}$ = 6.8 Hz, H2), 4.03–4.05 (m, H4), 4.16 (dd, $J_{4,5}$ = 2.7 Hz, H5), 4.28 (d, H1), 4.59, 4.88 (ABq, J = 11.8 Hz, PhCH_2), 7.26–7.36 (m, Ph). ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 28.10 (C*Me*$_3$), 63.16 (C5), 70.63 (Ph*C*H_2), 71.96, 72.14 (C2,3), 82.82 (*C*Me$_3$), 83.25 (C4), 101.78 (Cl), 127.85, 128.05, 128.40, 137.02 (Ph), 157.96 (CO). Anal. calcd. for $C_{17}H_{25}NO_7$: C 57.4, H 7.1; found: C 57.5, H 7.1.

4-*O*-[(*tert*-butoxycarbonyl)amino]-D-arabinose (18)

Diol **17** (850 mg), palladium-on-carbon (85 mg of 10%), and hydrochloric acid (0.4 mL of 1 M) in H_2O–THF (1:2, 30 mL) were treated with hydrogen (24 h at 1 atm). The mixture was filtered through Celite, washing with H_2O–THF (1:1). The combined filtrate and washings were neutralized with resin (Amberlite IRA 400, OH^- form), filtered, and then concentrated to give a colourless solid. Flash chromatography (MeOH–$CHCl_3$, 7:93 then 15:85) gave hemiacetal **18** (600 mg, 94%) as a colourless solid; mp 121–123°C; $[\alpha]_D$ +35.2 (MeOH). ^{1}H NMR (500 MHz, MeOH-d_4) δ: 1.50 (s, CMe_3), 3.51 (dd, $J_{1,2}$ = 4.0, $J_{2,3}$ = 8.8 Hz, H2), 3.57–3.65 (m, H3,4), 3.68 (dd, $J_{4,5}$ = 6.6, $J_{5,5}$ = 12.8 Hz, H5), 3.88 (dd,

(4*R*,5*S*,6*R*)-5,6-Dihydro-4,5-dihydroxy-6-hydroxymethyl-4*H*-1,2-oxazine (4)

Hemiacetal **18** (130 mg) was heated at reflux in water (7 mL) for 10 min. Freeze drying gave dihydrooxazine **4** (72 mg) as a colourless solid, a portion of which was recrystallized; mp 142–145°C (MeOH–EtOAc–Et_2O); $[\alpha]_D$ = +18.3 (MeOH). ^{1}H NMR (500 MHz, D_2O) δ: 3.80–3.86 (m, H5), 3.89–4.02 (m, 3H, H6,7), 4.29 (dd, $J_{3,4}$ = 1.6, $J_{4,5}$ = 8.3 Hz, H4), 7.29 (d, H3). ^{13}C NMR (125.8 MHz, D_2O) δ: 59.41 (C7), 65.83, 68.40 (C4,5), 80.51 (C6), 151.96 (C3). EI-HRMS calcd. for $C_5H_9NO_4$ (M^+): 147.0532, found: 147.0534. Anal. calcd. for $C_5H_9NO_4$: C 40.8, H 6.2; found: C 41.0, H 6.2.

(4*R*,5*S*,6*R*)-4,5-Dihydroxy-6-hydroxymethyl-3,4,5,6-tetrahydro-2*H*-1,2-oxazine (2)

Dihydrooxazine **4** (140 mg, 0.97 mmol) in AcOH (12 mL) was treated with $NaCNBH_3$ (64 mg, 95%, 0.97 mmol) (40 min, rt). The mixture was concentrated and the residue dissolved in hydrochloric acid (6 mL of 0.05 M) and then applied to a column of cation-exchange resin (Dowex 50W-X2, H^+ form). The column was washed with water, then eluted with hydrochloric acid (3 M). Concentration of the eluate gave a colourless oil that was taken up in MeOH and treated with resin (Amberlite IRA 400, OH^- form). The mixture was filtered and concentrated to give tetrahydrooxazine **2** (160 mg) as a colourless foam, a portion of which was crystallized; mp 149–151°C (MeOH–EtOAc); $[\alpha]_D$ –36.4 (MeOH). ^{1}H NMR (500 MHz, D_2O) δ: 2.92 (dd, $J_{3,3}$ = 13.2, $J_{3,4}$ = 10.7 Hz, H3), 3.28 (dd, $J_{3,4}$ = 5.4 Hz, H3), 3.41 (t, $J_{4,5} \approx J_{5,6}$ = 9.3 Hz, H5), 3.58 (ddd, $J_{6,7}$ = 2.1, 6.2 Hz, H6), 3.67–3.73 (m, H4,7), 3.90 (dd, $J_{7,7}$ = 12.7 Hz, H7). ^{13}C NMR (125.8 MHz, D_2O) δ: 53.26 (C3), 60.54 (C7), 71.05, 71.07 (C4,5), 84.33 (C6) (7). EI-HRMS calcd. for $C_5H_{11}NO_4$ (M^+): 149.0688, found: 149.0692. Anal. calcd. for $C_5H_{11}NO_4$: C 40.3, H 7.4, N 9.4; found: C 40.1, H 7.2, N 9.2.

Benzyl 4-*O*-(imidazyl-1-sulfonyl)-2,3-*O*-isopropylidene-β-L-xyloside (20)

Sodium hydride (60% in mineral oil, 1.0 g, 25 mmol) was added to a chilled mixture of alcohol **13** (5.4 g, 20 mmol) in DMF (30 mL, 0°C) and the mixture stirred (30 min, rt). The mixture was cooled (−40°C) and *N*,*N*′-sulfuryldiimidazole (5.0 g, 25 mmol) in DMF (40 mL) was added dropwise, then the mixture allowed to stir (30 min). MeOH (3 mL) was added and, after a further 30 min, the mixture was allowed to warm to room temperature, then subjected to normal workup (CH_2Cl_2) to give a pale yellow oil. Flash chromatography (EtOAc–petrol, containing 0.5% Et_3N, 1:3 then 1:2) gave imidazole sulfonate **20** (5.75 g, 72%) as a colourless solid. A small portion was recrystallized to give colourless needles; mp 90–92°C (EtOAc–petrol); $[\alpha]_D$ +86.6 ($CHCl_3$). ^{1}H NMR. (300 MHz, $CDCl_3$) δ: 1.30, 1.37 (s, CMe_2), 3.47 (dd, $J_{1,2}$ = 6.9, $J_{2,3}$ = 10.1 Hz, H2), 3.60 (dd, $J_{4,5}$ = 4.7, $J_{5,5}$ = 13.2 Hz, H5), 3.64 (dd, $J_{3,4}$ = 8.2 Hz, H3), 4.17 (dd, $J_{4,5}$ = 5.2 Hz, H5), 4.62, 4.81 (ABq, J = 11.6 Hz, $PhCH_2$), 4.82 (ddd, H4), 4.83 (d, H1), 7.12–7.43 (m, 7H, Ph,Im), 7.97–7.99 (m, Im). ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 26.29, 26.50 (C*Me*$_2$), 63.40 (C5), 70.27 (Ph*C*H$_2$), 76.43, 76.66, 82.22 (C2,3,4), 99.77 (C1), 113.01 (*C*Me$_2$), 117.80 (2C, Im), 128.05, 128.48, 131.17, 136.52 (Ph), 137.32 (Im). FAB-HRMS calcd. for $C_{18}H_{23}N_2O_7S$ (M + 1): 411.1226, found: 411.1221. Anal. calcd. for $C_{18}H_{22}N_2O_7S$: C 52.7, H 5.4; found: C 53.0, H 5.5.

Benzyl 4-cyano-4-deoxy-2,3-*O*-isopropylidene-α-D-arabinoside (21)

Imidazole sulfonate **20** (4.58 g, 11.2 mmol) was treated with trimethylsilyl cyanide (2.94 mL, 22.3 mmol) in MeCN (100 mL) and the mixture heated under reflux. Tetrabutylammonium fluoride (1.0 M in THF, 17 mmol) was added dropwise over 30 min. After a further 1 h, the mixture was cooled to room temperature, concentrated, and normal work-up (EtOAc) gave a red oil. Flash chromatography (EtOAc–petrol, containing 0.5% Et_3N, 1:5 then 1:3) of the oil gave nitrile **21** as a pale yellow oil (2.61 g, 81%), which crystallized. A small portion was recrystallized to give off-white needles; mp 89–90°C (Et_2O–petrol); $[\alpha]_D$ –21.2 ($CHCl_3$). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.47, 1.51 (s, CMe_2), 3.29 (ddd, $J_{3,4}$ = 4.9, $J_{4,5}$ = 1.8, 3.1 Hz, H4), 3.58 (dd, $J_{2,3}$ = 9.4 Hz, H3), 3.64 (dd, $J_{5,5}$ = 12.5 Hz, H5), 3.80 (dd, $J_{1,2}$ = 7.6 Hz, H2), 4.30 (dd, H5), 4.68 (d, H1), 4.69, 4.93 (ABq, J = 11.8 Hz, Ph*C*H$_2$), 7.27–7.42 (m, Ph). ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 26.39, 26.65 (C*Me*$_2$), 32.82 (C4), 63.66 (C5), 70.38 (Ph*C*H$_2$), 74.53, 76.00 (C2,3), 101.45 (C1), 111.97 (*C*Me$_2$), 116.59 (CN), 120.10, 128.02, 128.48, 136.55 (Ph). FAB-HRMS calcd. for $C_{16}H_{20}NO_4$ (M + 1): 290.1392, found: 290.1398. Anal. calcd. for $C_{16}H_{19}NO_4$: C 66.4, H 6.6; found: C 66.3, H 6.4.

Benzyl 4-{[(*tert*-butoxycarbonyl)amino]methyl}-4-deoxy-2,3-*O*-isopropylidene-α-D-arabinoside (23)

Nitrile **21** (2.0 g, 6.9 mmol) in ether (40 mL) was added dropwise to a mixture of lithium aluminium hydride (730 mg, 17 mmol) in ether (40 mL) and this mixture stirred (1 h). The mixture was quenched with successive additions of H_2O (730 μL), aqueous NaOH (3 M, 730 μL), and H_2O (2.2 mL). The mixture was filtered, washing with ether, and the combined filtrate and washings were concentrated to give an oil (2.5 g). This oil was dissolved in $CHCl_3$ (120 mL) and treated with triethylamine (2 mL) and di-*tert*-butyl dicarbonate (1.7 g, 7.6 mmol). The mixture was heated at reflux overnight, then concentrated to give a colourless solid. Recrystallization gave carbamate **23** as fine needles (1.52 g, 56%); mp 146–148°C (EtOAc–petrol); $[\alpha]_D$ +29.9 ($CHCl_3$). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.46 (s, 15H, Me), 2.33–2.43 (m, H4), 3.26–3.49 (m, CH_2N), 3.58 (dd, $J_{4,5}$ = 3.8, $J_{5,5}$ = 12.6 Hz, H5), 3.61–3.69 (m, H2), 3.72 (dd, $J_{2,3}$ = 9.8, $J_{3,4}$ = 5.3 Hz, H3), 3.91 (dd, $J_{4,5}$ = 2.6 Hz, H5), 4.61 (d, $J_{1,2}$ = 7.3 Hz, H1), 4.65, 4.85 (ABq, J = 11.7 Hz, Ph*C*H$_2$), 5.00–5.09 (m, NH), 7.27–7.41 (m, Ph). ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 26.54, 26.63 (C*Me*$_2$), 28.39 (C*Me*$_3$), 38.08 (CH_2N), 38.99 (C4), 64.93 (C5), 70.10 (Ph*C*H$_2$), 74.43, 77.54 (C2,3), 79.29 (*C*Me$_3$), 101.84 (C1), 110.60

(CMe_2), 127.79, 128.05, 128.37, 137.00 (Ph), 155.89 (CO). FAB-HRMS calcd. for $C_{21}H_{32}NO_6$ (M + 1): 394.2230, found: 394.2247. Anal. calcd. for $C_{21}H_{31}NO_6$: C 64.1, H 7.9; found: C 64.0, H 7.7.

Benzyl 4-{[(*tert*-butoxycarbonyl)amino]methyl}-4-deoxy-α-D-arabinoside (24)

A mixture of carbamate **23** (1.50 g, 3.82 mmol) and pyridinium *p*-toluenesulfonate (80 mg, 310 (mol) in MeOH–$CHCl_3$ (25 mL, 1:1) was heated under reflux (1 h) and allowed to cool. The mixture was treated with resin (Amberlite IRA 400, OH^- form), filtered, and then concentrated, co-evaporating with toluene, to afford diol **24** as a colourless solid (1.30 g). A small portion was recrystallized to give colourless micro-needles; mp 159–162°C (EtOAc–petrol); $[\alpha]_D$ +77.8 ($CHCl_3$). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.43 (s, CMe_3), 1.98 (br s, OH), 2.16–2.27 (m, H4), 2.89 (br s, OH), 3.18–3.32 (m, CH_2N), 3.53 (dd, J = 4.0, 11.9 Hz, 1H), 3.68 (dd, J = 3.9, 5.5 Hz, 1H), 3.76–3.87 (m, 2H), 4.53, 4.81 (ABq, J = 11.8 Hz, PhCH_2), 4.59 (d, $J_{1,2}$ = 3.7 Hz, H1), 5.00–5.08 (m, NH), 7.27–7.39 (m, Ph). ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 28.39 (CMe_3), 37.41 (C4), 38.95 (CH_2N), 60.17 (C5), 69.46, 70.31 (C2,3), 70.04 (PhCH_2), 79.49 (CMe_3), 100.31 (C1), 128.08, 128.55, 136.71 (Ph), 156.34 (CO). FAB-HRMS calcd. for $C_{18}H_{28}NO_6$ (M + 1): 354.1917, found: 354.1924. Anal. calcd. for $C_{18}H_{27}NO_6$: C 61.2, H 7.7; found: C 61.4, H 7.8.

Isofagomine (HCl salt) (1)

Diol **24** (1.3 g) was treated with trifluoroacetic acid (6 mL; 5 min, rt) and the mixture concentrated, co-evaporating with H_2O. The residue was dissolved in MeOH, treated with resin (Amberlite IRA 400, OH^- form), filtered, and then concentrated. MeOH (40 mL), AcOH (1.5 mL), and palladium-on-carbon (150 mg of 10%) were added to the residue and this mixture was treated with hydrogen (overnight, 1 atm). The mixture was filtered through Celite, washing with MeOH, followed by concentration, to give a pale-brown gum (720 mg). This gum was dissolved in hydrochloric acid (4 mL of 1 M) and applied to a cation-exchange column (Dowex 50W-X2, H^+ form). The column was washed with water, then eluted with aqueous NH_3 (1.5 M). The eluate was concentrated and flash chromatography (*i*-PrOH–aqueous NH_3 (7 M), 6:1 then 4:1) gave a colourless oil. This oil was treated with hydrochloric acid (10 mL of 1 M) and concentrated. Freeze drying of the residue gave isofagomine (**1**) (HCl salt) as a colourless gum (660 mg, 96%); $[\alpha]_D$ +16.5 (H_2O). ^{1}H NMR (500 MHz, D_2O) and ^{13}C NMR (125.8 MHz, D_2O) spectral data were in good agreement with those reported previously (12, 14).

A sample of **1** was applied to a cation-exchange column (Dowex 50W-X2, H^+ form). The column was washed with water and then eluted with aqueous NH_3 (1.5 M). The eluate was concentrated to give **1** as the free amine; $[\alpha]_D$ +20.5 (EtOH, lit. (12) +19.6).

Acknowledgments

We thank the Australian Research Council for financial assistance and Dr. Jon Fairweather (working in the laboratory of Professor Marc Claeyssens, Gent, Belgium) for determining the inhibition constants of the dihydrooxazine.

On expanding the repertoire of glycosynthases: Mutant β-galactosidases forming β-(1,6)-linkages

David L. Jakeman and Stephen G. Withers

Abstract: Oligosaccharide synthesis by enzymatic processes offers the potential for thrusting oligosaccharides to the forefront of pharmaceutical research, in part, due to expedient and scalable reaction protocols. Glycosynthases are an emerging class of mutant enzymes capable of synthesizing glycosidic linkages in high yield. We report a new glycosynthase enzyme generated by a point mutation of *E. coli* β-galactosidase that condenses α-galactosyl fluoride with aryl glucosides forming a β-(1,6) glycosidic linkage. A further point mutation within the enzyme, proximal to the active site, increases the yields significantly.

Key words: glycosyl transfer, glycosynthase, enzymatic oligosaccharide synthesis.

Résumé : La synthèse d'oligosaccharides par des procédés enzymatiques offre la possibilité de projeter les oligosaccharides à l'avant-plan de la recherche pharmaceutique en raison, en partie, au fait que les protocoles de réaction sont relativement simples et qu'il est possible de les réaliser à grande échelle. Les glycosynthases font partie d'une classe d'enzymes mutants en émergence capable de réaliser la synthèse de liens glycosidiques avec des rendements élevés. Dans ce travail, on la préparation d'une nouvelle glycosyntase, obtenue par mutation ponctuelle de la β-galactosidase du *E. coli*, qui permet de condenser le fluorure d'α-galactosyle avec des glucosides d'aryles pour former une liaison β-(1,6) glycosidique. Une autre mutation ponctuelle à l'intérieur de l'enzyme, à proximité du site actif, permet d'augmenter le rendement de façon significative.

Mots clés : transfert d'un glycosyle, glycosynthase, synthèse enzymatique d'un oligosaccharide.

[Traduit par la Rédaction]

Introduction

Oligosaccharides are ubiquitious throughout nature and play a multitude of important roles in biological systems ranging from leukocyte trafficking by glycosaminoglycans (1–3) to the localization of glycoproteins via their glycan moieties (4–9). The diverse roles played by oligosaccharides therefore provide possibilities for the generation of new therapeutics for numerous disease states. Inspired by the possibilities for disease treatment and by the challenges posed by the complex structural architecture of oligosaccharides, chemists have devised and implemented impressive synthetic routes toward these challenging molecules. The very complexity of these compounds, however, hinders development of the efficient and economical syntheses required to produce the quantities of oligosaccharides needed for biological testing. Particularly demanding are the many protecting group manipulations that are needed to ensure control of regio- and stereochemistry. Enzymatic syntheses offer the promise of inherently scalable and shorter routes towards quantities of oligosaccharides because the vital regio- and stereochemical control is governed by the enzyme, thus avoiding laborious protecting group manipulation (10–15).

Glycosynthases (16) are a new class of mutant enzymes for the synthesis of oligosaccharides derived from retaining β-glycoside hydrolases, which cleave glycosides through a double displacement mechanism that proceeds via a covalent glycosyl–enzyme intermediate (Fig. 1*a*). Wild-type β-glycoside hydrolases have been used successfully in the synthesis of glycosides through the coupling of an activated donor sugar to the desired acceptor moiety via a transglycosylation mechanism (Fig. 1*b*). The yields are almost always modest because the product from the transglycosylation reaction is a substrate for hydrolysis (17). These low product yields have been circumvented by using glycosynthases: mutant glycosidases in which the nucleophilic carboxylic acid residue is engineered into a non-nucleophilic residue. The single-point mutation within the enzyme is sufficient to remove all hydrolytic activity yet maintain an active-site architecture appropriate for the condensation of an activated donor sugar (glycosyl fluoride) of the opposite anomeric configuration to that of the natural substrate, with an acceptor sugar. α-Glycosyl fluorides are therefore used with β-glycosynthases, binding into the enlarged active-site pocket generated by the mutation and mimicking the reactive α-glycosyl-enzyme intermediate formed during catalysis by the wild-type enzymes (Fig. 2). Since the report of the initial glycosynthase (AbgGlu358Ala) several glycosynthases have been reported in the literature. These condense various α-hexosyl fluorides onto acceptors with formation of β-(1,3)- or β-(1,4)- glycosidic linkages (18–23). Of particular importance has been the discovery that replacement of the nucleophilic amino

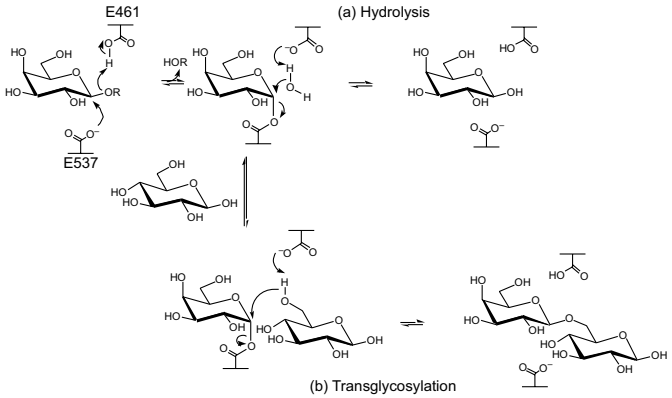
Fig. 1. Mechanisms of the hydrolysis and transglycosylation reactions catalyzed by wild-type LacZ α-galactosidase.



acid with serine rather than alanine leads to more active glycosynthase mutants (19, 23).

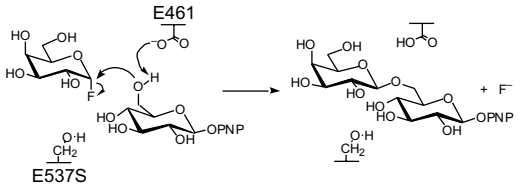
In this paper we describe the development of a glycosynthase from glycosyl hydrolase family 2 *Escherichia coli* β-galactosidase (LacZ), which synthesises Gal-β-(1,6)-linkages, a glycosidic linkage hitherto unavailable using known glycosynthases (Fig. 2).

Results and discussion

E. coli LacZ-galactosidase (EC 3.2.1.23) is one of the most commonly used enzymes within molecular biology and was instrumental in determining the operon model of gene regulation. It is responsible for the hydrolysis of lactose (Gal-β-(1,4)-Glc) to provide glucose as a starting point for glycolysis. It also performs transglycosylation reactions between the galactose and glucose moieties from lactose, to form allolactose (Gal-β-(1,6)-Glc), the natural lac-operon inducer. This enzyme is functional as a tetramer of 4 × 116 kDa, thus solution of its 3-D structure represented a considerable "tour de force" of X-ray crystallography (24). Previous work had identified the nucleophilic residue within the active site of LacZ galactosidase as Glu537 by trapping the covalent intermediate through the use of the mechanism-based inactivator, 2,4-dinitrophenyl 2-deoxy-2-fluoro-β-D-galactopyranoside, coupled with electrospray ionization mass spectrometric analysis of HPLC-separated proteolytic digests of the 2-fluorogalactosyl-enzyme intermediate (25).

The stage was therefore set for generation of a glycosynthase from LacZ. To simplify the purification of the enzyme and also allow separation of the mutant from any chromosomally encoded wild-type contaminant, a construct was used that coded a N-terminal His_6-tag fusion. Upon mutation of the nucleophile to serine (Glu537Ser), the mutant protein was over-expressed in *E. coli* strain BL21 λDE3 and isolated by affinity chromatography on a nickel column. Unfortunately, the protein retained significant wild-type activity (1/200) as demonstrated by removal of all activity after incubation of the recombinant protein with sub-stoichiometric amounts of the mechanism-based inactivator. We surmized that this low wild-type activity arose from monomers of the wild-type LacZ galactosidase expressed constitutively from the lac operon associating with the mutant to form active tetrameric units within the cell. These tetrameric units presumably remain associated throughout the affinity purification and, therefore, a small but significant quantity of wild-type LacZ is co-purified with the mutant, despite its lack of an affinity tag. To circumvent wild-type contamination we obtained *E. coli* strain W2244 that has one third of the LacZ gene deleted, and consequently fails to grow on lactose as the sole carbon source (26). The strain was lysogenized with λDE3 phage to introduce the T7 RNA polymerase gene into the W2244 genome as is necessary for expression of genes under control of a T7 promoter. Purification of the gene product from *E. coli* strain W2244 λDE3 resulted in a lower yield of protein than from BL21 λDE3 stocks but, more significantly, wild-type activity was not observed.

Fig. 2. Transglycosylation catalyzed by LacZ glycosynthase mutants.



The results of transglycosylation reactions catalyzed by LacZ (Glu537Ser) glycosynthase are summarized in Table 1. Reaction between α-D-galactosyl fluoride (α-GalF) and *para*-nitrophenyl β-D-glucopyranoside (*p*NPGlc) catalyzed by the Glu358Ser mutant resulted in a modest 40% yield of a disaccharide product. To determine the regiochemistry of the linkage, the disaccharide product was acetylated and characterized by NMR. The relative downfield chemical shift of the glucopyranoside ring C-6 in comparison to the other centers, which are acetylated, indicated a β-(1,6)-linkage. The glycosidic linkage formed by the glycosynthase reaction is therefore the same as the linkage formed in the wild-type transglycosylation reaction, consistent with a preferred binding mode for galactose in the aglycone (+1) site in which the 6-hydroxyl of glucose is located close to the anomeric center of the galactosyl enzyme. Comparable yields of product were obtained using a transglycosylation reaction catalyzed by wild-type enzyme to synthesise 3-*O*-methyl allolactose. As with all transglycosylation reactions, product hydrolysis occurred over longer reaction times (27). The glycosynthase reaction yield was significantly greater than that obtained with the wild-type enzyme (40% vs. 10% total of allolactose, lactose and Gal-β-(1,3)-Glc) (28).

The reaction of α-GalF and *p*NP β-cellobioside was also catalyzed by the Glu537Ser mutant enzyme, affording a 63% isolated yield of Gal-β-(1,6)-Glc-β-(1,4)-Glc-*p*NP. While the reaction of α-GalF and phenyl β-D-glucoside afforded a 61% yield of Gal-β-(1,6)-Glc-Ph. Further improvements in yield were therefore sought through additional protein engineering.

Huber and co-workers (29) had reported earlier a single-point mutation (Gly794Asp) that increased the rate of glycosidic-bond cleavage 25-fold relative to the wild-type enzyme, using lactose as substrate. It therefore seemed likely that inclusion of this point mutation within the glycosynthase could improve the performance of this catalyst. The double mutant Glu537Ser/Gly794Asp was therefore generated and the protein was isolated. Two parallel reactions with *p*NP β-cellobioside and α-GalF as the reactants were monitored, one catalyzed by Glu537Ser and the other

[a]Reaction performed with an enzyme concentration of 34 μM

catalyzed by Glu537Ser/Gly794Asp. TLC analysis revealed that the double mutant was considerably more active, and upon isolation of the disaccharide product the double mutant gave a higher product yield (80% vs. 51%). With phenyl β-D-glucoside as the acceptor improvements in yield were also observed for the double mutant (85% vs. 61%). The importance of a 794–804 amino-acid residue loop has been shown through recent X-ray crystallographic studies of the structures of LacZ and mutants bound to various substrate, transition-state, and intermediate analogues. Upon the binding of transition-state analogues, this loop was found to move up to 10 Å closer to the active site (30). Figure 3 shows the position of Gly794Asp modeled into the Glu537Gln LacZ-allolactose crystal structure (1jz8.pdb) to minimize steric interactions. This structure confirms that the introduced aspartic acid lies well within the active site and may well interact with the acceptor sugar to facilitate transglycosylation. In addition, since Gly794 resides at one end of this mobile loop, which seems to play a role in catalysis, it is quite possible that the mutation may well affect the preferred conformation of this loop in a way that optimizes turnover.

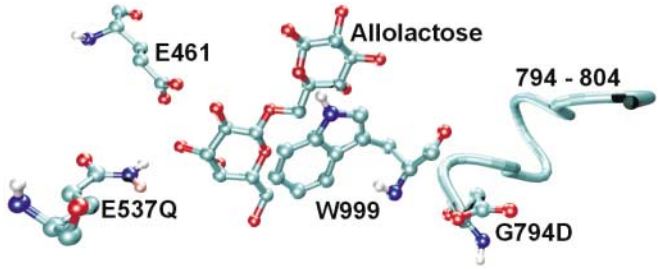
In conclusion, the existing glycosynthase methodology has been extended to the synthesis of Gal-β-(1,6)-linkages using a serine-nucleophile mutant of LacZ. Improvements in product yield have been obtained by an additional point mutation within the enzyme, which is close to the enzyme active site. Further improvements in the reaction rate should be possible using a combination of random mutagenesis and an appropriate screening protocol similar to that used for selecting improved glycosynthases from *Agrobacterium sp.* glucosidase (18).

Experimental

Enzyme mutagenesis: expression and purification

The plasmid pRSETlacZ was obtained from Invitrogen and codes for a N-terminal His-tagged LacZ gene under the control of a T7 promotor. It was mutated using the Promega GeneEditor in vitro Site-Directed Mutagenesis System as described in the manual with the following oligonucleotide to generate the Glu537Ser mutation: 5′-(P)GATCCTTGCAGTTACGCCCACG-3′ (the mutated codon is underlined). The Gly794Asp mutation was introduced into the wild-type gene using the Promega kit with the following oligonucleotide 5′-(P)AACGACATTGACGTCAGTGAAGCGACC-3′. Both mutants were digested with SacI and AccI restriction endonucleases and run on a 2% agarose gel. The 5000 bp and 800 bp fragments were cut out and purified using a Qiaex II gel extraction kit. The 5000 bp vector backbone from mutant Glu537Ser was ligated with the 800 bp insert encoding Gly794Asp and transformed into XL1-Blue cells to afford the double mutant Glu537Ser/Gly794Asp. Mutations were confirmed by sequence analysis.

Fig. 3. The crystal structure of E537Q LacZ (1jz8.pdb) with allolactose bound in the +1/+2 (shallow) binding site showing the acid–base catalyst (E461), the mutated nucleophile (E537Q), and allolactose bound over W999. The mutation G794D was generated using swisspdbviewer. The loop residues that move during catalysis in the wild-type enzyme are represented as a tube (794–804).



The plasmid coding for Glu537Ser was transformed by electroporation into *E. coli* BL21 λDE3 and induced at OD_{600} = 0.6 with IPTG (0.4 mM final concentration) and allowed to grow for a further four hours. Cells were harvested by centrifugation and passed twice through a French press at 4°C. The mutant, Glu537Ser, was isolated from the supernatant by Ni^{2+} chelation chromatography (His-bind resin, Novagen); yields of 50 mg L^{-1} were obtained. Protein was concentrated using Centricon Plus 20 kDa molecular-weight cut-off membranes.

Strain W2244 (*E. coli* genetic stock centre) was lysogenized with phage λDE3 using the Novagen λDE3 lysogenization protocol. Plasmids coding for Glu537Ser and Glu537Ser/Gly794Asp mutants were transformed into electrocompetent W2244 λDE3 cells. Protein expression and purification in W224 λDE3 was performed exactly as described for strain BL21 λDE3 except that final yields were 5 mg L^{-1}. Protein concentrations were determined by absorbance at 280 nm using the extinction coefficient $E_{280}^{0.1\%}$ = 2.1 cm^{-1}, determined from the amino acid sequence.

Oligosaccharide synthesis and characterization

Enzyme reactions were performed in 200 mM phosphate buffer, pH 7.5, 1 mM $MgCl_2$. Reaction mixtures were monitored by TLC (Kieselgel 60 F_{254} (Merck), ethyl acetate–methanol–water, 7:2:1) and visualized under UV light and by exposure to 10% ammonium molybdate in 2 M H_2SO_4. Reaction mixtures were passed through a 30-kDa ultrafiltration membrane to remove protein, applied to a TosaHaas Amide 80 HPLC column and separated by gradient elution of 80% acetonitrile to 60% acetonitrile. After analysis

and identification by mass spectrometry (ESI), products were acetylated with acetic anhydride–pyridine (1:2) and purified by flash chromatography (ethyl acetate–hexanes) on silica gel (230–400 mesh). ^{1}H and ^{13}C NMR (Bruker Avance, 400 MHz) spectra were internally referenced to the solvent.

4-Nitrophenyl* β-D-*galactopyranosyl-(1,6)*-β-D-*glucopyranoside

4-Nitrophenyl β-D-glucopyranoside (8.7 mg, 29.1 μM) and α-D-galactosyl fluoride (10.6 mg, 58 μM) were dissolved in phosphate buffer (1 mL) containing LacZ E537S (34 μM). After incubation at room temperature for 48 h, with TLC monitoring, the reaction mixture was purified to yield the disaccharide (5.4 mg, 40%).

An identical reaction was performed for the double mutant, with the exception that LacZ E537S G794D (17 μM) was used as catalyst to yield the disaccharide (9.4 mg, 70%). ESI-MS *m*/*z*: 486 $[M + Na]^+$.

4-Nitrophenyl hepta-O-*acetyl* β-D-*galactopyranosyl-(1,6)*-β-D-*glucopyranoside*

^{1}H NMR δ: 1.82, 1.98, 2.02, 2.05, 2.06, 2.08, 2.18 (s, 21H, C*H*$_3$), 3.65 (dd, *J* = 8.1 Hz, 1H, H6), 3.02–3.91 (m, 2H, H5′, H6), 3.96 (ddd, *J* = 8.2, 1.8 Hz, 1H, H5), 4.09 (dd, *J* = 6.4, 11.3 Hz, 1H, H6′), 4.19 (dd, *J* = 6.7, 11.3 Hz, 1H, H6′), 4.48 (d, *J* = 8.0 Hz, 1H, H1′), 4.91–5.00 (m, 2H, H3′, H4), 5.12 (d, *J* = 7.2 Hz, 1H, H2), 5.21 (dd, *J* = 10.5, 8.0 Hz, 1H, H2′), 5.26 (dd, *J* = 9.3, 8.2 Hz, 1H, H3), 5.28 (d, *J* = 7.2 Hz, 1H, H1), 5.39 (d, *J* = 2.6 Hz, 1H, H4′), 7.10 (d, *J* = 7.2 Hz, 2H, Ph), 8.25 (d, *J* = 7.2 Hz, 2H, Ph). ^{13}C NMR δ: 20.5, 20.6, 20.6, 20.6, 61.3, 67.0, 68.3, 68.5, 68.7, 70.7, 70.9, 71.1, 72.5, 73.8, 98.2, 101.2, 116.6, 128.1, 143.2, 161.4, 169.2, 169.6, 170.0, 170.1, 170.3. Potential for using antibiotics combined with a Shiga toxin-absorbing agent for treating 0157:H7 *Escherichia coli* infections

George Mulvey, David J. Rafter, and Glen D. Armstrong

Abstract: Antibiotics are not recommended for treating O157:H7 *Escherichia coli* infections because they may promote Shiga toxin (Stx) release from these bacteria. This could increase the risk of Stx-mediated complications in patients suffering from such infections. Here, we observed increased cell-free Stx in *E. coli* O157:H7 cultures exposed to subinhibitory concentrations of several antibiotics. Synsorb-Pk, an agent with a high affinity for Stx, absorbed Stx activity from the antibiotic-treated cultures. These data suggest certain antibiotics, given in combination with an orally administered Stx-binding agent, may be useful in treating O157:H7 *E. coli* infections.

Key words: Shiga toxin, Synsorb, *Escherichia coli*, O157:H7, antibiotics, therapy.

Résumé : Les antibiotiques ne sont pas recommandés pour le traitement d'infections au *Escherichia coli* 0157:H7 parce que leur utilisation pourrait provoquer la libération de la toxine Shiga (Stx) de ces bactéries et, pour les patients atteints de telles infections, elle pourrait augmenter le risque de complications liées à Stx. Dans ce travail, on a pu observer une augmentation de Stx sans cellule dans des cultures d'*E. coli* 0157:H7 exposées à des concentrations sous-inhibitrices de plusieurs antibiotiques. Le Synsorb-Pk, un agent ayant une grande affinité pour Stx, absorbe l'activité de Stx à partir des cultures traitées par les antibiotiques. Ces données suggèrent que certains antibiotiques, donnés en combinaison en association avec un agent fixant le Stx administré oralement, pourrait s'avérer utile pour traiter des infections au *E. coli* 0157:H7.

Mots clés : toxine Shiga, Synsorb, *Escherichia coli*, 0157:H7, antibiotiques, thérapie.

[Traduit par la Rédaction]

Introduction

Enterohemorrhagic *Escherichia coli* (EHEC) express virulence factors that enable them to colonize in the human intestine, where they cause diarrhea, hemorrhagic colitis, and, occasionally, complications involving the kidneys and, potentially, the central nervous system (1). These EHEC-mediated complications are collectively called the hemolytic-uremic syndrome (HUS). Although numerous *E. coli* serotypes have been isolated from patients with hemorrhagic colitis, the majority of cases in Europe, Japan, and North America involve *E. coli* O157:H7 (1).

The complications associated with EHEC infections are partly cytotoxin-mediated. These EHEC cytotoxins are structurally and functionally related to Shiga toxin (Stx), expressed by *Shigella dysenteriae* type 1 (2). EHEC express functionally related but serologically distinct Stx (2). The first of these, Shiga toxin 1 (Stx1), is virtually identical to the prototypic Stx (3). The second, Stx2, is more distantly related to Stx1 and Stx (2). Variant forms of Stx2 have also been described (2). Regardless of their serological differences, all the Stx's are classic AB_5-type exotoxins composed of an A subunit and a pentamer of five identical B subunits (2). The B pentamer of all Stx's allows them to bind to specific host-cell receptors, the α-Gal-(1,4)-β-Gal disaccharide sequence, which is common to the human P-blood-group antigens (4).

In North America, antibiotics are not recommended for treating EHEC infections because of evidence that these drugs may increase the risk of HUS developing in patients who might otherwise recover from an uncomplicated course of illness (1, 5). In addition, several studies have revealed that subinhibitory doses of antibiotics can increase the amount of Stx released by O157:H7 *E. coli* (6–10).

Previously (11), we described a product, Synsorb-Pk, which is diatomaceous earth (Chromosorb) containing covalently coupled 8-methoxycarbonyloctyl (MCO) α-Gal-(1,4)-β-Gal-(1,4)-β-Glc (Pk-blood group) triglycoside sequences (12). Synsorb-Pk was found to be resistant to digestion in the human GI tract and, because of the attached carbohydrate receptors, effectively bound Stx1 and Stx2 in stools from EHEC-infected children (13). These results suggested that Synsorb-Pk may be helpful in preventing HUS developing

in subjects suffering from O157:H7 *E. coli*-mediated colitis, an assumption which is presently being tested in a double-blind placebo-controlled clinical trial (14).

Here, we examined the ability of Synsorb-Pk to remove cell-free Stx from culture supernatants of a clinical O157:H7 *E. coli* isolate exposed to subinhibitory concentrations of several antibiotics. Our objective was to determine the feasibility of using a combination of orally administered Synsorb-Pk and antibiotics for treating patients with EHEC-mediated hemorrhagic colitis. The rationale would be to limit further growth of the bacteria in the intestines of these patients, while concurrently providing a specific absorbent capable of preventing the extra-intestinal dissemination of Stx released from dying organisms.

Methods

For our study, we chose the same antibiotics used by Walterspiel et al. (6). Fosfomycin was included because of the recent Japanese experience with this drug (15–18). Cefixime (Suprax™), Co-trimoxazole (Trimethoprim–Sulfamethoxazole, Bactrim™, 16 mg mL^{-1} and 80 mg mL^{-1} of Trimethoprim and Sulfamethoxazole, respectively), and Ciprofloxacin (Cipro™, i.v.) were from the University of Alberta Hospital Pharmacy (Edmonton, Alberta). The disodium and calcium salts of Fosfomycin, Norfloxacin, and Tetracycline were purchased from Sigma-Aldrich. We used *E. coli* O157:H7 (EEU 396, a University of Alberta Hospital clinical isolate producing Stx 1 and Stx 2) in this study.

With the exception of Tetracycline, all antibiotic stock solutions (1 to 2 mg mL^{-1}) were first prepared using the concentration of antibiotic given on the product label in double-distilled deionized water. Tetracycline was dissolved at a concentration of 2 mg mL^{-1} in 100% ethanol. The antibiotic inhibitory concentrations in EEU 396 *E. coli* O157:H7 were determined using an adaptation of the procedure described in ref. 19. The modification to the procedure, which involved increasing the bacterial-cell density of the cultures, was necessary because the amount of Stx produced by cultures at the recommended cell density (10^5 cfu mL^{-1}) would have been too low to allow us to accurately evaluate the potential beneficial activity of Synsorb-Pk. Serial twofold dilutions of the antibiotic stock solutions were prepared in Mueller-Hinton (MH) broth and each of these diluted antibiotic solutions (30 μL) was transferred to the appropriate wells of a 96-well microtiter plate. In addition, a culture of *E. coli* (EEU 396) was grown overnight, with shaking, in MH broth, and then diluted to an OD of 0.6 (1×10^7 cfu mL^{-1} at 625 nm, in the same medium). This diluted bacterial culture (200 μL) was then mixed with the antibiotics in each of the microtiter plate wells. The microtiter plate was covered with a transparent lid and the OD in each well was automatically recorded every 20 min for a total incubation time of 24 h. The microtiter plate reader was programmed to gently agitate the plates for 10 s before recording the data. The resulting OD vs. time plots were used to determine the minimum growth-inhibiting concentration for each antibiotic.

A control experiment was performed to investigate whether the antibiotics bound to Synsorb-Pk. Synsorb-Pk was added (10 mg mL^{-1}, same concentration used in the Synsorb-Pk Stx binding experiments described below) to each of the antibiotic stock solutions for 24 h. The concentration of antibiotics in the resulting Synsorb-Pk-treated antibiotic solutions was then determined by the modified minimum-bacterial growth-inhibition procedure described above.

Table 1. *Escherichia coli* O157:H7 (strain EEU 396) antibiotic inhibitory concentrations.

Antibiotic	Inhibitory concentration (μg mL^{-1})
Cefixime	0.20
Tetracycline	0.78
Co-trimoxazole	0.10
Fosfomycin (Ca)	12.50
Fosfomycin (DiNa)	12.50
Norfloxacin	0.10
Ciprofloxacin	0.01

To determine the combined effect of antibiotics and Synsorb-Pk on the cell-free Stx concentration in the *E. coli* cultures, bacteria were first grown overnight, with shaking, at 37°C in 200 mL of MH broth. This culture was then diluted to an OD of 0.6 (1×10^7 cfu mL^{-1}) at 625 nm and 50-mL aliquots were proportioned into 125-mL Erlenmeyer flasks. Duplicate flasks were prepared for each of the antibiotics being tested. Antibiotics were added, at one half of their inhibitory concentrations, determined by the procedure described above, to the appropriate groups of flasks and the cultures were incubated for an additional 24 h with shaking at 37°C. Synsorb-Pk (10 mg mL^{-1}, Synsorb Biotech Inc., Calgary, Alberta) was added to one flask in each group and Chromosorb (10 mg mL^{-1}, Chromatographic Specialties Inc.) was added to the second flask of each group at the same time as the antibiotics. A single 24-h-old 50-mL control culture received no antibiotics, Synsorb-Pk, or Chromosorb.

To normalize the various antibiotic-treated cultures for growth-rate-related differences in Stx production, separate aliquots of the single antibiotic-free control culture were diluted with MH medium to the same OD as that of each of the respective antibiotic-treated cultures. The fold increase in cell-free Stx in each of the antibiotic-treated cultures was then calculated relative to the concentration of cell-free toxin in the normalized aliquots of the antibiotic-free cultures.

The amount of cell-free Stx1 and Stx2 in each of the 24-h-old O157:H7 *E. coli* cultures was quantified by the Verocytotoxicity assay described previously (11). Briefly, serial dilutions of the cell-free culture supernatant solutions were added to pre-confluent Vero-cell monolayers in 96-well microtiter plates. These plates were incubated at 37°C in an atmosphere of CO_2–air (5:95) for 48 h. Vero cells remaining attached to the plastic well bottoms were then fixed using 100% methanol and Giemsa stained. The data were recorded using a Spectramax (model 340) microtiter-plate reader set to a wavelength of 620 nm. CD_{50} (the dilution of culture supernatant causing detachment of 50% of the Vero cells from the plastic well bottoms) values were extrapolated from the resulting OD vs. log culture dilution plots. The difference between the CD_{50} values from the Synsorb-Pk-treated and the Chromosorb-treated culture supernatants was used to

calculate the percent Synsorb-Pk-mediated reduction in Stx concentration.

Results and discussion

Table 1 lists the antibiotic inhibitory concentrations for *E. coli* O157:H7 (strain EEU 396). As recommended by Walterspiel et al. (6), we used each of these antibiotics at half the respective inhibitory concentrations listed in Table 1 in the 24-h-old cultures to maximize enhanced expression of cell-free Stx by *E. coli*.

It is clear from Table 2 that all the antibiotics increased the amount of cell-free Stx in the EEU 396 culture medium. Moreover, the enhanced production of Stx in Table 2 roughly correlated with the mode of action of the antibiotics tested. For example, Norfloxacin and Ciprofloxacin (both DNA gyrase inhibitors) caused the greatest increases in Stx production. The effect of Fosfomycin, a cell-wall biosynthesis inhibitor, was variable, mediating increases in Stx from 3.3- to 7.3-fold, depending on the ionic form of the drug. Cefixime, another cell-wall biosynthesis inhibitor, mediated a 23-fold increase in Stx production. The combination of Trimethoprim and Sulfamethoxazole (Co-trimoxazole), which acts at the level of dihydrofolate reductase, caused the lowest average (only 5.9-fold) increase in Stx production. Tetracycline, an inhibitor of protein biosynthesis in bacteria, caused an intermediate increase in Stx production. These correlations, however, should be viewed with extreme caution because of the low number of drugs tested in each class and the high degree of variability in the data (Table 2). Nonetheless, regardless of the mode of drug action or the fold of antibiotic-induced increases in Stx, Synsorb-Pk (relative to underivatized Chromosorb) decreased the amount of Stx in the cell-free media in all of the antibiotic-treated cultures (Table 2). This Synsorb-Pk-mediated reduction in antibiotic-induced cell-free Stx ranged from an average of 41.7% for Ciprofloxacin to 98.7% for the calcium form of Fosfomycin.

Our rationale for presenting the data from each of the three experimental trials was to emphasize that we, like others (6, 7, 9, 10), found that the magnitude of the enhancing effect of the various antibiotics on Stx production was quite unpredictable, resulting in the very large standard deviations in Table 2. We attribute this variability to the biological nature of the system and the fact that we performed only a limited number of trials. Nonetheless, we might imagine that this unpredictability, even under strictly controlled laboratory-growth conditions, might be even more acute in the highly variable environments of the intestines of subjects infected by these organisms. Our experimental data, therefore, further emphasize the necessity for exercising prudence when considering the use of any antibiotics for treating patients suffering from an *E. coli* O157:H7 infection in the absence of compounds designed to neutralize Stx.

The reduced cell-free Stx activity in the Synsorb-Pk–antibiotic co-cultures may have resulted if the Synsorb-Pk absorbed the antibiotics, thereby reducing their effective concentrations and preventing an increase in the amount of cell-free Stx in these cultures. The addition of 10 mg mL^{-1} of Synsorb-Pk alone to the antibiotic stock solutions, however, did not alter their effective concentrations as determined by inhibitory concentration measurements. Turbidity measurements confirmed the growth-inhibiting effect of the antibiotics on bacterial growth in cultures containing either Chromosorb or Synsorb-Pk, compared with the antibiotic-free control culture. We therefore feel that the alternative explanation of an indirect Synsorb-Pk effect in our experiments is unlikely.

The observation that the antibiotics listed in Table 2 do not bind to Synsorb-Pk, and are therefore not antagonized by this Stx-absorbing agent, indicates that a combination of antibiotics and orally administered Synsorb-Pk may be effective in reducing the HUS incidence in patients suffering from an EHEC infection. Since clinical trials revealed it is possible to achieve intestinal concentrations of Synsorb-Pk in excess of 10 mg mL^{-1} in *E. coli* O157:H7-infected subjects (14), we speculate that Synsorb-Pk could absorb sufficient amounts of Stx released into the intestinal lumen by the antibiotic-treated bacteria to prevent toxin uptake into the subject's circulatory system. This may allow antibiotics to inhibit the growth of the organisms without increasing the incidence of HUS in these patients. It is also clear from

© 2002 NRC Canada

Table 2 that certain antibiotics, notably the fluoroquinolones, Norfloxacin, and Ciprofloxacin, caused the greatest increase in cell-free Stx in each of the independent trials with these drugs. Further research is needed to determine the precise mechanisms for the variable effect of antibiotics in promoting Stx release from enterohemorrhagic *E. coli* serotypes. In the meantime, our results suggest that should it be deemed clinically necessary to use antibiotics for treating subjects suffering from EHEC-mediated colitis, drugs with a similar mode of action as Norfloxacin and Ciprofloxacin, even in combination with an Stx absorbing agent, should probably be avoided.

Fosfomycin, on the other hand, consistently caused the lowest increases in cell-free Stx in antibiotic-treated *E. coli* O157:H7 cultures and Synsorb-Pk removed virtually all of this released toxin in all three independent trials. In a retrospective study of treatment modalities in Japanese victims of the 1996 O157 EHEC outbreak, 96% received some form of antimicrobial treatment, 84% involving Fosfomycin (20). In another study (16), Fosfomycin significantly reduced the rate of HUS developing in patients, but only if the drug was given within two days of the onset of their illness. Testing in mice further suggests that early application of antibiotics, including Fosfomycin, may attenuate the effects of O157 EHEC infections (21, 22).

Despite the evidence that antibiotics may be useful for treating EHEC-infected patients (16, 20), the data in Table 2 and independent reports of the unpredictable effects of subinhibitory levels of antibiotics on Stx production by different EHEC strains and serotypes (6–10) cannot be disregarded. Nonetheless, the cumulative results imply that a combination of orally administered Synsorb-Pk, or one of the other Stx-binding agents described more recently (23, 24), and possibly Fosfomycin, could be safely used to decrease the incidence of HUS in children suffering from an EHEC infection. Although we cannot say for certain what percent reduction in the amount of Stx would be beneficial in patients receiving antibiotics for an EHEC infection, it can only be assumed that any reduction would probably be beneficial. This assumption will require testing in a relevant EHEC animal-infection model. The study described here limits the number of antibiotics that will need to be tested in such an animal model. We are currently planning to conduct animal studies to further validate proposed combined therapeutic approaches to human *E. coli* O157:H7 infections. Such animal studies will also involve Stx inhibitors, such as Starfish, that have proven to be even more potent than Synsorb-Pk (23).

Use of the transannular Diels–Alder (TADA) reaction to probe biological receptors: Rational design and synthesis of tricyclic TADA adducts capable of rigidly holding pharmacophore parts

Yves A. Chantigny, Yves L. Dory, András Toró, and Pierre Deslongchamps

Abstract: Transannular Diels–Alder (TADA) adducts constitute a collection of rigid structures, whose conformational diversity is rich. It is possible to design such specifically functionalized molecules capable of binding to known biological targets by molecular modelling MCSS–HOOK (multiple copy simultaneous search). Here we show that such carefully designed compounds can be easily built from small synthons. TADA adducts are very interesting due to their huge conformational diversity, their rigidity (biological interest), and their ease of synthesis (chemical interest).

Key words: tricycles, synthesis, transannular Diels–Alder, macrocyclization, conformation, diversity.

Résumé : Les adduits de la réaction Diels–Alder transannulaire (DATA) constituent une banque de structures rigides dont la diversité conformationnelle est riche. Il est possible de concevoir de telles molécules spécifiques fonctionnalisées capables de se lier à des cibles biologiques connues, par modélisation moléculaire MCSS–HOOK. Nous montrons ici que de tels composés soigneusement sélectionnés peuvent être aisément assemblées à partir de petits synthons. L'intérêt de telles molécules se situe donc à trois niveaux : leur diversité conformationnelle étendue, leur rigidité (intérêt biologique), et leur relative facilité de synthèse (intérêt chimique).

Mots clés : tricycles, synthèse, Diels–Alder transannulaire, macrocyclisation, conformation, diversité.

Introduction

Generating molecular diversity constitutes an important tool for pharmaceutical chemists to discover new drug leads and to study biological targets (1). To date, nature is still one of the most important sources of original structures, although chemists have devised numerous ways to generate the sought-after diversity (2). We too have added milestones to this continuous and general synthetic effort by preparing libraries of macrocycles (3–7). By incorporating a diene and a dienophile within a macrocycle, a transannular Diels–Alder (TADA) reaction can occur (8–10). We have already made a thorough investigation of this reaction and showed that it is a powerful method in organic synthesis. In this work, we want to further demonstrate that the TADA reaction also offers a realistic potential for the creation of molecular diversity and for the synthesis of original structures.

Molecular modelling design of our targets

The TADA macrocyclic precursors can be easily prepared from building blocks, and each of these macrocycles can be divided into four regions (Fig. 1). The reacting part includes two regions: the dienophile, which can be either *cis* (C) or *trans* (T), and the diene, which can be TT, TC, or CT, but not CC since no TADA adducts have ever been obtained from that particular diene geometry (11). The other two regions are the tethers, which define the size and shape of the resulting A and C rings of the TADA adducts. Our previous studies indicated that TADA adducts can reasonably be expected for five- to seven-membered rings for A and C (12). According to these limitations, there are 54 TADA macrocyclic precursors that can be prepared, which yield 144 tricycles after the reaction. The adducts are more numerous than the macrocyclic trienes because each TT diene can give rise to two products and because the enantiomers must also be included. It is obvious that many positions of these 54 bare macrocycles can be substituted so that the diversity expands accordingly. Such huge diversity can, in principle, be exploited in combinatorial libraries.

Another important aspect of the TADA approach resides in the rigidity of the resulting tricyclic frameworks. The 144 tricycles are sufficiently different from each other, so that conformational diversity arises as well. This important aspect can be fruitfully used when carrying out computa-

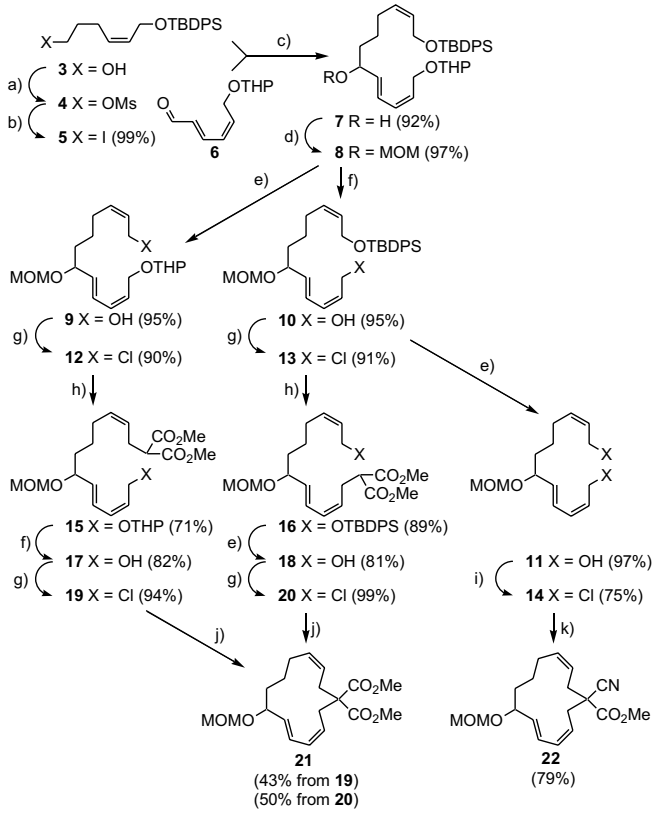
tional drug design, in particular by means of MCSS–HOOK (multiple copy simultaneous search) (13–15). A search on the stain P1/Mahomey of the polyovirus by means of the MCSS method yielded valuable information about the positions, where simple molecules such as water, methanol, amines, and amides, could best interfere with the virus (16). Given the positions and orientations of the suitable functional sites (Fig. 2), HOOK then systematically searched a database of our tricyclic adducts for skeletons that logically connected these binding sites in the presence of the virus. Two structures (**1** and **2**), having a *trans-syn-cis* (TSC) geometry, were obtained as result of that protocol. Both compounds differ only by the nature of their amine moiety; therefore, they can be prepared from the same adequately protected 13-membered tricycle bearing a *cis* (C) dienophile and a *trans–cis* (TC) diene, as previously shown in our model studies (17).

Synthesis

In terms of ease of synthesis, the macrocyclic trienes **21** and **22** (Scheme 1) were identified as being the most suitable TADA precursors. They were prepared in 10 and eight steps, respectively, from the same starting materials **3** and **6** (18, 19). Alcohol **3** was activated as its corresponding mesylate **4**, and subsequently treated with sodium iodide in acetone without purification. Resulting iodide **5** was obtained in 99% yield for the two steps. Upon treatment with *tert*-butyllithium at –78°C, iodide **5** was transformed into its corresponding anion. Addition of aldehyde **6** to the reaction mixture led to alcohol **7** as a mixture of diastereoisomers with a yield of 92%. The alcohol functionality was protected as methoxymethyl ether **8** in 97% yield. The silyl ether was then cleaved with tetrabutyl ammonium fluoride (TBAF) to yield allylic alcohol **9** (95% yield). Allylic chloride **12** was obtained from the preceding alcohol by means of hexachloroacetone (HCA) and triphenylphosphine (Ph_3P) (90%) (20). S_N2 nucleophilic attack of sodium dimethyl malonate onto the allylic iodide (formed in situ by sodium iodide) led to monosubstituted malonate **15** in 71% yield.

Scheme 1.



a) MsCl, Et_3N, CH_2Cl_2, 0ºC. b) NaI, acetone, reflux. c) *t*-BuLi, THF, -78ºC. d) KHMDS, MOMCl, THF, 0ºC to 70ºC. e) TBAF, THF, rt. f) PPTS, *i*-PrOH, reflux.g) Ph_3P, HCA, CH_2Cl_2, 0ºC. h) $CH_2(CO_2Me)_2$, NaH, NaI, THF 0ºC to 70ºC. i) Ph_3P, HCA, CH_2Cl_2, -20ºC. j) Cs_2CO_3, CsI, MeCN, 70ºC, slow addition. k) $NCCH_2CO_2Me$, Cs_2CO_3, THF:DMF (2:1), 80ºC, slow addition.

The remaining allylic ether was then cleaved with PPTS to yield alcohol **17** (82%), which was transformed as before into its corresponding allylic chloride **19** (94%). The other macrocyclization precursor (**20**), which would lead to the same macrocycle (**21**), was prepared from the same triether (**8**) by a very similar pathway, with an overall yield of 62% for the five-step sequence. Alternatively, alcohol **10** (obtained from **8** with a yield of 95%) en route to **20**, was transformed into diol **11** by means of TBAF (97% yield). Dichloride **14** was then prepared in 75% yield by means of HCA and Ph_3P as before, but at lower temperature. All three allylic chlorides (**19**, **20**, and **22**) were then subjected to high-dilution macrocyclization conditions. Isomeric chlorides **19** and **20** yielded the same racemic macrocycle (**21**) with similar yields (43 and 50%, respectively) when slowly injected into a mixture of cesium carbonate in acetonitrile. A much better yield of 79% was obtained for the synthesis of macrocycle **22** (mixture of racemic diastereoisomers) when a mixture of methyl cyanoacetate and dichloride **14** in THF was added slowly to a suspension of cesium carbonate in THF and DMF (21). In summary, **21** was obtained from **3**, via **19** and **20**, with overall yields of 18 and 27%, respectively; the yield for **22**, however, was as high as 51%. Consequently, it proved easier to prepare substantial quantities of macrocycle **22** to carry on with the synthesis of **1** and **2**.

Both macrocycles **21** and **22** were heated at 140°C to provoke the TADA reaction (Scheme 2) — the expected TSC

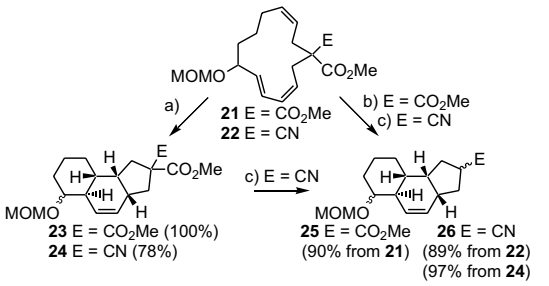
Scheme 2.



a) xylenes, 140ºC, 4h. b) NaCl, DMSO, 160ºC. c) NaCN, DMSO, 160ºC.

tricycles **23** and **24** were obtained with good yields of 100 and 78%, respectively. Tricycle **23** was produced as a 2:1 mixture (α or β at C4) of two racemic diastereoisomers, whereas **24** was obtained as a mixture of racemic diastereoisomers at C4 and C12. Demethoxycarbonylation of **24** was then performed at 160°C in dimethyl sulfoxide with sodium cyanide (97% yield) (22). Since demethoxycarbonylation occurs at high temperature, we tried successfully to induce both demethoxycarbonylation and TADA together by treating macrocycles **21** and **22** under demethoxycarbonylation conditions. Thus, **21** led to tricycle **25** (90%), when heated at 160°C in DMSO that contained sodium chloride (22); **22** gave **26** in 89% yield when it was treated under identical conditions previously used to prepare **26** from **24**. This confirmed our choice of selecting cyanide **26** (rather than methyl ester **25**) for further work, since it is obtained from **3** with an overall yield of 45%.

All that remained to be done were functional-group manipulations to introduce the amides at the nitrile position and to address the stereochemistry of the amide and the alcohol. To do this, methoxymethyl (MOM) ether **26** was cleaved by means of concentrated HCl to yield alcohol **27** (99% yield) (Scheme 3). Dess–Martin oxidation of this alcohol gave a separable mixture of two racemic ketones **28** (48% yield) and **29** (32% yield). To identify the relative stereochemistry of the nitrile, the major ketone (**28**) was first reduced with a bulky borohydride (lithium triisobutylborohydride) to give exclusively β-OH TSC tricycle **30** (85%) in which the secondary alcohol exists in the axial orientation. The nitrile was then hydrolyzed under basic conditions to corresponding acid **31** (90%), which could undergo iodolactonization to generate lactone **32**. The identities of nitriles **28** and **29** were inferred from that latter experiment, because no lactone can be obtained from the carboxylic acid derived from nitrile **29**. Alcohol **30** was protected as its triisopropyl silyl (TIPS) ether (**33**), with a yield of 99%, by means of TIPS triflate and 2,6-lutidine as a base. Hydrolysis of the nitrile, as before, yielded acid **34** in 83% yield. The acid group was activated as its acid chloride with oxalyl chloride (23). Amylamine was added to the crude acid chloride, and racemic amide-ether **35** was obtained in 80% yield. Alternatively, addition of (*S*)-(+)-1-aminoindane to the acid chloride provided the corresponding amide-ether as an inseparable mixture of racemic diastereoisomers **36** and **37** (73%). Finally, strong acidic conditions (6 N HCl) had to be used to cleave the silyl ethers to afford desired amide-alcohol **1**, together with its enantiomer (81%). The other target (**2**) was prepared in a similar manner from a mixture of **36** and **37**; it could not be separated from its diastereoisomer **38** (yield of 84%).

Conclusion

Compounds **1** and **2** proved not to have a significant affinity for the target virus, at least no better than the threshold of the assay, which was set in the sub-micromolar range. Nevertheless, our main goal during this preliminary work was first to demonstrate the chemical utility of TADA adducts for drug design. Thus, TADA tricycles could be used in combinatorial libraries, but the lack of mobility of the tricyclic framework is usually so severe that they should be more useful at the lead optimization stage. Rigidity, however, can be an asset when the shape of the target is precisely known from different theoretical sources (molecular docking or other computational techniques like MCSS–HOOK). In the latter case, rigid skeletons are necessary to hold binding sites (functional groups) uncovered by the theoretical protocol. A collection of reasonably rigid TADA-adduct tricyclic cores can easily provide the diversity necessary to ensure that any combination of two or three binding functional groups can be successfully held in the desired spatial arrangement (within the limits of the span of tricycles). In this work we have proven that, from MCSS–HOOK calculations, adequate tricycles capable of holding binding sites can be selected from a theoretical library of TADA-adduct structures. The resulting chemical targets can be synthesized in a reasonable number of steps, so that the suggested targets can be rapidly tested. In summary, TADA adducts are structurally attractive because their various geometries can cover a large conformational space; they are also chemically attractive because they come from macrocycles easily assembled from smaller pieces.

Experimental

The infrared (IR) spectra were taken on a PerkinElmer 1600 series FT-IR. The NMR spectra were recorded on a Brüker AC 300 instrument. The mass spectra (MS) were obtained on a ZAB-IF spectrometer. Flash chromatography was performed on silica gel Merck 60, 230–400 mesh.

Synthesis

Methanesulfonic acid 6-(*tert*-butyl-diphenyl-silanyloxy)hex-(4Z)-enyl ester (4)

To a solution of alcohol **3** (11.6 g, 32.6 mmol) and triethylamine (6.82 mL, 48.9 mmol) in dichloromethane (150 mL) at 0°C, was added methanesulfonyle chloride (2.78 mL, 35.9 mmol). The mixture was stirred for 1 h and a HCl 1 N solution (100 mL) was added. The mixture was extracted with dichloromethane (3 × 100 mL). The combined organics were dried over $MgSO_4$, filtered, and concentrated under vacuo to yield the crude title compound as an oil (used as is in the next step). IR (cm^{-1}): 3021, 2936, 2859, 1469, 1428, 1356, 1175, 1109, 936, 823, 704, 613. ^1H NMR ($CDCl_3$) δ: 7.70 and 7.40 (2m, 10H, 2 phenyl), 5.65 (m, 1H, C*H*=CHCH$_2$OSi), 5.45 (m, 1H, CH=C*H*CH$_2$OSi), 4.26 (d, *J* = 6.5 Hz, 2H, C*H*$_2$OSi), 4.12 (t, *J* = 7.0 Hz, 2H, C*H*$_2$OMs), 2.92 (s, 3H, SO$_3$C*H*$_3$), 2.00 (q, *J* = 7.0 Hz, 2H, CH$_2$C*H*$_2$CH=CH), 1.71 (quintet, *J* = 6.5 Hz, 2H, C*H*$_2$CH$_2$CH=CH), 1.06 (s, 9H, SiC(C*H*$_3$)$_3$). ^{13}C NMR ($CDCl_3$) δ: 135.4, 133.6, 130.7, 129.6, 128.6, 128.5, 69.0, 60.0, 37.1, 28.7, 26.7, 23.2, 19.0. 2-[7-Methoxymethoxy-12-(tetrahydropyran-2-yloxy)-dodeca-(2Z,8E,10Z)-trienyl]malonic acid dimethyl ester (15) (diastereoisomers)

To a suspension of sodium hydride 60% (200 mg, 5 mmol) in a DMF–THF solution (2:1, 15 mL) at 0°C, was added dropwise dimethylmalonate (640 μL, 5.6 mmol). The mixture was allowed to warm to room temperature and stirred 30 min. This solution was added to a solution of chloride **12** (397 mg, 1.12 mmol) and sodium iodide (168 mg, 1.12 mmol) in THF (10 mL) and heated to 70°C for 2 h. A saturated NH_4Cl solution (40 mL) was added to the cooled mixture and extracted with hexanes (3 × 20 mL). The combined organics were washed with brine, dried over $MgSO_4$, filtered, and concentrated under vacuo. The residue was purified by flash chromatography (hexanes–ether, 9:1) to yield the title compound as an oil (358 mg, 71%). IR (cm^{-1}): 2949, 1738, 1437, 1343, 1272, 1234, 1201, 1150, 1030. ^{1}H NMR ($CDCl_3$) δ: 6.44 (dd, *J* = 15.0, 11.1 Hz, 1H, CH=CH-C*H*=CHCH$_2$), 6.10 (t, *J* = 11.0 Hz, 1H, CH=C*H*HC=CHCH$_2$), 5.65–5.40 (m, 3H, CH=C*H*CH$_2$CH and C*H*=CHCH=C*H*), 5.30 (m, 1H, C*H*=CHCH$_2$CH), 4.67 and 4.51 (2d, *J* = 6.5 Hz, 2 × 1H, OCH_2O), 4.65 (t, *J* = 3.0 Hz, 1H, OC*H*O), 4.42–4.15 (m, 2H, CH_2OTHP), 4.07 (q, *J* = 5.6 Hz, 1H, C*H*OMOM), 3.87 (m, 1H, OC*H*H of THP), 3.52 (m, 1H, OCH*H* of THP), 3.76 (s, 6H, CO$_2$CH_3), 3.40 (t, *J* = 4.0 Hz, 1H, C*H*(CO$_2$Me)$_2$), 3.36 (s, 3H, OCH$_2$OCH_3), 2.64 (t, *J* = 7.5 Hz, 2H, CH_2CH(CO$_2$Me)$_2$), 2.09 (q, *J* = 7.0 Hz, 2H, CH$_2$CH_2CH=CH), 1.90–1.40 (m, 10H, other CH$_2$). ^{13}C NMR ($CDCl_3$) δ: 169.3, 135.1, 132.7, 130.3, 127.6, 127.1, 124.6, 98.0, 97.8, 93.5, 76.1, 62.8, 62.7, 62.2, 62.1, 55.3, 52.4, 51.5, 35.0, 30.5, 26.9, 26.6, 25.3, 25.2, 19.4.

2-[12-(tert-Butyl-diphenyl-silanyloxy)-6-methoxymethoxy-dodeca-(2Z,4E,10Z)-trienyl]malonic acid dimethyl ester (16)

Preparation was similar to malonate **15** (89%). IR (cm^{-1}): 3014, 2953, 2859, 1739, 1429, 1344, 1150, 1033, 824, 703. ^{1}H NMR ($CDCl_3$) δ: 7.66 and 7.40 (2m, 10H, 2 phenyl), 6.43 (dd, *J* = 15.0, 11.0 Hz, 1H, CH=C*H*CH=CHCH$_2$), 6.04 (t, *J* = 11.0 Hz, 1H, CH=CHC*H*=CHCH$_2$), 5.67–5.29 (m, 4H, C*H*=C*H*CH$_2$OSi and C*H*=CHCH=C*H*), 4.66 and 4.49 (2d, *J* = 7.0 Hz, 2 × 1H, OCH_2O), 4.24 (d, *J* = 6.5 Hz, 2H, CH_2OSi), 4.00 (q, *J* = 7.0 Hz, 1H, C*H*OMOM), 3.72 (s, 3H, CO$_2$*Me*), 3.73 (s, 3H, CO$_2$*Me*), 3.42 (t, *J* = 7.5 Hz, 1H, C*H*(CO$_2$Me)$_2$), 3.34 (s, 3H, OCH$_2$OCH_3), 2.77 (dt, *J* = 7.5, 1.0 Hz, 2H, CH_2CH(CO$_2$Me)$_2$), 1.89 (q, *J* = 7.0 Hz, 2H, CH$_2$CH_2CH=CH), 1.60–1.20 (m, 4H, other CH_2), 1.06 (s, 9H, SiC(CH_3)$_3$). ^{13}C NMR ($CDCl_3$) δ: 169.0, 135.5, 135.4, 134.8, 133.7, 130.5, 129.5, 129.4, 129.3, 127.5, 126.9, 126.5, 93.5, 76.1, 60.1, 55.2, 52.3, 51.4, 35.1, 27.3, 27.0, 26.7, 25.3, 19.0. 7-Methoxymethoxy-cyclotrideca-(3Z,5E,11Z)-triene-1,1-dicarboxylic acid (21)

A solution of chloride **19** (or **20**) (280 mg, 0.72 mmol) in acetonitrile (10 mL) was added over 12 h via a syringe pump, to a solution of cesium carbonate (2.4 g, 7.5 mmol) and cesium iodide (390 mg, 1.5 mmol) in acetonitrile (600 mL) at 70°C (final concentration = 1 mM). Three hours after the final addition, the mixture was cooled to room temperature, filtered on florisil, and concentrated under vacuo. Water (20 mL) was added to the residue and the mixture was extracted with a 1:1 ether–hexanes solution (3 × 20 mL). The combined organics were washed with brine, dried over $MgSO_4$, filtered, and concentrated under vacuo. The residue was purified by flash chromatography (hexanes–ether, 9:1) to yield the final compound as an oil (113 mg, 43%). IR (cm^{-1}): 2951, 1737, 1437, 1208, 1037. ^{1}H NMR ($CDCl_3$) δ: 6.42 (dd, *J* = 15.0, 11.0 Hz, 1H, CH=CHC*H*=CHCH$_2$), 6.21 (t, *J* = 11.0 Hz, 1H, CH=C*H*CH=CHCH$_2$), 5.82 (dd, *J* = 16.0, 5.5, 1H, C*H*=CHCH=CHCH$_2$), 5.45 (m, 1H, C*H*=CHCH$_2$C), 5.10–4.95 (m, 2H, C*H*=CHCH$_2$C and CH=CHCH=C*H*CH$_2$), 4.62 and 4.67 (2d, *J* = 7.0 Hz, 2 × 1H, OCH_2O), 4.13 (m, 1H, C*H*OMOM), 3.75 (s, 6H, CO_2CH_3), 3.38 (s, 3H, OCH_2OCH_3), 2.69 (d, *J* = 8.5 Hz, 2H, CH=CHCH=CHCH_2), 2.51 (d, *J* = 7.0 Hz, 2H, CH=CHCH_2C), 2.20–1.30 (m, 6H, other CH_2). ^{13}C NMR ($CDCl_3$) δ: 171.3, 171.2, 135.6, 135.0, 133.0, 126.5, 124.7, 123.8, 94.4, 76.5, 56.9, 55.3, 52.6, 30.0, 29.2, 29.0, 25.9, 24.8.

1-Cyano-7-methoxymethoxy-cyclotrideca-(3Z,5E,11Z)-trienecarboxylic acid methyl ester (22) (diastereoisomers)

A solution of bischloride **14** (720 mg, 2.25 mmol) and methyl cyanoacetate (298 μL, 3.38 mmol) in THF (20 mL) was added over 10 h using a syringe pump, to a solution of cesium carbonate (11.0 g, 33.8 mmol) in a THF–DMF solution (2:1, 800 mL) at 80°C. The DMF was purged with nitrogen for 1 h before use. One hour after the final addition, the solution was cooled to room temperature, filtered, and concentrated under vacuo. The residue was purified by flash chromatography (hexanes–ether, 8:2) to yield the title compound as an oil (568 mg, 79 %). IR (cm^{-1}): 2934, 2249, 1748, 1440, 1219. ^{1}H NMR ($CDCl_3$) δ: 6.47–6.26 (m, 2H, CH=C*H*C*H*=CHCH$_2$), 5.90 (dt, *J* = 15.0, 6.0 Hz, 1H, CH=CHCH=C*H*CH$_2$), 5.62–5.50 (m, 1H, CH_2CH_2CH=CH), 5.38 (q, *J* = 9.0 Hz, 1H, CH=C*H*CH$_2$C), 5.24 (m, 1H, C*H*=CHCH=CHCH$_2$), 4.62 (m, 2H, OCH_2O), 4.18 (q, *J* = 8.0 Hz, 1H, C*H*OMOM), 3.86 (s, 3H, CO_2CH_3), 3.37 (s, 3H, OCH_2OCH_3), 2.80–2.43 (m, 4H, CH=CHCH_2C), 2.22–1.30 (m, 6H, other CH_2). ^{13}C NMR ($CDCl_3$) δ: 168.7, 137.8, 137.4, 136.7, 134.8, 134.7, 126.8, 126.4, 123.6, 123.1, 122.8, 119.4, 95.1, 77.0, 76.7, 56.0, 54.2, 46.8, 42.9, 46.8, 42.9, 32.1, 31.6, 30.5, 30.2, 29.8, 26.8, 25.2, 24.9. *6-Methoxymethoxy-2,3,3a,5a,6,7,8,9,9a,9b-decahydro-1*H-*cyclopenta[a]naphthalene-2-carboxylic acid methyl ester (25) (diastereoisomers)*

A solution of macrocycle **21** (92 mg, 261 μmol), sodium chloride (39 mg, 653 μmol), and water (10 μL) in DMSO (1 mL) was stirred at 160°C for 7 h. Water (10 mL) was added to the cooled solution and the mixture was extracted with a hexanes–ether solution (1:1, 3 × 10 mL). The combined organics were washed with brine, dried over $MgSO_4$, filtered, and concentrated under vacuo to yield the title compound as an oil (66 mg, 90%). ^{1}H NMR (DMSO-d_6) δ: 5.75 (d, *J* = 6.5 Hz, 1H, C*H*=CH), 5.41 (m, 1H, CH=C*H*), 4.71–4.50 (m, 2H, OCH_2O), 3.82 (m, 0.33H, C*H*OMOM, H *alpha*), 3.65 (s, 2H, CO_2*Me*), 3.60 (s, 1H, CO_2*Me*), 3.28 (s, 2H, OCH_2O*Me*), 3.23 (s, 1H, OCH_2O*Me*), 3.10 (m, 0.66H, C*H*OMOM, H *beta*), 2.70 (m, 1H, C*H*CH=CH), 2.53–2.38 (m, 2H, C*H*CH=CH and C*H*CO_2), 2.20–1.00 (m, 12H, other CH_2 and CH).

*6-Methoxymethoxy-2,3,3a,5a,6,7,8,9,9a,9b-decahydro-1*H-*cyclopenta[a]naphthalene-2-carbonitrile (26) (diastereoisomers)*

A solution of macrocycle **22** (1.7 g, 5.43 mmol) and sodium cyanide (293 mg, 6 mmol) in DMSO (25 mL) was stirred at 160°C for 8 h. Water (100 mL) was added to the cooled solution and the mixture was extracted with a hexanes–ether solution (1:1, 3 × 100 mL). The combined organics were washed with brine, dried over $MgSO_4$, filtered, and concentrated under vacuo to yield the title compound as an oil (1.27 g, 89%, OMOM, α:β = 2:1). Alternatively, a solution of tricycle **24** (50 mg, 157 μmol) and sodium cyanide (9.6 mg, 195.6 μmol) in DMSO (500 μL) was stirred at 160°C for 8 h. The mixture was diluted with water (15 mL) and extracted with a hexanes–ether solution (1:1, 3 × 15 mL). The combined organics were washed with brine, dried over $MgSO_4$, filtered, and concentrated under vacuo to yield the title compound as an oil (40 mg, 97%). IR (cm^{-1}): 2927, 2237, 1446, 1149, 1099, 1040. ^{1}H NMR ($CDCl_3$) δ: 5.92–5.88 (m, 1H, C*H*=CH), 5.60–5.42 (m, 1H, CH=C*H*), 4.80–4.57 (m, 2H, OCH_2O), 3.98–3.90 (m, 0.33H, C*H*OMOM, H_{ax}), 3.40 (s, 1H, OCH_2O*Me*), 3.39 (s, 1H, OCH_2O*Me*), 3.36 (s, 0.5H, OCH_2O*Me*), 3.35 (s, 0.5H, OCH_2O*Me*), 3.25–3.10 (m, 0.66H, C*H*OMOM, H_{eq}), 2.90–2.60 (m, 2H, C*H*CH=CHC*H*), 2.9–0.5 (m, 13H, other CH_2 and CH). ^{13}C NMR ($CDCl_3$) δ: 131.3, 131.0, 130.6, 130.1, 129.9, 128.6, 126.2, 123.4, 95.6, 95.1, 79.3, 75.2, 55.5, 55.3, 43.3, 43.2, 41.5, 41.2, 41.0, 40.6, 39.9, 39.6, 39.2, 39.1, 38.6, 36.7, 36.3, 33.7, 32.8, 31.1, 31.0, 30.7, 30.6, 30.3, 29.9, 29.6, 29.5, 27.3, 26.3, 24.3, 24.1, 21.0, 20.8. *6-Oxo-2,3,3a,5a,6,7,8,9,9a,9b-decahydro-1*H-*cyclopenta[a]naphthalene-2-carbonitrile (28) and (29)*

To a solution of alcohol **27** (145 mg, 671 μmol) in dichloromethane (22 mL) at 0°C, was added Dess–Martin periodinane (370 mg, 872 μmol). The solution was allowed to warm to room temperature and stirred for 30 min. A saturated $NaHCO_3$ solution (30 mL) and sodium thiosulfate (477 mg, 1.92 mmol) were added and stirred 30 min. The mixture was extracted with dichloromethane (3 × 30 mL). The combined organics were dried over $MgSO_4$, filtered, and concentrated under vacuo. The residue was purified by flash chromatography (hexanes–ether, 9:1) to yield two racemic diastereoisomeres as oils (α-nitrile 66 mg and β-nitrile 50 mg, total yield: 80%).

Ketone **28** (α-nitrile). Penicillamine as a ligand in the catalytic asymmetric reduction of ketones

Stephen Hanessian, Eric Jnoff, and Andrew M. Griffin

Abstract: Amino acids derived from D-penicillamine and thiazolidines were studied as ligands for the catalytic asymmetric reduction of ketones with borane. Enantioselectivities up to 83% ee were observed.

Key words: asymmetric reduction, penicillamine, thiazolidine, amino acid.

Résumé : On a étudié le potentiel d'acides aminés dérivés de la D-pénicillamine et de la thiazolidine comme ligands pour la réduction asymétrique catalytique de cétones à l'aide du borane. On a observé des énantiosélectivités allant jusqu'à 83% ee.

Mots clés : réduction asymétrique, pénicillamine, thiazolidine, acide aminé.

[Traduit par la Rédaction]

Introduction

Much effort has focussed on the development of catalysts for the asymmetric reduction of ketones with borane in recent years (for reviews see ref. 1). The best examples to date are the Corey "CBS" oxazaborolidine (2) **1** (Fig. 1), and related precedents reported by Itsuno et al. (3). The Corey catalyst **1**, derived from a functionally biased *S*-prolinol, has been shown to reduce a variety of ketones to the corresponding alcohols in high yields and excellent enantiomeric excesses. The enantioselective reduction of ketones with borane catalyzed by other β-amino alcohols has also been studied by other groups (for recent publications see ref. 4).

We were intrigued by the potential use of readily available, α-amino acids as ligands for the catalytic asymmetric reduction of ketones, rather than the commonly utilized β-amino alcohols. In particular, we were interested in using the relatively inexpensive penicillamine **2**, a trifunctional amino acid, available in both D- and L-form (Fig. 1).

To the best of our knowledge, only three reports of the use of α-amino acids as ligands for the reduction of ketones can be found in the literature. Buono and co-workers (5) reported that *S*-proline is an efficient ligand for the reduction of a variety of aryl and alkyl ketones in the presence of excess borane in refluxing toluene. Enantioselectivities have been reported to range from 81 to >95% in the presence of 10 mol% of *S*-proline. However, a more extensive study by Martens and co-workers (6) has found much lower selectivities with proline as well as a variety of cyclic and bicyclic α-amino acids. In fact, under the conditions reported by Buono and co-workers (5), much lower selectivities ranging from 17 to 30% ee were reported (6). Higher enantioselectivities were obtained with the corresponding amino alcohols (6). In our hands, we could not achieve enantioselectivities higher than 30% in agreement with Martens and co-workers (6). There are only few precedents concerning the use of sulfur-containing amino acids in the asymmetric reduction of ketones (for sulfur-containing amino alcohols see ref. 7). Utilizing cysteine, homocysteine, and derivatives, Xingshu and Rugang (7*e*) reported an ee of 72% for the catalytic reduction of α-bromoacetophenone in presence of thiazolidine **3** at 60°C (Fig. 1). Martens and co-workers (7*a*–7*d*) have obtained moderate to high enantioselectivities with L-methionine and related amino acids.

Results and discussion

Following promising results with the reduction of acetophenone in the presence of 10 mol% D-penicillamine **2**, we decided to briefly investigate the functional requirements of representative amino acids. Thus, with D-valine **4**, D-cysteine **5**, and thiazolidine **3** the enantioselectivities were lower than with penicillamine **2**, which was comparable to thiazolidine **6** (Scheme 1). Although enantioselectivities were relatively poor, the yield of phenethyl alcohol was good and all reactions were complete in 10 min at room temperature. It is also interesting to note that the alcohol with the opposite configuration was formed when thiazolidine **6** was used as ligand.

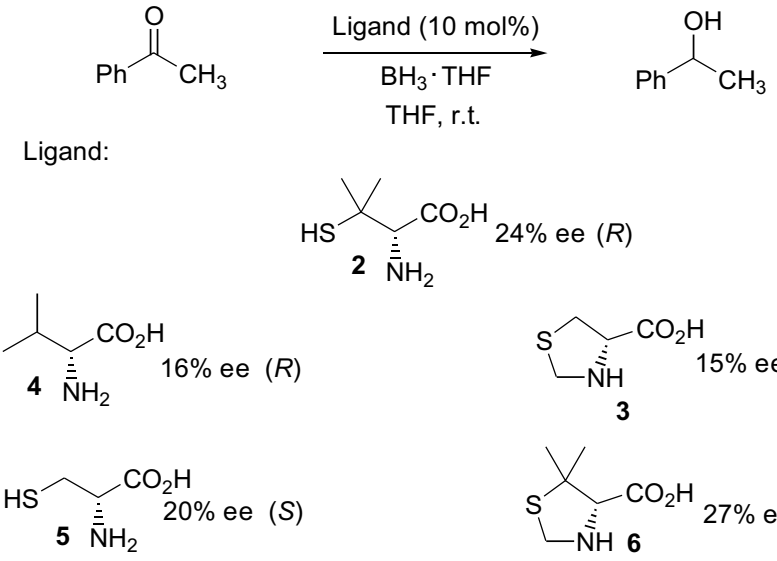
Scheme 1. Reduction of acetophenone with sulfur-containing amino acids.



Our initial results using penicillamine **2** as ligand with various ketones and under varying reaction conditions are shown in Table 1. We noticed that when a solution of acetophenone was added to a preformed solution of ligand and borane, an exothermic reaction occurred. We then decided to add the ketone to the reducing mixture at room temperature over a period of 1 h. Under these conditions, the enantioselectivity was increased to 43% with acetophenone, although no enhancement of selectivity was observed for the reduction of α-tetralone and α-bromoacetophenone. Conducting the reactions at 0°C or at room temperature did not change the enantioselectivity significantly. No induction was observed in refluxing toluene (Table 1).

It was apparent that the catalyst derived from penicillamine **2** could only give low to modest enantioselectivities under the reaction conditions employed. We, therefore, turned our attention to the thiazolidine **6**, which was synthesized in one step from penicillamine **2** (8). Addition of acetophenone to the mixture of the borane and catalyst over a period of 1 h gave *S*-phenethyl alcohol with an enantioselectivity of 81% (Table 2). *p*-Substituted acetophenones gave the same level of enantioselectivity. A substantial improvement of enantioselectivity was observed with various tetralones with ee values ranging from 65 to 70% compared to 23% with D-penicillamine. In the case of α-bromoacetophenone, an ee of 74% compared to 16% with D-penicillamine as a catalyst was observed. These results clearly show that thiazolidine **6** is a better ligand than the parent amino acid **2** in these borane reductions of representative ketones. It is also of interest that the sense of induction was reversed.

In view of the well-known precedents utilizing β-amino alcohols as catalysts in borane reductions (1–4), we studied the reduced thiazolidine **7**. Curiously, lower enantioselectivities were observed in the case of acetophenone and α-bromoacetophenone utilizing **7** as catalyst (Table 3, entry 3 vs. 1; entry 7 vs. 5). The use of a basic additive such as *N*,*N*-dimethylaniline has been reported to be beneficial in such reductions (9). Adding 10% of this amine showed no

enhancement of selectivity when **6** was used as a catalyst (Table 3, entries 1, 2, and 5, 6). However, a substantial improvement of enantioslectivity was observed when the additive was used with the amino alcohol **7** as a catalyst (Table 3, entries 3, 4 and 7, 8).

It is possible that in the presence of the basic additive, the reducing specie is the cyclic oxazaborolidine **9** (Scheme 2) (9). The added base may prevent a second hydride transfer by removing one of the reactive hydrogens from intermediate **8**. As previously mentioned, the additive has an enhancing effect on the enantioselectivity only when **7** is used as a catalyst, but not in the case of **6**. It follows that the effective

catalyst in the latter case is the oxazaborolidine **9** which is formed directly (Scheme 2).

In conclusion, we have demonstrated that penicillamine **2** and its thiazolidine derivative **6** may be used as a ligand in the catalytic reduction of ketones with borane at room temperature. Up to 81% ee was observed with acetophenone and related ketones in the presence of 10% mol catalyst. Comparable ee values were observed with the corresponding amino alcohol **7**, in the presence of *N*,*N*-dimethylaniline as an additive.

Experimental

[(4*S*)-5,5-Dimethyl-1,3-thiazolidin-4-yl]methanol (7)

To a solution of 0.5 g (3.10 mmol, 1 equiv) of thiazolidine **6** in 10 mL THF were added 15.5 mL (5 equiv) of BH_3·THF (1 M THF). After 1 h stirring at room temperature (r.t.), the mixture was quenched with 2 N HCl. The mixture was diluted with water (10 mL) and the organic phase was extracted with dichloromethane (3 × 10 mL) and dried over $MgSO_4$. Concentration in vacuo, afforded the corresponding oxazaborolidine hydride **8** as a colorless oil. R_f: 0.9 (AcOEt). MS (FAB): 176 ($[M + H]^+$, 7%), 160 ($M^{+\cdot}$-Me$^\cdot$, 100%), 158 ($M^{+\cdot}$-HO$^\cdot$, 24%), 157 ($M^{+\cdot}$-$H_2O^\cdot$, 8%), 146 ($M^{+\cdot}$-[BHOH]$^\cdot$, 25%), 116 (146-$CH_2^\cdot$, 17%). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 4.90–4.75 (br s,1H), 4.31 (dd, 1H, *J* = 11.1 Hz and *J* = 3.3 Hz), 4.15 (dd, 1H, *J* = 12.6 Hz and *J* = 3.0 Hz), 4.02 (t, 1H, *J* = 10.5 Hz), 3.80 (dd, 1H, *J* = 12.6 Hz and *J* = 3.0 Hz), 2.76 (dt, 1H, *J* = 11.1 Hz and *J* = 3.3 Hz), 2.55–2.40 (br s,1H), 1.52 (s, 3H), 1.42 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 76.1, 57.4, 54.7, 54.4, 29.5, 27.8. This compound was dissolved in 50 mL of MeOH in presence of 1 mL of triethylamine. After 3 h stirring at 70°C, the mixture was concentrated in vacuo, then purified by flash chromatography (AcOEt–MeOH, 95:5), to give 0.31 g of amino alcohol **7**. Yield: 69%. R_f: 0.2 (AcOEt–MeOH 95:5, silica). $[\alpha]_D$: –29.4 (c 0.18., $CHCl_3$). HRMS (EI) *m*/*z* calcd. for $C_6H_{13}NOS$: 148.0796; found: 148.0799. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 4.26 (AB system, 2H, *J* = 9.9 Hz), 3.71 (dd, 1H, *J*= 4.2 Hz and *J* = 10.5 Hz), 3.57 (dd, 1H, *J* = 10.5 Hz and *J* = 9.3 Hz), 2.99 (dd, 1H, *J* = 4.2 Hz and *J* = 9.3 Hz), 2.35–2.10 (br s, 2H), 1.51 (s, 3H), 1.30 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 73.9, 59.9, 56.5, 52.3, 30.7, 25.7.

Representative reductions

Reduction of ketones in presence of amino acid 6 or amino alcohol 7

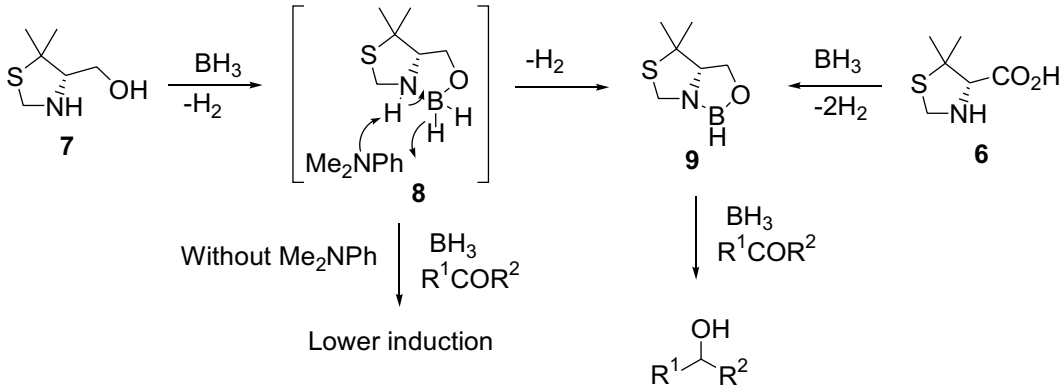
To a solution of thiazolidine **6** (8) (30 mg, 0.19 mmol, 0.1 equiv) or amino alcohol **7** (27.9 mg, 0.19 mmol, 0.1 equiv) in 1 mL THF were added 2.8 mL of BH_3·THF (1 M THF, 1.5 equiv) at 0°C. After stirring 10 min, the cooling bath was removed and a solution of ketone (1 equiv) in 1 mL of THF was added over 60 min via a syringe-pump. After 10 min, the mixture was quenched at 0°C by adding 5 mL of 2 N HCl diluted with water (10 mL), the organic phase was extracted with AcOEt (3 × 10 mL), dried over $MgSO_4$, and the product was purified by flash chromatography (AcOEt–hexane). Enantiomeric excesses were measured by HPLC. PhCHOHMe: OB column, λ: 210 nm, flow: 1 mL min^{-1}, hexane–isopropanol 90:10, R_{t1}: 6.44 min (*S*) and R_{t2}: 9.73 min. *p*-$FC_6H_4CHOHMe$: OB column, λ: 210 nm, flow: 1 mL min^{-1}, hexane–isopropanol 98:2, R_{t1}: 17.77 min (*S*) and R_{t2}: 19.89 min. *p*-$MeOC_6H_4CHOHMe$: OB column, λ: 210 nm, flow: 1 mL min^{-1}, hexane–isopropanol 90:10, R_{t1}: 13.54 min (*S*) and R_{t2}: 18.56 min. $PhCHOHCH_2Br$: OB column, λ: 210 nm, flow: 1 mL min^{-1}, hexane–isopropanol 90:10, R_{t1}: 8.02 min and R_{t2}: 10.38 min. (*S*). 8-methoxytetralol: OB column, λ: 210 nm, flow: 1 mL min^{-1}, hexane–isopropanol 90:10, R_{t1}: 6.61 min and R_{t2}: 10.50 min (*S*).

Reduction of ketones in presence of amino alcohol 7 and* N,N-*dimethylaniline

To a solution of amino alcohol **7** (28 mg, 0.19 mmol, 0.1 equiv) and 0.24 mL of *N*,*N*-dimethylaniline in 1 mL

© 2002 NRC Canada

Scheme 2. Effect of an *N*,*N*-dimethylaniline on the reduction of ketones.



THF was added 1.21 mL of BH_3·THF (1 M THF, 0.65 equiv) at 0°C. After stirring for 2 h at reflux, the mixture was cooled to r.t. and 1.21 mL of BH_3·THF (1 M THF, 0.65 equiv) was added. A solution of ketone (1.9 mmol, 1 equiv) in 1 mL THF was added over 60 min via a syringe-pump. After 10 min, the mixture was quenched at 0°C by adding 5 mL of 2 N HCl. After dilution with water (10 mL), the organic phase was extracted with AcOEt (3 × 10 mL) and dried over $MgSO_4$. The corresponding alcohol was purified by flash chromatography (AcOEt–hexane, 15:85). Enantiomeric excesses were measured by HPLC.

Investigation of the reactivity difference between thioglycoside donors with variant aglycon parts

Martina Lahmann and Stefan Oscarson

Abstract: The reactivity of perbenzoylated thioglycosides with various thiol aglycons has been compared and quantified using competitive glycosylation experiments. Methyl 2,3,4-tri-*O*-benzyl-α-D-glucopyranoside was employed as acceptor and DMTST as a promoter. The reactivity was found, as expected, to depend on the electron donating properties of the aglycon. Hence, the most reactive donor, the cyclohexyl thioglycoside, was found to be about three times as reactive as the thioethyl glycoside, which in turn was twice as reactive as the thiomethyl donor. The thiophenyl donor was even less reactive, whereas *p*-halophenyl donors were inert under the glycosylation conditions used — but could be activated using NIS–TfOH as promoter. Furthermore, it was found that galactosyl donors were three to four times more reactive than the corresponding glucosyl derivative. These results allowed the design of an orthogonal coupling between thioglycosides with the same protecting groups (benzoyls) but with different thiol aglycons.

Key words: thioglycosides, orthogonal glycosylations, competititive glycosylations.

Résumé : En se basant sur des expériences de glycosylations compétitives, on a comparé et quantifié la réactivité de thioglycosides perbenzoylés avec diverses thioaglycones. On a utilisé le 2,3,4-tri-*O*-benzyl-α-D-glucopyranoside de méthyle comme accepteur et le DMTST comme promoteur. On a trouvé, tel que prévu, que la réactivité dépend du caractère électrodonneur de l'aglycone. On a donc trouvé que le donneur le plus réactif, le thioglycoside de cyclohexyle, est trois fois plus réactif que le glycoside de thioéthyle qui est lui-même deux fois plus réactif que le donneur thiométhyle. Le donneur thiophényle est encore moins réactif alors que les donneurs *p*-halophényles sont inertes dans les conditions de glycosylation utilisées; ils peuvent toutefois être activés en utilisant le NIS–TfOH comme promoteur. De plus, on a trouvé que les donneurs galactosyles sont de trois à quatre fois plus réactifs que le dérivé glucosyle correspondant. Ces résultats ont permis de mettre au point un couplage orthogonal entre des thioglycosides avec les mêmes groupes protecteurs (benzoyles), mais des thioaglycones différentes.

Mots clés : thioglycosides, glycosylations orthogonales, glycosylations compétitives.

[Traduit par la Rédaction]

Introduction

The reactivity of a glycosyl donor in a glycosylation reaction is dependent on its structure and the reaction conditions. This has enabled orthogonal glycosylations and one-pot synthesis of oligosaccharides using less reactive donors as acceptors. To achieve such glycosylations, various approaches have been used employing the reactivity diversity of, for example, various types of glycosyl donors (1, 2) and differently protected glycosyl donors (3–5). In the latter approach, quantification of the influence of the various protecting schemes on the reactivity was performed using model acceptors and competitive glycosylation studies (4, 5). Additionally, the effect of the promoter and solvent on the reactivity must be considered (6).

Thioglycoside donors have, apart from being stable substances allowing most protective group manipulations but still easily activated by chemoselective promoters (7–9), an additional advantage — their reactivity can be manipulated by the introduction of different thiol aglycons. A few examples of couplings using this approach have been reported (10–12), but no general study of the reactivity differences has been performed. Here, we describe efforts to quantify the reactivity difference between thioglycoside donors differing only in the aglycon moiety using competitive glycosylation studies. In addition, a sample trisaccharide was synthesized to relate the influence of the leaving group to other preparative conditions.

Results and discussion

As glycosyl donors, perbenzoylated thioglycosides with methyl (13), ethyl (13), phenyl (14), halophenyl (13), tolyl (11), benzyl (13), *n*-butyl (13), *n*-hexyl (15, 16), isopropyl (13), *t*-butyl (17), and cyclohexyl (18) aglycon substituents (Fig. 1) have been prepared and used. As a model acceptor, methyl 2,3,4-tri-*O*-benzyl-α-D-glucopyranoside (**15**) was chosen. Both glucosyl and galactosyl donors were tested. Competitive glycosylations were performed using mainly the ethyl thioglycoside (**Glc-13** or **Gal-13**) as a reference donor

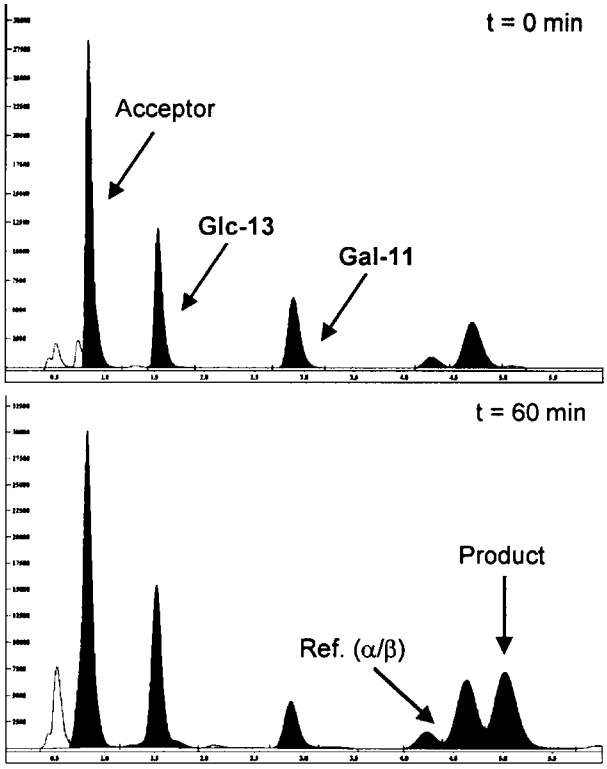
and dimethyl(methylthio)sulfonium trifluoromethylsulfonate (DMTST) (19) as a promoter (Scheme 1). The reaction mixtures were analyzed by HPLC (Fig. 2). Since the product is the same in most reactions, the relative reactivity was estimated by comparing the amounts of non-reacted donors. The results are summarized in Table 1.

As expected, the reactivity is correlated to the electron withdrawing (donating) capacity of the aglycon substituent. Tolyl and phenyl glycosides were slow (Table 1, entries 1–4, 15, 19, and 20), and an even more pronounced difference was observed with halosubstituted phenyl derivatives, which were inert under the conditions used. The latter donors were, however, easily activated by using NIS–AgOTf as the promoter. Of the alkyl glycosides tested, the methyl derivative showed a rather low reactivity (entries 6 and 7), whereas the *n*-butyl and benzyl glycosides were slightly faster (entries 8 and 10). The *n*-hexyl glycoside was comparable to the ethyl glycoside in reactivity (entries 11 and 12), while the branched alkyl glycosides, isopropyl and cyclohexyl, were the most reactive donors. As can be seen, the cyclohexyl derivative is an interesting effective donor (entries 13, 16, and

Fig. 2. HPLC spectra for entry 21 before addition of promoter and 60 min after addition (see *Experimental*).



18), but has so far not been widely used (20). The *tert*-butyl glycoside disappeared fastest (entry 22), but mainly gave the decomposition product of the donor and very little of the disaccharide product. In contrast, the perbenzylated *tert*-butyl thioglucoside donor was found to be an excellent donor, as was shown also by Stauch and Boons (21) using IDCP as the promoter.

Competition glycosylations between glucosyl and galactosyl donors showed the galactosides to be more reactive (Table 1, entries 5, 9, 14, 17, and 21 compared with entries 2, 3, 6, 12, and 18, respectively). A good correlation between the different derivatives was obtained, with a reactivity difference of about three to four in favour of the galactoside, which is in good agreement with a result of Wong and co-workers (5).

The reactivity difference between thioglycosides differing only in their thiol aglycons is most often to small to allow efficient orthogonal couplings, especially since the removal of a benzoyl group is activating. Often sugars of different reactivity and protecting group patterns as well as with different thiol aglycons are compared (11). *p*-NO_2-Phenyl thioglycosides have been used as inert acceptors, but to function as donors they have to be activated by conversion of the nitro functionality into an acetamido group, and even then the donor capacity is limited except for neuraminic acid donors (22–25). So far, the only report on orthogonal couplings between thioglycosides varying only in the aglycon functionality to give disaccharide donors was performed using steric effects by Boons et al. (12). Couplings between some of the more reactive (cHex, *i*-Pr, Et) perbenzoylated glycosides donors and less reactive acceptors (Ph, Tol, PhX,

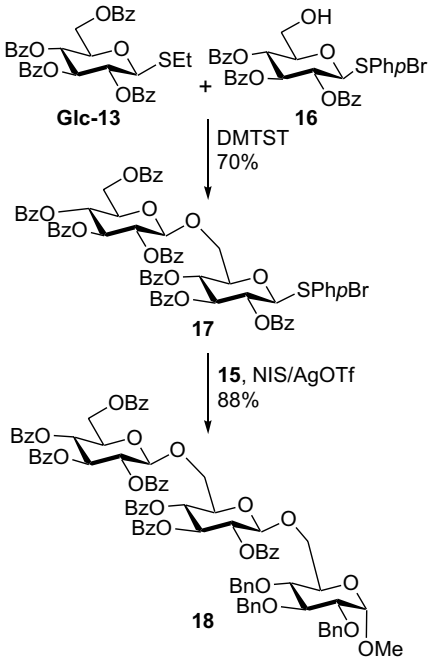
22	Glc-10 (*t*-Bu)	Glc-13 (Et)	12.5[b]

[a]The reactivity factors were calculated as followed: The peak area of the reference donor (D_{ref}) and the test donor (D_{test}) were normalized to the integral of the reference (R_β) (β-anomer): $D^\circ_{ref} = D_{ref^\circ}/R^\circ_\beta$; $D^\circ_{test} = D_{test^\circ}/R^\circ_\beta$; $D^n_{ref} = D_{ref^n}/R^n_\beta$; and $D^n_{test} = D_{test^n}/R^n_\beta$. From these values the amount of unused donor was calculated, as was the yield of product formed from that particular donor: $Y_{ref} = 1 - D^n_{ref}/D^\circ_{test}$. Resulting in the reactivity of the test donor: $R_{test} = Y_{test}/Y_{ref}$.
[b]Donor decomposes.

4-OH, or 6-OH) were carried out, but were found to be ineffective due to concomitant activation of the supposed acceptor. The combination of employing thiocyclohexyl or thioethyl glycosides as donors and thio *p*-Br-phenyl derivative **16** as acceptor, however, led to efficient product formation (Scheme 2). The amount of promoter (DMTST) had to be reduced compared with standard conditions (1.5 equiv instead of 2–4 equiv), which not only slowed down the couplings but also effectively suppressed activation of the acceptor. The *p*-Br-phenyl group of the obtained disaccharide **17** could then be smoothly activated in a NIS–AgOTf-promoted coupling with model acceptor **15** to produce a trisaccharide **18** (26) in high yield (Scheme 2).

In conclusion, a study of the reactivity of thioglycosides with different aglycon moieties has been performed using competitive glycosylations. The results gave a quantitative estimation of the differences between slow-reacting donors with electron withdrawing aglycons and fast-reacting donors with more electron donating aglycons, as well as the reactivity difference between glucosyl and galactosyl donors. A preparative example of a coupling between an ethyl thioglycoside (donor) and *p*-bromophenyl thioglycoside (acceptor), both carrying benzoyl protecting groups, is also described. Although other factors such as choice of solvent and promoter must be taken into account, these results, in combination with earlier investigations regarding the influence of protecting groups, should be of value for designing efficient orthogonal glycosylations between thioglycosides.

Scheme 2.



Experimental

All organic solvents were distilled before use. Organic solutions were dried over $MgSO_4$, before concentration, which was performed under reduced pressure at <40°C (bath temperature). NMR spectra were recorded at 300 MHz or 400 MHz (Varian) (^{1}H) or at 75 MHz or 100 MHz (^{13}C), respectively, in $CDCl_3$. For the ^{1}H NMR spectra, TMS was used as internal standard (δ = 0); the ^{13}C NMR spectra were referenced to the chloroform signal (δ = 77.17). Silica gel MERCK 60 (0.040–0.063) was used for flash chromatography. For the competition reactions, several stock solutions were prepared in dry CH_2Cl_2. The HPLC reference was dissolved together with the acceptor. The DMTST solution was left for one day at 4°C to stabilize the solution. The activity of the promoter solution was checked before (and after) each set of competition experiments performing a standard coupling experiment following the coupling procedure for competition experiments but using two equivalents of the reference donor (thioethyl glucoside) instead. All vials and sample tubes were dried and stored in an desiccator before use. For taking aliquots to prepare the reaction mixtures, glass pipettes with fixed volumes (50 μL, 500 μL) were used. The HPLC solvents (CH_3CN–H_2O (83:17), containing 0.1% TFA) were filtered (0.45 μm pores) before use. The reaction mixtures were analyzed on an analytical reversed phase column [column: RP C-18 (Rocket, 33 mm, ID 7 mm, beads size 3 μ, Alltima C18) pH 2.0–7.5] with UV detection (215 nm). During the analysis a low stream of helium was bubbled through the solvents. Once the coupling product was isolated and characterized by proton and carbon NMR. To check for the occurrence of decomposition products, the reactions were followed by TLC (toluene–EtOAc, 3:1; silica-gel F_{254} (E. Merck)) with detection by UV-light and (or) charring with 8% sulphuric acid. MALDI-TOF spectra were

© 2002 NRC Canada

recorded on a Bruker Biflex III with 2′,4′,6′-trihydroxyacetophenone monohydrate (THAP) as the matrix.

Typical preparation of the donors

The peracetylated sugar (2.5 mmol, 1.0 equiv) was dissolved in dry CH_2Cl_2 (2 mL per mmol sugar). Thiol (1.2–1.5 equiv) and $BF_3{\cdot}Et_2O$ (1.5–2 equiv) were successively added. When the reaction was complete (TLC: toluene–EtOAc, 3:1) the reaction mixture was quenched with Et_3N (2.5 equiv), evaporated, and redissolved in CH_2Cl_2, then washed with brine, dried, and concentrated. The crude product was filtered through a plug of silica gel (toluene–EtOAc, 9:1) and after crystallization (95% ethanol or pentane–Et_2O) the β-compounds were obtained. After removal of the acetates with NaOMe, the crude material was benzoylated in pyridine.

Competitive glycosylation experimental procedure

A mixture of the glycoside donor (10 μmol, 1.0 equiv, 1 mmol in CH_2Cl_2), the reference donor (10 μmol, 1.0 equiv, 1 mmol in CH_2Cl_2), the HPLC reference compound (5 μmol, 0.5 equiv, α/β 17:83, 0.5 mmol in CH_2Cl_2), the acceptor (20 μmol, 2.0 equiv, 2 mmol in CH_2Cl_2), and molecular sieves (4 Å) was stirred at room temperature for 30 min. An HPLC sample (5 μL) was taken, centrifuged, and analyzed. DMTST (10 μmol, 1.0 equiv., 1 mmol in CH_2Cl_2) was added and HPLC samples (20 μL) were taken at regular intervals (first set: 30 min, 1 h, 2 h, 4 h, 24 h; second set: 1 h, 3 h), centrifuged, and analyzed. All couplings were carried out as a double experiment at the same time to minimize errors.

4-Bromophenyl 2,3,4-tri-*O*-benzoyl-1-thio-β-D-glucopyranoside (16)

4-Bromophenyl 1-thio-β-D-glucopyranoside (680 mg, 1.92 mmol), dissolved in pyridine (5 mL), was stirred with TBDMSCl (350 mg, 2.3 mmol) and DMAP (cat.) at room temperature over night ($CHCl_3$–MeOH, 9:1). Then benzoyl chloride (2 mL) was added and the mixture was left stirring for additional 2 h (toluene–EtOAc, 6:1). After aqueous work-up, the raw material was purified by silica gel flash-chromatography (pentane–Et_2O, 3:1) to yield 4-bromophenyl 2,3,4-tri-*O*-benzoyl-6-*O*-*tert*-butyldimethylsilyl-1-thio-β-D-glucopyranoside (1.34 g, 1.72 mmol, 90%). ^{1}H NMR δ: 8.3–7.1 (m, 19H), 5.9 (t, *J* = 9.3 Hz, 1H), 5.5 (t, *J* = 9.6 Hz, 1H), 5.4 (t, *J* = 9.9 Hz, 1H), 5.0 (d, *J* = 9.6 Hz, 1H, H-1), 4.0–3.8 (m, 3H), 0.9 (s, 9H, *t-Bu*Si), 0.0 (2s, 6H, Me_2Si). ^{13}C NMR δ: 165.9, 165.1, 165.1 (Ph*C*O), 134.5, 133.8, 133.4, 132.1, 130.3, 129.9, 129.8, 128.5, 128.5, 128.3 (aromatic C), 122.8 (*C*-Br), 85.8 (C-1), 79.7, 74.5, 70.6, 69.1, 62.7, 25.9 (*t-Bu*Si), 18.4 (*t-Bu*Si), –5.2, –5.3 (Me_2Si).

To a cooled (0°C) solution of 4-bromophenyl 2,3,4-tri-*O*-benzoyl-6-*O*-*tert*-butyldimethylsilyl-1-thio-β-D-glucopyranoside (1.28 g, 1.65 mmol) in CH_2Cl_2 (50 mL), was slowly added $BF_3{\cdot}Et_2O$ (520 μL, 4.1 mmol). After 2 h, the reaction mixture was diluted with CH_2Cl_2, washed consecutively with H_2O, $NaHCO_3$, and brine, then dried and concentrated. The crude product was purified by silica gel flash-chromatography (toluene → toluene–EtOAc, 6:1) to yield **16** (0.94 g, 1.42 mmol, 86%). ^{1}H NMR δ: 8.0–7.8 (m, 6H), 7.6–7.1 (m, 13H), 5.9 (t, *J* = 9.6 Hz, 1H), 5.4 (t, *J* = 9.6 Hz, 2H), 5.0 (d, *J* = 9.6 Hz, 1H, H-1), 3.9–3.7 (m, 3H). ^{13}C NMR δ: 166.1, 165.8, 165.1 (Ph*C*O), 135.0, 133.8, 133.5, 133.4, 132.2, 130.0, 129.9, 129.8, 128.6, 128.5, 128.5, 128.4 (aromatic C), 123.1 (*C*-Br), 85.8 (C-1), 79.0, 73.9, 70.5, 69.2, 61.5. MALDI-TOF MS calcd. for $C_{33}H_{27}BrO_8S$: 662.06 [M(^{79}Br)], 664.06 [M(^{81}Br)]; found: 685.05 [M(^{79}Br) + Na]$^+$, 687.06 [M(^{81}Br) + Na]$^+$, 701.03 [M(^{79}Br) + K]$^+$, 703.02 [M(^{81}Br) + K]$^+$.

4-Bromophenyl (2,3,4,6-tetra-*O*-benzoyl-β-D-glucopyranosyl)-(1→6)-2,3,4-tri-*O*-benzoyl-1-thio-β-D-glucopyranoside (17)

A solution of donor **Glc-13** (100 mg, 156 μmol) and acceptor **16** (100 mg, 150 μmol) in dry CH_2Cl_2 (5 mL) was stirred with powdered molecular sieves (4 Å, 200 mg) under argon for 1 h, then DMTST (54 mg, 209 μmol dissolved in 500 μL CH_2Cl_2) was added. The reaction, followed by TLC (toluene–EtOAc, 6:1), was quenched after 4 h by addition of Et_3N (100 μL) and the mixture was diluted with CH_2Cl_2 (20 mL), filtered, and concentrated. The residue was subjected to silica gel column chromatography (pentane–Et_2O, 1:1 followed by toluene–EtOAc, 20:1) to obtain **17** (130 mg, 105 μmol, 70%) as a white solid. ^{1}H NMR δ: 8.0–7.7 (m, 14H), 7.5–6.9 (m, 25H), 5.9 (t, *J* = 9.6 Hz, 1H), 5.8 (t, *J* = 9.4 Hz, 1H), 5.6 (t, *J* = 9.9 Hz, 1H), 5.5 (dd, *J* = 7.7, 9.9 Hz, 1H), 5.3 (t, *J* = 9.6 Hz, 1H), 5.2 (t, *J* = 9.9 Hz, 1H), 4.9 (d, *J* = 7.7 Hz, 1H, H-1′), 4.8 (d, *J* = 9.9 Hz, 1H, H-1), 4.6 (dd, *J* = 3.3, 12.1 Hz, 1H), 4.4 (dd, *J* = 4.4, 12.1 Hz, 1H), 4.0 (m, 3H), 3.9 (dd, *J* = 7.1, 11.5 Hz, 1H). ^{13}C NMR δ: 166.1, 165.9, 165.7, 165.4, 165.2, 165.0 (Ph*C*O), 134.8, 133.6, 133.5, 133.4, 133.3, 132.2, 130.7, 130.0, 129.9, 129.8, 129.6, 129.3, 129.2, 128.9, 128.7, 128.5, 128.4, 128.3, 125.4, 123.0 (aromatic C), 101.5 (C-1′), 85.6 (C-1), 78.2, 74.1, 73.0, 72.5, 71.9, 70.5, 69.6, 68.7, 65.0. MALDI-TOF MS calcd. for $C_{67}H_{53}BrO_{17}S$: 1240.22 [M(^{79}Br)], 1242.42 [M(^{81}Br)]; found: 1263.25 [M(^{79}Br) + Na]$^+$, 1265.25 [M(^{81}Br) + Na]$^+$, 1279.24 [M(^{79}Br) + K]$^+$, 1281.25 [M(^{81}Br) + K]$^+$.

Methyl (2,3,4,6-tetra-*O*-benzoyl-β-D-glucopyranosyl)-(1→6)-(2,3,4-tri-*O*-benzoyl-β-D-glucopyranosyl)-(1→6)-2,3,4-tri-*O*-benzyl-α-D-glucopyranoside (18) (26)

A solution of donor **17** (40 mg, 32 μmol) and acceptor **15** (18 mg, 39 μmol) in dry CH_2Cl_2 (2 mL) was stirred with powdered molecular sieves (4 Å, 100 mg) under argon for 1 h. The mixture was cooled (0°C) and NIS (11 mg, 49 μmol) and AgOTf (cat.) were added. The reaction, followed by TLC (toluene–EtOAc, 6:1), was quenched after 30 min by addition of Et_3N (50 μL), the mixture was then diluted with CH_2Cl_2 (20 mL), filtered, and concentrated. The residue was subjected to silica gel column chromatography (toluene → toluene–EtOAc, 10:1) to yield **18** (42 mg, 28 μmol, 88%). ^{1}H NMR δ: 8.0–7.7 (m, 14H), 7.5–6.9 (m, 36H), 5.8 (t, *J* = 10 Hz, 1H), 5.7 (t, *J* = 10 Hz, 1H), 5.6 (t, *J* = 10 Hz, 1H), 5.4 (m~dd, *J* = 10 Hz, *J* = 8 Hz, 2H), 5.3 (t, *J* = 10 Hz, 1H), 5.0 (d, *J* = 7.8 Hz, 1H,), 4.9 (d, *J* = 11 Hz), 4.7 (d, *J* = 12 Hz, 1H), 4.6 (d, *J* = 11 Hz, 1H), 4.5 (m, 3H), 4.4 (d, *J* = 8 Hz, 1H), 4.3 (m, 2H), 4.1 (d, *J* = 11 Hz, 1H), 4.0 (m, 2H), 3.8 (m, 4H), 3.5–3.3 (m, 4H), 3.3 (s, 3H) ppm. ^{13}C NMR δ: 166.1, 165.8, 165.4, 165.1, 164.9 (Ph*C*O), 139.7–137.5, 133.5–127.4 (aromatic C), 101.5, 100.8 (C-1′, C-1″), 98.2 (C-1), 81.9, 79.8, 75.5, 74.5, 74.4, 73.5, 72.8,

Anomeric effects of sulfones

Guangwu Chen, Richard W. Franck, Guangli Yang, and Michael Blumenstein

Abstract: The anomeric effect of the sulfone group in tetrahydropyrans has been determined. The value is >2 kcal mol^{-1}, which is larger than the *A*-value of a methyl group but less than the *A*-value of the sulfone in a tetrahydropyran. Hence, in an unsubstituted tetrahydropyranyl sulfone, the equatorial conformer predominates, whereas in a properly substituted methyltetrahydropyranyl sulfone, an axial sulfone is preferred over an axial methyl group.

Key words: sulfone, tetrahydropyran, anomeric effect.

Résumé : On a déterminé l'effet anomère du groupe sulfone dans les tétrahydropyranes. La valeur est supérieure à 2 kcal mol^{-1} et elle est nettement supérieure à la valeur de *A* d'un groupe méthyle, mais elle est inférieure à la valeur de *A* de la sulfone dans un tétrahydropyrane. Il en résulte que dans un tétrahydropyranylsulfone non substituée l'isomère équatorial prédomine alors que dans une méthyltétrahydropyranylsulfone substituée de façon appropriée la sulfone occupera la position axiale de façon préférentielle par rapport à un groupe méthyle axial.

Mots clés : sulfone, tétrahydropyrane, effet anomère.

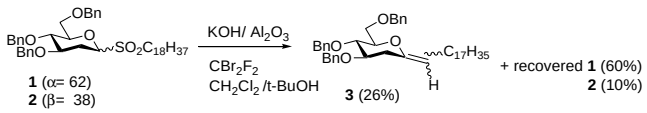
[Traduit par la Rédaction]

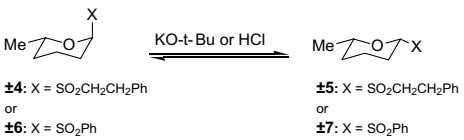
Introduction

The discovery and understanding of the anomeric effect in carbohydrate chemistry begins with Raymond Lemieux and John T. Edward (1). The original arguments rationalized the observation of a diminished equatorial preference of oxygen substituents at the anomeric carbon of carbohydrates in comparison to their equatorial preference in cyclohexanes; similar behavior of other electronegative substituents have since been observed and are included in the rationalization. The sulfone group is an often-prepared and well-known anomeric substituent, used as a starting material for the direct preparation of *C*-glycosides (2), through their lithiation and subsequent desulfonylation (3), via intermediate anomeric lithium (4) and samarium reagents (5) as well as the Ramberg–Bäcklund reaction (6). The sulfone has also been used, rather infrequently, as a leaving group for *O*-glycosylations (7). It was a surprise to us that the anomeric effect of sulfones had not been observed earlier (8). In this paper, experiments that show a large anomeric effect for sulfones are described.

Results and discussion

In our work on applying the Ramberg–Bäcklund reaction to carbohydrate anomeric sulfones, we observed that the α–β ratio of unreacted sulfones **1** and **2** recovered from the basic reaction mixture was not the same as the starting ratio, with the amount of α-isomer enhanced (eq. [1]). This observation could be explained in two ways: (*i*) the β-isomer was reactive whereas the α was not; and (or) (*ii*) the β-isomer was isomerizing to the α-isomer. These two explanations were easily verified. When pure α-isomer **1** was subjected to the Ramberg–Bäcklund conditions, no reaction was observed, consistent with the former explanation; however, when pure β-isomer **2** was subjected to the same conditions, the α-isomer was recovered along with Ramberg–Bäcklund product **3**. These reaction conditions were not an equilibration. The sulfones were, therefore, equilibrated with *t*-BuOK–benzene with no brominating agent present. The equilibrium ratio of β–α achieved in both directions was 57:43. This corresponds to an apparent *A*-value of 0.167 kcal mol^{-1} for the dodecyl sulfone group. Simpler tetrahydropyranyl phenyl sulfones **4**–**7** (eq. [2]) gave similar results (Table 1),





although a different *A*-value was recorded, presumably because of the absence of the electronegative substituents found in **1** and **2**. Tetrahydropyranyl phenethyl sulfones **4** and **5** failed to equilibrate under basic conditions. We assumed that proton exchange was not occurring at the anomeric carbon but at the α′-carbon of the phenethyl group. Thus, we turned to acid-catalyzed equilibration (Table 2). Both the phenyl and phenethyl sulfones gave similar *A*-values,

[a]No equilibrium obtained.

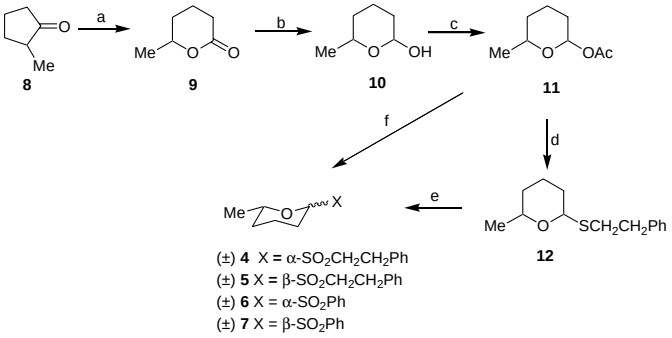
Scheme 1. Reagents and conditions: (*a*) MMPP, DMF, RT, 70%; (*b*) DiBAL, DCM, –78°C, 111% (raw yield); (*c*) Ac_2O, Et_3N, 4-DMAP, 0°C → RT, 73% (3 steps); (*d*) phenylethanethiol, K-10, benzene, RT, 78%; (*e*) MMPP, THF–H_2O–EtOH (4:4:1), 0°C, 1 h, 95%; (*f*) $NaSO_2Ph$, TFA, DCM, 78%.

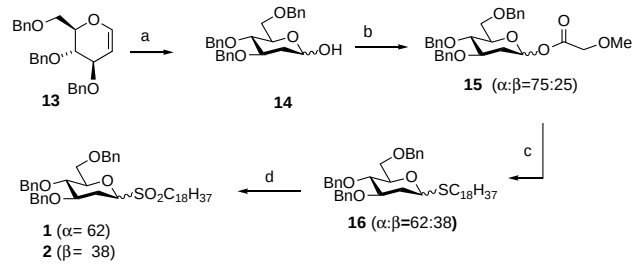


and in the former case, the acid- and base-catalyzed isomer ratios were in good agreement.

The apparent size of the sulfone group was observed by a different method. Thus, *trans*-sulfones **4** and **6** were observed to exist in conformations where the sulfones were axial and the methyls were equatorial. Low-temperature NMR experiments (–110°C) did not succeed in producing spectra that displayed resolved peaks for each of the two possible chair conformers. Only a slight decreased in the $J_{5a,6a}$ value (10.6 Hz) for **6** compared with the value of isomer **7** (11.0 Hz), where the methyl is 100% equatorial, suggests the presence of the flipped-conformer of **6**.

The evaluation of an anomeric effect for a substituent group requires a comparison of the apparent size of the group in an axial position in cyclohexane (where there can be no effect) to its apparent size in tetrahydropyran where an effect may be revealed. The *A*-value for CH_3 in cyclohexane is 1.8 kcal mol^{-1}, while that for SO_2CH_3 is 2.5 kcal mol^{-1} (9). Thus, in cyclohexane, sulfone is larger than methyl by 0.7 kcal mol^{-1}. From the equilibration and conformational

Scheme 2. Reagents and conditions: (*a*) $Ph_3P{\cdot}HBr$, H_2O, ether, 81% (*b*) $CH_3OCH_2CO_2H$, DCC, ether, 87% (*c*) $Yb(OTf)_3$, $C_{18}H_{37}SH$, CH_3CN, 60°C, 89% (*d*) MMPP, 95%.



data of the simple methyl tetrahydropyranyl sulfones we have studied, the sulfone appears to be smaller than methyl. We estimate that the apparent *A*-value for the sulfonyl group is 0.7 kcal mol^{-1}. If we assume that the sulfone *A*-value in tetrahydropyran, in the absence of an anomeric effect, should be equal to 2.5 kcal mol^{-1} (the same as the cyclohexane value) then the anomeric effect for the sulfone is $2.5_{predicted} - 0.7_{obsd} = 1.8$ kcal mol^{-1}. It is known, however, that the apparent size of axial groups in tetrahydropyran is larger than in cyclohexanes. We have proposed a correction factor of 1.5 in converting a cyclohexane *A*-value to that for a tetrahydropyran. This factor has been derived by comparison of the *A*-value of CH_3 (1.8) in cyclohexane to that of 2.7 at C-2 in tetrahydropyran (10). Hence the sulfone *A*-value could be as high as $2.5 \times 1.5 = 3.75$ kcal mol^{-1}, which leads to an anomeric effect of $3.75_{predicted} - 0.7_{obsd} = 3.05$ kcal mol^{-1}. In either case, the anomeric effect in favor of an axial sulfone is approximately 70% of the steric effect favoring the equatorial conformer. Hence, in the parent phenylsulfonyl tetrahydropyran itself, the group will appear to be equatorial. This is a different situation from the oxygen anomeric effect, which although a smaller force, overrides an equivalent or somewhat smaller steric effect. It is therefore possible to detect significant amounts of axial anomeric oxygen species in the parent tetrahydropyran under equilibrium

© 2002 NRC Canada

circumstances. Clearly, in the one carbohydrate sulfone we have examined, the anomeric effect is even larger than in the simple cases. Further experiments on a family of carbohydrate sulfones are planned.

Experimental

General methods

^{1}H NMR spectra were recorded on GE QE 300, JEOL FX 400, and Varian 500 spectrometers. Chemical shifts are reported in ppm relative to internal tetramethylsilane (δ = 0.00), chloroform (δ = 7.26), methanol (δ = 3.31), or tetrahydrofuran (δ = 3.58). Coupling constants (*J*) are given in Hertz (Hz). Multiplicities are described by using the following abbreviations: s = singlet; d = doublet; t = triplet; q = quartet; m = multiplet; br = broad. ^{13}C NMR spectra were recorded on GE QE 300 and JEOL FX 400 spectrometers. Chemical shifts are reported in ppm relative to internal standards chloroform (δ = 77.0), acetone (δ = 29.8), or tetrahydrofuran (δ = 67.6). Multiplicities refer to the resonance in the off-resonance spectra and were elucidated using the distortionless enhancement by polarization transfer (DEPT) spectral editing technique, with secondary pulses at 90° and 135°. Coupling constants ($^1J_{C,H}$) are described by using the following abbreviations: s = singlet (due to quaternary carbon); d = doublet (methine); t = triplet (methylene); q = quartet (methyl). Mass spectra were obtained on Agilent Techologies 1100 LC/MSD instrument using electrospray ionization (ESI) mode. Ion mass (*m*/*z*) signals are reported as values in atomic mass units followed, in parentheses, by peak intensities relative to the base peak (100%). Elution of all reactions were monitored by analytical thin layer chromatography (TLC) using silica gel 60 PF^{254} precoated plates (E. Merck), and spots were detected either by UV-absorption or by charring with H_2SO_4–4-methoxybenzaldehyde in methanol or ethanol — R_f values are also given under these conditions. Flash column chromatography was performed using E. Merck silica gel 60 (230–400 mesh). Unless otherwise stated, all commercially available chemicals were used without further purification, but some reagents were dried under vacuum before use. All reactions involving air- and (or) moisture-sensitive reagents were performed under nitrogen atmosphere with dry, freshly distilled solvents using standard syringe–cannula/septa techniques. All solvents were dried by usual methods and stored under nitrogen atmosphere in the dark in well-stoppered bottles. The synthesis of the starting sulfones, illustrated in Schemes 1 and 2, were routine and used known methods.

Oxidation of 2-methylcyclopentanone (8) for synthesis of lactone 9 (11)

To a solution of 2-methylcyclopentanone (8) (3.688 g, 37.6 mmol) in DMF (40 mL) was added MMPP (80%, 35 g, 56.6 mmol, 1.5 equiv). The slightly green suspension was stirred at RT overnight and became a white sticky mixture, whereupon TLC (PE–EE, 1:1) indicated that the oxidation was complete. The mixture was diluted with CH_2Cl_2 (40 mL) and washed with aqueous HCl (2 N, 2 × 30 mL). The combined organic phases were further washed with a saturated solution of $NaHCO_3$ (2 × 30 mL) and water (5 × 30 mL). After drying over Na_2SO_4, the solvent was evaporated under reduced pressure to afford a crude product, which was employed for the next step without further purification. Yield: 3.023 g (26.5 mmol, 70%); R_f = 0.48 (silica gel, PE–EE, 1:1); light yellow oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 4.47 (m, 1H, 5-H), 2.67–2.53 (m, 1H, 2-H), 2.52–2.38 (m, 1H, 2-H′), 1.92–1.45 (m, 4H, 2 × 3-H and 2 × 4-H), 1.40 (d, *J* = 6.2 Hz, 3H, 6-H).

6-Methyltetrahydropyran-2-ol (10) (12)

To a stirred solution of lactone **9** (230 mg, 2.0 mmol) in dry CH_2Cl_2 (15 mL) at –78°C was added a solution of *i*-Bu_2AlH in hexane (1.0 M, 4.0 mL, 4.0 mmol, 2.0 equiv). The mixture was allowed to stir for 2 h, at which time TLC indicated that the reduction was clean and complete. The reaction was quenched by careful addition of MeOH (5 mL) and warmed to ambient temperature, whereupon it was treated with a saturated aqueous solution of Rochelle's salt (15 mL) and was allowed to stir for about 2 h until the phases clearly separated. The aqueous phase was extracted with CH_2Cl_2 (3 × 6 mL) and the combined organic phases were dried over Na_2SO_4. Evaporation of the solvents under reduced pressure afforded the crude lactol **10** in a *trans–cis* ratio of 1:1.7. Yield: 258 mg (2.2 mmol, >99%); R_f = 0.60 (silica gel, PE–EE, 1:1); brown yellow oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.30 (br s, 1H, 2-H of *trans*), 4.72 (dd, *J* = 9.5, 2.2 Hz, 1H, 2-H of *cis*), 3.58 (dqd, *J* = 11.2, 6.2, 2.2 Hz, 1H, 6-H of *trans*), 3.88 (br s, 1H, OH of *cis*), 3.60 (dqd, *J* = 11.2, 6.2, 2.2 Hz, 1H, 6-H of *cis*), 3.25 (br s, 1H, OH of *trans*), 2.00–1.20 (m, 12H, 3 × CH_2 of *cis* and 3 × CH_2 of *trans*), 1.22 (d, *J* = 6.2 Hz, 3H, Me of *cis*), 1.13 (d, *J* = 6.2 Hz, 3H, Me of *trans*).

Acetylation of lactol 10

6-Methyltetrahydropyran-2-ol (**10**) (crude product, ca. 26.5 mmol) was dissolved under nitrogen in $DCM_{abs.}$ (60 mL). To this solution were added triethylamine (5.3 mL, 2 equiv) and acetic anhydride (7.2 mL, 2 equiv). After addition of a catalytic amount of 4-DMAP (64 mg, 0.02 equiv) the mixture was allowed to stir at RT for 1 h, whereupon TLC (PE–EE, 4:1) showed that the acetylation was complete. The mixture was concentrated in controlled vacuo to afford a crude product **11**, which, according to NMR, was so clean that further purification was not necessary. Yield: 4.311 g (27.3 mmol, 73% over 3 steps, *trans–cis* = 1:6.8); R_f = 0.78 (silica gel, PE–EE, 4:1); brown yellow oil with sweet odor. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 6.09 (br s, 1H, 2-H of *trans*), 5.61 (dd, *J* = 9.3, 2.3 Hz, 1H, 2-H of *cis*), 3.90 (dqd, *J* = 11.0, 6.3, 1.8 Hz, 1H, 6-H of *trans*), 3.63 (dqd, *J* = 11.0, 6.0, 2.2 Hz, 1H, 6-H of *cis*), 2.06 (s, 3H, CH_3CO of *cis*), 2.04 (s, 3H, CH_3CO of *trans*), 1.90–1.29 (m, 12H, 3 × CH_2 of *cis* and 3 × CH_2 of *trans*), 1.19 (d, *J* = 5.86 Hz, 3H, Me of *cis*), 1.10 (d, *J* = 6.2 Hz, 3H, Me of *trans*). ^{13}C NMR of *cis*-isomer (75 MHz, $CDCl_3$) δ: 169.1 (s, *C*OCH_3), 94.7 (d, O*C*HOAc), 73.2 (d, *C*HOCHOAc), 31.9, 29.7, 21.7 (3t, 3 × CH_2), 21.5, 21.2 (2q, CO*C*H_3 and CH_3).

Synthesis of thioglycoside 12 (13)

To a solution of lactol acetate **11** (1.824 g, 11.5 mmol) and benzeneethanethiol (1.547 mL, 1.0 equiv) in dry benzene (80 mL) was added montmorillonite K-10 (3 g). The mixture was stirred at RT for 2 h, whereupon TLC (PE–EE,

© 2002 NRC Canada

20:1) showed that the thioglycosylation was complete. After filtration with suction, the solid residue was washed with DCM. The combined filtrates were evaporated in vacuo to afford a crude product, which was purified and partially separated by flash chromatography on silica gel (PE–EE, 20:1). Yield: 2.131 g (9.0 mmol, 78%).

trans-Isomer: R_f = 0.46 (silica gel, PE–EE, 20:1). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.35–7.15 (m, 5H, Ph), 5.37 (d, *J* = 5.1 Hz, 1H, 2-H), 4.19 (dqd, *J* = 11.0, 6.2, 2.2 Hz, 1H, 6-H), 2.98–2.75 (m, 4H, CH_2CH_2Ph), 2.00–1.22 (m, 6H, 2 × 3-H, 2 × 4-H, and 2 × 5-H), 1.17 (d, *J* = 6.2 Hz, 3H, Me). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 140.7 (s, Ph-C1), 128.4, 128.2 (2d, Ph-C2,6 and Ph-C3,5), 126.1 (d, Ph-C4), 81.9 (d, O*C*HOCH$_2$CH$_2$Ph), 64.8 (d, *C*HOCHOCH$_2$CH$_2$Ph), 36.7, 33.3, 32.0, 30.3, 19.6 (5t, 5 × CH_2), 21.7 (q, CH_3).

cis-Isomer: R_f = 0.40 (silica gel, PE–EE, 20:1). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.30–7.14 (m, 5H, Ph), 4.47 (dd, *J* = 11.0, 2.2 Hz, 1H, 2-H), 3.46 (dqd, *J* = 11.0, 6.2, 1.8 Hz, 1H, 6-H), 3.02–2.84 (m, 4H, CH_2CH_2Ph), 1.92–1.10 (m, 6H, 2 × 3-H, 2 × 4-H, and 2 × 5-H), 1.22 (d, *J* = 6.2 Hz, 3H, Me). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 140.8 (s, Ph-C1), 128.4, 128.3 (2d, Ph-C2,6 and Ph-C3,5), 126.1 (d, Ph-C4), 82.6 (d, O*C*HOCH$_2$CH$_2$Ph), 75.0 (d, *C*HOCHOCH$_2$CH$_2$Ph), 36.8, 32.6, 31.8, 31.5, 24.4 (5t, 5 × CH_2), 22.1 (q, CH_3). ES-MS *m*/*z* (%): 254.2 (100) $[M + NH_4]^+$; 498.2 (25) $[2M + NH_4]^+$; 263.1 (70) $[M + Na]^+$; 503.2 (18) $[2M + Na]^+$.

Oxidation of thioglycoside for syntheses of anomeric sulfones (±)-4 and (±)-5 (14)

The isomeric mixture of thioglycosides (±)-**12** (1.076 g, 4.0 mmol) was dissolved in a mixed solvent (54 mL, THF–H_2O–EtOH, 4:4:1) and to it at 0°C was added MMPP (7.9 g, 2.5 equiv). The mixture was allowed to stir at 0°C for 1 h, at which time TLC (PE–EE, 6:1) indicated the completion of the oxidation. The mixture was neutralized with a saturated solution of $NaHCO_3$ (30 mL). The aqueous phase was extracted with DCM (3 × 20 mL). The combined organic phases were dried over Na_2SO_4. Evaporation of the solvent in vacuo afforded a crude product, which was subsequently purified by flash chromatography (PE–EE, 8:1 to 5:1) to afford the pure title phenylethylsulfone of both (±)-**4** (*trans*) and (±)-**5** (*cis*) in a ratio of 2:3. Yield: 1.16 g (4.32 mmol, 95%). Pure *trans*-sulfide (60 mg, 0.254 mmol) was oxidized according to the same procedure. After work-up and flash chromatography pure *trans*-anomeric sulfone (±)-**4** was obtained (yield: 64 mg, 0.239 mmol, 94%) without observing any isomerization at the anomeric position under the oxidation conditions.

(±)-**4**: R_f = 0.40 (silica gel, PE–EE, 6:1). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.42–7.22 (m, 5H, Ph), 4.73 (dd, *J* = 6.2, 2.2 Hz, 1H, 2-H), 4.48 (dqd, *J* = 10.4, 6.2, 2.2 Hz, 1H, 6-H), 3.40–3.12 (2m, 4H, CH_2CH_2Ph), 2.15–1.21 (m, 6H, 2 × 3-H, 2 × 4-H, and 2 × 5-H), 1.23 (d, *J* = 6.2 Hz, 3H, Me). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 140.7 (s, Ph-C1), 128.0, 127.6 (2d, Ph-C2,6 and Ph-C3,5), 126.1 (d, Ph-C4), 86.3 (d, O*C*HSO$_2$CH$_2$CH$_2$Ph), 68.9 (d, *C*HOCHSO$_2$CH$_2$CH$_2$Ph), 50.7 (t, SO$_2$*C*H$_2$CH$_2$Ph), 30.9, 27.2, 20.1, 17.8 (4t, 4 × CH_2), 20.9 (q, CH_3). ES-MS *m*/*z* (%): 286.2 (100) $[M + NH_4]^+$; 554.2 (9) $[2M + NH_4]^+$; 291.1 (38) $[M + Na]^+$; 559.2 (8) $[2M + Na]^+$.

(±)-**5**: R_f = 0.26 (silica gel, PE–EE, 6:1). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.45–7.25 (m, 5H, Ph), 4.25 (dd, 1H, *J* = 11.4, 2.2 Hz, 2-H), 3.52–3.42 (m, 2H, 6-H and SO$_2$C*H*H), 3.32 (m, 1H, SO$_2$CH*H*), 3.18 (m, 2H, CH_2Ph), 2.10–1.28 (m, 6H, 2 × 3-H, 2 × 4-H, and 2 × 5-H), 1.26 (d, *J* = 6.3 Hz, 3H, Me). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 140.8 (s, Ph-C1), 128.7, 128.5 (2d, Ph-C2,6 and Ph-C3,5), 126.9 (d, Ph-C4), 90.3 (d, O*C*HSO$_2$CH$_2$CH$_2$Ph), 76.1 (d, *C*HOCHSO$_2$CH$_2$CH$_2$Ph), 50.0 (SO$_2$*C*H$_2$CH$_2$Ph), 27.8 (SO$_2$CH$_2$*C*H$_2$Ph), 32.2, 22.3, 21.9 (3t, 3 × CH_2), 21.8 (q, CH_3). Preparation of phenylsulfone (±)-6 and (±)-7 (15)

Lactol acetate **11** (50 mg, 0.32 mmol) was dissolved in dry DCM (15 mL) and to it was added sodium benzenesulfinate (109 mg, 0.66 mmol, 2 equiv). After addition of trifluoroacetic acid (0.1 mL, 4 equiv) the mixture was allowed to stir for 4 h at RT, whereupon TLC (PE–EE, 4:1) indicated the completion of the reaction. The mixture was diluted with DCM (15 mL) and then decanted into a saturated solution of $NaHCO_3$ (30 mL). The organic phase was washed once with water (20 mL) and dried over Na_2SO_4. Evaporation of the solvent in vacuo gave a crude product, which was subsequently purified by flash chromatography (PE–EE, 4:1) to afford each pure title phenylsulfone (±)-**6** and (±)-**7** Yield: 59 mg (0.246 mmol, 78%, *trans*-(±)-**6**–*cis*-(±)-**7** = 2:1, separable).

(±)-**6**: R_f = 0.30 (silica gel, PE–EE, 6:1); amorphous solid. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.90–7.40 (m, 5H, Ph), 4.38 (dd, *J* = 6.6, 1.5 Hz, 1H, 2-H), 3.45 (dqd, *J* = 10.6, 6.2, 2.3 Hz, 1H, 6-H), 2.10–1.29 (m, 6H, 2 × 3-H, 2 × 4-H, and 2 × 5-H), 1.19 (d, *J* = 6.2 Hz, 3H, Me). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 133.6 (s, Ph-C1), 129.0, 128.6 (2d, Ph-C2,6 and Ph-C3,5), 128.8 (d, Ph-C4), 92.1 (d, O*C*HSO$_2$Ph), 69.6 (d, *C*HOCHSO$_2$Ph), 32.2, 23.6, 18.6 (3t, 3 × CH_2), 21.6 (q, CH_3).

(±)-**7**: amorphous solid; R_f = 0.22 (silica gel, PE–EE, 6:1). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.90–7.40 (m, 5H, Ph), 4.73 (dd, *J* = 11.0, 2.2 Hz, 1H, 2-H), 4.60 (dqd, *J* = 11.0, 6.2, 2.2 Hz, 1H, 6-H), 2.20–1.29 (m, 6H, 2 × 3-H, 2 × 4-H, and 2 × 5-H), 1.13 (d, *J* = 6.2 Hz, 3H, Me). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 133.5 (s, Ph-C1), 129.6, 128.7 (2d, Ph-C2,6 and Ph-C3,5), 128.8 (d, Ph-C4), 90.6 (d, O*C*HSO$_2$Ph), 74.5 (d, *C*HOCHSO$_2$Ph), 31.8, 22.5, 21.9 (3t, 3 × CH_2), 21.6 (q, CH_3). ES-MS *m*/*z* (%): 258.2 (100) $[M + NH_4]^+$; 498.2 (25) $[2M + NH_4]^+$; 263.1 (70) $[M + Na]^+$; 503.2 (18) $[2M + Na]^+$.

Isomerization

Initially, isomerization was carried out under basic conditions. Molecules *trans*-(±)-**6** and *cis-(±)-***7** were separately dissolved in dry benzene (2 mL). After addition of *t*-BuOK (10 mg) the solution was isomerized by heating at reflux for 5 days, whereupon the equilibrium was achieved according to the NMR analysis. isomerizations with compounds (±)-**4** and (±)-**5** were done under the similar conditions (*t*-BuOK); however, no isomerization was detected after heating at reflux for 5 days by NMR analysis. (Table 1).

Interestingly, after *trans*-isomer (±)-**4** was stored in $CDCl_3$ in the refrigerator for 3 weeks isomerization was observed,

© 2002 NRC Canada

although equilibrium was not reached. Similarly *trans*-isomer (±)-**6** was isomerized and reached equilibrium after storing in deuterated chloroform in a refrigerator for 7 weeks. Compound (±)-**6** was also stored in THF-d_6 in the refrigerator for 10 weeks; however, according to the NMR analysis, no isomerization was detected.

Acidic isomerization was preformed in NMR tubes at RT by treatment with small amounts of TMSCl and *t*-BuOH. The equilibrium ratios are given in Table 2.

2-Deoxyglucose series

In our synthesis, benzylated thioglycoside **16** was made from benzylated 2-deoxyglucose derivative **15** via the Inanaga–Yb(OTf)$_3$ method (16). Sulfide **16** was oxidized using MMPP to form sulfone **1**,**2** in good yield.

Tri-*O*-benzyl-2-deoxyglucose (14)

To a mixture of **13** (2.083 g, 5 mmol) and THF (15 mL) was added $Ph_3P{\cdot}HBr$ (0.0858 g, 0.25 mmol). The solution was stirred at RT for 10 min, then H_2O was added (0.135 mL, 0.017mol). This mixture was stirred at RT for 3 h. The mixture was treated with saturated $NaHCO_3$ solution (5 mL) and H_2O (10 mL) and extracted with EtOAc (3 × 20 mL). The organic phase was washed by brine, dried over Na_2SO_4, and concentrated. The residue was chromatographed on a column of 100 g silica gel (eluted with 30% EtOAc–petroleum ether) to afford 1.78 g of **14** (81%). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.20–7.30 (m, 15H), 5.41 (d, J = 2.3 Hz, 1H), 4.90 (dd, J = 6.4, 3.0 Hz, 1H), 4.80 (m, 6H), 4.05 (m, 1H), 3.60 (m, 2H), 2.85 (s, 1H, OH), 2.32 (m, 1H), 1.70 (m, 1H).

Tri-*O*-benzyl-2-deoxy-1-*O*-methoxyacetylglucose (15)

To a mixture of 2-deoxyglucose **14** (0.194 mL, 2.53 mmol) and ether (20 mL) was added DCC (0.522 g, 2.53 mmol). The mixture was stirred at RT for 10 min, then methoxyacetic acid (1.10 g, 2.3 mmol) was added, followed by 4-pyrrolidinopyridine (0.034 g, 0.23 mmol). After standing overnight, the solution was filtered to remove the solid phase, and then it was washed with brine (50 mL). The aqueous phase was extracted with ether (3 × 20 mL), dried over Na_2SO_4, and concentrated. The residue was chromatographed on a column of 50 g of silica gel (eluted with 20% EtOAc–petroleum ether) to afford 0.110 g of **15** as a colorless oil (87%, α:β = 3:1). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.20–7.30 (m, 15H), 6.30 (d, J = 2.7 Hz, 1H), 5.77 (dd, J = 10.5, 2.7 Hz, 1H), 4.88 (m, 1H), 4.60 (m, 6H), 3.98 (s, 2H), 3.41 (s, 3H, OMe), 2.35 (m, 1H), 1.85 (m, 1H).

Thioglycoside (16)

A solution of **15** (0.358 g, 0.707 mmol) and octadecyl mercaptan (0.263 g, 0.919 mmol) in dry acetonitrile (10 mL) was warmed to 53°C (bath temp) under nitrogen, and to this mixture was added a solution of Yb(OTf)$_3$ in acetonitrile (5 mmol L^{-1}, 0.71 mL, 0.5 mol%). After stirring for 2 h, the reaction was quenched with saturated $NaHCO_3$ solution (10 mL), and extracted by CH_2Cl_2 (3 × 20 mL). The organic phase was washed by H_2O, dried over Na_2SO_4, and concentrated. The residue was chromatographed on a column of 20 g of silica gel (eluted with 10% EtOAc–petroleum ether) to afford 0.442 g of **16** (89%, α:β = 8:5) as a white solid. Anal. calcd for $C_{45}H_{66}O_4S$: C 76.87, H 9.46, S 4.56; found: C 76.59, H 9.15, S 4.68.

α-Isomer: ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.20–7.30 (m, 15H), 4.91–4.53 (m, 6H), 4.52–4.47 (dd, J = 1.5, 11.7 Hz, 1H), 3.78–3.63 (m, 3H), 3.53–3.40 (m, 2H), 2.70 (m, 2H), 2.34 (m, 1H), 1.75 (m, 1H), 1.60 (m, 2H), 1.20 (s, 30H), 0.88 (t, 3H). ^{13}C NMR ($CDCl_3$, 75 MHz) δ: 139.22, 139.15, 138.80, 129.03, 128.94, 128.50, 128.46, 128.35, 128.23, 81.34, 79.31, 78.85, 75.63, 74.17, 72.55, 71.72, 69.72, 36.75, 36.74, 31.79, 30.51, 30.36, 30.16, 30.03, 29.75, 23.51, 14.94.

β-Isomer: ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.35–7.21 (m, 15H), 5.45 (d, J = 5.1 Hz, 1H), 4.92–4.49 (m, 6H), 4.19 (m, 1H), 3.95 (m, 1H), 3.83 (dd, J = 3.67, 11.0 Hz, 1H), 3.66 (m, 2H), 2.53 (m, 2H), 2.30 (dd, J = 4.76, 13.19 Hz, 1H), 2.08 (m, 1H), 1.59 (m, 2H), 1.35 (s, 30H), 0.91 (t, 3H).

Sulfone 2

A solution of MMPP (0.227 g, 0.45 mmol) in H_2O (2 mL) was added to a solution of **16** (β-isomer, 0.112 g, 0.159 mmol) in EtOH (2 mL) and THF (2 mL), and the mixture was kept at 55°C for 2 h. The mixture was concentrated to dryness in vacuo. The residue was treated with saturated $NaHCO_3$ solution (10 mL), and extracted with EtOAc (3 × 15 mL), dried over Na_2SO_4, and evaporated to dryness. The residue was purified by chromatography on silica gel (eluted with 25% EtOAc–petroleum ether) to afford pure sulfone **2** (β-isomer) as a white solid 0.11 g (95%). MS calcd. for $C_{45}H_{66}O_6S$: 734; found: 757 ([M + Na]$^+$). When the identical reaction was carried out with the (isomer of **16** as starting material, the α-sulfone **1** was afforded.

α-Isomer: mp 58–60°C. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.20–7.30 (m, 15H), 4.84 (dd, J = 7.0, 3.3 Hz, 1H, H-1), 4.80–4.45 (m, 6H, OCH_2Ph), 4.37 (m, 1H, H-5), 4.20 (m, 1H, H-3), 3.68 (d, J = 3.3 Hz, 2H, H-6), 3.58 (dd, J = 7.2, 9.3 Hz, 1H, H-4), 3.06 (t, 2H), 2.82 (m, 1H, H-2e), 2.06 (m, 1H, H-2a), 1.30 (s, 30H), 0.90 (t, 3H). ^{13}C NMR ($CDCl_3$, 75 MHz) δ: 138.78, 138.71, 138.53, 129.10, 129.02, 128.97, 128.44, 128.37, 128.308, 86.67, 77.53, 76.59, 75.62, 74.76, 74.06, 72.76, 69.73, 50.51, 32.73, 30.50, 30.32, 30.16, 30.08, 29.84, 29.39, 26.31, 23.50, 22.44, 14.93.

β-Isomer: mp 87–88°C. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.34–7.20 (m, 15H), 4.95–4.50 (m, 6H, OCH_2Ph), 4.30 (dd, J = 11.0, 3.0 Hz, 1H, H-1), 3.76–3.51 (m, 5H), 3.60 (t, 2H), 2.65 (m, 1H, H-2e), 1.88 (m, 1H, H-a), 1.27 (s, 30H), 0.88 (t, 3H). ^{13}C NMR ($CDCl_3$, 75 MHz) δ: 137.60, 137.55, 137.32, 128.04, 127.92, 127.60, 127.38, 127.29, 127.19, 127.13, 96.90, 86.78, 79.70, 78.99, 76.78, 74.80, 72.89, 71.02, 68.60, 48.86, 31.47, 29.23, 29.06, 28.89, 28.83, 28.59, 28.15, 27.42, 22.22, 20.75, 13.64.

Isomerization of the α,β isomers of 1 and 2

To a solution of β-sulfone **2** (12 mg, 0.016 mmol) in benzene (1 mL) and *t*-BuOH (0.2 mL) was added *t*-BuOK (10 mg, 0.107 mmol). The reaction mixture was refluxed at 70°C for 24 h. The mixture was diluted by dichloromethane, filtered, and dried in vacuo. The α:β ratio (36:64) was determined by the H-1 peak in ^{1}H NMR.

To a solution of α-sulfone **1** (12 mg, 0.016 mmol) in benzene (1 mL) and *t*-BuOH (0.2 mL) was added *t*-BuOK (10 mg, 0.107 mmol). The reaction mixture was refluxed at

© 2002 NRC Canada

70°C for 24 h. The mixture was diluted by dichloromethane, filtered, and dried in vacuo. The α:β ratio (53:47) was determined by ^{1}H NMR analysis.

To a solution of sulfone **1**,**2** (α:β = 3:1) (20 mg, 0.027 mmol) in THF (5 mL), *t*-BuOH (1 mL), and KOH–Al_2O_3 (20 mg, 50% (by weight), 0.107 mmol) was added crown ether-18 (0.2 equiv). The reaction mixture was heated at reflux (52°C) for one week. The mixture was diluted by dichloromethane, filtered, and dried in vacuo. The α:β ratio (42:58) was determined by the H-1 peak in ^{1}H NMR.

Pure α-sulfone **1** was treated under the above conditions. The α:β ratio (44:56) was determined by ^{1}H NMR.

Large-scale preparation of α-D-(1→4)-oligogalacturonic acids from pectic acid

Hong-Ni Fan, Mei-Zheng Liu, and Yuan C. Lee

Abstract: An efficient and inexpensive method for large-scale preparation of α-D-(1→4)-oligogalacturonic acids (oligo-GalA), up to DP 5, from pectic acid is described. Pectic acid was digested with a commercially available pectinase to yield a mixture of oligo-GalA, which was effectively separated by a combination of low-pressure – size-exclusion chromatography based on ion-exchange chromatography to obtain pure oligo-GalA of DP 2–5.

Key words: pectic acid, galacturonic acid, galabiose, galatriose, pectinase.

Résumé : On décrit une méthode efficace et peu coûteuse de préparation à grande échelle des acides α-D-(1→4)-oligogalacturoniques (oligo-GalA), jusqu'à 5 DP, à partir de l'acide pectique. L'acide pectique est soumis à une digestion avec une pectinase commercialement disponible pour conduire à un mélange d'oligo-GalA que l'on peut séparer efficacement par une combinaison de chromatographie d'exclusion de taille à basse pression et de chromatographie d'échange ionique pour obtenir les oligo-GalA de DP allant de 2 à 5.

Mots clés : acide pectique, acide galacturonique, galabiose, galatriose, pectinase.

[Traduit par la Rédaction]

Introduction

Pectic acid, derivable from an abundant plant polymer, pectin, is essentially composed of a repeating unit of α-(1→4)-linked D-galacturonic acid. α-D-(1→4)-Oligogalacturonic acids (oligo-GalA) have been shown to be physiologically active elicitors of plant-defense responses to pathogens (1). On the other hand, galabiose (α-Gal-(1→4)-Gal) has the same anomeric and positional linkages as the repeating unit of pectic acid, differing only by the presence of hydroxymethyl group rather than the carboxyl group at C-6. Galabiose is an important structural unit of some glycolipids, such as Gb3 and Gb4, and is the recognition marker for bacterial toxins (e.g., Shiga toxin and Shiga-like toxins) as well as for certain microbial invasions of human tissues, e.g., uropathogenic *Escherichia coli*, which causes hemorrhagic colitis and hemolytic uremic syndrome (2–6). Synthetic glycoconjugates containing the carbohydrate moiety of Gb_3 (globotriose, α-Gal-(1→4)-β-Gal-(1→4)-Glc) proved to be effective biomimetics for detecting and trapping of certain bacteria toxins and viruses (6–8). Galabiose has been prepared from pectic acid by first obtaining (α-GalA-(1→4)-α-GalA)$_n$ oligomers by partial digestion with pectinase followed by chemical reduction of the carboxylic groups (9–11). There are also some reports describing analysis, separation, and preparation of oligo-GalA with different degrees of polymerization (DP) (9–15). These methods, however, either require non-commercial enzymes, an expensive special ion-exchange resin, or preparative HPLC, and are not suitable for economical large-scale preparation of oligo-GalA. We wanted to prepare large amounts of galabiose and oligosaccharides containing galabiose by an inexpensive procedure, for the purpose of preparing high-affinity inhibitors for some toxins (e.g., Shiga toxin, Shiga-like toxins) and for certain pathogenic bacterial adhesion (16).

In this paper, we describe an efficient large-scale preparation of oligo-GalA (DP 2–5) from pectic acid by partial hydrolysis of pectic acid with a commercially available pectinase and a combination of inexpensive low-pressure column-chromatographic separation methods based on size exclusion and ion exchange.

Materials and methods

Materials

Apple pectic acid was obtained from Sigma-Aldrich-Fluka (Milwaukee, WI). Pectinase from *Aspergillus niger* (EC 3.2.1.15), galacturonic acid (GalA), di- and tri-galacturonic acid ($(GalA)_2$ and $(GalA)_3$, respectively), Dowex-50 W × 8 resin (H^+ form, 200 mesh), Dowex-1 × 4 resin (400 mesh), and Sephadex G-25 were from Sigma (St. Louis, MO). Ultrafiltration membranes (YM3, NMWL 3 000) were from Millipore (Bedford, MA).

General methods

Analysis of GalA-oligomers was carried out with high-performance anion-exchange chromatography, HPAEC (17) using a Bio-LC (Dionex, Sunnyvale, CA) with a CarboPac PA-1 column (4.6 × 250 mm) in combination with a pulsed amperometric detector (PAD-2). The detector sensitivity was set at 1 μA. Potential and time settings of the detector were:

E_1 = +0.05 V (t_1 = 0.42 s), E_2 = +0.65 V (t_2 = 0.18 s), and E_3 = –0.10 V (t_3 = 0.36 s). Oligo-GalA samples were eluted using the gradients shown in Table 1.

Carbohydrates were determined with a version of the phenol–sulfuric acid method (18). Thin layer chromatography (TLC) was performed on a 0.25-mm layer of silica gel 60 coated on aluminum sheets (E. Merck, Darmstadt, Germany).

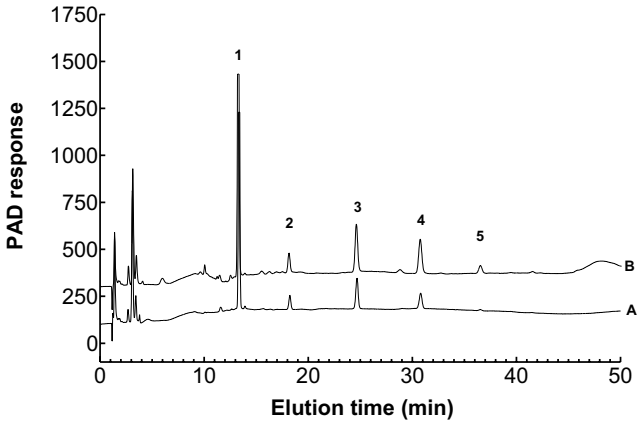
Results and discussion

Optimizing conditions for generation of oligo-GalA with DP 1–5 by pectinase digestion

Mixtures of oligo-GalA with different DPs can be obtained by hydrolysis of pectic acid with autoclaving or enzymatic digestion (9–12), but the enzymatic method was found to be the more efficient to degrade pectic acid. For example, depolymerization of pectic acid or pectin (partially esterified pectic acid) with an endopolygalacturonase (19) produces the desired saturated oligo-GalA, while with pectin lyases or pectate lyases, both saturated and unsaturated oligo-GalAs are produced. Unfortunately, such enzymes are not readily available, and thus we chose to use a commercially available pectinase to generate oligo-GalA from pectic acid.

The optimal conditions for generating oligo-GalA (DP 1–5) mixtures were determined by TLC and HPAEC–PAD analysis of the oligosaccharides released in the process of pectinase digestion. During the digestion with 10 or 20 units of pectinase–pectic acid (1.0 g) in 0.1 M acetate buffer, pH 4.0 (see below) at room temperature for 24 h, portions of the digest were removed after 0.5, 1, 3, and 24 h, immediately frozen in a dry-ice acetone bath, and stored frozen. Before analysis, the samples were thawed and heated at 100°C for 10 min to inactivate the pectinase and the precipitate was removed by microcentrifugation. Digestion with 20 units of pectinase–pectic acid (1.0 g) yielded α-(1→4)-oligo-GalA (DP 1–4) as the main products, in which GalA was predominant (Fig. 1). On the other hand, when 10 units of pectinase–pectic acid (1.0 g) were used under the same conditions, a much lower amount of GalA was produced, and the yields of oligo-GalA (DP 2–5) were higher (Fig. 2).

Fig. 2. Elution profiles of pectic acid digested with different amounts of pectinase by HPAEC. A: pectinase (20 units)/pectic acid (1.0 g); B: pectinase (10 units)/pectic acid (1.0 g). The numbers show the DP of the oligogalacturonic acid in the indicated peaks.



Preparation of oligo-GalA (DP 1–5) mixtures

Pectic acid powder (10.0 g) was suspended in HOAc–NaOAc buffer (each 0.1 M, 500 mL, pH 4.0) and the mixture was incubated at 55°C, sonicated, and stirred until the pectic acid was totally dissolved. The homogeneous but viscous solution was again adjusted to pH 4.0 with 0.1 M NaOAc, and the pectinase (250 μL, ca. 100 units) was added. The solution was gently stirred for 24 h at room temperature; the enzymatic hydrolysis was terminated by heating the mixture at 100°C for 10 min. After cooling, the precipitate and the remaining polymer were removed by ultrafiltration with a stirred cell (200-mL, Millipore, Bedford, MA) using a YM3 membrane. To remove the cations, the filtrate was applied to a column (2.5 × 17.6 cm) of Dowex-50W × 8 resin (H^+ form, 200 mesh) and washed with distilled water (200 mL). The washing was concentrated by rotary evaporation, and the residue was lyophilized to afford 7.68 g of oligo-GalA mixture (76.8% yield).

Size-exclusion chromatography

The oligo-GalA mixture (4.0 g) in HOAc (0.1 M, 20 mL) was applied to a Sephadex G-25 column (5.0 × 218 cm) in 0.1 M HOAc and eluted at a flow rate of 4 mL min^{-1} in 0.1 M HOAc. Fractions (16 mL) were analyzed for carbohydrates by the phenol–H_2SO_4 method (Fig. 3). The

Fig. 3. Elution of oligo-GalA on a Sephadex G-25 column (5.0 × 218 cm). The *y* axis is $A_{480\ nm}$ obtained by the phenol–sulfuric acid method. Approximate positions of the DP of the oligogalacturonic acid are indicated.

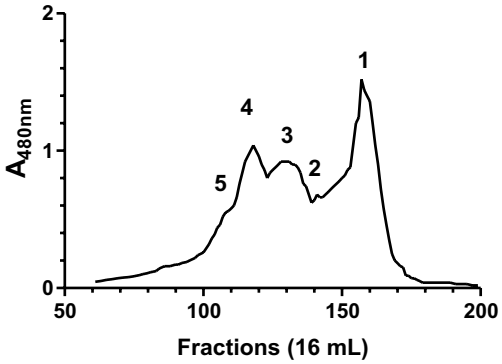

Fig. 4. Separation of oligo-GalA on Dowex-1 × 4 column (2.5 × 46 cm). The column was eluted with a linear gradient generated with 1 L each of 0.4 M and 1.0 M NaOAc (pH 6.0). The numbers indicate the DP of oligo-GalA in the peaks.

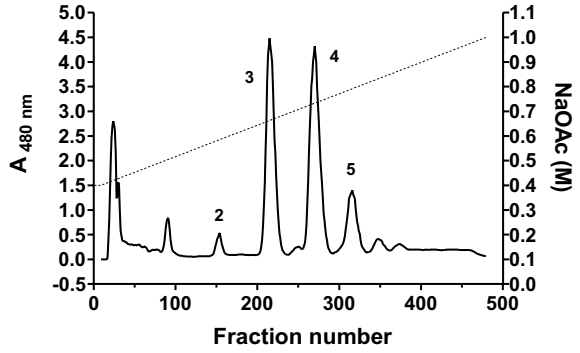
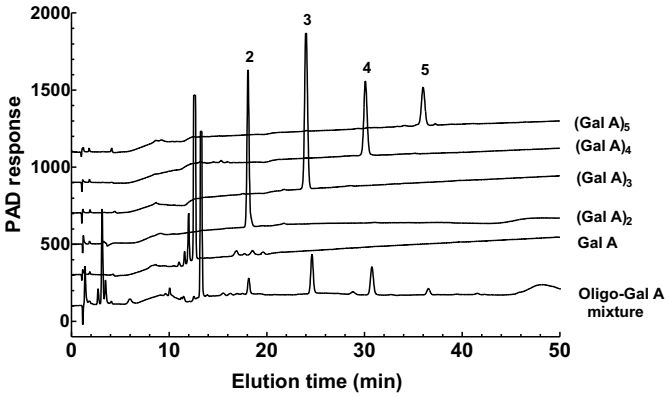


carbohydrate-containing fractions were examined by TLC using silica gel 60 sheets with 1-butanol–formic acid–water (v/v, 4:6:1) as the developing solvent. The R_f values of the oligo-GalA with DPs 1, 2, 3, 4, and 5 were ca. 0.48, 0.35, 0.28, 0.22, and 0.17, respectively. The fractions containing oligo-GalA of DP 2–5 were combined, concentrated by rotary evaporation, and lyophilized to give 2.58 g of product (64.5% yield). Although the Sephadex G-25 column did not fully separate oligo-GalA of DP 2–5, most of the monomer (GalA), which constituted a fairly large proportion of the total digest, could be removed.

Anion-exchange chromatography of oligo-GalA

An example of the anion-exchange chromatography of oligo-GalA is described below. The oligo-GalA mixture (DP 2–5, 1 g) was dissolved in water (10 mL), and the solution was adjusted to pH 12 with 50% aqueous NaOH solution. The mixture was left at room temperature for 1 h and the pH was re-adjusted to 6.0 with 2 M HOAc. The resulting solution was applied to a column (46.5 × 2.5 cm) of Dowex-1 × 4 resin (400 mesh) that had been equilibrated in 0.4 M NaOAc buffer, pH 6.0. The column was washed with 25 mL of the equilibration buffer, and eluted with a linear gradient generated with 1 L each of 0.4 M and 1.0 M NaOAc (pH 6.0). Finally, the column was washed with 1 L of 2.0 M NaOAc (pH 6.0). Fractions were analyzed for carbohydrate

Fig. 5. Identification of each oligo-GalA peak isolated from the Dowex-1 × 4 column (see Fig. 4) with HPAEC.



content by the phenol–H_2SO_4 method; the results are shown in Fig. 4. The carbohydrate-containing fractions were analyzed by HPAEC for identification of DP. The purity of each of the isolated peaks is shown in Fig. 5. The individual oligo-GalA peaks were pooled and passed through a column (17.6 × 2.5 cm) of Dowex-50W × 8 resin (H^+ form, 200 mesh) for decationization; the effluent was concentrated by rotary evaporation, followed by lyophilization to give di-, tri-, tetra-, and pentagalacturonic acid ($(GalA)_2$, $(GalA)_3$, $(GalA)_4$, $(GalA)_5$, respectively), with the yields of 1.8, 18.2, 19.9, and 4.9%, respectively.

The alkaline treatment of the oligo-GalA mixture (pH 12 for 1 h) was to open any lactone rings that might have been formed during the gel filtration procedure. Lactonization under acidic condition is often a problem for separation of anionic oligo/polysaccharides with anion-exchange chromatography (20). The separation of oligo-GalA mixture on Dowex 1, a common anion-exchange resin, was excellent (Fig. 4), separating the oligomers better than those reported previously with sophisticated instrumentation (14, 15). Although the column described above has a loading capacity of ~1.0 g of the oligo-GalA mixture, it can be used repeatedly or can be readily scaled up.

Summary

We present here a simple and efficient preparative method of oliogalacturonic acids, up to DP 5, from an inexpensive source, pectic acid. The advantages of our method are the use of an inexpensive commercial enzyme and low-cost chromatographic procedures to yield pure oligo-GalA of DP 2–5 in good overall yield.

Carbohydrate–antibody interactions by NMR for a ^{13}C-labelled disaccharide ligand

Dušan Uhrín, A.V. Krishna Prasad, Jean-Robert Brisson, and David R. Bundle

Abstract: Incorporation of a ^{13}C label into a carbohydrate ligand, methyl 3-*O*-(3,6-dideoxy-α-D-xylohexopyranosyl)-2-*O*-methyl-α-D-mannopyranoside permitted by NMR spectroscopy the study of its binding to the Fab from a monoclonal antibody, Se 155-4. The signals of the free and bound form were observed in the ^{13}C spectrum of the carbohydrate–protein complex. The dissociation rate constants were consequently determined by full lineshape analysis of the ^{13}C spectrum. Comparison with simplified analyses relying only on the linewidth of the ^{1}H and ^{13}C signals of the free ligand were made and the justifications of underlying assumptions used in these analyses were discussed. For ^{1}H NMR, the protein resonances were purged with a ^{13}C filter to observe only the ligand resonances and NOEs between the ligand and the protein.

Key words: carbohydrate, binding, NMR, C-13 label, chemical exchange.

Résumé : L'incorporation d'un marqueur ^{13}C dans un hydrate de carbone servant de ligand, le 3-*O*-(3,6-didésoxy-α-D-xylohexopyranosyl)-2-*O*-méthyl-α-D-mannopyranoside de méthyle a permis d'utiliser la spectroscopie RMN pour étudier sa fixation sur le Fab d'un anticorps monoclonal, Se 155-4. Les signaux des formes libres et liées (conjuguées) ont été observés dans le spectre ^{13}C du complexe glucide–protéine. En se basant sur une analyse complète de la forme des bandes du spectre du ^{13}C, on a par la suite déterminé les constantes de vitesse de la dissociation. On a fait une comparaison avec les analyses n'utilisant que la largeur des bandes des signaux du ^{1}H et du ^{13}C et on discute des hypothèses sous-jacentes utilisées dans ces analyses. Pour la RMN du ^{1}H, les résonances de la protéine ont été purgées à l'aide d'un filtre de ^{13}C afin de n'observer que les résonances du ligand et les eOn entre le ligand et la protéine.

Mots clés : hydrate de carbone, fixation, RMN, marqueur au C-13, échange chimique.

[Traduit par la Rédaction]

Introduction

The realization of the importance of oligosaccharide ligands as potential agonists has highlighted the need for kinetic data of carbohydrate–protein interactions. Here, a synthetically trivial and inexpensive introduction of an isotopic label exploits the observation that replacement of OH by OCH_3 frequently provides oligosaccharide epitopes with virtually unchanged binding strength (1–3). Saccharide sites of this type are ideal candidates for the facile introduction of a $^{13}CH_3O$ group, that yield a singlet resonance well-suited to line-broadening studies in ^{1}H or ^{13}C NMR spectra (4, 5). Incorporation of such a ^{13}C label in methyl 3-*O*-(3,6-dideoxy-α-D-xylohexopyranosyl)-2-*O*-methyl-α-D-mannopyranoside (**1**), was thus used to study binding to the 50 K Dalton Fab from a monoclonal antibody, Se 155-4. From high resolution X-ray (6) structures of Fab–oligosaccharide complexes, the site of methylation at mannose O-2 is solvent exposed and in the native ligand it represents the site of attachment of the third hexose that completes the epitope.

The free and bound signals of the ^{13}C-labelled disaccharide ligand (**1**) were observed in the ^{13}C spectrum permitting full lineshape analysis and determination of dissociation rate constants. Comparison with simplified analyses and more sensitive methods relying only on the linewidth of the ^{1}H and ^{13}C signals of the free ligand were made and the justifications of underlying assumptions used in these analyses were ascertained. For ^{1}H NMR, the protein resonances were purged with a ^{13}C filter to observed only the ligand resonances and NOEs between the ligand and the protein.

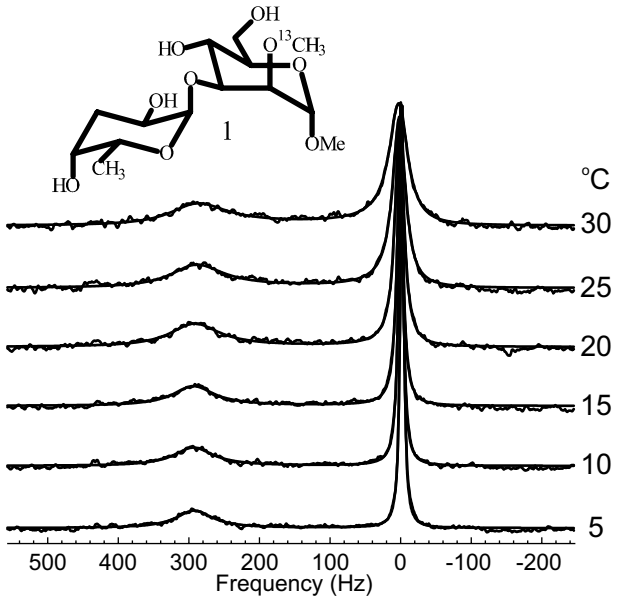
^{13}C lineshape

The ^{13}C spectra of the complex (0.37 mM protein, 1.4 mM sugar) revealed a broader resonance of the bound ligand located 292 ± 2 Hz downfield from the intense OMe signal of the unbound form (Fig. 1). Hence, full lineshape analysis (7) of the bound and free signals was possible and

 DOI: 10.1139/V02-063 © 2002 NRC Canada

Fig. 1. ^{13}C exchange spectra at 150 MHz of the Fab (0.37 mM) and disaccharide (1.4 mM) complex at different temperatures, acquired with 10 000–16 000 scans, 90° pulse, and a recycle delay of 13 s. The simulated spectra using full lineshape analysis are shown as smooth lines.



k_{diss} values could be extracted without making any assumptions about the exchange rate (Table 1). The bound form of the sugar could be observed since the bound fraction varied from 0.32 to 0.36 as the temperature increased. The linewidth of the free form increased significantly with temperature (Fig. 1). Since, the fraction bound varied little with temperature, changes in linewidths were due to changes in k_{diss} (7). Values for k_{diss} were also obtained by measuring changes in the linewidth of the free OMe signal at several temperatures, constant protein concentration (0.37 mM), and sugar concentrations from 2.1 to 6.8 mM (fraction of bound sugar from 0.17 to 0.05). Since, the bound fraction was smaller, only the free OMe signal could be detected for reasonable accumulation times. In past studies, since the bound form was not observed, various assumptions had to be made about the exchange regime (4, 5, 8, 9). In our case, since the bound form could be observed ($\Delta\delta = 292 \pm 2$ Hz), the system was in the moderately slow exchange regime (10–13) on the ^{13}C chemical shift time scale ($2\pi\Delta\delta >> k_{diss}$) and the following relation applies (see *Appendix*):

$$[1] \qquad [S_T] = k_{diss}\, n[P_T]/\pi\Delta\Delta\upsilon_{1/2} + n[P_T] - K_D/p_f$$

where $[S_T]$ is the total sugar concentration, $n[P_T]$ is the concentration of protein binding sites, $\Delta\Delta\nu_{1/2} = \Delta\nu_{1/2}^{obs} - \Delta\nu_{1/2}^{free}$ is the contribution of the exchange to the linewidth of the spectral line of the free form, K_D represents the dissociation constant of the sugar–protein complex, and p_f is the molar fraction of the free sugar. Since K_D (1×10^{-5} M) was known from microcalorimetry[3], the last term in eq. [1] can be omitted ($K_D/p_f << n[P_T]$) and k_{diss} determined from the slope of $[S_T]$ vs. $1/\Delta\Delta\nu_{1/2}$ (Fig. 2). The resulting values for k_{diss} were in good agreement with those obtained from the full lineshape analysis (Table 1).

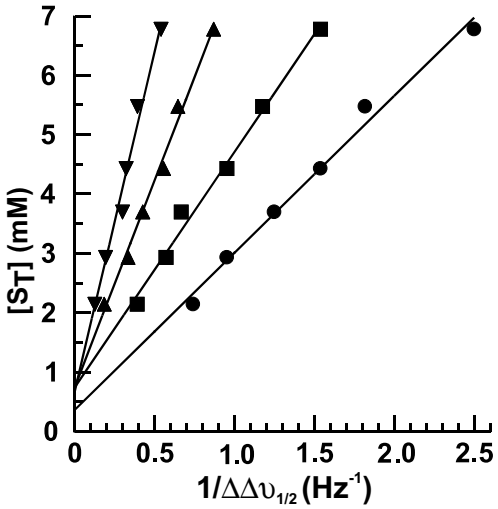
Fig. 2. Plot of the total ligand concentration ($[S_T]$) vs. the reciprocal line broadening ($1/\Delta\Delta\nu_{1/2}$) for the free form of the OMe ^{13}C resonance of disaccharide **1** at 15 (●), 20 (■), 25 (▲), and 30°C (▼).



^1H lineshape

The more sensitive method of observing the proton resonances of the sugar by purging the Fab resonances (Fig. 3*a*) with a ^{13}C filter (14, 15) was also used (Fig. 3*b*). The OCH_3 signal of the bound form was not observed for any of the sugar concentrations or temperatures used. Hence, since only the free form was observed, eq. [1] was applied for analysis of its line broadening (Table 1). While there was agreement at lower temperatures (15 and 20°C), values of k_{diss} deviated significantly at higher temperatures (25 and 30°C), indicating that the condition of slow exchange on the chemical shift scale was likely violated and the ^1H resonance of the bound OMe group, although not observed, was much closer to the free OMe signal, ($\Delta\delta \cong 0$). A ^{13}C ω_1-filtered 2D

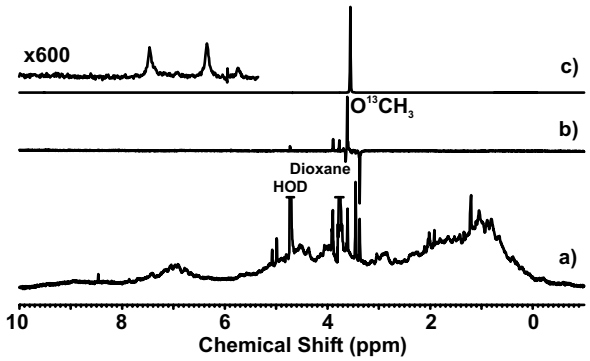
Fig. 3. Proton detected spectra at 600 MHz of the Fab (0.37 mM) and disaccharide (2.1 mM) complex at 30°C: (*a*) ^{1}H spectrum, number of scans, NS = 8; (*b*) ^{13}C filtered proton spectrum with 64 transients, and the spin-echo period of the X-filter set to 1.75 ms; (*c*) F1 trace through the ^{13}C- filtered 2D NOE spectrum at the chemical shift of the free OMe resonance. The vertical expansion shows the NOEs from the OMe protons of the saccharide to the aromatic residues of the Fab. The X-filter was set to 3.5 ms and 48 scans were acquired for each of 512 increments. Water was suppressed both during the relaxation (3 s) and NOE mixing intervals (50 ms). The phase-sensitive spectrum was acquired with ^{13}C decoupling during the t_1 and t_2 periods.



NOESY (16) spectrum was therefore acquired with the intention of locating the chemical shift of OMe protons in the bound form. Only the crosspeaks between the protein and carbohydrate at the F_1 frequency of the free OMe signal were observed (Fig. 3*c*). The intensity of these crosspeaks increased several times with an increase in temperature and thus the exchange rate. Hence, these NOEs were thought to arise through cross relaxation from the protein to the OMe protons in the bound state and then exchange to the free OMe signal (17). Therefore, the chemical shifts of the OMe protons in the bound form could not be determined from this experiment either.

Discussion

The agreement between the k_{diss} values obtained from ^{1}H- and ^{13}C-detected experiments at lower temperatures can be rationalized when considering the following exchange regime for ^{1}H and ^{13}C nuclei. For conditions of: (*i*) fast exchange on the chemical shift scale with $\Delta\delta \cong 0$; (*ii*) slow exchange on the relaxation time scale; and (*iii*) $p_f > 0.7$, a similar linear dependence as eq. [1] had been derived but with the *y*-intercept equal to $-K_D$ (4, 5, 8, 9). When conditions (*ii*) and (*iii*) are satisfied, simulations show that $\Delta\Delta\nu_{1/2}$, is practically independent of $\Delta\delta$, and k_{diss} can be determined from the slope of $[S_T]$ vs. $1/\Delta\Delta\nu_{1/2}$. In our case, at 15 and 20°C, these conditions were satisfied. At lower temperatures, the line broadening changes were too small and difficult to observe. At higher temperatures, condition (*ii*) was violated for protons, which was the source of discrepancy for the k_{diss} values obtained from the ^{1}H linewidths.

For the ^{13}C spectrum, observation of the bound form ($\Delta\delta$ = 292 ± 2 Hz) permitted full lineshape analysis and the determination of dissociation rate constants. In this study, eq. [1] was thus derived for the moderately slow exchange regime to obtain k_{diss} from the linewidth of the free form only. Both type of analyses lead to similar values for k_{diss} (Table 1). In past studies, since the bound form was not observed, $\Delta\delta \cong 0$ had been assumed (4, 5, 8, 9). In our case, if this assumption had been made, the correct values for k_{diss} would still have been determined, since conditions (*ii*) and (*iii*) were met. However, the value of the *y*-intercept would have been wrong, $-K_D$ in the later and $n[P_T]$ in our case (eq. [1]). From Fig. 2, values of 0.7 mM or 0.4 mM were obtained with an error of ±50% taking into account errors of the measurements. This is in agreement with $n = 1$ and $[P_T] = 0.37$ mM.

Hence, the combined use of NMR techniques using a ^{13}C-labelled carbohydrate ligand provided kinetic information to understand the binding of carbohydrate antigens to antibodies. The association rate constants ($k_{assoc} = k_{diss}/K_D$) were also calculated (Table 1) which showed that $k_{assoc} \sim 10^7$ M^{-1} s^{-1} was not diffusion limited, a condition frequently assumed for ligand antibody binding. Under such conditions, it is generally the case that k_{diss} determines the equilibrium constant K_D. Here this is not the case, the variation of K_D with temperature is the product of changes in both the k_{assoc} and k_{diss}.

Experimental

NMR samples were prepared in PBS buffer at pH 7.2 containing 0.02% sodium azide.

Experiments were performed on a 600 MHz (^{1}H) spectrometer using an indirect detection probe for the ^{13}C-filtered experiments and a broadband probe for the ^{13}C experiments. Protein concentrations were 0.13, 0.32, or 0.37 mM. *p*-Dioxane was used as an internal standard. Linewidths, measured at half-height of the ^{13}C or ^{1}H resonance of $O^{13}CH_3$, were corrected for magnetic field inhomogeneity by using the half-width of the *p*-dioxane resonance. Full lineshape analysis of the bound and free form of the ^{13}C resonance of $O^{13}CH_3$ was based on the equations and programs for simulation of lineshapes of an exchanging system for a noncoupled system (7). This permits reliable and efficient iterative total lineshape analyses for multisite exchange systems (18, 19). A simplex minimization method was employed where the chemical shift of the bound and free forms, spin–spin relaxation time of the bound form (T_{2b}), fraction of the ligand bound, and the dissociation rate constant (k_{diss}) were varied. Only the linewidth of the free ligand in the absence of exchange, $\Delta\nu_{1/2}^{free}$ (= $1/\pi T_{2f}$), was fixed.

Acknowledgements

We thank Karol Mikulash for computer programming and full lineshape analysis and Eva Eichler for providing the labelled disaccharide.

Appendix A

Determination of the k_{diss} from the linewidth of the free-state signal for slow chemical exchange on the chemical shift scale.

The exchange contribution to the line width of the signal of the free ligand ($\Delta\Delta\upsilon_{1/2}$) is calculated (A1, A2) for slow exchange on the chemical shift scale ($2\pi\Delta\delta >> k_{diss}$) as

$$[A1] \quad \Delta\Delta\upsilon_{1/2} = \Delta\nu_{1/2}^{obs} - 1/\pi T_{2f} = (k_{diss}/\pi)(p_b/p_f)$$

where $\Delta\nu_{1/2}^{obs}$ is the observed half-width, T_{2f} is the spin–spin relaxation time of the ligand in the absence of exchange, p_b and p_f are molar fractions of the bound and free ligands, respectively, and k_{diss} is the dissociation rate constant. By changing the p_b/p_f ratio and measuring the change in the linewidth of the free state, k_{diss} is determined from the slope of the linear dependence of $\Delta\Delta\upsilon_{1/2}$ vs. p_b/p_f. The p_b/p_f ratio, however, is not known unless the dissociation constant (K_D) is determined independently by an alternate method. Approximate solution to this problem has been proposed previously (A3). Equation [A1], derived in this section, offers a more general solution.

In a simple dynamic bimolecular equilibrium, involving a sugar ligand (S) and a protein (P), denoted by S + P $\Leftrightarrow$ SP, the dissociation constant K_D, is given as

$$[A2] \quad K_D = [S][P]/[SP] = ([S_T] - [SP])(n[P_T] - [SP])/[SP]$$

where $[SP]$ is the concentration of the complex, $[S_T]$ and $[P_T]$ are total saccharide and protein concentrations, n is the number of carbohydrate binding sites of the protein. By substituting $[SP] = p_b[S_T]$ and using the identity $p_b + p_f = 1$, K_D can be expressed as:

$$[A3] \quad K_D = [S_T](1 - p_b)(n[P_T] - p_b[S_T])/p_b[S_T] = n[P_T](p_f/p_b) - p_f[S_T]$$

and the total sugar concentration can be written as:

$$[A4] \quad [S_T] = n[P_T]/p_b - K_D/p_f = n[P_T](p_f/p_b) + n[P_T] - K_D/p_f$$

By substituting (p_f/p_b) from [A1] into [A4], eq. [1] is obtained:

$$[1] \quad [S_T] = k_{diss}\, n[P_T]/\pi\Delta\Delta\upsilon_{1/2} + n[P_T] - K_D/p_f$$

When $K_D/p_f << n[P_T]$ a linear dependency of $[S_T]$ on $1/\Delta\Delta\upsilon_{1/2}$ is obtained:

$$[A5] \quad [S_T] = k_{diss}\, n[P_T]/\pi\Delta\Delta\upsilon_{1/2} + n[P_T]$$

Equation [A5] was applied for determination of k_{diss} during the course of this work.

Sialoside clusters as potential ligands for siglecs (sialoadhesins)

Zhonghong Gan and René Roy

Abstract: Clusters of *O*- and *S*-linked α-sialosides with valencies of two to four were constructed to serve as potential multivalent inhibitors towards sialoadhesins (siglecs). Thus, *O*- and *S*-prop-2-ynyl α-sialosides (**3**, **7**), together with 4-iodophenyl sialoside **5** were prepared from acetochloroneuraminic acid derivative **1** using silver salicylate and propargyl alcohol for **3** and phase-transfer catalysis for **5** and **7**, respectively. Oxidative acetylenic homocoupling of **3** and **7** under Glaser conditions (CuCl, O_2) provided 1,3-diynes **8** and **9** in 83–86% yields. Palladium catalyzed cross-coupling of *O*-prop-2-ynyl sialoside **3** with **5** using $Pd_2(dba)_3$ and PPh_3 gave nonsymmetrical dimer **10** (82%). Alternatively, symmetrical clusters were then prepared as above under Sonogashira cross-coupling conditions with 1,4-diiodobenzene (**11**), 1,3,5-triodobenzene (**14**), and finally 1,2,4,6-tetraiodobenzene (**17**) to provide both *O*- and *S*-linked dimers **12** (93%) and **13** (88%), trimers **15** (81%) and **16** (76%), while only *O*-linked tetramer **18** was prepared in 87% yield. Finally, treatment of the *O*-linked prop-2-ynyl sialoside **3** with Grubbs' metathesis catalyst $Cl_2Ru(PCy_3)_2$=CHPh (**19**) gave, as expected, benzeneannulation regioisomeric trimers **20a**, **20b** in 68% yield.

Key words: siglec, sialoadhesins, sialic acid, Sonogashira, palladium cross-coupling.

Résumé : On a préparé une série d'agrégats d'α-sialosides liés par l'oxygène ou le soufre et de valence allant de deux à quatre qui pourraient éventuellement servir d'inhibiteurs multivalents vis-à-vis des sialoadhésines (siglecs). On a ainsi préparé les α-sialosides de *O*- et de *S*-prop-2-ynyle (**3**, **7**) ainsi que le sialoside de 4-iodophényle (**5**) à partir du dérivé **1** de l'acide acétochloroneuraminique, en utilisant le salicylate d'argent et l'alcool propargylique pour le composé **3** et une catalyse de transfert de phase pour les composés **5** et **7** respectivement. L'homocouplage acétylénique oxydant des composés **3** et **7** dans des conditions de Glazer (CuCl, O_2) a permis d'obtenir les composés **8** et **9** avec des rendements allant de 83 à 86%. Un couplage croisé catalysé par le palladium du sialoside de *O*-prop-2-ynyle **3** avec le composé **5**, à l'aide de $Pd_2(dba)_3$ et de PPh_3, fournit le dimère non symétrique **10** (82%). De façon alternative, des agrégats symétriques ont alors été préparés de la façon mentionnée ci-dessus, en utilisant les conditions de couplage croisé de Sonagashira et du 1,4-diiodobenzène (**11**), du 1,3,5-triiodobenzène (**14**) et finalement du 1,2,4,6-tétraiodobenzène (**17**); on a ainsi obtenu des produits liés par l'oxygène et le soufre dont les dimères **12** (93%) et **13** (88%) et les trimères **15** (81%) et **16** (76%) ainsi que le produit **18** (87%) un tétramère lié uniquement à l'oxygène. Enfin, le traitement du sialoside de prop-2-ynyle lié à l'oxygène, **3**, avec le catalyseur de métathèse de Grubbs, $Cl_2Ru(PCy_3)_2$=CHPh (**19**), conduit, tel que prévu, aux trimères de benzèneannellation régioisomérique **20a**, **20b** avec un rendement de 68%.

Mots clés : siglec, sialoadhésines, acide sialique, Sonogashira, couplage croisé au palladium.

Introduction

Sialic acid is a generic term representing over 40 different structures derived from neuraminic acid, a nine-carbon amino acid sugar (1). The most prevalent member, *N*-acetylneuraminic acid, is usually present as a capping residue on natural glycoproteins and glycolipids. As such, it plays the role of a "terminal elaboration factor" (2) and is thus well-suited in mediating molecular recognition at the cell surface, a property well exploited by several pathogens (1). Conversely, siglecs, a subgroup of immunoglobulin-type animal lectins that mediate cell adhesion and signaling, recognize sialoconjugates. Several siglecs are expressed on cells of the innate immune system and sialoadhesin (or siglec-1) is found on macrophages and has been implicated in lymphocyte adhesion and myeloid cell development (3).

Although siglecs are known to possess only one carbohydrate recognition domain (CRD) (4), multivalent sialosides have been shown to dramatically increase their inhibitory potency towards sialoadhesin (5). Given the importance of multivalent glycoforms in the study of carbohydrate–protein interactions at the molecular level (6) and their potential

roles in receptor clustering, we propose herein the synthesis of sialic acid clusters using a variety of metal-catalyzed cross-coupling strategies (7).

Results and discussion

The syntheses of the requisite prop-2-ynyl α-sialosides **3**, **5**, and **7** necessary for the palladium-catalyzed homo- and cross-coupling reactions are depicted in Scheme 1. Prop-2-ynyl α-*O*-sialoside **3** was readily accessible from β-acetochloroneuraminic acid **1** using propargyl alcohol in the presence of silver salicylate. The Koenigs–Knorr glycosylation occurred with complete stereocontrol giving rise to the α form as previously observed for analogous cases (8). The pure product can be obtained by recrystalizing the crude sample from ethanol (69%). 4-Iodophenyl α-sialoside **5** was also prepared from **1** using improved phase-transfer catalysis (PTC) conditions developed in our laboratory (9). The synthesis of aryl α-sialosyl derivatives was achieved at room temperature in a two-phase system using ethyl acetate, 1 M sodium carbonate, and tetrabutylammonium hydrogensulfate as phase-transfer catalyst. The reaction was entirely stereoselective and provided **5** in 55% yield. Prop-2-ynyl α-thiosialoside **7** was synthesized from the corresponding thioacetate derivative **6**, itself obtained from **1** under PTC conditions (10). Chemoselective de-*S*-acetylation of **6** under low-temperature Zemplén conditions followed by low-temperature quenching by acidic (H^+) resin generated a sialic acid thiol intermediate (10, 11). The thiol intermediate was then coupled to propargyl bromide to give **7** in 85% yield as previously observed from other glycosyl thioacetates (12) (Scheme 1).

The syntheses of homo-coupling symmetrical diynes can be accomplished by using the Glaser or alternative methods (13). Thus, oxygen was bubbled through a solution of prop-2-ynyl α-sialoside **3**, copper(I) chloride, and TMEDA in DMF at 40°C for 2 h. The desired dimer (**9**) was obtained in 86% yield. The structure of (**9**) was confirmed from its ^{1}H NMR spectrum which did not contain a signal with a chemical shift close to δ 2.24 ppm, the position of the acetylenic proton in the spectrum of the monomer. The mass spectrum of compound (**9**) gave a $M^+ + 1$ peak at 1057.2 Da. This procedure was also successfully applied to prop-2-ynyl α-thiosialoside **7** to afford the corresponding dimer **8** in 83% yield (Scheme 2).

According to our previous studies (14), the use of Sonogashira cross-coupling conditions modified by removal of the copper(I) iodide cocatalyst, can eliminate the formation

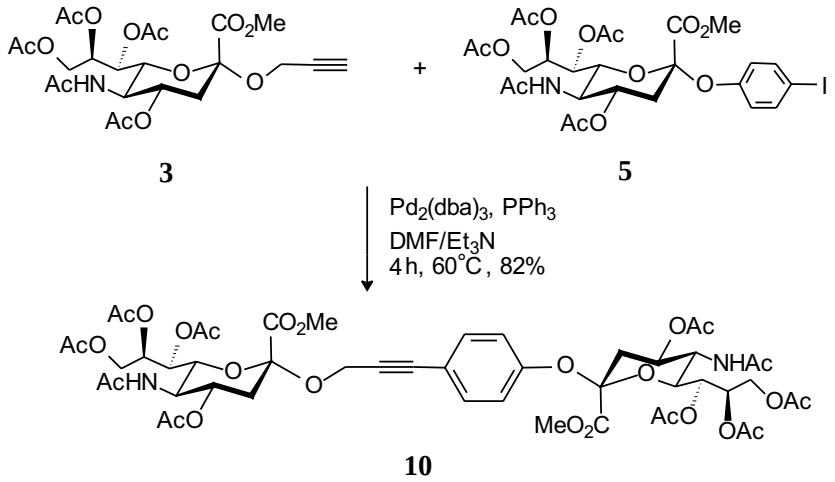
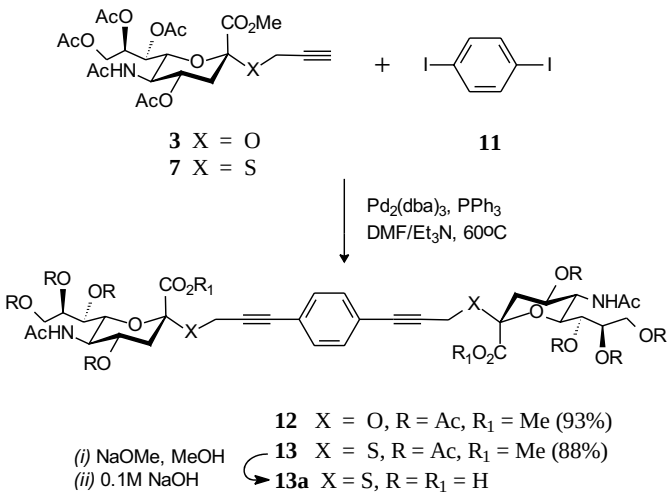


Scheme 4.



of symmetrical diyne. This new protocol was thus used for the treatment of prop-2-ynyl α-sialoside **3** (1.1 equiv) and 4-iodophenyl *O*-α-sialoside **5** (1 equiv) using tris(dibenzylideneacetone)dipalladium(0) ($Pd_2(dba)_3$) as catalyst at 60°C to afford cross-coupling dimer **10** in 82% yield. As expected, no symmetrical diyne (**9**) was found (Scheme 3).

Similarly, treatment of **3** with 1,4-diiodobenzene (**11**, 1 equiv) under the above reaction conditions provided dimer **12** in 93% yield (Scheme 4). Again, no symmetrical diyne (**9**) was observed. The distinction between the homodimer (**9**) and the crossdimer **12** can be clearly distinguished from two marked differences between their respective ^{13}C NMR spectra. The acetylene peaks of the crossdimer **12** were shifted downfield at δ 86.2 and at 85.6 ppm compared with those of the homodimer (**9**) at δ 74.7 and at 70.1 ppm and the spectra of **12** contained peaks in the aromatic region while those of **9** did not. Previous results showed that thioethers could also undergo cross-coupling with aryl halides under Sonogashira conditions (15). Thus, prop-2-ynyl α-thiosialosides **7** reacted with 1,4-diiodobenzene in the presence of $Pd_2(dba)_3$ at 60°C to afford dimer **13** in 88% yield. Fully protected dimer **13** was sequentially hydrolyzed with NaOMe in methanol followed by 0.1 M NaOH to provide water-soluble **13a**.

Encouraged by the successful synthesis of divalent sialoside derivatives by the Sonogashira reaction, we further expanded this reaction toward the synthesis of larger clusters. As already mentioned, the formation of symmetrical diynes as minor by-products that cause purification problems can be avoided using CuI. However, CuI is a particularly effective co-catalyst which allows the reaction to occur at room temperature. Without CuI, the reaction has to be accomplished at higher temperatures and longer reaction times are required. Since sialic acid trimers and tetramers are easily separated from their corresponding symmetrical diynes, the addition of CuI was employed to help the reactions to occur smoothly and rapidly with more hindered tri- or tetraiodobenzenes.

1,3,5-Triiodobenzene (**14**) was prepared from 1,3,5-tribromobenzene following a known procedure (16). Treatment of 1,3,5-tribromobenzene with KI, I_2, and Ni powder in refluxing DMF afforded 1,3,5-triiodobenzene in 52% yield. Direct polyiodination of benzene with periodic acid and iodine in sulfuric acid at room temperature (rt) provided 1,2,4,6-tetraiodobenzene (**17**) in good yield (73%) (17).

Prop-2-ynyl α-sialoside **3** was treated with 1,3,5-triiodobenzene (**14**) ($Pd_2(dba)_3$, CuI, PPh_3, DMF–Et_3N, rt, 1 h) to give trimer **15** (81%). Trimer **15** was readily separated from a small amount of symmetrical diyne (**9**) as a by-product by silica gel chromatography. Trimer **16** was analogously prepared from prop-2-ynyl α-thiosialoside **7** in 76% yield (Scheme 5).

Treatment of prop-2-ynyl α-sialoside **3** with 1,2,4,6-tetraiodobenzene (**17**) using the above conditions gave *O*-linked tetramer **18** in 87% yield (Scheme 6). Because of the steric hindrance, the reaction with tetraiodobenzene needed longer reaction time for completion (4 h). The structure for **18** was confirmed by its ^1H NMR and ^{13}C NMR spectra and from the molar mass determined by FAB-MS.

Grubbs' catalyst **19** can also be used to catalyze intermolecular cyclotrimerization of three terminal alkynes according to our previous findings (18). Prop-2-ynyl α-sialoside **3** was treated with Grubbs' catalyst **19** in refluxing 1,2-dichloroethane for 24 h. The desired regioisomeric trisubstituted

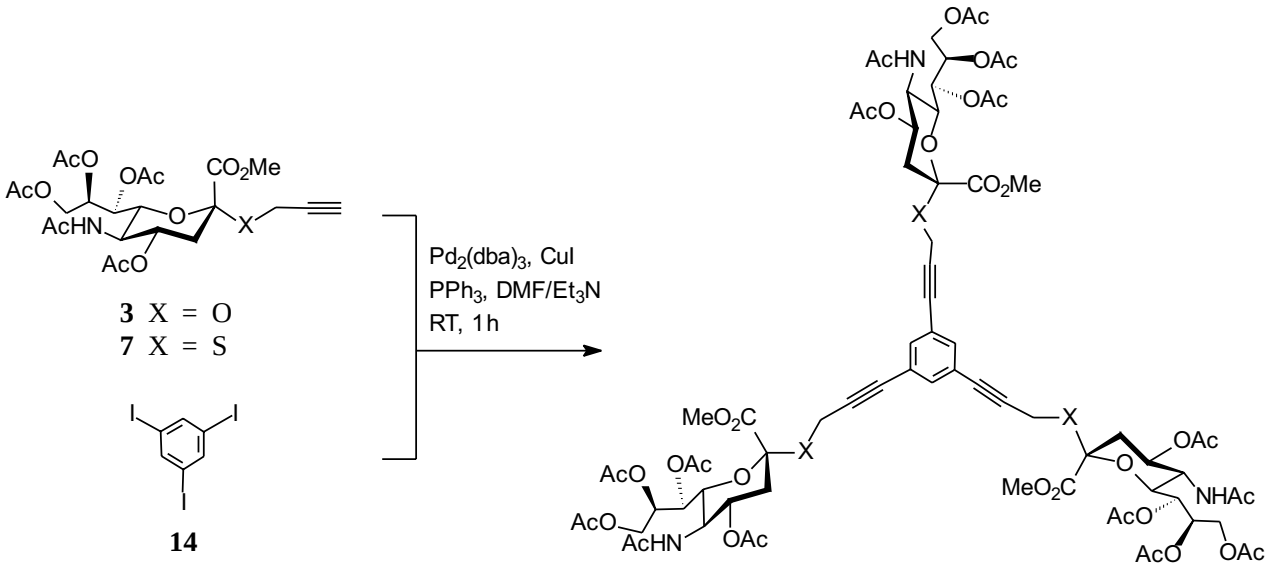
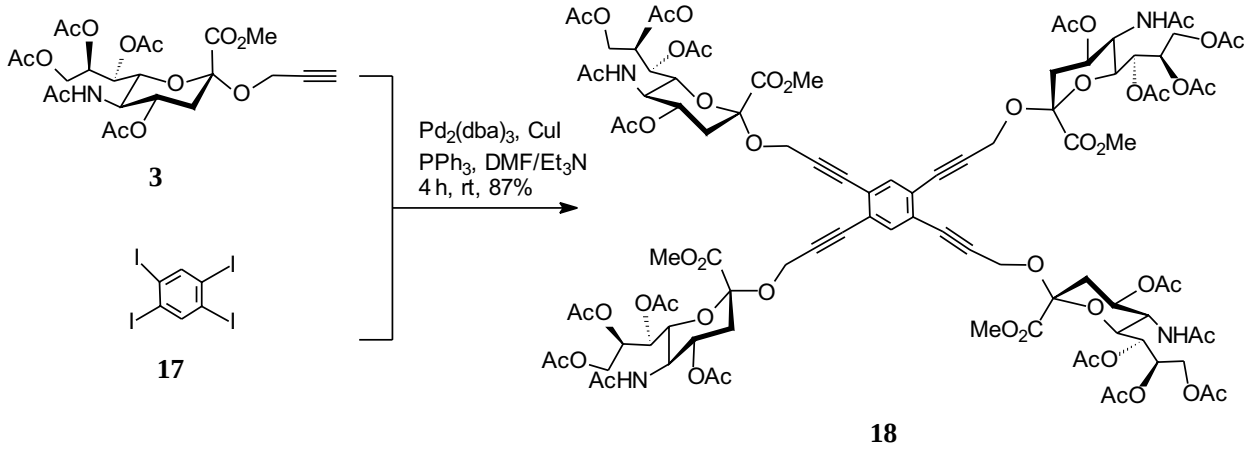


Scheme 6.



benzene derivatives **20a**, **20b** were isolated as a mixture of 1,2,4-(**20a**) and 1,3,5-(**20b**) regioisomers in 68% yield (Scheme 7). The reaction was found to be highly regioselective in favor of the 1,2,4-regioisomer **20a** over that of **20b** (4.5:1). The regioisomeric structures and the ratio were determined from the ^{1}H NMR spectrum by comparing the data of analogous products reported in the literature (18, 19). The aromatic protons for the 1,2,4-isomer **20a** appeared at δ 7.27 ppm (d, J = 7.8 Hz), 7.23 (s), and 7.19 (d, J = 7.8 Hz) and for the symmetrical 1,3,5-isomer **20b** as a singlet at δ 7.14 ppm. The ^{13}C NMR showed aromatic carbon signals at 136.4, 135.4, 135.0 ppm (quaternary carbons) and 128.7, 127.9, 127.1 ppm (tertiary carbons) for the 1,2,4-isomers and those for 1,3,5-isomer appeared at 137.2 ppm (quaternary carbon) and at 126.4 ppm (tertiary carbon). This novel procedure is therefore complementary to that using dicobalt octacarbonyl [$Co_2(CO)_8$] (19).

Experimental section

General methods

^{1}H and ^{13}C NMR were recorded on a Bruker AMX500 spectrometer at 500 MHz for protons and 125.7 MHz for carbons, respectively. Proton chemical shifts (δ) are given relative to internal chloroform (7.24 ppm) for $CDCl_3$. For carbon spectra, chemical shifts were given relative to $CDCl_3$ (77.0 ppm). Spectral analyses were performed as first-order approximations and were based on correlation spectroscopy (COSY), heteronuclear multiple quantum coherence (HMQC), and one- and two-dimensional distortionless

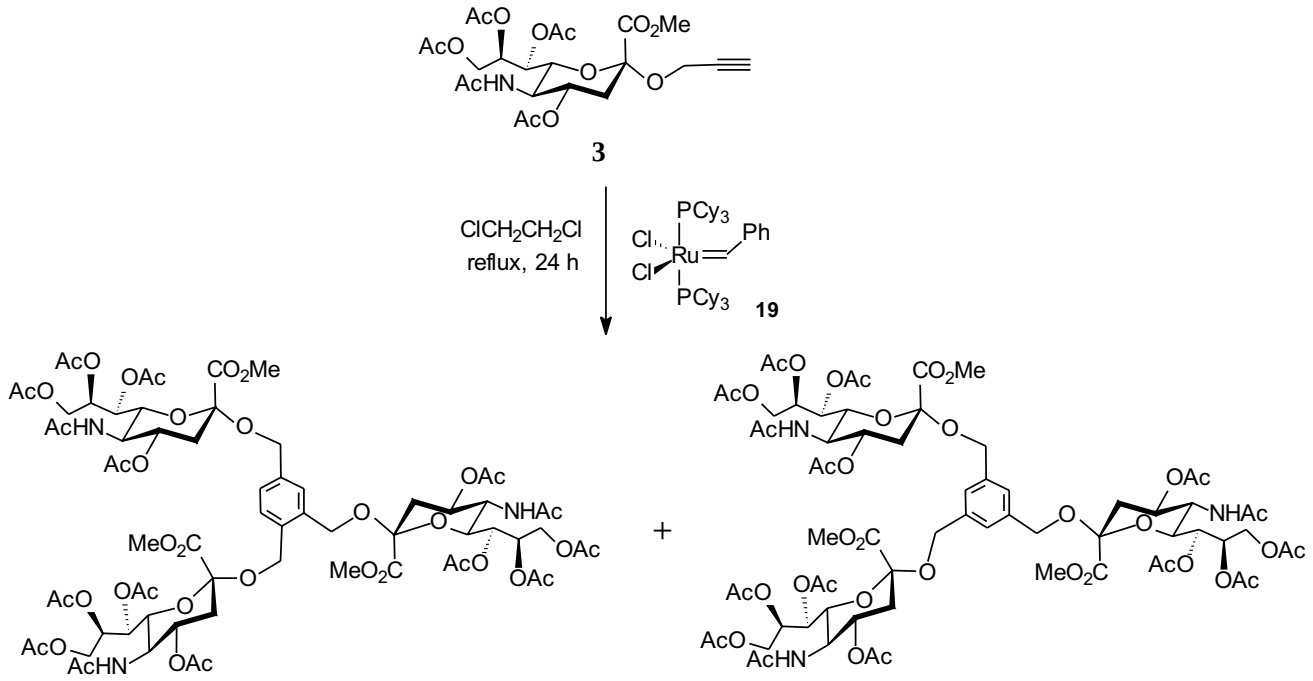
Scheme 7.



enhancement by polarization transfer (DEPT) experiments. Optical rotations were measured on a PerkinElmer 241 polarimeter. FAB-MS spectra were recorded on a Kratos Concepts IIH with Cs^+ beam and are not high resolution unless stated otherwise. Thin layer chromatography (TLC) was performed using silica gel 60-F_{254} glass plates. Reagents used for developing plates include ceric sulfate (1% w/v) and ammonium sulfate (2.5% w/v) in 10% (v/v) aqueous sulfuric acid, iodine, dilute aqueous potassium permanganate, and UV light. TLC plates were heated to approximately 150°C when necessary. Purifications were performed by gravity or flash chromatography on silica gel 60 (230–400 mesh, E. Merck no. 9385). Solvents were evaporated under reduced pressure using a Büchi rotary evaporator connected to a water aspirator. All chemicals used in the experiments were of reagent grade. Solvents were purified by the published procedures.

*Methyl (prop-2-ynyl 5-acetamido-4,7,8,9-tetra-*O*-acetyl-3,5-dideoxy-*D*-glycero-*α*-*D*-galacto-2-nonulopyranosid) onate (3)*

To a solution of freshly prepared β-acetochloroneuraminic acid **1** (1.18 g, 2.31 mmol) in dry propargyl alcohol (20 mL) containing 4 Å molecular sieves (2 g) was added freshly prepared silver salicylate (0.85 g, 3.47 mmol). The reaction was stirred for 2 h under nitrogen at room temperature in the dark. The slurry was filtered over Celite, washed with dichloromethane, and evaporated to dryness. The residue was dissolved in dichloromethane (30 mL). The organic solution was successively washed with sat. $NaHCO_3$ solution, 5% $Na_2S_2O_3$ solution, and brine. The organic phase was dried over Na_2SO_4 and concentrated under reduced pressure. The crude syrup was crystallized from ethanol to afford pure **3** (840 mg, 69%) as a colorless solid: mp 162–164°C; $[\alpha]_D$ +69.4° (*c* 0.5, CH_3CN). HR-MS calcd. for $C_{23}H_{32}N_1O_{13}(MH^+)$ (*m*/*z*): 530.1874; found: 530.1895. ^{1}H NMR ($CDCl_3$) δ: 5.44 (d, 1H, $J_{5,NH}$ = 9.0 Hz, NH), 5.34 (m, 1H, H-8), 5.25 (dd, 1H, $J_{6,7}$ = 1.3 Hz, $J_{7,8}$ = 8.3 Hz, H-7), 4.80 (m, 1H, H-4), 4.35 (dd, 1H, *J* = 15.7 Hz, -OC*H*$_2$C≡), 4.22 (dd, 1H, $J_{9a,9b}$ = 12.4 Hz, $J_{8,9a}$ = 2.7 Hz, H-9a), 4.10 (dd, 1H, -OC*H*$_2$C≡), 4.04–3.97 (m, 3H, H-5, H-6, H-9b), 3.75 (s, 3H, OCH_3), 2.57 (dd, 1H, $J_{3a,3e}$ = 12.8 Hz, $J_{3e,4}$ = 4.6 Hz, H-3e), 2.39 (dd, 1H, *J* = 2.4 Hz, -C≡C*H*), 2.09, 2.07, 1.98, 1.96, 1.81 (s, 15H, OAcs, NHAc), 1.91 (dd, 1H, $J_{3a,4}$ = 12.5 Hz, H-3a). ^{13}C NMR ($CDCl_3$) δ: 170.8–170.0 (O=Cs), 167.8 (C-1), 98.2 (C-2), 78.9 (-*C*≡CH), 74.4 (-C≡*C*H), 72.6 (C-6), 68.8 (C-4), 68.4 (C-8), 67.2 (C-7), 62.3 (C-9), 52.8 (OCH_3), 52.7 (-O*C*H$_2$C≡), 49.2 (C-5), 37.8 (C-3), 23.0, 21.0, 20.9, 20.7, 20.6 (NHAc, OAcs).

*Methyl (4-iodophenyl 5-acetamido-4,7,8,9-tetra-*O*-acetyl-3,5-dideoxy-*D*-glycero-*α*-*D*-galacto-2-nonulopyranosid) onate (5)*

To a solution of freshly prepared acetochloroneuraminic acid **1** (680 mg, 1.33 mmol) in EtOAc (20 mL) was added a solution of *p*-iodophenol (587 mg, 2.67 mmol) and TBAHS (453 mg, 1.33 mmol) in 1 M Na_2CO_3 (20 mL). The mixture was stirred vigorously for 1 h at room temperature and next diluted with EtOAc (20 mL). The organic phase was separated and washed with brine. The organic phase was dried over Na_2SO_4 and concentrated under reduced pressure. The residue was purified by silica gel column chromatography using CH_2Cl_2–EtOH (30:1, v/v) as eluent to give compound **5** (509 mg, 55%) as a white solid, mp 88–90°C; $[\alpha]_D$ +10.8° (*c* 1.0, $CHCl_3$). FAB-MS calcd. for $C_{26}H_{32}IO_{13}N_1$: 693.45; found: 694.1 ($[M + 1]^+$, 33.9%). ^{1}H NMR ($CDCl_3$) δ: 7.49

General procedure for the homo-coupling of acetylenic thiosugar by Glaser reaction

In a mixture of thiosugar (1 mmol), CuCl (0.3 mmol), and TMEDA (0.6 mmol) in *N*,*N*-dimethylformamide (10 mL) was bubbled O_2 at 40°C for 2 h. Then the brownish green solution was poured into water (100 mL). The mixture was extracted with CH_2Cl_2 (3 × 20 mL). The combined organic phases were washed with brine, dried over Na_2SO_4, and concentrated under vacuum. The residue was purified by silica gel column chromatography.

General procedure for the cross-coupling of acetylenic thiosugar by Sonogashira reaction

To acetylenic thiosugar (1 mmol) and 1,4-diiodobenzene (0.45 mmol) in a degassed solution of DMF and Et_3N (5 mL, 1:1, v/v) were added $Pd_2(dba)_3$ (0.05 mmol) and PPh_3 (0.1 mmol). The solution was stirred at 60°C under nitrogen atmosphere for 2 h. The solution was diluted with CH_2Cl_2 (20 mL), and then washed successively with 5% HCl and brine. The organic phase was dried over Na_2SO_4 and concentrated under vacuum. The residue was purified by silica gel column chromatography.

1,3,5-Triiodobenzene (14)

1,3,5-Tribromobenzene (1.10 g, 3.5 mmol), KI (3.50 g, 21 mmol), Ni powder (2.00 g), I_2 (5.10 g), and DMF (12.5 mL) were added into a 50 mL round-bottomed flask. The flask was evacuated on the vacuum line at 0°C for 15 min. The mixture was refluxed under N_2 for 3 h. After cooling, the solution was poured into a separation funnel. The flask was washed with 3% aq HCl (50 mL) and CH_2Cl_2 (50 mL) until all material, except for Ni powder, was transferred into the separation funnel. The CH_2Cl_2 layer was separated, and the aqueous layer was extracted with CH_2Cl_2. The combined organic phase was washed with distilled water and dried over Na_2SO_4. The solvent was evaporated, leaving a light-brown crude product. This was further purified by sublimation at 60°C overnight. The residue was sublimed at 120–140°C to afford compound **15** (0.83 g, 52%).^{13}C NMR ($CDCl_3$) δ: 144.4, 95.2 (lit. (16) value).

1,2,4,5-Tetraiodobenzene (17)

H_5IO_6 (1.59 g, 6.97 mmol) was dissolved with stirring in conc. H_2SO_4 (25 mL), iodine (5.20 g, 20.5 mmol) was crushed and added to the clear solution. After 30 min of stirring, the dark mixture was placed in an ice bath. Benzene (0.95 g, 12.20 mmol) was then added slowly. The reaction was allowed to stir at room temperature for 2 days. The mixture was poured onto crushed ice. The resulting solid was collected by suction filtration and washed well with methanol to remove iodine. The crude lavender powder was crystallized from 2-methoxyethanol, giving white needles **17** (5.16 g, 73%), mp 253 to 254°C (lit. (17) value mp 253°C). ^{1}H NMR ($CDCl_3$) δ: 7.98 (s, 2H, aromatic H).

General procedure for the homo-coupling of acetylenic sialic acid derivatives (3, 7)

In a mixture of propargyl glycoside (0.2 mmol), CuCl (0.06 mmol), and TMEDA (0.12 mmol) in DMF (5 mL) was bubbled O_2 at 40°C. Then the brownish green solution was poured into water (50 mL). The mixture was extracted with CH_2Cl_2 (3 × 20 mL). The combined organic phases were washed with 5% HCl and brine, dried overNa_2SO_4, and concentrated under vacuum. The residue was purified by silica gel column chromatography CH_2Cl_2–MeOH (20:1, v/v) as eluent.

Anal. calcd. for $C_{52}H_{64}N_2O_{24}S_2$: C 50.73, H 5.55, N 2.57; found: C 50.83, H 5.69, N 2.56.

Fully deprotected divalent sialoside (13a)

To peracetylated sialoside **13** (75 mg, 0.064 mmol) dissolved in MeOH (2 mL) was added 1 M NaOMe in MeOH (1 mL) and the solution was stirred at 25°C. After 4 h, MeOH was removed and 0.1 N NaOH (5 mL) was added. The mixture was stirred at 25°C overnight. The solution was treated with Amberlite IR-120 H^+ resin for 10 min, and filtrered. The filtrate was then freeze-dried to afford compound **13a** in quantitative yield: $[\alpha]_D$ +32.7° (*c* 2.6, H_2O). MS (ES^+) calcd. for $C_{34}H_{44}N_2O_{16}S_2$: 800.86; found: 801.1 ($[M + 1]^+$). ^1H NMR (D_2O) δ: 7.10 (s, 4H, aromatic H), 2.75 (dd, 2H, $J_{3a,3e}$ = 12.4 Hz, $J_{3e,4}$ = 4.5 Hz, H-3e), 1.91 (s, 6H, NHAc), 1.80 (dd, 2H, $J_{3a,4}$ = 12.2 Hz, H-3a). ^{13}C NMR (D_2O) δ: 175.4 (C=O), 170.8 (C-1), 131.3, 122.7 (aromatic C), 88.2 (-SCH$_2$*C*≡C-), 83.4 (C-2), 82.5 (-CH$_2$C≡*C*-), 75.4 (C-6), 71.7 (C-4), 68.8 (C-8), 69.5 (C-7), 63.2 (C-9), 52.1 (C-5), 40.2 (C-3), 22.5 (NHAc), 18.3 (-S*C*H$_2$C≡).

General procedure for the cross-coupling of acetylenic sialic acid derivatives with 1,3,5-triiodobenzene (14)

To a degassed solution of the propargyl sialic acid (0.2 mmol) and 1,3,5-triiodobenzene (**14**) (27.8 mg, 61 μmol) in DMF–Et_3N (4 mL, 1:1) were added $Pd_2(dba)_3$ (9.2 mg, 10 μmol), CuI (3.8 mg, 20 μmol), and PPh_3 (10.5 mg, 40 μmol). The mixture was stirred under N_2 at room temperature for 1 h. The solution was poured into water (50 mL). The mixture was extracted with CH_2Cl_2 (3 × 10 mL). The combined organic phases were washed with 5% HCl and brine, dried over Na_2SO_4, and concentrated under vacuum. The residue was purified by silica gel column chromatography using CH_2Cl_2–MeOH (15:1, v/v) as eluent.

1,3,5-Tris-(methyl 5-acetamido-4,7,8,9-tetra-*O*-acetyl-3,5-dideoxy-D-glycero-α-D-galacto-2-nonulopyranosyloxyonate prop-2-ynyl)benzene (15)

H-3e). ^{13}C NMR ($CDCl_3$) δ: 170.9–168.1 (C=Os), 137.2, 126.4 (Ar for sym. Isomer), 136.4, 135.4, 135.0, 128.7, 127.9, 127.1 (Ar), 98.6, 98.3, 98.3 (C-2), 72.5, 72.4, 72.3 (C-6), 69.4 (C-4), 68.5, 68.4 (C-8), 67.3, 67.2 (C-7), 66.5, 64.3, 64.1 (CH_2), 62.3, 62.2, 62.1 (C-9′), 52.6, 52.5, 52.5 (OCH_3), 49.4 (C-5), 38.0, 38.0, 37.9 (C-3), 23.1 (NHAc), 21.1, 20.8, 20.7, 20.7 (Oacs).

Conclusions

In summary, the palladium-catalyzed Sonogashira reaction has been successfully applied for the synthesis of sialic acid clusters of restricted conformational mobility. The procedure is general, high yielding, compatible with the easily removable acetate protecting group, and the sialic acid clusters were isolated in excellent yields. The reactions are applicable to thioglycosides. The choice for these "rigidified" scaffolds is based on the assumption that lesser entropic penalty will be paid upon binding with the siglecs, as previously observed by isothermal titration calorimetry (ITC) for analogous mannoside clusters upon binding to the phytohemagglutinin concanavalin A (20).

The activation of fibroblast growth factors by heparin: Synthesis and structural study of rationally modified heparin-like oligosaccharides

Rafael Ojeda, Jesús Angulo, Pedro M. Nieto, and Manuel Martín-Lomas

Abstract: Heparin-like hexasaccharide **3** and octasaccharide **4** have been synthesized using a convergent block strategy and their solution conformations have been determined by NMR spectroscopy. Both oligosaccharides contain the basic structural motif of the regular region of heparin but have been constructed as to display negatively charged sulfate groups only on one side of their solution helical structures. This charge distribution along the saccharide chain has been designed to get insight into the proposed mechanism for fibroblast growth factors (FGFs) activation that involves heparin-induced FGF dimerization.

Key words: heparin oligosaccharides, synthesis design, conformational analysis, FGF activation.

Résumé : On a réalisé la synthèse d'un hexasaccharide (**3**) et d'un octasaccharide (**4**) apparenté à l'héparine en faisant appel à une stratégie de synthèse convergente par blocs et on a déterminé leurs conformations en solution à l'aide de la spectroscopie RMN. Les deux oligosaccharides comportent le motif structurel de base de la région régulière de l'héparine, mais leurs structures ont été organisées d'une façon telle qu'elles ne comportent des groupes sulfates chargés négativement que sur un seul côté de leurs structures hélicoïdales en solution. Cette distribution des charges ainsi que la chaîne du saccharide ont été choisies afin d'avoir un aperçu du mécanisme proposé pour l'activation des facteurs de croissance du fibroblaste (FCF) qui implique une dimérisation des FCF induite par l'héparine.

Mots clés : oligosaccharides de l'héparine, modèle de synthèse, analyse conformationnelle, activation des FCF.

[Traduit par la Rédaction]

Introduction

The fibroblast growth factors (FGFs) constitute a family of signaling polypeptides that intervene in a variety of biological processes by stimulating key cellular functions after binding to specific receptor tyrosine kinases at the cell surface (FGFRs) (1). The biological activity of FGFs is tightly regulated by heparin or heparan sulfate glycosaminoglycans (GAGs) (2, 3). Binding of these GAGs to FGFs protects FGFs from degradation (4), however, the precise structural requirements for the GAG chains to regulate the biological activity of the FGFs are not yet well understood at the molecular level. A number of crystal structures of FGF complexes with heparin fragments (5–7), and of FGF-2 (basic FGF) and FGF-1 (acidic FGF) bound to variants of FGFR (8–11) have been determined and several hypotheses on the structure–activity relationship of these complexes have been expressed (12). It is widely accepted that heparin and (or) heparan sulfate would bind to FGFs to cause FGF oligomerization and that these oligomers would interact with FGFRs in the presence of divalent cations giving rise to FGFR dimerization, thus inducing the cellular response (13). According to sedimentation equilibrium experiments, the formation of FGF-2 dimers in the presence of heparin having a *trans* (with two FGF molecules on each side of the polysaccharide chain) or a *cis* (with two FGF molecules on the same side of the polysaccharide chain) configuration has been proposed (14). The existence of both types of dimeric structures has been confirmed by NMR spectroscopy and light scattering (15). The *trans* dimer has also been observed for the FGF-1-heparin complex using X-ray crystallography (7).Whether this type of mechanism, which was originally proposed for FGF-2 (14), would be generally applicable to all the members of the FGF family is still a matter of discussion as the biologically active configuration of the heparin-FGF and the heparin-FGF–FGFR complexes are still open questions (16, 17). The establishment of the molecular basis of the entire biological process and the understanding of the

different functions of the FGF family at the molecular level remain, therefore, a difficult problem of chemical and biomedical interest.

One of the difficulties of these investigations resides in the inherent heterogeneity of the GAGs. Heparin and heparan sulfate are primarily constituted by disaccharide repeating units of L-iduronic acid and D-glucosamine linked by $\alpha 1 \rightarrow 4$ glycosidic linkages and typically containing sulfate groups at position 2 of the L-iduronic acid units and positions 2 and 6 of the D-glucosamine units. But these polysaccharides show significant heterogeneity in terms of sulfation pattern, size, and even carbohydrate sequence (18–20). For this reason it is highly desirable to develop effective syntheses of these heparin-like oligosaccharide chains with defined size, sequence, and charge distribution to be used in the interaction studies. In this context, we recently reported a synthetic strategy the effectiveness of which was illustrated by the preparation of hexasaccharide **1** and octasaccharide **2** (21). It has to be mentioned that these oligosaccharides contain L-iduronic acid residues at the reducing end, a sequence which is not available either by enzymatic or chemical degradation of heparin, and that oligosaccharides with the alternative sequence (22–24) and di- and tetrasaccharide sequences containing the above structural motif (25) have previously been synthesized. The overall structures of **1** and **2** in solution (21) resulted in stable right hand helixes with four residues per turn as those reported for natural heparin fragments (26–30). Therefore, **1** and **2** were used as chemically well-defined structural models of naturally occurring heparin-like oligosaccharides to investigate the activation of FGF-1 (21). Both compounds **1** and **2** induced the mitogenic activity of FGF-1 but, as may be expected (31–35), the activating effect of octasaccharide **2** reached a maximum at approximately the same concentration than natural low molecular weight heparin while considerably higher concentrations of **1** were needed to reach an equivalent maximal activation (21). Most interestingly, sedimentation equilibrium analysis results showed that the profile of FGF-1 solutions in the presence of activating concentrations of **2** corresponded to monomeric species thus suggesting that heparin-induced dimerization of FGF-1 in the culture medium surrounding the cell may not be an absolute requirement for FGF-1-induced mitogenesis signaling (21).

The above result prompted us to apply our synthetic strategy to the preparation of hexasaccharide **3** and octasaccharide **4** and to investigate their behavior in FGF-1 activation. We reasoned that, assuming that **3** and **4** would present a solution conformation similar to that shown by **1** and **2**, these structures (**3** and **4**) would display negatively charged sulfate groups only on one side of their right-handed helical structures (Fig. 1). Therefore, if the interaction with the polypeptide is primarily electrostatic in nature, the ability of **3** and **4** to form *trans* dimers with FGF-1would be greatly decreased and, because of their relatively reduced size, both of them would hardly be involved in the formation of *cis* dimers.

In this paper, we report the synthesis of **3** and **4** and present data that indicate that, as expected, their overall solution

structures are right-handed helixes with four residues per turn. These compounds showed an unexpected biological behavior that will be discussed in detail elsewhere.

Results and discussion

Synthesis

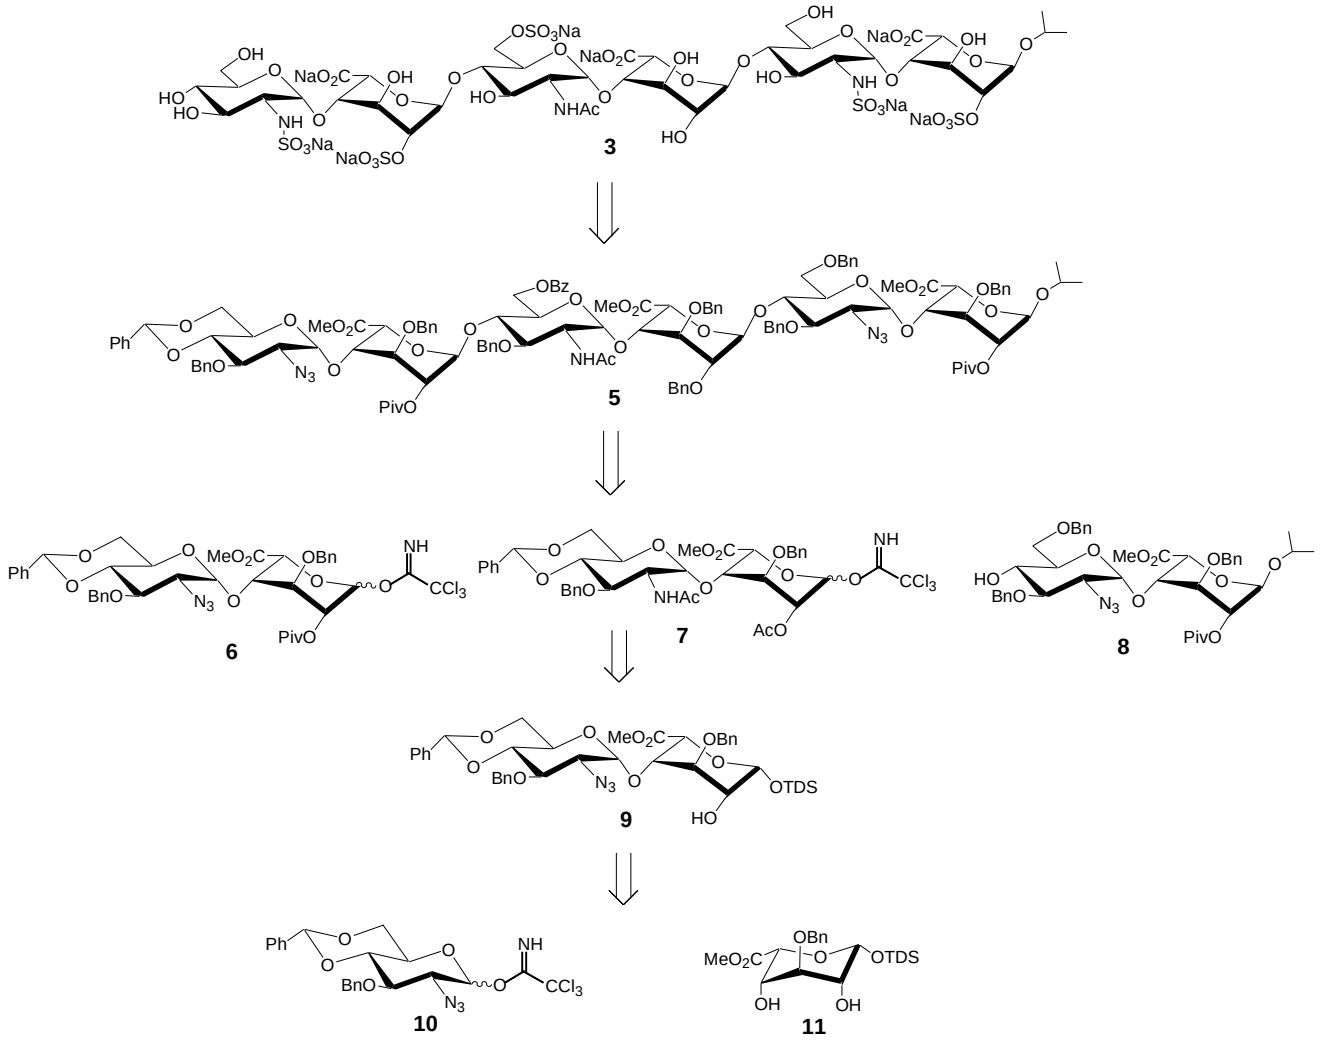
We have reported the synthesis of hexasaccharide **1** and octasaccharide **2** using a convergent $n + 2$ block approach from key disaccharide structures, that may operate as glycosyl donors or as glycosyl acceptors, having protective group patterns that permit formation of the required stereochemistry of the glycosidic linkages and to locate the sulfate groups at the desired positions at a later stage (21). This approach has now proven to be of wide applicability allowing the synthesis of oligosaccharide sequences with different size and sulfation patterns as the target hexasaccharides **3** and **4**. As indicated in Scheme 1 the synthesis of **3** was envisaged from the fully protected hexasaccharide **5** that could be prepared from disaccharide building blocks **6**, **7**, and **8**. These building blocks were obtained from a common disaccharide (**9**) that is readily available from the 2-azido-2-deoxy-D-glucopyranosyl trichloroacetimidate **10** and the iduronic acid glycosyl acceptor **11** (21).

Scheme 2 summarizes the synthesis of the disaccharide building blocks. The nonreducing-end building block **6** was prepared from **9** as already reported (21). This disaccharide (**6**) also provided the reducing-end building block **8** after glycosylation with isopropanol to give **12** (21) followed by regioselective reductive opening of the benzylidene acetal (36). The alternative building block **14** was also prepared from **12** that was transformed into diol **13** (21) and regioselectively acetylated (4% of **13** was recovered). The inner region building block **7** was also prepared from **9** that was transformed into **17** either by selective reduction of the azido group with thioacetic acid (37) to give **15** followed by conventional acetylation or by using the reverse sequence **9** $\rightarrow$ **16** $\rightarrow$ **17**. This latter route was more convenient as acetylation of **15** took place sluggishly most likely as a consequence of hydrogen bonding between the hydroxyl and the acetamido groups.

Glycosylation of low-reactive acceptor **8** with donor **7** afforded tetrasaccharide **19** in 50% yield and unreacted acceptor (46%) (Scheme 3). Compound **19** was deacetylated to give **20** which was benzylated under neutral conditions (38) to yield **21**. Hydrolysis of the benzylidene acetal (39) gave diol **22** that was regioselectively benzoylated (40) to afford tetrasaccharide acceptor **23**.

© 2002 NRC Canada

Scheme 1.



In spite of the moderate yield of the glycosylation reaction, this synthetic route to **23** was more convenient than that using acceptor building block **14** since the deactivating effect of the acetyl group in **14** further complicated the coupling with **7** to give **24** with formation of orthoester and considerable elimination (25% of 2-acetoxyglycal). Compound **24** could be conventionally deacetylated to give **25** that was benzylated to yield **21** (52%).

The coupling of **23** with donor **6** afforded hexasaccharide **5** in 65% yield. The methoxycarbonyl and acyl groups in **5** were removed by treatment with lithium hydroperoxide and then hydroalcoholic potasium hydroxide (41, 42) and the resulting partially protected hexasaccharide **26** was sulfonated and isolated as the sodium salt **27**. Hydrogenolytic cleavage of the benzylidene acetal and benzyl groups and simultaneous reduction of the azido groups in **27** followed by selective *N*-sulfonation yielded compound **3** that was purified using a protocol partially based on the reported purification of synthetic oligosaccharides of the irregular region of heparin (42).

The elongation of the oligosaccharide chain to obtain an octasaccharide (**4**) was performed by adding a new disaccharide building block (**34**) to the nonreducing end of the previously constructed hexasaccharide structure **5**. This building block (**34**) was prepared as indicated in Scheme 4 from the iduronic acid derivative **11** (21, 43) and trichloroacetimidate **29** that was obtained from **28** (21, 44). Coupling of **29** with **11** gave disaccharide **30** that was transformed into trichloroacetimidate **34** following the sequence **30** → **31** → **32** → **33** → **34** as indicated in Scheme 4. Building block acceptor **35** was prepared by regioselective reductive opening of the benzylidene acetal group in **5** (Scheme 5). As expected (21), the glycosylation reaction between **34** with **35** took place in only moderate yield (40%). However, no attempt was made to optimize this reaction since a reasonable amount of octasaccharide **36** was isolated that allowed the subsequent transformations leading to sufficient **4** for structural and biological investigation. The relevance of **4** for these further studies, which was not yet known at this stage, would dictate whether working out some changes in this synthetic strategy may be worthwhile in the near future. The introduction of a needed permanent protecting group at position 2 of the G unit was satisfactorily carried out by selective deacylation using catalytic sodium methoxide in methanol to obtain **37** (80%) followed by benzylation under neutral conditions (38) to afford **38**. The carboxymethyl and *O*-acyl groups were then removed by treatment with lithium hydroperoxide then alcoholic potasium

hydroxide to give **39** that was *O*-sulfonated to yield **40**. Hydrogenolytic cleavage of the benzyl groups with concomitant reduction of the azido groups of **40** followed by *N*-sulfonation gave finally octasaccharide **4** that was purified as **3**.

Structural study

The ^1H and ^{13}C NMR spectra of **3** and **4** were fully assigned using conventional 1D and 2D spectroscopy (Table 1). These assignments were carried out by identification of the spin systems of the residues and further connection based on inter-residue NOE. The substitution pattern in **3** and **4** led to a better signal dispersion than that observed in the spectra of hexasaccharide **1** and octasaccharide **2.** The chemical shift values were in agreement with those expected according to reported data for chemicaly modified heparin (45, 46). Three bond coupling constants were obtained from 2D DQF-COSY(47). As expected, the D-glucosaminyl residues showed a single $^4C_1$ conformation and the ω rotamer of the 6-*O*-sulfated units appeared as in **1** (21) as the *gg* conformer. The observed values for the coupling constants of the iduronate residues could be accounted for by the existence of a conformational equilibrium between $^1C_4$ and ^2S_o forms as reported for heparin (Table 2), also confirmed by the H2-H5 NOE (30). Therefore, the lack of the 2-*O*-sulfate group in the C and G units and the further modifications in the neighboring glucosamine residues, absence of 6-*O*-sulfate group in the B and F units and of *N*-sulfate group in the D and H units, do not seem to qualitatively modify the conformational behavior of these iduronate rings with respect to heparin. This result is also in agreement with previous findings that similar structural changes in natural heparin fragments do not influence the inner iduronate ring conformational equilibrium (48).

With regard to the conformation around the glycosidic linkages, the NOEs pattern observed for hexasaccharide **3** was compared to that previously obtained for the parent hexasaccharide **1** (see supplementary data).[2] There were no indications of conformational changes as no major differences were observed and only small intensity variations, which could be attributed to differences in correlation times, were detected. The possibility that the changes in charge distribution in **3** with respect to **1** may partially drive the glycosidic angles towards an *anti*-ψ arrangement could, therefore, be discarded. Furthermore, the exclusive NOEs that should be expected for such *anti*-ψ situations (H1′-H5 for the IdoA–GlcN linkages and H5′-H3 for the GlcN–IdoA ones) could not be observed in NOESY experiments with hexasaccharide **3**.

The above qualitative NMR study indicated that the synthetic compounds **3** and **4** present the main structural features of natural heparin oligosaccharides (46). The structural definition of **3** was further improved with a semiquantitative analysis of the NOE data. Heparin fragments larger than five monosaccharide units usually show an anisotropic hydrodynamic behavior with a shape close to a prolate ellipsoid. This feature can be determined through the analysis of σ^{NOE} and (or) the apparent correlation times for the fixed glucosamine interprotonic vectors H1-H2 and H2-H4. As the H1-H2 vector is almost parallel and the H2-H4 almost perpendicular to the main axis of inertia and both distances are

C-6		62.5		69.0		63.0

nearly equal, the observed variation of σ^{NOE} can be attributed to a difference in parallel and perpendicular correlation times. The σ^{NOE} values for **3** were calculated from the NOE growing rate, assuming the isolated spin pairs approximation, by integration of the NOE cross-peaks at several mixing times (200–600 ms) (49). The apparent correlation times for glucosamine vectors H1-H2 and H2-H4, calculated from the σ^{NOE} ratio at 400 and 500 MHz provided a clear indication of this anisotropic tumbling (Table 3) (50). This behavior, which also was previously observed for **1** (21), prevented the accurate calculation of distances from NOE data and a complex full-motion model, which accounts both for internal motions and anisotropy, has to be considered. However, because of the above-mentioned parallel and perpendicular orientation of the H1-H2 and H2-H4 vectors with respect to the main axis of inertia, the known glucosamine H1-H2 and H2-H4 distances can be used as extreme reference values for the estimation of distances from interglycosidic NOEs. The upper and the lower distance limits may be given by considering the parallel and perpendicular correlation times derived from H1-H2 and H2-H4 σ^{NOE}, respectively. The distances thus obtained were in agreement with those expected for a *syn*-Φ disposition of the glycosidic linkages (Table 4) as that reported for heparin and related oligosaccharides.

Table 3. σ^{NOE} (500) and σ^{NOE} (400) (s^{-1}) and apparent correlation times (ns) for internal glucosamine NOEs of **3**.

		GlcN (**B**)	GlcN (**D**)	GlcN (**F**)
H1-H2	σ^{NOE} (500)	0.16	0.20	0.13
	σ^{NOE} (400)	0.14	0.19	0.12
	τ_c	1.04	1.37	1.10
H2-H4	σ^{NOE} (500)	0.05	0.09	0.02
	σ^{NOE} (400)	0.03	0.08	0.01
	τ_c	0.60	1.22	0.55

The small differences observed for the H1′-H3:H1′-H4 ratio of the C–D linkage in comparison with those of the A–B and E–F linkages can be attributed to changes of the local flexibility as a consequence of the different substitution pattern.

Finally, a model of hexasaccharide **3** was constructed on the basis of a previous model constructed for **1**. A minimization including TIP3P water and sodium counterions was performed. The system was preequilibrated by several cycles of molecular dynamics with frozen solute coordinates. After minimization of the overall system, the relaxed structure showed the typical helical symmetry of heparin with the five sulfate groups located on one face. The backbone of this structure can be superimposed on the backbone of structure **1** (Fig. 2) This model is in agreement with the key interglycosidic distances calculated from NOE data (Table 4).

Although more detailed structural studies are presently underway, the results presented here clearly indicate that the key three-dimensional elements present in the structure of heparin, helical symmetry and iduronate ring conformational equilibrium, are adequatelly modeled by compounds **3** and **4**.

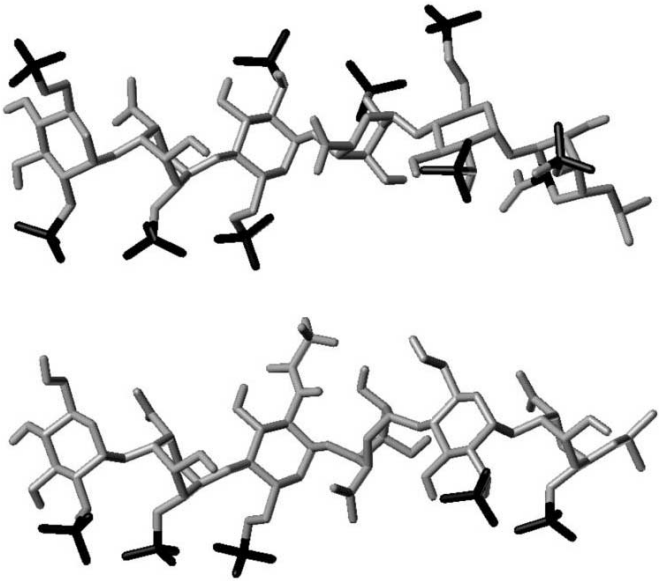
The induction of the mitogenic activity of FGF-1 by these synthetic compounds (**3** and **4**) in comparison with that promoted by compounds **1** and **2** is now under investigation. Preliminary results indicate that hexasaccharide **3** shows the maximum activating effect. On the other hand, sedimentation equilibrium analysis also shows, in this case, that the profile of FGF-1 solutions in the presence of activating concentrations of **3** and **4** correspond to monomeric species. These results and further studies on the structure–reactivity relationship will be reported in due time.

Experimental

General methods

The ^{1}H NMR spectra were measured at 500 MHz (Bruker DRX-500) with tetramethylsilane or the residual signal of the solvent as the internal standard. The ^{13}C NMR spectra were recorded at 125 MHz. Optical rotations were measured at room temperature in a 1 dm cell on a PerkinElmer 341 polarimeter. Elemental analyses were carried out in a Leco CHNS 932 analyzer. Permeation gel chromatography was performed using Sephadex LH-20 and G-25 (Pharmacia). Ionic exchange chromatography was carried out using Dowex 50WX4 resin (Fluka). Thin-layer chromatography was performed on precoated plates of silica gel (60-F254, E. Merck, Darmstadt) and visualized with H_2SO_4–EtOH (1:9, v/v) or anisaldehyde followed by heating. For column chromatography, silica gel 60 (0.2–0.5 mm, 0.2–0.063 mm, or 0.04–0.015 mm, E. Merck, Darmstadt) and distilled solvents were used. All solvents and reagents were purified and dried according to standard procedures.

Fig. 2. Relaxed structures of hexasaccharides **1** and **3**.



NMR measurements

1D and 2D experiments were recorded in D_2O at 298 K on Bruker DRX-500 and DRX-400 instruments using acetone as the external reference in a 6 mM sample. pH* was adjusted to 7.0. DQF-COSY (51), TOCSY (52), and HMQC (53) experiments were recorded using standard *z*-pulsed field gradient enhanced or selected pulse sequences when possible. Phase-sensitive experiments were performed in all cases using the TPPI (time proportional phase increment) method (54). Data were transformed into phase-sensitive mode after weighting with shifted- square sine-bells functions.

NOESY (55) experiments were carried out at 500 and 400 MHz with mixing times of 250, 300, 325, 350, 400, 500, 550, and 600 ms. The volumes of the cross and diagonal peaks were integrated using standard Bruker software. The normalized cross-peak's volume variation as a function of the mixing time indicated good linearity of the NOE build up curves for the range of mixing times considered. Cross-relaxation rates (σ) were calculated from these

curves assuming the isolated spin pairs approximation at short mixing times by extrapolation to zero time. The apparent correlation times were calculated using the spectral density function of an isotropic rigid molecule, from the ratio σ (500)/σ (400) (56).

Molecular modeling

Molecular modeling was performed using AMBER force field (57) (parameter set "parm91") as integrated in the AMBER 5.0 program (58), modified for carbohydrate molecules by the GLYCAM_93 parameter set (59). Specific parameters for sulfates and sulfamate groups were also included, as described by Huige and Altona (60). The initial structure of the hexasaccharide **3** was built using the ϕ/ψ values found for a minimized structure of the regular heparin-like synthetic hexasaccharide **1** (21). Minimization was carried out using periodic boundary conditions with TIP3P water molecules. Box dimensions were 53 × 50 × 50 Å, large enough to allow for the faces of the box to extend 12 Å beyond the sugar in each direction, reducing in this way the possibility of border effects that could take place if a reorientation of the solute happened during the calculation. It involved the introduction of 3933 water molecules and eight sodium counterions. To enable the cations to solvate appropriately, they were initially located randomly far enough from the solute. The initial water and counterions configuration was subjected to 500 cycles of energy minimization, with the conformation of the sugar frozen. Following this step, a 50 ps volume constant MD simulation was performed, in which only the water molecules were allowed to move. After this preequilibration of the solvent, the next step consisted of 500 cycles of energy minimization of the water molecules, keeping constant the Cartesian coordinates of the solute and counterions. To reach the equilibrium value for the density of the system, the water molecules were subjected to 50 ps pressure constant MD simulation with both the solute and the counterions frozen. Finally, the solvent equilibration procedure involved 500 cycles of steepest descent energy minimization of the water molecules. At this point, the energetic minimum of **3** was obtained using 1500 cycles of conjugated gradient minimization for the whole system.

Methyl (isopropyl 4-*O*-(2-azido-3-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-3-*O*-benzyl-2-*O*-pivaloyl-α-L-idopyranosyl) uronate (13)

To a solution of **12** (800 mg, 1.02 mmol) in dry CH_2Cl_2 (9 mL), EtSH (374 μL, 5.06 mmol), and catalytic PTSA were added. After stirring for 3 h under an argon atmosphere, the reaction was neutralized with saturated $NaHCO_3$ solution, diluted with CH_2Cl_2 (200 mL), and washed with H_2O (200 mL). The organic layer was dried ($MgSO_4$) and concentrated to dryness. The mixture was purified by flash chromatography (hexane–EtOAc, 1:1) to yield **13** (639 mg, 90%). TLC: 0.14 (hexane–EtOAc, 2:1). $[\alpha]_D^{23}$ –6.6° (*c* 0.6, $CHCl_3$). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.37–7.24 (m, 10H, *2 Ph*), 5.18 (d, 1H, *H-1*, $J_{1,2}$ = 4.5 Hz), 5.05 (d, 1H, *H-1′*, $J_{1,2}$ = 3.6 Hz), 4.93 (m, 1H, *H-2*), 4.89 (d, 1H, *1 CH*$_2$Ph, J_{gem} = 11.2 Hz), 4.79–4.69 (m, 4H, *3 CH*$_2$Ph, *H-5*), 4.15 (m, 1H, *H-4*), 3.97–3.91 (m, 2H, *H-3*, *CH*$(CH_3)_2$), 3.80–3.55 (m, 5 H, *H-3′*, *H-4′*, *H-5′*, *H-6′a*, *H-6′b*), 3.75 (s, 3H, COO*CH*$_3$), 3.17 (t, 1H, *H-2′*, $J_{2,1} \approx J_{2,3}$ = 10.7 Hz), 1.22 (s, 9H, C(*CH*$_3$)$_3$), 1.19–1.15 (2d, 6H, CH(*CH*$_3$)$_2$, *J* = 6.2 Hz).

Methyl (isopropyl 4-*O*-(6-*O*-acetyl-2-azido-3-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-3-*O*-benzyl-2-*O*-pivaloyl-β-L-idopyranosyl) uronate (14)

To a solution of **13** (540 mg, 0.77 mmol) in dry CH_2Cl_2 (12 mL) at –10°C, Py (63 μL, 0.78 mmol) and acetic anhydride (74 μL, 0.78 mmol) were added. After stirring for 24 h, MeOH (1 mL) was added, and was concentrated in vacuo. The crude was purified by flash chromatography (hexane–EtOAc, 2:1) to yield **14** (488 mg, 85%) as well as nonreacting starting material **13** (22 mg, 4%). TLC: 0.33 (hexane–EtOAc, 2:1). $[\alpha]_D^{23}$ –10.1° (*c* 1.0, $CHCl_3$). Isopropyl *O*-(2-azido-3-*O*-benzyl-4,6-di-*O*-benzylidene-2-deoxy-α-D-glucopyranosyl)-(1→4)-*O*-(3-*O*-benzyl-2-*O*-sulfo-α-L-idopyranosyluronic acid)-(1→4)-*O*-(2-acetamido-3-*O*-benzyl-2-deoxy-6-*O*-sulfo-α-D-glucopyranosyl)-(1→4)-*O*-(2,3-di-*O*-benzyl-α-L-idopyranosyluronic acid)-(1→4)-*O*-(2-azido-3,6-di-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-(1→4)-3-*O*-benzyl-2-*O*-sulfo-α-L-idopyranosyl)uronic acid hexasodium salt (27)

A mixture of **26** (33 mg, 16.7 μmol) and complex $SO_3\cdot$Py (40 mg, 0.25 mmol) in dry Py (1.5 mL) was stirred under an argon atmosphere. After 24 h, the mixture was cooled and MeOH (1 mL) and CH_2Cl_2 (1 mL) were added. The solution was eluted through a Sephadex LH-20 (MeOH–CH_2Cl_2,1:1). Fractions containing the hexasaccharide were concentrated and passed through a Dowex 50WX4-Na^+ (MeOH–H_2O, 2:1) to yield **27** (28 mg, 72%). TLC: 0.65 (EtOAc–Py–H_2O–AcOH, 8:5:3:1). ^{1}H NMR (500 MHz, MeOD) δ: 7.42–7.10 (m, 50H, 10 *Ph*), 5.56 (s, 1H, Ph-*CH*-), 5.46 (s, 1H, *H-1a* or *e*), 5.32 (s, 1H, *H-1c*), 5.28 (s, 1H, *H-1a* or *e*), 5.15 (d, 1H, *H-1b* or *f*), 5.06 (d, 1H, *H-1b* or *f*), 4.82 (m, 1H, *H-1d*), 1.26 (m, 3H, NHCOCH_3), 1.20 (d, 6H, CH(CH_3)$_2$, J = 6.0 Hz). ^{13}C NMR (125 MHz, MeOD) δ: 101.4 (Ph-*CH*-), 98.8 (*C-1c*), 98.1 (*C-1a* or *e*), 97.5 (*C-1a* or *e*), 96.1 (*C-1b* or *f*), 95.7 (*C-1b* or *f*), 95.5 (*C-1d*).

Isopropyl *O*-(2-deoxy-2-sulfamide-α-D-glucopyranosyl)-(1→4)-*O*-(2-*O*-sulfo-α-L-idopyranosyluronic acid)-(1→4)-*O*-(2-acetamido-2-deoxy-6-*O*-sulfo-α-D-glucopyranosyl)-(1→4)-*O*-(α-L-idopyranosyluronic acid)-(1→4)-*O*-(2-deoxy-2-sulfamide-α-D-glucopyranosyl)-(1→4)-2-*O*-sulfo-α-L-idopyranosyluronic acid octasodium salt (3)

To a solution of **27** (17 mg, 7.24 μmol) in MeOH–H_2O (1.5 mL, 9:1) was hydrogenolyzed in the presence of 10% Pd/C. After 24 h, the suspension was filtered and concentrated to give the desired product which was directly used in the next step without further purification.

© 2002 NRC Canada

The hydrogenolyzed hexasaccharide was dissolved in H_2O (1mL) and the pH of the solution was adjusted to 9.5 with 1 N solution of NaOH. Complex SO_3·Py (24 mg, 10 equiv for each amine group) was added in three portions during 1 h and the pH was maintained at 9.5 by subsequent addition of a 1 N solution of NaOH. A second, third, and fourth portion of complex SO_3·Py were added after 2, 4, and 6 h stirring, respectively. After 24 h, the mixture was neutralized with 0.1 N HCl to pH 7 and then passed through a column of Sephadex G-25 with 0.9% NaCl. The appropriate fractions were pooled and passed through a column of Dowex 50WX4-Na^+ with 0.5 M NaCl and then a column of Sephadex G-25 with H_2O–EtOH (9:1). The fractions which contained the final hexasaccharide were lyophilized to give **3** (9.1 mg, 75% from **27**). Before NMR studies, it was useful to make a last elution on a column of Dowex 50WX4-Na^+ to avoid the formation of calcium salts instead of sodium salts and get a better resolution in the spectra. ^{1}H NMR (500 MHz, D_2O) δ: 5.38 (d, 1H, *H-1f*, $J_{1,2}$ = 3.7 Hz), 5.32 (d, 1H, *H-1b*, $J_{1,2}$ = 3.7 Hz), 5.22 (d, 1H, *H-1a*, $J_{1,2}$ = 3.0 Hz), 5.18 (d, 1H, *H-1e*, $J_{1,2}$ = 3.0 Hz), 5.15 (d, 1H, *H-1d*, $J_{1,2}$ = 4.0 Hz), 4.89 (d, 1H, *H-1c*, $J_{1,2}$ = 3.5 Hz), 1.99 (m, 3H, NHCO*CH*$_3$), 1.17 (d, 3H, CH(*CH*$_3$)$_2$, *J* = 6.2 Hz), 1.16 (d, 3H, CH(*CH*$_3$)$_2$, *J* = 6.2 Hz). ^{13}C NMR (125 MHz, D_2O) δ: 102.9 (*C-1c*), 99.8 (*C-1e*), 97.8 (*C-1a*), 97.6 (*C-1b*), 97.3 (*C-1f*), 94.9 (*C-1d*).

2-Azido-6-*O*-benzoyl-3,4-di-*O*-benzyl-2-deoxy-α,β-D-glucopyranose trichloroacetimidate (29)

To a solution of **28** (1 g, 2.12 mmol) in dry MeOH (8 mL), solid KOH (119 mg, 2.12 mmol) was added, and was stirred for 20 min. The solution was diluted with CH_2Cl_2 (200 mL) and saturated NH_4Cl solution (2 × 100 mL) and H_2O (2 × 100 mL). The organic layer was dried ($MgSO_4$) and concentrated in vacuo. The residue was directly used in the next step without further purification.

To this residue dissolved in Py (10 mL), BzCl (2 mL) was added and stirred at room temperature for 24 h. The reaction was diluted with CH_2Cl_2 (100 mL), washed with H_2O (75 mL) and 1 N HCl solution (75 mL), dried ($MgSO_4$), and concentrated to dryness. The residue was purified by flash chromatography and used in the next step.

To a solution of this residue (1.2 g, 2.04 mmol) in dry Et_2O (10 mL), benzylamine (1.2 mL, 10.9 mmol) was added and was stirred for 4 h. The residue was concentrated to dryness and purified by flash chromatography (hexane–EtOAc, 3:1) and then to a solution of this compound (625 mg, 1.27 mmol) in dry CH_2Cl_2 (7 mL), Cl_3CCN (1.9 mL, 19 mmol) and catalytic DBU were added. After stirring for 1 h the residue was concentrated to dryness. The residue was purified by flash chromatography (hexane–EtOAc (4:1) + 1% Et_3N) to yield **29** (703 mg, 87%) as a mixture of anomers α and β. TLC (α and β): 0.50 and 0.43 (hexane–EtOAc, 3:1). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 8.71 (s, 1H, O(C=*NH*)CCl_3 (α)), 8.69 (s, 1H, O(C=*NH*)CCl_3 (β)), 7.29–7.24 (m, 30H, *3 Ph* (α and β)), 6.42 (d, 1H, *H-1* (α), $J_{1,2}$ = 4.1 Hz), 5.65 (d, 1H, *H-1* (β), $J_{1,2}$ = 8.5 Hz), 4.99–4.84 (m, 6H, *6 CH*$_2$Ph (α and β)), 4.65–4.45 (m, 6H, *2 CH*$_2$Ph (α and β), *H-6a* (α and β), *H-6b* (α and β)), 4.17 (m, 1H, *H-5* α), 4.09 (t, 1H, *H-3* (α), $J_{3,2} \approx J_{3,4}$ = 9.5 Hz), 3.80–3.70 (m, 5H, *H-2* (α and β), *H-4* (α and β), *H-5* (β)), 3.61 (t, 1H, *H-3* (β), $J_{3,2} \approx J_{3,4}$ = 9.0 Hz).

Methyl dimethylthexylsilyl 2-*O*-acetyl-4-*O*-(2-azido-6-*O*-benzoyl-3,4-di-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-3-*O*-benzyl-β-L-idopyranuronate (31)

To a solution of **11** (600 g, 0.95 mmol) in dry CH_2Cl_2 (20 mL) at 0°C TMSOTf (8.6 μL, 0.048 mmol) was added under an argon atmosphere. A solution of **29** (720 mg, 1.63 mmol) in dry CH_2Cl_2 (30 mL) was added dropwise for 30 min. The reaction was neutralized with saturated $NaHCO_3$ solution and diluted with CH_2Cl_2 (100 mL). The organic layer was washed with H_2O (75 mL), dried ($MgSO_4$), and concentrated in vacuo. The residue was purified by flash chromatography (hexane–EtOAc, 4:1) to yield a mixture of isomers containing **30** which was used directly in the next step.

To a solution of this mixture in Py (10 mL), acetic anhydride (5 mL) was added and was stirred for 24 h. The reaction was diluted with CH_2Cl_2 (100 mL) and washed with H_2O (80 mL) and 1 N HCl solution (80 mL). The organic layer was dried ($MgSO_4$) and concentrated to dryness. The residue was purified by flash chromatography (hexane–EtOAc, 6:1) to yield **31** (391 mg, 43% from **11**). TLC: 0.36 (hexane–EtOAc, 6:1). $[\alpha]_D^{23}$ +76.0° (*c*, 1.0, CH_2Cl_2). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.99–7.20 (m, 20H, *4 Ph*), 5.06 (d, 1H, *H-1*, $J_{1,2}$ = 1.5 Hz), 4.99 (b.s., 1H, *H-2*), 4.90 (d, 1H, *H-1′*, $J_{1,2}$ = 3.4 Hz), 4.86 (d, 1H, *1 CH*$_2$Ph, J_{gem} = 11.2 Hz), 4.82 (s, 2H, *2 CH*$_2$Ph), 4.74–4.58 (m, 4H, *3 CH*$_2$Ph, *H-6′a*), 4.47 (d, 1H, *H-5*, $J_{5,4}$ = 1.2 Hz), 4.41 (dd, 1H, *H-6′b*, $J_{6b,5}$ = 2.6 Hz, $J_{6b,6a}$ = 12.3 Hz), 4.22 (m, 1H, *H-5′*), 4.11 (b.s., 1H, *H-4*), 3.99–3.95 (m, 2H, *H-3′*, *H-3*), 3.73 (s, 3H, COO*Me*), 3.70 (m, 1H, *H-4′*), 3.28 (dd, 1H, *H-2′*, $J_{2,1}$ = 3.4 Hz, $J_{2,3}$ = 10.3 Hz), 2.04 (d, 3H, OCO*CH*$_3$), 1.60 (m, 1H, *CH*(CH$_3$)$_2$), 0.86–0.83 (m, 12H, CH(*CH*$_3$)$_2$, C(*CH*$_3$)$_2$), 0.24 and 0.14 (2s, 6H, Si(*CH*$_3$)$_2$). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 170.6, 168.9, 166.1 (*C=O*), 137.8–127.5 (*Ph*), 97.4 (*C-1′*), 93.6 (*C-1*), 80.0 (*C-3′*), 77.9 (*C-4′*), 75.5, 74.9, 74.3, 73.2, 72.9, 72.8, 69.9 (*C-5*), 67.2 (*C-2*), 63.5 (*C-2′*), 62.8 (*C-6*), 52.1 (COO*Me*), 34.1, 24.8, 20.9, 20.2, 19.8 18.6, –2.1, –3.5 (O*TDS*, OCO*CH*$_3$). The residue was purified by Sephadex LH-20 (MeOH–CH_2Cl_2, 1:1) to yield **39** (32 mg, 94%). TLC: 0.47 (CH_2Cl_2–MeOH, 8:1). ^{1}H NMR (500 MHz, CD_3OD) δ: 7.37–7.06 (m, 65H, *13 Ph*), 5.30–5.19 (m, 3H, *H-1b*, *H-1f*, *H-1a* or *e*), 5.06 (s, 1H, *H-1a* or *e*), 5.00 (d, 1H, *H-1c* or *g*, $J_{1,2}$ = 3.4 Hz), 4.98 (d, 1H, *H-1c* or *g*, $J_{1,2}$ = 3.2 Hz), 4.79 (m, 2H, *H-1d*, *H-1h*), 1.61 (s, 6H, *2* NHCO*CH*$_3$), 1.30–1.15 (m, 6H, CH$(CH_3)_2$). ^{13}C NMR (125 MHz, CD_3OD) δ: 99.7 (*C-1a* or *e*), 98.2 (*C-1b* or *f*), 97.6 (*C-1a* or *e*), 97.3 (*C-1b* or *f*), 96.6, 96.4 (*C-1d*, *C-1h*), 95.1 (*C-1c*, *C-1g*).

Isopropyl *O*-(2-acetamido-3,4-di-*O*-benzyl-2-deoxy-6-*O*-sulfo-α-D-glucopyranosyl)-(1→4)-*O*-(2,3-di-*O*-benzyl-α-L-idopyranosyluronic acid)-(1→4)-*O*-(2-azido-3-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-(1→4)-*O*-(3-*O*-benzyl-2-*O*-sulfo-α-L-idopyranosyluronic acid)-(1→4)-*O*-(2-acetamido-3-*O*-benzyl-2-deoxy-6-*O*-sulfo-α-D-glucopyranosyl)-(1→4)-*O*-(2,3-di-*O*-benzyl-α-L-idopyranosyluronic acid)-(1→4)-*O*-(2-azido-3,6-di-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-(1→4)-3-*O*-benzyl-2-*O*-sulfo-α-L-idopyranosyluronic acid octasodium salt (40)

A mixture of **39** (32 mg, 11.4 μmol) and complex SO_3·Py (37 mg, 0.23 mmol) in dry Py (1.5 mL) was stirred under an argon atmosphere. After 24 h, the mixture was cooled and MeOH (1 mL) and CH_2Cl_2 (1 mL) were added. The solution was eluted through a Sephadex LH-20 (MeOH–CH_2Cl_2, 1:1). Fractions containing the hexasaccharide were concentrated and passed through a Dowex 50WX4-Na^+ (MeOH–H_2O, 2:1). Finally, the product was purified by reverse phase HPLC to yield **40** (23 mg, 64%). TLC: 0.62 (EtOAc–Py–H_2O–AcOH, 8:5:3:1). ^{1}H NMR (500 MHz, CD_3OD) δ: 7.42–7.00 (m, 65H, *13 Ph*), 5.45–5.15 (5H, *H-1a*, *H-1b*, *H-1e*, *H-1f*, *H-1c* or *g*), 5.05–4.70 (3H, *H-1d*, *H-1h*, *H-1c* or *g*), 1.56 (m, 3H, NHCO*CH*$_3$), 1.46 (m, 3H, NHCO*CH*$_3$), 1.18 (d, 6H, CH*(CH*$_3$*)*$_2$, *J* = 6.0 Hz).

Isopropyl *O*-(2-acetamido-2-deoxy-6-*O*-sulfo-α-D-glucopyranosyl)-(1→4)-*O*-(α-L-idopyranosyluronic acid)-(1→4)-*O*-(2-deoxy-2-sulfamide-α-D-glucopyranosyl)-(1→4)-*O*-(2-*O*-sulfo-α-L-idopyranosyluronic acid)-(1→4)-*O*-(2-acetamido-2-deoxy-6-*O*-sulfo-α-D-glucopyranosyl)-(1→4)-*O*-(α-L-idopyranosyluronic acid)-(1→4)-*O*-(2-deoxy-2-sulfamide-α-D-glucopyranosyl)-(1→4)-2-*O*-sulfo-α-L-idopyranosyluronic acid decasodium salt (4)

To a solution of **40** (23 mg, 7.15 μmol) in MeOH–H_2O (1.5 mL, 9:1) was hydrogenolyzed in the presence of 10% Pd/C. After 24 h, the suspension was filtered and concentrated to give the desired product which was directly used in the next step without further purification.

The hydrogenolyzed hexasaccharide was dissolved in H_2O (1 mL) and the pH of the solution was adjusted to 9.5 with a 1 N solution of NaOH. Complex SO_3·Py (24 mg, 10 equiv for each amine group) was added in three portions over 1 h and the pH was maintained at 9.5 by subsequent addition of a 1 N solution of NaOH. A second, third, and fourth portion of complex SO_3·Py were added after 2, 4, and 6 h stirring, respectively. After 24 h, the mixture was neutralized with a 0.1 N solution of HCl to pH 7 and then chromatographed on a column of Sephadex G-25 with a 0.9% solution of NaCl. The appropriate fractions were pooled and passed through a column of Dowex 50WX4-Na^+ with a 0.5 M solution of NaCl and then a column of Sephadex G-25 with H_2O–EtOH (9:1). The fractions which contained the final hexasaccharide were lyophilized to give **4** (10.4 mg, 66% from **40**). Before NMR studies, it was useful to make a last elution on a column of Dowex 50WX4-Na^+ to avoid the formation of calcium salts instead of sodium salts and get a better resolution in the spectra. ^{1}H NMR (500 MHz, D_2O) δ: 5.38 (d, 1H, *H-1f*, $J_{1,2}$ = 3.3 Hz), 5.30 (d, 1H, *H-1b*, $J_{1,2}$ = 3.3 Hz), 5.23 (d, 1H, *H-1a*, $J_{1,2}$ = 1.8 Hz), 5.19 (d, 1H, *H-1e*, $J_{1,2}$ = 2.7 Hz), 5.16 (d, 1H, *H-1h*, $J_{1,2}$ = 3.8 Hz), 5.14 (d, 1H, *H-1d*, $J_{1,2}$ = 3.3 Hz), 4.88–4.86 (m, 2H, *H-1c*, *H-1g*), 1.99

Synthesis of 1,4-anhydro-D-xylitol heteroanalogues of the naturally occurring glycosidase inhibitor salacinol and their evaluation as glycosidase inhibitors

Ahmad Ghavami, Blair D. Johnston, Matthew D. Maddess, Sarah M. Chinapoo, Morten T. Jensen, Birte Svensson, and B. Mario Pinto

Abstract: The syntheses of two 1,4-anhydro-D-xylitol heteroanalogues (**8** and **9**) of the naturally occurring sulfonium ion, salacinol (**3**), containing a sulfur or nitrogen atom in the ring are described. Salacinol (**3**) is one of the active principles in the aqueous extracts of *Salacia reticulata* that are traditionally used in Sri Lanka and India for the treatment of Type 2 diabetes. The synthetic strategy relies on the nucleophilic attack of sulfur or nitrogen analogues of 1,4-anhydro-D-xylitol at the least-hindered carbon of 2,4-*O*-benzylidene-L-erythritol-1,3-cyclic sulfate. The sulfonium ion **8** inhibited barley-α-amylase (AMY1) and porcine pancreatic-α-amylase (PPA), with K_i values of 109 ± 11 and 55 ± 5 μM, respectively. In contrast, the ammonium ion **9** showed no significant inhibition of either AMY1 or PPA. Compounds **8** and **9** also showed no significant inhibition of glucoamylase.

Key Words: glycosidase inhibitors, salacinol analogues, anhydro-D-xylitol heteroanalogues, enzyme inhibition.

Résumé : On décrit les synthèses de deux hétéroanalogues du 1,4-anhydro-D-xylitol (**8** et **9**) qui comportent un atome de soufre ou d'azote dans le cycle de l'ion sulfonium, salacinol (**3**), que l'on retrouve dans la nature. Le salacinol (**3**) est un des principes actifs que l'on retrouve dans la phase d'extraction aqueuse du *Salacia reticulata* utilisée au Sri-Lanka et aux Indes dans le traitement du diabète de type 2. La stratégie de la synthèse repose sur une attaque nucléophile d'analogues soufrés ou azotés du 1,4-anhydro-D-xylitol au niveau du carbone le moins encombré du sulfate 1,3-cyclique du 2,4-*O*-benzylidène-L-érythritol. L'ion sulfonium **8** inhibe l'α-amylase de l'orge (AMY1) et de l'α-amylase du pancréas de porc (PPA) avec des valeurs de K_i de 109 ± 11 et 55 ± 5 μM, respectivement. Par ailleurs, l'ion ammonium **9** ne provoque pas d'inhibition significative de l'AMY1 ou de la PPA. Les composés **8** et **9** n'inhibent pas de façon significative la glucoamylase.

Mots clés : inhibiteurs de glycosidase, analogues du salacinol, hétéroanalogues de l'anhydro-D-xylitol, inhibition enzymatique.

[Traduit par la Rédaction]

Introduction

A program of research to investigate the nature and origin of carbohydrate mimicry is in progress in our laboratory. Thus, we have recently reported the study of the peptide mimicry of carbohydrates recognized by antibodies directed against the Group A *Streptococcus* cell-wall polysaccharide (1) and have recently communicated our results with an antibody directed against the *Shigella flexneri* Y *O*-antigen (2). In the latter study, the crystal structures of the Ab-peptide mimetic and Ab-pentasaccharide complexes were compared. The results indicated that although both ligands engage some common groups on the Ab receptor in H-bonding and hydrophobic interactions, each ligand also displays unique interactions with groups on the protein, lending support to our previous hypothesis that "functional" and not "structural" mimicry might be the mode of mimicry with peptide mimetics (1).

We have also studied the mimicry of carbohydrates by glycomimetics as potential glycosidase inhibitors. Thus, for example, we have described the synthesis and conformational analysis of a sulfonium-ion analogue (**1**) of the glycosidase inhibitor castanospermine (**2**) (3). Our reasoning was inspired by the pioneering work of the late B. Belleau who synthesized sulfonium-ion analogues of the morphinans, levorphanol, and isolevorphanol, and showed that they were agonists or antagonists of morphine for the opiate receptor (*4a–d*). Recently, a new class of glycosidase inhibitor with an intriguing inner-salt sulfonium-sulfate structure was

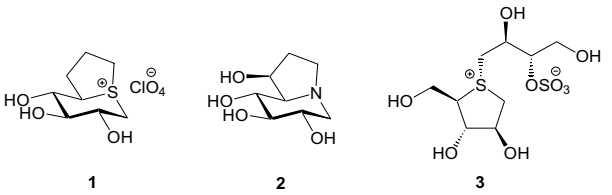
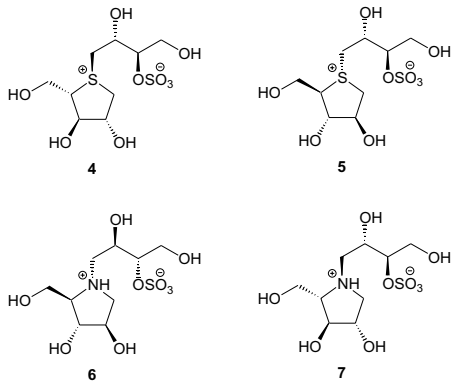
isolated from the roots and stems of the plant *Salacia reticulata*. Extracts of this plant have been traditionally used in the Ayurdevic method of Indian medicine as a treatment



1 **2** **3**

for diabetes. One of the active ingredients of these extracts is the sulfonium salt salacinol (**3**) (5).

We (6) and others (7) have recently reported the synthesis of salacinol (**3**) and its stereoisomers (**4**, **5**), and provided conclusive proof of structure of the natural product. We have also reported the syntheses of the hitherto unknown nitrogen congeners (**6**, **7**) as potential glycosidase inhibitors (8). Enzyme inhibition assays indicated that salacinol (**3**) is a weak (K_i = 1.7 mM) inhibitor of glucoamylase, whereas compounds **6** and **7** inhibit glucoamylase with K_i values in the range about 10-fold higher. The nitrogen analogues **6** and **7** showed no significant inhibitory effect of either barley α-amylase (AMY1) or porcine pancreatic α-amylase (PPA) at concentrations of 5 mM. In contrast, salacinol (**3**) inhib-



4 **5** **6** **7**

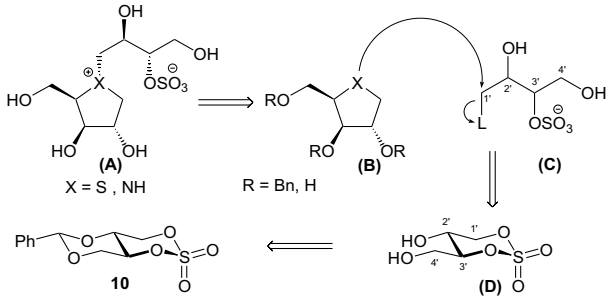
ited AMY1 and PPA in the micromolar range, with K_i values of 15 ± 1 μM and 10 ± 2 μM, respectively (8).

Yuasa and et al. (9) have also investigated the glucosidase inhibitory activities of compounds (**3**) and (**5**) and showed that although salacinol (**3**) is a better inhibitor (IC_{50} = 1.1 μM) of rice α-mannosidase than its diastereomer **5** (IC_{50} = 0.38 mM), the inhibitory activities are comparable for almond α-glucosidase (IC_{50} = 2.1 mM for **3**; 3.6 mM for **5**). In the case of almond β-glucosidase, (**5**) is a better inhibitor than (**3**) ((**3**) showed no activity; IC_{50} = 3.4 mM for (**5**)).

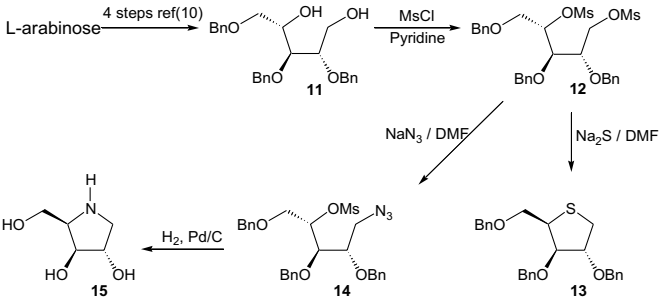
In a recent study, Muraoka et al. (10) showed that salacinol (**3**) inhibits intestinal α-glucosidases: maltase, sucrase, and isomaltase with IC_{50} values of 9.6 μM, 2.5 μM, and 1.8 μM, respectively, whereas compound (**6**) inhibits these enzymes with IC_{50} values of 306 μM, 44 μM, and 136 μM, respectively.

The results described above suggest that the stereochemistry at the different stereogenic centres and the nature of the ring heteroatom in the candidate inhibitors play a significant role in discriminating between different glycosidase

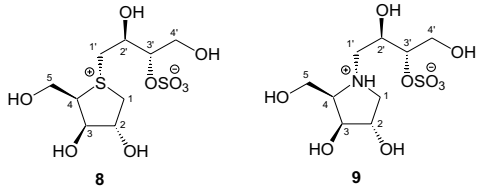
Scheme 1.



Scheme 2.



enzymes. Therefore, to probe these structure–function studies further, we now report the syntheses of the thio and iminoxylitol analogues (**8**, **9**) of salacinol (**3**) and their evaluation as glycosidase inhibitors of AMY1, PPA, or glucoamylase.



8 **9**

Results and discussion

Retrosynthetic analysis indicated that salacinol (**3**) or its analogues (**A**) could be obtained by alkylation of anhydroalditol derivatives at the ring heteroatom (Scheme 1). As in our previous work (6, 8), the benzylidene acetal **10** of **D** was chosen as the alkylating agent. We envisaged that selective attack of the heteroatom at the least-hindered primary centre would afford the desired sulfonium or ammonium ions.

The cyclic sulfate (**10**) was synthesized in five steps starting from L-glucose (6). The thio- and iminoxylitols (**13**, **15**) were synthesized from L-arabinose. Thus, the diol (**11**) was synthesized from L-arabinose in four steps according to the procedure used by van der Klein et al. (11) to synthesize its enantiomer (Scheme 2). Treatment of the diol (**11**) with methanesulfonyl chloride in pyridine then afforded the dimesylated compound (**12**) (88% yield). Compound (**12**) was used as a key intermediate to synthesize both the thio- and iminoxylitols. Treatment of (**12**) with sodium sulfide in DMF produced compound (**13**) in 95% yield, whereas treatment with sodium azide in DMF followed by

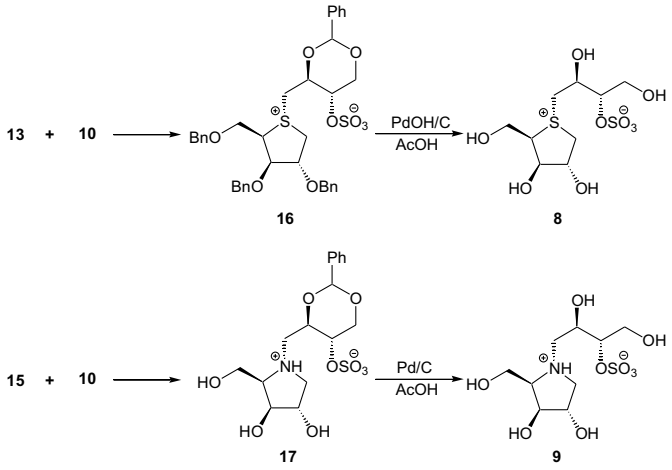
Scheme 3.



hydrogenolysis afforded the iminoxylitol (**15**) in 55% yield for the two steps (12).

To synthesize the target sulfonium ion **8**, compound **16** was first synthesized by alkylation of 1,4-anhydro-2,3,5-tri-*O*-benzyl-4-thio-D-xylitol (**13**) with the cyclic sulfate **10** (1.2 equiv) in acetone containing K_2CO_3 at 60–70°C in 72% yield. Compound **16** was obtained as the sole coupled product (Scheme 3). The stereochemistry at the stereogenic sulfonium centre in **16** was established by means of a NOESY experiment. Thus, a correlation between H-1′ and H-4, confirmed the trans relationship between the erythritol side chain and C-4 substituent on the anhydroxylitol moiety, which is similar to the stereochemistry at the stereogenic sulfur atom in salacinol (**3**). Deprotection of **16** by hydrogenolysis over a palladium hydroxide catalyst on carbon was problematic because of poisoning of the catalyst but afforded compound **8** in 50% yield.

The corresponding nitrogen congener **17** was synthesized in an analogous manner although, in this case, the increased nucleophilicity of the nitrogen atom did not necessitate benzylation of the hydroxyl groups. Thus, alkylation of 1,4-dideoxy-1,4-imino-D-xylitol (**15**) with the cyclic sulfate **10** (1.2 equiv) in methanol containing K_2CO_3 at 60–70°C afforded compound **17** in 63% yield. The stereochemistry at the stereogenic nitrogen centre in **17** was established by means of a NOESY experiment, as above. In this case, a correlation between H-1′ and H-3, confirmed the trans relationship between the erythritol side chain and the C-3 substituent on the iminoxylitol moiety. Deprotection of **17** by hydrogenolysis over a Pd/C catalyst afforded compound **9** in 83% yield.

Enzyme inhibition assays

Compounds **8** and **9** were tested for their inhibition of three glycosidase enzymes, namely glucoamylase G2, (13, 14) porcine pancreatic α-amylase, and barley α-amylase (15). The effects were compared to those of salacinol (**3**). Glucoamylase G2 was weakly inhibited by salacinol (**3**) (K_i = 1.7 mM) whereas compounds **8** and **9** showed no significant inhibition of glucoamylase. The sulfonium ion **8** inhibited barley α-amylase (AMY1) and porcine pancreatic α-amylase (PPA), with K_i values of 109 ± 11 and 55 ± 5 μM, respectively, as compared to salacinol (**3**), with K_i values of 15 ± 1 and 10 ± 2 μM, respectively. In contrast, the ammonium ion **9** showed no significant inhibition of either AMY1 or PPA (Table 1). It would appear then that analogues **8** and **9** and salacinol (**3**) show discrimination or selectivity for certain glycosidase enzymes, and further testing against a wider panel of enzymes that includes human small intestinal maltase–glucoamylase (16) and human pancreatic α-amylase (17) is planned to map the enzyme selectivity profiles of these compounds.

Table 1. K_i (mM) values of compounds **1** and **3**–**9** against barley α-amylase (AMY1), porcine pancreatic α-amylase (PPA), and glucoamylase.

Compound	AMY1	PPA	Glucoamylase
1	>5	>5	1.32
3	0.015	0.01	1.71
4	>5	>5	2.17
5	>5	>5	1.06
6	>5	>5	>2.5
7	>5	>5	>8
8	0.109	0.052	>5
9	>5	>5	>30

Experimental section

General

Optical rotations were measured at 23°C. ^1H and ^{13}C NMR spectra were recorded at 400.13 and 100.6 MHz. All assignments were confirmed with the aid of two-dimensional ^1H, ^1H (COSYDFTP), or ^1H, ^{13}C (INVBTP) experiments using standard Bruker pulse programs. Column chromatography was performed with Merck Silica gel 60 (230–400 mesh). High resolution mass spectra were measured with liquid secondary ionization fast atom bombardment (LSI-MS (FAB)), run on a Kratos Concept H double focussing mass spectrometer at 10 000 RP, using *meta*-NO_2-benzyl alcohol as the matrix.

Enzyme inhibition assays

The glucoamylase G2 form from *Aspergillus niger* was purified from a commercial enzyme (Novo Nordisk, Bagsvaerd, Denmark) as described (13, 14). The initial rates of glucoamylase G2-catalyzed hydrolysis of maltose was tested with 1 mM maltose as substrate in 0.1 M sodium acetate pH 4.5 at 45°C using an enzyme concentration of 7.0×10^{-8} M and five inhibitor concentrations in the range 1 μm – 5 mM. The effect of the inhibition on rates of substrate hydrolysis were compared for the different compounds. The glucose released was analyzed in aliquots removed at appropriate time intervals using a glucose oxidase assay adapted to microtiter plate reading and using a total reaction volume for the enzyme reaction mixtures of 150 or 300 μL (18). The K_i values were calculated assuming competitive inhibition from $1/v = (1/V_{max}) + [(K_m)/(V_{max}[S]K_i)] \times [I]$, where v is the rate measured in the presence or absence of inhibitor, $[I]$ and $[S]$ the concentrations of inhibitor and substrate, K_m 1.6 mM, and k_{cat} 11.3 s^{-1}, using ENZFITTER (19).

© 2002 NRC Canada

Porcine pancreatic α-amylase (PPA) and bovine serum albumin (BSA) were purchased from Sigma. Amylose EX-1 (DP17; average degree of polymerization 17) was purchased from Hayashibara Chemical Laboratories (Okayama, Japan). Recombinant barley α–amylase isozyme 1 (AMY1) was produced and purified as described (15). An aliquot of the porcine pancreatic α-amylase (PPA) crystalline suspension (in ammonium sulfate) was dialyzed extensively against the assay buffer without BSA. The enzyme concentration was determined by aid of amino acid analysis as determined using an LKB model Alpha Plus amino acid analyzer. The inhibition of AMY1 (3×10^{-9} M) and PPA (9×10^{-9} M) activity towards DP17 amylose was measured at 37°C in 20 mM sodium acetate (pH 5.5, 5 mM $CaCl_2$, 0.005% BSA (for AMY1)) and 20 mM sodium phosphate (pH 6.9, 10 mM NaCl, 0.1 mM $CaCl_2$, 0.005% BSA (for PPA)). Six different final inhibitor concentrations were used in the range 1 μM – 5 mM. The inhibitor was preincubated with enzyme for 5 min at 37°C before addition of substrate. Initial rates were determined by measuring reducing sugar by the copper-bicinchoninate method as described (15, 20). The K_i values were calculated assuming competitive inhibition, as described above for the case of glucoamylase, and a K_m of 0.57 mg mL^{-1} and k_{cat} of 165 s^{-1} for AMY1 and 1 mg mL^{-1} and 1200 s^{-1} for PPA, as determined in the substrate concentration range 0.03–10 mg mL^{-1} using ENZFITTER (19). For the K_i determinations, [S] = 0.7 mg mL^{-1} amylose DP 17 for the AMY1 binding and [S] = 2.5 mg mL^{-1} amylose DP 17 for the PPA binding.

2,3,5-Tri-O-benzyl-L-arabinitol (11)

The diol **11** was synthesized from L-arabinose according to the procedure used by van der Klein et al. (11) to synthesize its enantiomer. $[\alpha]_D^{22}$ –4.6° (*c* 1.0, CH_2Cl_2) (lit. (10) value +6.8° (*c* 1, $CHCl_3$)). ^{1}H NMR (CD_2Cl_2) δ: 7.38–7.25 (15H, m, Ar), 4.65 and 4.61 (2H, 2d, $J_{A,B}$ = 11.4 Hz, C*H*$_2$Ph), 4.60 and 4.57 (2H, 2d, $J_{A,B}$ = 11.2 Hz, C*H*$_2$Ph), 4.55 and 4.51 (2H, 2d, $J_{A,B}$ = 11.9 Hz, C*H*$_2$Ph), 4.00 (1H, dddd, H-4), 3.81–3.74 (3H, m, H-2, H-1a, H-1b), 3.70 (1H, dd, $J_{3,4}$ = 7.0, $J_{2,3}$ = 3.6 Hz, H-3), 3.67 (1H, dd, $J_{5a,5b}$ = 12.2, $J_{4,5a}$ = 3.9 Hz, H-5a), 3.63 (1H, dd, $J_{4,5b}$ = 5.2 Hz, H-5b), 2.90 (1H, d, $J_{OH,4}$ = 5.4 Hz, 4-OH), 2.20 (1H, dd, $J_{OH,1a}$ = 6.1, $J_{OH,1b}$ = 4.6 Hz, 1-OH). ^{13}C NMR (CD_2Cl_2) δ: 138.68, 138.58 ($3C_{ipso}$), 128.76–128.07 ($15C_{Ar}$), 80.08 (C-2), 79.16 (C-3), 74.14, 73.72, 73.15 (3*C*H$_2$Ph), 71.63 (C-5), 70.84 (C-4), 61.82 (C-1).

2,3,5-Tri-O-benzyl-1,4-di-O-methanesulfonyl-L-arabinitol (12)

To a solution of the diol **11** (4.0 g, 9.5 mmol) in pyridine (20 mL) at 0°C was added a solution of methanesulfonyl chloride (1.8 mL, 2.5 equiv) in pyridine (3.0 mL). Stirring was continued at 0°C, and under an N_2 atmosphere until TLC (hexanes–EtOAc, 3:2) showed complete disappearance of the starting material. The solvent was removed under high vacuum, and the residue was dissolved in CH_2Cl_2 (100 mL) and washed with 1 M aq HCl (2 × 30 mL), H_2O (30 mL), and sat. aq $NaHCO_3$ (30 mL), and dried (Na_2SO_4). The solution was concentrated on a rotary evaporator and the product was purified by flash chromatography (hexanes–EtOAc, 3:2) to give **12** as a colourless oil (4.8 g, 88%). $[\alpha]_D^{22}$ +4.1° (*c* 1.5, CH_2Cl_2). ^{1}H NMR (CD_2Cl_2) δ: 7.42–7.20 (15H, m, Ar), 5.01 (1H, ddd, $J_{4,5b}$ = 6.8, $J_{4,5a}$ = $J_{3,4}$ = 3.2 Hz, H-4), 4.72 and 4.59 (2H, 2d, $J_{A,B}$ = 11.1 Hz, C*H*$_2$Ph), 4.65 and 4.61 (2H, 2d, $J_{A,B}$ = 11.0 Hz, C*H*$_2$Ph), 4.53 (2H, s, C*H*$_2$Ph), 4.34–4.29 (2H, m, H-1a, H-1b), 3.96–3.91 (2H, m, H-2, H-3), 3.87 (1H, dd, $J_{5a,5b}$ = 11.3 Hz, H-5a), 3.81 (1H, dd, H-5b), 3.00 (3H, s, OSO_2CH_3), 2.93 (3H, s, OSO_2CH_3). ^{13}C NMR (CD_2Cl_2) δ: 137.95, 137.87, 137.72 ($3C_{ipso}$), 128.84–128.29 ($15C_{Ar}$), 81.52 (C-4), 77.98 (C-2), 77.32 (C-3), 74.75, 73.96, 73.77 (3*C*H$_2$Ph), 6916 (C-5), 68.64 (C-1), 39.04 (OSO_2CH_3), 37.67(OSO_2CH_3). Anal. calcd. for $C_{28}H_{34}O_9S_2$: C 58.12, H 5.92; found: C 58.21, H 6.02.

1,4-Anhydro-2,3,5-tri-O-benzyl-4-thio-D-xylitol (13)

Compound **12** (1.6 g, 2.8 mmol) was dissolved in DMF (10 mL) and $Na_2S \cdot H_2O$ (1.1 g, 1.5 equiv) was added. The mixture was stirred at 100°C until TLC (hexanes–EtOAc, 4:1) showed complete disappearance of the starting material. The solvent was removed under high vacuum, and the residue was dissolved in EtOAc (100 mL) and washed with H_2O (30 mL). The organic phase was dried (Na_2SO_4) and concentrated on a rotary evaporator. The product was purified by flash chromatography (hexanes–EtOAc, 4:1) to give a colourless syrup (1.1 g, 95%). $[\alpha]_D^{22}$ +67° (*c* 1.3, CH_2Cl_2). ^{1}H NMR (CD_2Cl_2) δ: 7.37–7.25 (15H, m, Ar), 4.57–4.47 (6H, m, 3C*H*$_2$Ph), 4.21 (1H, ddd, H-2), 4.13 (1H, dd, $J_{2,3}$ = 3.8, $J_{3,4}$ = 3.5 Hz, H-3), 3.85 (1H, dd, $J_{4,5a}$ = 7.5 Hz, H-5a), 3.80 (1H, ddd, H-4), 3.60 (1H, dd, $J_{5a,5b}$ = 8.2, $J_{4,5b}$ = 5.5 Hz, H-5b), 3.10 (1H, dd, $J_{1a,1b}$ = 11.4, $J_{1a,2}$ = 4.4 Hz, H-1a), 2.85 (1H, dd, $J_{1b,2}$ = 2.1 Hz, H-1b). ^{13}C NMR (CD_2Cl_2) δ: 138.87, 138.56 ($3C_{ipso}$), 128.70–127.86 ($15C_{Ar}$), 83.52 (C-3), 83.47 (C-2), 73.52, 72.95, 71.60 (3*C*H$_2$Ph), 69.85 (C-5), 48.55 (C-4), 33.46 (C-1). Anal. calcd. for $C_{26}H_{28}O_3S$: C 74.25, H 6.71; found: C 74.05, H 6.63.

2,3,5-Tri-O-benzyl-1,4-dideoxy-1,4-[[(2′S,3′S)-2′,4′-O-benzylidene-3′-(sulfooxy)butyl]-episulfoniumylidene]-D-xylitol inner salt (16)

A mixture of the thioxylitol **13** (100 mg, 0.24 mmol) and 2,4-*O*-benzylidene-L-erythritol-1,3-cyclic sulfate (**10**) (80 mg, 1.2 equiv) was dissolved in dry acetone (0.5 mL) and anhyd K_2CO_3 (15 mg) was added. The mixture was stirred in a sealed tube in an oil bath (60–70°C) overnight. The solvent was removed under reduced pressure and column chromatography ($CHCl_3$–MeOH, 10:1 + 0.1% Et_3N) of the crude product gave an amorphous solid (120 mg, 72%). $[\alpha]_D^{22}$ +28° (*c* 0.3, CH_2Cl_2). ^{1}H NMR (CD_2Cl_2) δ: 7.54–7.07 (20H, m, Ar), 5.52 (1H, s, C*H*Ph), 4.60 and 4.49 (2H, 2d, $J_{A,B}$ = 11.7 Hz, C*H*$_2$Ph), 4.57–4.47 (2H, m, H-3′, H-4′ eq), 4.47 and 4.44 (2H, 2d, $J_{A,B}$ = 11.3 Hz, C*H*$_2$Ph), 4.41 (1H, dd, H-1′a), 4.41–4.36 (2H, m, H-2, H-3), 4.27 (1H, ddd, $J_{2',3'}$ = 9.1, $J_{1'a,2'}$ = $J_{1'b,2'}$ = 3.3 Hz, H-2′), 4.09 (1H, ddd, $J_{4,5a}$ = 9.4, $J_{4,5b}$ = 6.0, $J_{3,4}$ = 3.2 Hz, H-4), 4.02 and 3.96 (2H, 2d, $J_{A,B}$ = 11.4 Hz, C*H*$_2$Ph), 3.92 (1H, dd, $J_{1'b,1'a}$ = 13.6 Hz, H-1′b), 3.87 (1H, dd, $J_{1a,1b}$ = 14.4, $J_{1a,2}$ = 3.1 Hz, H-1a), 3.82 (1H, dd, $J_{5a,5b}$ = 9.4 Hz, H-5a), 3.76 (1H, dd, $J_{4'ax,4'eq}$ = $J_{3',4'ax}$ = 12.2 Hz, H-4′ ax), 3.71 (1H, brd, H-1b), 3.67 (1H, dd, H-5b). ^{13}C NMR (CD_2Cl_2) δ: 137.42, 137.17, 136.46 ($4C_{ipso}$), 129.82–126.65 ($20C_{Ar}$), 101.76 (*C*HPh), 82.64 (C-3), 81.74 (C-2), 76.63 (C-2′), 73.92, 73.84, 72.64 (3*C*H$_2$Ph), 69.54 (C-4′), 66.56 (C-4), 66.40 (C-3′), 64.00 (C-5), 51.51 (C-1′),

47.42 (C-1). Anal. calcd. for $C_{37}H_{40}O_9S_2$: C 64.14, H 5.82; found: C 64.45, H 5.85.

1,4-Dideoxy-1,4-[[(2′S,3′S)-2′,4′-dihydroxy-3′-(sulfooxy)butyl]-episulfoniumylidene]-D-xylitol inner salt (8)

The protected compound **16** (150 mg, 0.22 mmol) was dissolved in AcOH–H_2O (4:1, 3 mL) and stirred with palladium hydroxide catalyst on carbon (100 mg) under H_2 (52 psi). After 72 h, the reaction mixture was filtered through a pad of Celite, which was subsequently washed with MeOH. The combined filtrates were concentrated and the residue was purified by column chromatography ($CHCl_3$–MeOH–H_2O, 7:3:1) to give an amorphous solid (36 mg, 50%). $[\alpha]_D^{22}$ +20° (*c* 1.2, MeOH). HR-MS calcd. for $C_9H_{18}O_9S_2$ (M + H): 335.0471; found: 335.0471. ^{1}H NMR (CD_3OD) δ: 4.64–4.59 (1H, m, H-2), 4.55 (1H, dd, $J_{2,3} = J_{3,4}$ = 2.9 Hz, H-3), 4.37 (1H, ddd, H-4), 4.35 (1H, ddd, $J_{1'a,2'}$ = 3.5 Hz, H-2′), 4.25 (1H, ddd, $J_{2',3'}$ = 7.2, $J_{3',4'a} = J_{3',4'b}$ = 3.4 Hz, H-3′), 4.16 (1H, dd, $J_{5a,5b}$ = 11.7, $J_{4,5a}$ = 6.0 Hz, H-5a), 4.07 (1H, dd, $J_{4,5b}$ = 9.0 Hz, H-5b), 3.95 (1H, dd, $J_{1'a,1'b}$ = 13.4 Hz, H-1′ a) 3.93 (1H, dd, H-4′ a), 3.91 (1H, dd, H-1a) 3.88 (1H, dd, $J_{1'b,2'}$ = 8.0 Hz, H-1′ b), 3.81 (1H, dd, $J_{4'b,4'a}$ = 12.1 Hz, H-4′ b), 3.58 (1H, brd, $J_{1b,1a}$ = 13.7 Hz, H-1b). ^{13}C NMR (CD_3OD) δ: 81.05 (C-3′), 79.55 (C-2), 78.56 (C-3), 71.69 (C-4), 67.71 (C-2′), 61.66 (C-4′), 58.92 (C-5), 52.60 (C-1′), 49.26 (C-1).

1′-((1,4-Dideoxy-1,4-imino-D-xylitol)-4-N-ammonium)-2′,4′-O-benzylidene-1′-deoxy-L-erythritol-3′-sulfate (17)

A mixture of 1,4-dideoxy-1,4-imino-D-arabinitol (**15**) (100 mg, 0.74 mmol) and 2,4-*O*-benzylidene-L-erythritol-1,3-cyclic sulfate (**10**) (240 mg, 1.2 equiv) was dissolved in dry MeOH (0.5 mL) and anhyd K_2CO_3 (15 mg) was added. The mixture was stirred in a sealed tube in an oil bath (60–70°C) overnight. The solvent was removed under reduced pressure, and column chromatography (CH_2Cl_2–MeOH, 5:1) of the crude product gave a white solid (191 mg, 63%) that was recrystallized from methanol; mp 202–204°C, $[\alpha]_D^{22}$ +30° (*c* 0.5, H_2O). ^{1}H NMR (D_2O) δ: 7.73–7.58 (5H, m, Ar), 5.93 (1H, s, C*H*Ph), 4.68 (1H, dd, $J_{4'eq,4'ax}$ = 11.0, $J_{3',4'eq}$ = 5.5 Hz, H-4′eq), 4.54 (1H, brt, $J_{2',3'} = J_{1'b,2'}$ = 9.9 Hz, H-2′), 4.50–4.41 (3H, m, H-3, H-3′, H-2), 4.20 (1H, dd, $J_{5a,5b}$ = 12.6, $J_{4,5a}$ = 5.5 Hz, H-5a), 4.18–4.12 (2H, m, H-1′a, H-5b), 4.10 (1H, dd, $J_{3',4'ax}$ = 11.0 Hz, H-4′ax), 4.11–4.01 (2H, m, H-1a, H-4), 3.66 (1H, br dd, $J_{1'b,1'a}$ = 11.6 Hz, H-1′b), 3.56–3.50 (1H, brd, H-1b). ^{13}C NMR (D_2O) δ: 138.50 (C_{ipso}), 132.45 (C_{para}), 131.26 (2C) and 128.62 (2C) (C_{ortho} and C_{meta}), 103.38 (*C*HPh), 78.08 (C-2′), 77.38 (C-3), 76.70 (C-2), 73.31 (C-4), 70.77 (C-4′), 70.41 (C-3′), 63.18 (C-1), 60.01 (C-1′), 59.55 (C-5). Anal. calcd. for $C_{16}H_{22}O_9SN$: C 47.51, H 5.49, N, 3.47; found: C 47.29, H 5.80, N 3.22.

1′-((1,4-Dideoxy-1,4-imino-D-xylitol)-4-N-ammonium)-1′-deoxy-L-erythritol-3′-sulfate (9)

The protected compound **17** (75 mg, 0.18 mmol) was dissolved in AcOH–H_2O (4:1, 5 mL) and stirred with Pd/C (30 mg) under H_2. After 16 h, the reaction mixture was filtered through a pad of Celite, which was subsequently washed with MeOH. The combined filtrates were concentrated and the residue was purified by column chromatography ($CHCl_3$–MeOH–H_2O, 7:3:1) to give an amorphous solid (49 mg, 83%). $[\alpha]_D^{22}$ –5.3° (c 0.8, H_2O). HR-FAB-MS calcd. for $C_9H_{18}O_9SN$ (M + H): 318.0859; found: 318.0859. ^{1}H NMR (D_2O) δ: 4.59–4.40 (4H, m, H-3, H-2, H-2′, H-3′), 4.27–4.17 (2H, m, H-5a, H-5b), 4.18–4.06 (2H, m, H-1a, H-4), 4.11 (1H, dd, $J_{4'a,4'b}$ = 12.6, $J_{3',4'a}$ = 2.0 Hz, H-4′a), 4.02 (1H, dd, $J_{3',4'b}$ = 3.3 Hz, H-4′b), 4.11–3.95 (1H, m, H-1′a), 3.68–3.57 (1H, m, H-1b), 3.57–3.45 (1H, m, H-1′b). ^{13}C NMR (D_2O) δ: 82.52 (C-3′), 77.46 (C-3), 76.56 (C-2′), 73.20 (C-4), 68.42 (C-2), 63.09 (C-1), 62.38 (C-1′), 61.93 (C-4′), 59.38 (C-5).

Acknowledgments

We are grateful to Sidsel Ehlers for technical assistance with the glucoamylase assays. We also thank the Natural Sciences and Engineering Research Council of Canada (NSERC) for financial support and the Michael Smith Foundation for Health Research for a trainee fellowship (to AG).

Synthesis of conjugates of L-fucose and *ortho*-carborane as potential agents for boron neutron capture therapy

Prakriti Basak and Todd L. Lowary

Abstract: The synthesis of three potential boron neutron capture therapy agents (**6**–**8**) is reported. The compounds synthesized are comprised of *ortho*-carborane covalently attached to L-fucose via C-6. Incorporation of the carborane moiety was achieved either through the reaction of an L-fucose-derived alkyne with decaborane or by the coupling of a 6-amino-L-galactopyranose derivative with carborane carboxylic acid chloride (**18**).

Key words: L-fucose, fucosyltransferase, boron neutron capture therapy, *ortho*-carborane.

Résumé : On a réalisé la synthèse de trois agents (**6**–**8**) pouvant éventuellement être utilisés dans la thérapie par capture de neutrons du bore. Les composés synthétisés comportent de l'*ortho*-carborane lié de façon covalente à du L-fucose par l'intermédiaire de C-6. L'incorporation de la portion carborane a été réalisée par la réaction du décaborane avec un alcyne dérivé du L-fucose ou par le couplage d'un dérivé 6-amino-L-galactopyranose avec le chlorure de l'acide carboxylique du carborane (**18**).

Mots clés : L-fucose, fucosyltransférase, thérapie par capture de neutrons du bore, *ortho*-carborane.

Introduction

The aberrant expression of cell surface oligosaccharides is among the many features that differentiate cancer cells from their healthy counterparts. Although the importance of changes in cell surface glycosylation in disease progression is not completely understood, it has been suggested that these abnormal glycans are involved in the metastasis of various cancers (1–3). The expression of these oligosaccharides is controlled by the activities of cellular glycosyltransferases and glycosidases, and it is known that in many cancerous cells the levels of these enzymes are altered in comparison to non-neoplastic cells (1–3).

In particular, tumor cells often show an increase in fucosylation of cell surface oligosaccharides due to elevated levels of fucosyltransferases (4, 5). These enzymes catalyze the transfer of fucose from guanosine diphosphate β-L-fucose (GDP-Fuc (**1**), Fig. 1) to an oligosaccharide acceptor (e.g., **2**) to give an elongated glycan (e.g., **3**). Given the increased levels of these enzymes in some cancer cells, it should be possible to deliver anti-cancer agents to tumor cells via the attachment of the drug to GDP-Fuc. In this paper we report our initial investigations directed toward the identification of such compounds.

Received 1 August 2001. Published on the NRC Research Press Web site at http://canjchem.nrc.ca on 18 July 2002.

The targets chosen were conjugates of L-fucose (**4**, Fig. 2) and *ortho*-carborane (**5**). *Ortho*-carborane, an icosahedral cage compound containing 10 boron atoms and two carbon atoms, is a substrate for boron neutron capture therapy (BNCT) of tumors. Initially developed in the 1950s, BNCT has attracted increasing attention in recent years (6, 7). The physical basis for the treatment is the capture reaction of thermal neutrons by ^{10}B atoms according to one of the two pathways shown in Fig. 3. The high energy particles produced during this reaction are transient species with ionization paths of approximately 10 μm. As a result, a large amount of energy is deposited within a small distance of the capture event. When these reactions occur within living cells, the lethal effect of these particles is limited to the cell itself. Consequently, if a high concentration of boron atoms can be selectively targeted to cancerous tissues, only these cells will be killed upon neutron capture. Carboranes are ideal substrates for BNCT not only because they possess a relatively large number of boron atoms per molecule, but also because there are efficient methods available for their attachment to organic molecules.

Previous reports have described the synthesis of carboranes covalently attached to a variety of biologically relevant organic molecules, including amino acids and peptides (8–10), nucleosides (11), and polyamines (12). Syntheses of glycosylated carboranes have also been carried out (13–18). To date, most of the previously reported glycoconjugates of this type have the carborane group attached to the sugar at the anomeric center. Such a linkage was unsuitable for our purposes and in designing the targets to be synthesized we chose to attach the boron cage to the C-6 methyl group of L-fucose. This choice was made based on previous work by Hindsgaul and co-workers (19, 20), which demonstrated that fucosyltransferases are tolerant of a range of

Fig. 1. Fucosyltransferase catalyzed reaction.

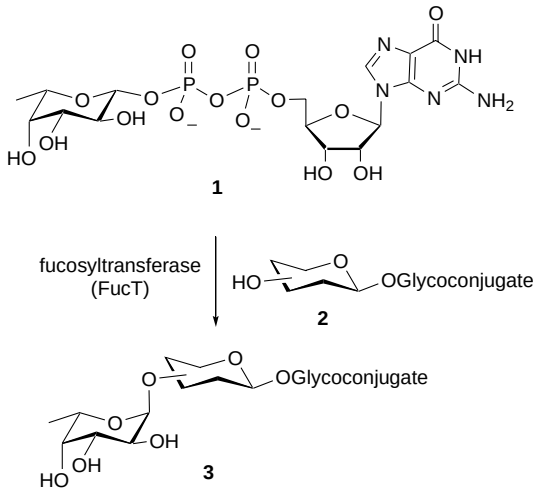

Fig. 2. Target Molecules.

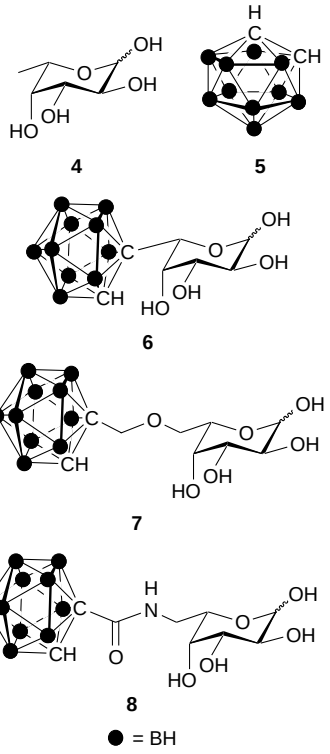
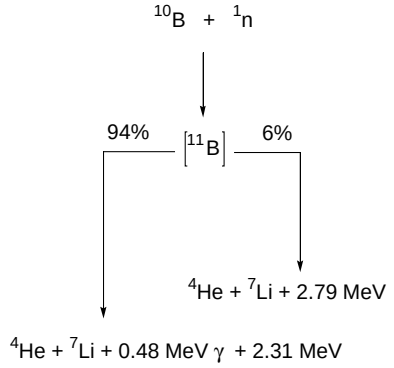


substituents at this position. These investigations showed that GDP-Fuc remains a substrate for fucosyltransferases even when groups as large as a trisaccharide are appended to C-6. We reasoned, therefore, that an *ortho*-carborane group attached at this position would also be tolerated by these enzymes; the volume of the carborane cage is about 50% larger than that of a phenyl group rotating about its C-1-C-4 axis (21). In this paper we describe the synthesis of the *ortho*-carboranyl pyranose[2] derivatives **6**–**8** (Fig. 2), which are precursors to the GDP-Fuc analogs that are expected to be fucosyltransferase substrates.

Fig. 3. Nuclear fission reactions that occur upon capture of a neutron (^{1}n) by a ^{10}B atom.



Results and discussion

In designing synthetic routes to **6**–**8**, the choice of protecting groups for the carbohydrate hydroxyls was important. The *ortho*-carborane moiety is base-labile but stable to acid. Although previous syntheses of carboranyl glycosides have employed acetyl protection of the sugar hydroxyl groups, in our hands the use of ester protecting groups gave poor yields of the products upon deprotection. We chose to avoid this problem altogether by using isopropylidene acetals that can be removed in high yield under conditions to which the carborane cage is stable.

The preparation of **6** is shown in Scheme 1. The known alcohol **9** (22) was oxidized with pyridinium chlorochromate to afford aldehyde **10**. Following filtration of the reaction mixture through a pad of silica gel to remove the oxidation reagent, the crude product (obtained in 77% yield) was converted into the dibromo-alkene **11** upon reaction with carbon tetrabromide and triphenylphosphine. The product was obtained in 70% yield. Treatment of **11** with *n*-butyllithium provided alkyne **12** and olefin **13** in 63% and 15% yields, respectively. Incorporation of the *ortho*-carborane moiety into **12** was achieved under standard conditions by reaction with decaborane and acetonitrile in toluene at 80°C, which produced **14** in 58% yield. The presence of the carborane moiety in **14** was demonstrated by the absence of the alkyne hydrogen in the ^{1}H NMR spectrum and the presence of the carborane CH resonance at 4.25 ppm. A broad multiplet from 1.7 to 2.9 ppm, arising from the BH protons, was also present. Furthermore, resonances characteristic of the *ortho*-carborane group were apparent in the ^{11}B NMR spectrum of **14**. Hydrolysis of the acetal protecting groups in **14** was accomplished by reaction with a 9:1 trifluoroacetic acid – water mixture, affording **6** in 91% yield. Inspection of the NMR spectrum of this compound (taken in CD_3OD) showed that all possible ring forms were present, with the pyranose isomers being favored (the α_{pyr}:β_{pyr}:α_{fur}:β_{fur} ratio was 2.9:3.4:1.0:1.2). Presumably, steric congestion between the ring and the relatively bulky *ortho*-carborane moiety destabilizes the pyranose form. Appreciable amounts of the normally minor furanose forms, in which the carborane is further removed from the ring, are therefore populated at equilibrium.

[2] Compound **6** was prepared as a mixture of furanose and pyranose isomers.

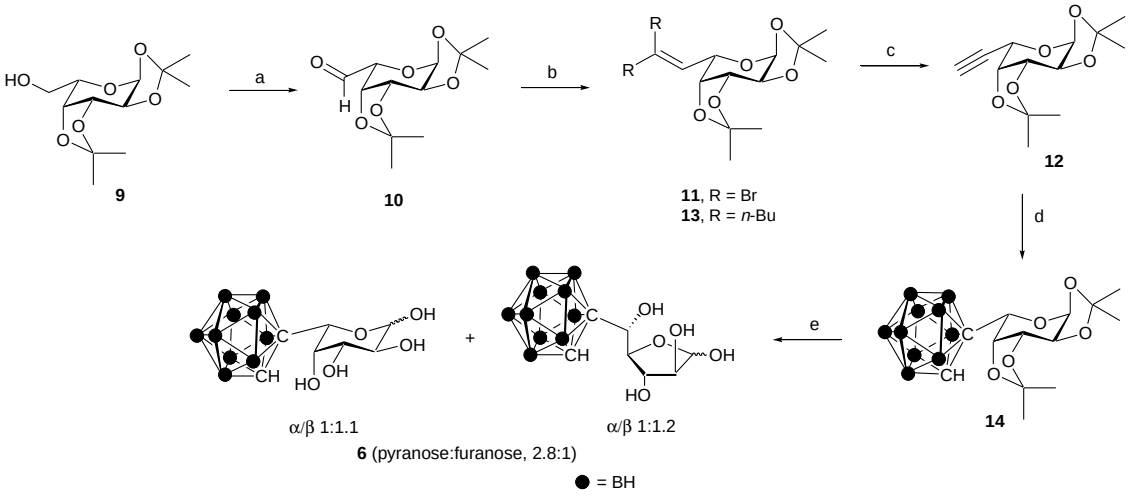
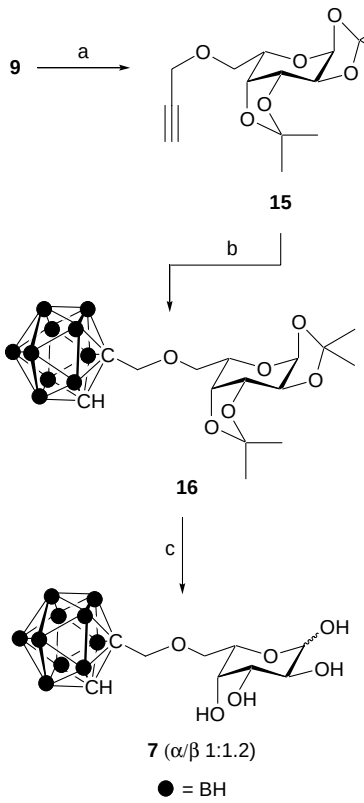
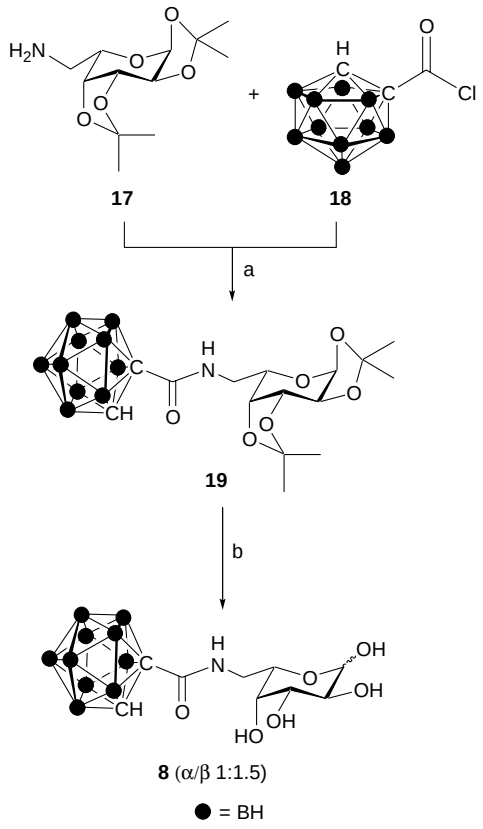
Scheme 1. (*a*) PCC, NaOAc, CH_2Cl_2, rt, 77%; (*b*) CBr_4, PPh_3, CH_2Cl_2, 0°C → rt, 70%; (*c*) BuLi, THF, –78 → 0°C, **12**: 63%, **13**: 15%; (*d*) $B_{10}H_{14}$, CH_3CN, 80°C, reflux, 58%; (*e*) TFA:H_2O (9:1), 0°C, 91%.



Scheme 2. (*a*) Propargyl bromide, *n*-Bu_4NI, NaH, THF, rt, 70%; (*b*) $B_{10}H_{14}$, CH_3CN, toluene, 80°C, 80%; (*c*) TFA:H_2O (9:1), 0°C, 90%.



Scheme 3. (*a*) Et_3N, CH_2Cl_2, rt, 92%; (*b*) TFA:H_2O (9:1), 0°C, 93%.



The preparation of **7** and **8** are outlined in Schemes 2 and 3. The synthesis of **7** (Scheme 2) began with alcohol **9** (22), which was alkylated (in 70% yield) with propargyl bromide. The product of this reaction, alkyne **15**, was then reacted with decaborane as was done for the preparation of **14**, to provide **16** in 80% yield. Deprotection by acid hydrolysis proceeded without incident, affording **7** in 90% yield. The preparation of **8** (Scheme 3) began with the known amine **17** (22), which was acylated with **18** (23) in excellent (92%) yield. Cleavage of the protecting groups from the product (**19**) was done as described for the previous two targets providing **8** in 93% yield. In contrast to **6**, both **7** and **8** adopted mostly the pyranose form in CD_3OD, as might be expected in that the carborane moiety is now further away from the carbohydrate ring. Only trace amounts of the furanose forms were detected by ^1H NMR.

Experimental

General Methods

1,2:3,4-Di-*O*-isopropylidene-α-L-galactopyranose (**9**) (22), 6-amino-6-deoxy-1,2:3,4-di-*O*-isopropylidene-α-L-galactopyranose (**17**) (22), and 1,2-dicarba-*ortho*-carboranyl acyl chloride (**18**) (23) were prepared as described previously. Decaborane was purified by sublimation. All reaction solvents were distilled from the appropriate drying agents before use. Reactions were carried out at room temperature under argon unless otherwise indicated. Solvents were evaporated under reduced pressure and below 40°C (bath). Column chromatography was performed on silica gel (43–75 μM). Thin layer chromatography was carried out on Merck silica gel 60 F_{254} plates. Plates were visualized by dipping them either in 10% (w/w) H_2SO_4 in ethanol or 0.5% (w/v) $PdCl_2$ in 10% concentrated HCl–CH_3OH (for boron-containing compounds) and then heating. Melting points are uncorrected. ^{1}H NMR spectra were recorded at 400 or 500 MHz, and chemical shifts are referenced to either TMS (δ: 0.0, $CDCl_3$) or CH_3OD (δ: 4.87, CD_3OD). ^{13}C NMR spectra were recorded at 100 or 125 MHz and ^{13}C chemical shifts are referenced to $CDCl_3$ (77.00, $CDCl_3$), or CD_3OD (49.15, CD_3OD). In the NMR data reported below, the carborane carbons are designated C_1' and C_2', with the former being the attachment site of the carbohydrate. All samples containing boron showed the characteristic spectral features of the *ortho*-carborane moiety in their ^{11}B NMR spectrum. Elemental analyses were performed in-house. Electrospray mass spectra were recorded on samples suspended in THF or CH_3OH.

*1,2:3,4-Di-*O*-isopropylidene-α-L-galacto-hexodialdo-1,5-pyranose (10)*

A suspension of pyridinium chlorochromate (650 mg, 3.0 mmol), sodium acetate (500 mg, 6.0 mmol) and 4 Å molecular sieves (1.33 g) in CH_2Cl_2 (9 mL) was stirred for 1 h. To this mixture was added, drop-wise, a solution of 1,2:3,4-di-*O*-isopropylidene-α-L-galactopyranose (22) (**9**, 264 mg, 1.0 mmol) in dry CH_2Cl_2 (4.5 mL). The reaction mixture was stirred for 2 h before a 1:1 mixture of hexanes and ether (25 mL) was added. The solution was filtered through a bed of silica and the filtrate was concentrated to give the crude aldehyde **10** as an oil (199 mg, 77%), which was carried on to the next step without further purification: ^{1}H NMR ($CDCl_3$) δ: 9.54 (s, 1H, H-6), 5.60 (d, 1H, $J_{1,2}$ = 4.9 Hz, H-1), 4.58 (dd, 1H, $J_{2,3}$ = 2.4 Hz, $J_{3,4}$ = 7.8 Hz, H-3), 4.53 (dd, 1H, $J_{3,4}$ = 7.8 Hz, $J_{4,5}$ = 1.8 Hz, H-4), 4.32 (dd, 1H, $J_{1,2}$ = 4.9 Hz, $J_{2,3}$ = 2.4 Hz, H-2), 4.13 (d, 1H, $J_{4,5}$ = 1.8 Hz, H-5), 1.44, 1.36, 1.28, 1.26 (s, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 199.1 (C=O), 108.0, 109.0 ($C(CH_3)_2$), 95.2 (C-1), 72.7, 70.7, 69.5, 69.4 (C-2, C-3, C-4, C-5), 25.0, 24.8, 23.8, 23.2 (CH_3).

*7,7-Dibromo-6,7-dideoxy-1,2:3,4-di-*O*-isopropylidene-α-L-galacto-hept-6-eno-pyranose (11)*

A solution of triphenylphosphine (1.53 g, 5.9 mmol) and carbon tetrabromide (0.97 g, 2.9 mmol) in dry CH_2Cl_2 (12 mL) was cooled to 0°C. To this solution was added, dropwise, a solution of **10** (190 mg, 0.73 mmol) in dry CH_2Cl_2 (6 mL). The reaction mixture was allowed to warm to room temperature and was stirred for 5 h before water (18 mL) was added. The organic layer was separated and the aqueous layer was extracted with CH_2Cl_2 (2 × 25 mL). The combined organic layers were washed with a saturated aqueous solution of $NaHCO_3$, water, and finally brine. The organic layer was then dried ($MgSO_4$) and concentrated. Chromatography (hexanes–EtOAc, 9:1 → 7:1) of the residue gave alkene **11** as an unstable white solid (210 mg, 70%): $[\alpha]_D^{25}$ + 78.9 (*c* 1.0, $CHCl_3$). R_f = 0.5 (hexanes–EtOAc, 7:1). ESI-MS calcd. for $C_{13}H_{18}Br_2O_5$ (M + Na): 436.9393; found: 436.9375. ^{1}H NMR ($CDCl_3$) δ: 6.63 (d, 1H, $J_{5,6}$ = 8.1 Hz, H-6), 5.52 (d, 1H, $J_{1,2}$ = 5.0 Hz, H-1), 4.63 (dd, 1H, $J_{2,3}$ = 2.5, $J_{3,4}$ = 7.8 Hz, H-3), 4.52 (dd, 1H, $J_{4,5}$ = 2.0 Hz, $J_{5,6}$ = 8.1 Hz, H-5), 4.33 (dd, 1H, $J_{1,2}$ = 5.0 Hz, $J_{2,3}$ = 2.5 Hz, H-2), 4.25 (dd, 1H, $J_{3,4}$ = 7.8 Hz, $J_{4,5}$ = 2.0 Hz, H-4), 1.60, 1.47, 1.34, 1.34 (s, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 135.0 (*C*=CBr_2), 109.4, 110.1 ($C(CH_3)_2$), 96.8 (C-1), 93.0 (C=*C*Br_2), 72.3, 71.2, 70.6, 69.7 (C-2, C-3, C-4, C-5), 26.6, 26.3, 25.4, 24.8 (CH_3).

*6,7-Dideoxy-1,2:3,4-di-*O*-isopropylidene-α-L-galacto-hept-6-ynopyranose (12)*

A solution of **11** (190 mg, 0.46 mmol) in dry THF (2.6 mL) was cooled to –78°C. *n*-BuLi (1.6 M in hexanes, 1.01 mL, 1.62 mmol) was added to the solution dropwise and the mixture was stirred for 1 h at –78°C, then 1 h at 0°C, and finally at room temperature for 3 h. The reaction mixture was treated with a saturated aqueous solution of $NaHCO_3$ (5 mL) and then ether (5 mL) was added. The aqueous and organic layers were separated and then the aqueous layer was extracted with ether (3 × 5 mL). The combined organic layers were washed with water, brine, and then dried ($MgSO_4$), and concentrated. Alkyne **12** was purified by chromatography (hexanes–EtOAc, 7:1 → 5:1) to yield the product as an oil (74 mg, 63%). $[\alpha]_D^{25}$ +126.8 (*c* 0.5, $CHCl_3$). R_f = 0.4 (hexanes–EtOAc, 4:1). ESI-MS calcd. for $C_{13}H_{18}O_5$ (M + Na): 277.1046; found: 277.1069. ^{1}H NMR ($CDCl_3$) δ: 5.49 (d, 1H, $J_{1,2}$ = 5.0 Hz, H-1), 4.56 (dd, 1H, $J_{2,3}$ = 2.5 Hz, $J_{3,4}$ = 7.7 Hz, H-3), 4.54 (dd, 1H, $J_{4,5}$ = 2.0 Hz, $J_{5,7}$ = 2.4 Hz, H-5), 4.25 (dd, 1H, $J_{1,2}$ = 5.0 Hz, $J_{2,3}$ = 2.5 Hz, H-2), 4.22 (dd, 1H, $J_{3,4}$ = 7.7, $J_{4,5}$ = 2.0 Hz, H-4), 2.47 (d, 1H, $J_{5,7}$ = 2.4 Hz, H–7), 1.48, 1.47, 1.32, 1.27 (s, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 110.3, 109.3 ($C(CH_3)_2$), 96.8 (C-1), 79.2 (internal alkyne C), 74.9, 73.0, 71.0, 70.5 (C-2, C-3, C-4, C-5), 60.4 (terminal alkyne C), 26.5, 26.3, 25.2, 24.8 (CH_3).

*7,7-Di-*n*-butyl-6,7-dideoxy-1,2:3,4-di-*O*-isopropylidene-α-L-galacto-hept-6-eno-pyranose (13)*

This compound (25 mg, 15%) was isolated as a by-product in the formation of **12**: $[\alpha]_D^{20}$ +66.7 (*c* 1.0, $CHCl_3$). R_f = 0.4 (hexanes–EtOAc 9:1). ESI-MS calcd. for $C_{21}H_{36}O_5$ (M + Na): 391.2455; found: 391.2428. ^{1}H NMR ($CDCl_3$) δ: 5.56 (d, 1H, $J_{1,2}$ = 5.2 Hz, H-1), 5.43 (d, 1H, $J_{5,6}$ = 8.7 Hz, H-6), 4.59 (dd, 1H, $J_{3,4}$ = 7.9 Hz, $J_{2,3}$ = 2.3 Hz, H-3), 4.51 (dd, 1H, $J_{5,6}$ = 8.7 Hz, $J_{4,5}$ = 1.8 Hz, H-5), 4.30 (dd, 1H, $J_{1,2}$ = 5.2 Hz, $J_{2,3}$ = 2.3 Hz, H-2), 4.12 (dd, 1H, $J_{3,4}$ = 7.9 Hz, $J_{4,5}$ = 1.8 Hz, H-4), 2.12–2.02 (m, 4H), 1.57, 1.49, (s, 3H, $C(CH_3)_2$), 1.46–1.37 (m, 4H, butyl CH_2), 1.35, 1.34 (s, 3H, $C(CH_3)_2$), 1.34–1.29 (m, 8H, butyl CH_2), 0.93–0.87 (m, 6H, butyl CH_3). ^{13}C NMR ($CDCl_3$) δ: 147.3 (C=*C*Bu_2), 119.6 (*C*=CBu_2), 109.4, 108.5 (2 $C(CH_3)_2$), 97.2 (C-1), 74.1, 71.4, 70.7, 64.5 (C-2, C-3, C-4, C-5), 37.2, 31.5, 31.5, 26.5,

26.5, 25.3, 24.8, 23.5, 23.1, 14.6, 14.4 (butyl CH_2 and CH_3 groups, and $C(CH_3)_2$).

*5-(1′,2′-Dicarba-*ortho*-carboranyl)-1,2:3,4-di-*O*-isopropylidene-α-L-arabino-pyranoside (14)*

A solution of **12** (48 mg, 0.19 mmol) and decaborane (58 mg, 0.48 mmol) in dry toluene (5.4 mL) was treated with dry acetonitrile (136 μL) and heated at 60°C until the solution became clear (15 min). The solution was then heated to 80°C and then stirred for 18 h at which point CH_3OH (2 mL) was added. After heating for a further 30 min, the mixture was cooled and concentrated. Chromatography (hexanes–EtOAc, 9:1 → 7:1) gave **14** as a white solid (40 mg, 58%); mp 84 to 85°C. $[\alpha]_D^{17}$ +92.2 (*c* 1.0, $CHCl_3$). R_f = 0.4 (hexanes–EtOAc, 7:1). ESI-MS calcd. for $C_{13}H_{28}B_{10}O_5$ (M + Na): 395.2832; found: 395.2854. ^{1}H NMR ($CDCl_3$) δ: 5.49 (d, 1H, $J_{1,2}$ = 4.8 Hz, H-1), 4.60 (dd, 1H, $J_{2,3}$ = 2.3 Hz, $J_{3,4}$ = 7.9 Hz, Hz, H-3), 4.37 (dd, 1H, $J_{3,4}$ = 7.9 Hz, $J_{4,5}$ = 2.4 Hz, H-4), 4.28–4.26 (m, 3H, carborane CH, H-5, H-2), 2.96–1.77 (br m, 10H, carborane BH), 1.51, 1.44, 1.33, 1.32 (4, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 111.6, 110.8 ($C(CH_3)_2$), 96.8 (C-1), 75.2 (C-1′), 73.1, 72.8 72.3, 69.7, (C-2, C-3, C-4, C-5), 60.1 (C-2′), 27.6, 27.1, 26.2, 25.7 (CH_3).

*5-(1′,2′-Dicarba-*ortho*-carboranyl)-L-arabinose (6)*

Compound **14** (30 mg, 0.07 mmol) was dissolved in trifluoroacetic acid–H_2O (9:1, 1 mL), stirred for 30 min at 0°C and then diluted with water and concentrated. The product was purified by chromatography (CH_2Cl_2–MeOH, 14:1 → 9:1) to afford **6** (20 mg, 91%) as a white solid. Both pyranose and furanose forms were present (ratio α_{pyr}:β_{pyr}:α_{fur}:β_{fur}, 2.9:3.4:1.0:1.2). $[\alpha]_D^{18}$ +1.9 (*c* 1.0, MeOH). ESI-MS calcd. for $C_7H_{20}B_{10}O_5$ (2M + Na): 607.4520; found: 607.4519. Partial ^{1}H NMR (500 MHz, CD_3OD) δ: 5.19 (d, $J_{1,2}$ 4.5 Hz, H-1 (α_{fur})), 5.16 (d, $J_{1,2}$ = 3.9 Hz, H-1 (α_{pyr})), 5.14 (d, $J_{1,2}$ = 2.9 Hz, H-1 (β_{fur})), 4.46 (d, $J_{1,2}$ = 7.4 Hz, H-1 (β_{pyr})). Partial ^{13}C NMR (125 MHz, CD_3OD) δ: 104.2 (C-1 (α_{fur})), 99.8 (C-1 (α_{pyr})), 97.2 (C-1 (β_{fur})), 94.9 (C-1 (β_{pyr})).

*1,2:3,4-Di-*O*-isopropylidene-6-*O*-propynyl-α-L-galactopyranose (15)*

A solution of alcohol **9** (22) (290 mg, 1.13 mmol) in dry THF (3.5 mL) was cooled to 0°C and NaH (60% dispersion in mineral oil, 50 mg, 1.36 mmol) was added. The reaction mixture was stirred at 0°C for 30 min at which point tetrabutylammonium iodide (8 mg, 0.07 mmol) and propargyl bromide (320 mg, 2.83 mmol) were added in succession. The reaction mixture was then allowed to warm to room temperature and was stirred overnight before ice water (0.5 mL) and ether (5 mL) were added. After separating the two layers, the aqueous phase was extracted with ether (3 × 5 mL). The combined organic extracts were dried ($MgSO_4$), concentrated, and the product purified by chromatography (hexanes–EtOAc, 9:1 → 7:1) to afford **15** (240 mg, 70%) as a white solid; mp 61°C. $[\alpha]_D^{25}$ +75.4 (*c* 1.0, $CHCl_3$). R_f = 0.36 (hexanes–EtOAc, 7:1). ESI-MS calcd. for $C_{15}H_{22}O_6$ (M + Na): 321.1309; found: 321.1290. ^{1}H NMR ($CDCl_3$) δ: 5.55 (d, 1H, $J_{1,2}$ = 5.0 Hz, H-1), 4.61 (dd, 1H, $J_{2,3}$ = 2.4 Hz, $J_{3,4}$ = 7.9 Hz, H-3), 4.32 (dd, 1H, $J_{1,2}$ = 5.0 Hz, $J_{2,3}$ = 2.4 Hz, H-2), 4.29–4.21 (m, 3H, H-4, 2 x propargyl CH_2), 4.00 (ddd, 1H, $J_{4,5}$ = 1.7 Hz, $J_{5,6}$ = 7.1 Hz, $J_{5,6'}$ = 5.3 Hz, H-5), 3.78 (dd, 1H, $J_{5,6'}$ = 5.3 Hz, $J_{6,6'}$ = 10.1 Hz, H-6′), 3.67 (dd, 1H, $J_{5,6}$ = 7.1 Hz, $J_{6,6'}$ = 10.1 Hz, H-6), 2.43 (d, 1H, ^3J = 2.4 Hz, alkyne H), 1.55, 1.46, 1.35, 1.33 (s, 3 H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 109.8, 109.0 ($C(CH_3)_2$), 96.8 (C-1), 80.1 (internal alkyne C), 75.0 (propargylic CH_2), 71.6, 71.1, 70.9, 69.1 (C-2, C-3, C-4, C-5), 67.2 (terminal alkyne C), 58.9 (C-6), 26.5, 26.4, 25.5, 24.9 (CH_3).

*6-O-(1′,2′-Dicarba-*ortho*-carboranyl) methyl-1,2:3,4-di-O-isopropylidene-α-L-galactopyranose (16)*

Reaction of decaborane (210 mg, 1.75 mmol), dry acetonitrile (1.25 mL) and propargyl ether **15** (210 mg, 0.7 mmol) in dry toluene (20 mL) as described for the synthesis of **14** (following purification by chromatography (hexanes–EtOAc, 4:1)) gave **16** (230 mg, 80%) as an oil. $[\alpha]_D^{17}$ +74.8 (*c* 0.1, $CHCl_3$). R_f = 0.5 (hexanes–EtOAc, 4:1). ESI-MS calcd. for $C_{15}H_{32}B_{10}O_6$ (M + Na): 439.3094; found: 439.3100. ^{1}H NMR ($CDCl_3$) δ: 5.50 (d, 1H, $J_{1,2}$ = 5.0 Hz, H-1), 4.60 (dd, 1H, $J_{2,3}$ = 2.4 Hz, $J_{3,4}$ = 7.9 Hz, H-3), 4.31 (dd, 1H, $J_{1,2}$ = 5.0 Hz, $J_{2,3}$ = 2.4 Hz, H-2), 4.15 (dd, 1H, $J_{3,4}$ = 7.9 Hz, $J_{4,5}$ = 1.9 Hz, H-4), 4.10 (br s, carborane CH), 3.94–3.89 (m, 3H, H-5, -CH_2OCH_2-carborane), 3.70 (dd, 1H, $J_{5,6'}$ = 4.7 Hz, $J_{6,6'}$ = 10.8 Hz, H-6′), 3.61 (dd, 1H, $J_{5,6}$ = 7.3 Hz, $J_{6,6'}$ = 10.8 Hz, H-6), 2.38–2.00 (br m, 10H, carborane BH), 1.53, 1.43, 1.33, 1.23 (s, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 111.6, 110.8 ($C(CH_3)_2$), 96.8 (C-1), 73.4 (C-1′), 73.0 (-CH_2OCH_2-carborane), 71.4, 71.4, 71.0, 70.8, 67.6 (C-2, C-3, C-4, C-5, C-2′), 58.1 (C-6), 26.4, 26.3, 25.3, 24.7 (CH_3).

*6-O-(1′,2′-Dicarba-*ortho*-carboranyl) methyl-L-galactose (7)*

Compound **16** (30 mg, 0.07 mmol) was deprotected as described for the preparation of **6** using trifluoroacetic acid and water (9:1, 1 mL). The product was purified by chromatography (CH_2Cl_2–CH_3OH, 14:1 → 12:1) to afford **7** (21 mg, 90%) as a white solid. The α_{pyr}:β_{pyr} ratio was 1:1.2 and only trace amounts of the furanose form were detected by NMR. $[\alpha]_D^{17}$ −41.9 (*c* 1.0, MeOH). ESI-MS calcd. for $C_9H_{24}B_{10}O_6$ (M + Na): 359.2468; found 359.2451. Partial ^{1}H NMR (500 MHz, CD_3OD) δ: 5.14 (d, $J_{1,2}$ = 3.5 Hz, H-1 (α_{pyr})) 4.44 (d, $J_{1,2}$ = 6.9 Hz, H-1 (β_{pyr})). Partial ^{13}C NMR (125 MHz, CD_3OD) δ: 99.1 (C-1 (β_{pyr})), 94.6 (C-1 (α_{pyr})).

*6-N-6-Amino-(1′,2′-dicarba-*ortho*-carboranyl carbonyl)-6-deoxy-1,2:3,4-di-*O*-isopropylidene-α-L-galactopyranose (19)*

1′,2′-Dicarba-*ortho*-carboranyl acyl chloride **18** (23) (75 mg, 0.36 mmol) was dissolved in dry CH_2Cl_2 (1.3 mL). Triethylamine (36 mg, 0.36 mmol) was added which produced a slurry. To this was added, dropwise, a solution of **17** (22) (74 mg, 0.29 mmol) in dry CH_2Cl_2 (650 μL). The reaction mixture gradually became clear and, after stirring for 1 h, it was diluted with CH_2Cl_2 (3 mL) and ice water (5 mL) was added. After stirring for 30 min, the two layers were separated and the aqueous layer was extracted with CH_2Cl_2 (2 × 5 mL). The combined organic layers were washed with 0.01 M HCl, a saturated aqueous solution of $NaHCO_3$, water, and brine. The organic layer was then dried ($MgSO_4$), concentrated, and the resulting residue purified by chromatography (hexanes–EtOAc, 5:1) to give **19**, as a white solid (115 mg, 92%); mp 69°C. $[\alpha]_D^{17}$ +16.8 (*c* 1.0, $CHCl_3$). R_f = 0.25 (hexanes–EtOAc, 5:1). ESI-MS calcd. for $C_{15}H_{31}B_{10}O_6$

(M + Na): 452.3047; found: 452.3066. ^{1}H NMR ($CDCl_3$) δ: 6.67 (br t, 1H, $J_{5,NH}$ = 4.6 Hz, NH), 5.51 (d, 1H, $J_{1,2}$ = 4.9 Hz, H-1), 4.61 (dd, 1H, $J_{2,3}$ = 2.4 Hz, $J_{3,4}$ = 7.9 Hz, H-3), 4.31 (dd, 1H, $J_{1,2}$ = 4.9 Hz, $J_{2,3}$ = 2.4 Hz, H-2), 4.28 (br s, carborane CH), 4.19 (dd, 1H, $J_{3,4}$ = 7.9 Hz, $J_{4,5}$ = 1.7 Hz, H-4), 3.86 (ddd, 1H, $J_{4,5}$ = 1.7 Hz, $J_{5,6'}$ = 6.2 Hz, $J_{5,6}$ = 6.1 Hz, H-5), 3.73 (ddd, 1H, $J_{5,6'}$ = 6.2 Hz, $J_{6,6'}$ = 11.3 Hz, $J_{6',NH}$ = 4.6 Hz, H-6′), 3.26 (ddd, 1H, $J_{5,6}$ = 6.1 Hz, $J_{6,6'}$ = 11.3 Hz, $J_{6,NH}$ = 4.6 Hz, H-6), 2.04–1.53 (br m, 10H, carborane BH), 1.48, 1.47, 1.34, 1.34, (s, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 160.1 (C=O), 110.1, 109.3 ($C(CH_3)_2$), 96.6 (C-1), 72.3, 71.2, 71.0, 65.7 (C-2, C-3, C-4, C-5), 60.5 (C-1′), 57.2 (C-2′), 42.2 (C-6), 26.5, 26.3, 25.3, 24.5 (CH_3).

6-N-*6-Amino-(1′,2′-Dicarba*-ortho-*carboranyl carbonyl)-6-deoxy-L-galactose (8)*

Compound **19** (30 mg, 0.07 mmol) was deprotected as described for **6** using trifluoroacetic acid and water (9:1, 1 mL). The product was purified by chromatography (CH_2Cl_2–CH_3OH, 15:1 → 12:1) to afford **8** (22 mg, 93%) as a white solid. The α_{pyr}:β_{pyr} ratio was 1:1.5 and only trace amounts of the furanose form were detected by NMR. $[\alpha]_D^{17}$ –32.9 (*c* 1.0, MeOH). ESI-MS calcd. for $C_9H_{23}B_{10}O_6$ (M + Na): 372.2421; found: 372.2432. Partial ^{1}H NMR (500 MHz, CD_3OD) δ: 5.06 (d, 1H, $J_{1,2}$ = 3.5 Hz, H-1 (α_{pyr})), 4.29 (d, 1H, $J_{1,2}$ = 7.1 Hz, H-1 (β_{pyr})). Partial ^{13}C NMR (125 MHz, CD_3OD) δ: 99.1 (C-1 (β_{pyr})), 94.6 (C-1 (α_{pyr})).

Conclusion

In this paper we have described efficient syntheses of three fucose-*ortho*-carborane derivatives, which can be converted into the corresponding GDP-Fuc analogs in 2 to 3 steps (24, 25). We anticipate, however, that such transformations may not be necessary because **6**–**8** may be substrates for the enzymes involved in the synthesis of **1** via a "salvage pathway" (26). In this pathway, fucose is converted to **1** via fucose 1-phosphate, by the action of two enzymes: L-fucose kinase (27) and GDP-L-fucose pyrophosphorylase (28). In this regard, compounds **7** and **8** may be of more utility than **6**, given the mixture of ring forms present at equilibrium in the latter. The conversion of **6**–**8** into the corresponding GDP analogs is in progress as is the biological evaluation of these compounds.

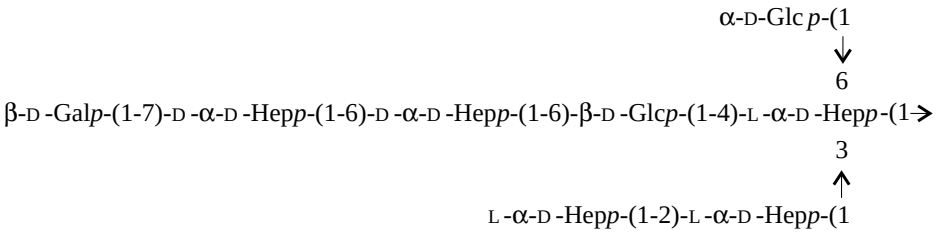
The core oligosaccharide component from *Mannheimia (Pasteurella) haemolytica* serotype A1 lipopolysaccharide contains L-*glycero*-D-*manno*- and D-*glycero*-D-*manno*-heptoses: Analysis of the structure and conformation by high-resolution NMR spectroscopy

Jean-Robert Brisson, Ellen Crawford, Dušan Uhrín, Nam Huan Khieu, Malcolm B. Perry, Wayne B. Severn, and James C. Richards

Abstract: Previous studies from our laboratory have indicated that the lipopolysaccharide (LPS) from *Mannheimia haemolytica* serotype A1 contains both L-*glycero*-D-*manno*-heptose and D-*glycero*-D-*manno*-heptose residues. NMR methods making use of 1D ^{1}H selective excitation and 2D (^{1}H, ^{13}C) and (^{1}H, ^{31}P) heteronuclear experiments were used for the structural determination of the major core oligosaccharide components of the deacylated low-molecular-mass LPS obtained following sequential treatment with anhydrous hydrazine and aq KOH. The core oligosaccharide region was found to be composed of a branched octasaccharide linked to the deacylated lipid A moiety via a 3-deoxy-4-phospho-D-*manno*-oct-2-ulosonate residue having the structure,



Heterogeneity was found to be present at several linkages. NMR methods were devised to distinguish between the diastereomeric forms of the heptose residues. Synthesized monosaccharides of L-D- and D-D-heptose were used as model compounds for analysis of the ^{1}H and ^{13}C NMR chemical shifts and proton coupling constants. Molecular modeling using a Monte Carlo method for conformational analysis of saccharides was used to determine the conformation of the inner core of the oligosaccharide and to establish the stereochemical relationships between the heptoses.

Key words: LPS, NMR, conformation, oligosaccharide, heptose.

Résumé : Des études antérieures effectuées dans notre laboratoire ont indiqué que le lipopolysaccharide (LPS) obtenu à partir de *Mannheimia haemolytica* sérotype A1 contient des résidus de L-*glycéro*-D-*manno*-heptose ainsi que de D-*glycéro*-D-*manno*-heptose. On a utilisé des méthodes de RMN faisant appel à l'excitation selective du ^{1}H en 1D et à des expériences hétéronucléaires (^{1}H,^{13}C) et (^{1}H,^{31}P) en 2D pour déterminer la structure des composants oligosaccharides principaux du noyau du LPS désacétylé, de faible masse moléculaire, obtenu après un traitement séquentiel avec de l'hydrazine anhydre et du KOH aqueux. On a trouvé que l'oligosaccharide de la région du noyau est formée d'un

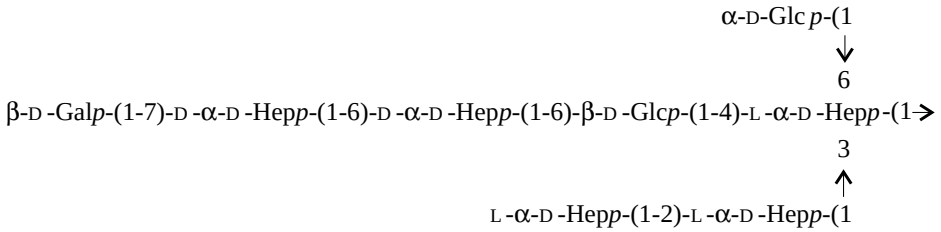
oligosaccharide ramifié lié à une portion désacétylée du lipide A par le biais d'un résidu 3-désoxy-4-phospho-D-*manno*-oct-2-ulosonate de structure,



On a observé de l'hétérogénéité à plusieurs points de ramification. On a mis au point des méthodes RMN qui permettent de faire la différence entre les formes diastéréomères des résidus heptoses. On a utilisé des monosaccharides de synthèse de L-D- et D-D-heptoses comme modèles pour l'analyse des déplacements chimiques du ^{1}H et du ^{13}C et des constantes de couplage du proton. On a utilisé la modélisation moléculaire basée sur la méthode de Monte Carlo pour faire l'analyse conformationnelle des saccharides afin déterminer la conformation du noyau de l'oligosaccharide et établir les relations stéréochimiques entre les heptoses.

Mots clés : LPS, RMN, conformation, oligosaccharide, heptose.

Introduction

Lipopolysaccharides (LPS) are a complex class of glycolipids that can trigger a cascade of immunological responses in mammals including endotoxic effects and serum antibody production (1). These molecules make up the outer leaflet of the outer membrane of Gram-negative bacteria. LPS has been found to exhibit a common molecular architecture consisting of at least two distinct regions: (*i*) an oligo- or polysaccharide region; and (*ii*) a lipid moiety referred to as lipid A (2). In certain bacteria, the carbohydrate containing region consists of a high-molecular-mass *O*-specific polysaccharide, which is covalently linked to a core oligosaccharide unit (3). Other bacteria, notably *Haemophilus* and *Neisseria s*pp. only produce short-chain LPS, devoid of *O*-polysaccharide chains, in which the carbohydrate region contains mixtures of low-molecular-mass but structurally diverse oligosaccharide components. The saccharide portion of LPS molecules has been found to be linked to the lipid A moieties via the eight-carbon sugar acid, 3-deoxy-D-manno-oct-2-ulosonate (Kdo). The lipid A from several bacterial species has been found (2) to have a relatively conserved structure consisting of a bisphosphorylated β-1,6-linked D-glucosamine (GlcN) disaccharide unit that is substituted by fatty acyl amide and ester groups.

The bacterium *Mannheimia haemolytica* is a new member of the Pasteurellaceae family (4). Originally referred to as *Pasteurella haemolytica*, this group of organisms was classified into two biotypes (designated A and T) which were further subdivided into 17 serotypes (5, 6). This biochemical distinction was based on the ability of the organisms to ferment either arabinose (A-biotype) or trehalose (T-biotype) (7). On the basis of genetic analyses, the *P. haemolytica* biotype T organisms (serotypes T3, T4, T10, and T15) were reclassified as *Pasteurella trehalos* in 1990 (8, 9). More recently the biotype A group of organisms was reclassified into the new genus *Mannheimia* (10). Twelve *M. haemolytica* serotypes are now recognized (A1, A2, A5, A6, A7, A8, A9, A12, A13, A14, A16, and A17). *M. haemolytica* serotype A1 is most frequently associated with bovine pneumonic pasteurellosis (shipping fever), a major cause of sickness and economic loss to the feed lot industry (11, 12). The pathogenesis of diseases caused by *M. haemolytica* in cattle has recently been reviewed (13). Several virulence factors, including a leukotoxin, capsular polysaccharide, and LPS have been identified. *M. haemolytica* LPS has been reported to have a severe damaging effect on bovine endothelial cells (14, 15).

In our laboratory we have undertaken the structural and antigenic characterization of *M. haemolytica* (16, 17) and *P. trehalos* (17–20) LPS to understand the role of these molecules in pathogenesis and protective immunity. Immunochemical studies have revealed that eight of the 12 *M. haemolytica* serotypes can elaborate LPS which contain a common *O*-polysaccharide side chain (17). The structure of the *O*-polysaccharide from serotype A1 is representative and was determined in detail. It consists of a trisaccharide repeating unit having the structure -4)-β-D-Gal*p*-(1–3)-β-D-Gal*p*-(1–3)-β-D-Gal*p*NAc-(1- (16). A detailed structural model for the core oligosaccharide of *M. haemolytica* LPS serotype A1 core oligosaccharide has not been proposed.

Many carbohydrate samples of biological origin are heterogeneous in nature and difficult to separate. To determine their three-dimensional structure, complete NMR assignments are desirable even for heterogeneous products. Only then can conformational analysis (21) be made with the goal of establishing a relationship between three-dimensional structure and biological function (22). Towards this goal, 1D selective NMR methods have been used to determine the structure of mixtures, where the resonances of specific components can be selected to characterize individual components (23–28). 1D selective excitation experiments are analogs of standard 2D and 3D experiments where hard pulses have been replaced by selective pulses. The original phase-cycled experiments (29–42) have more recently been adopted for the use of pulsed-field gradients (43–55). Particularly useful are 1D analogues of 3D experiments (53–55).

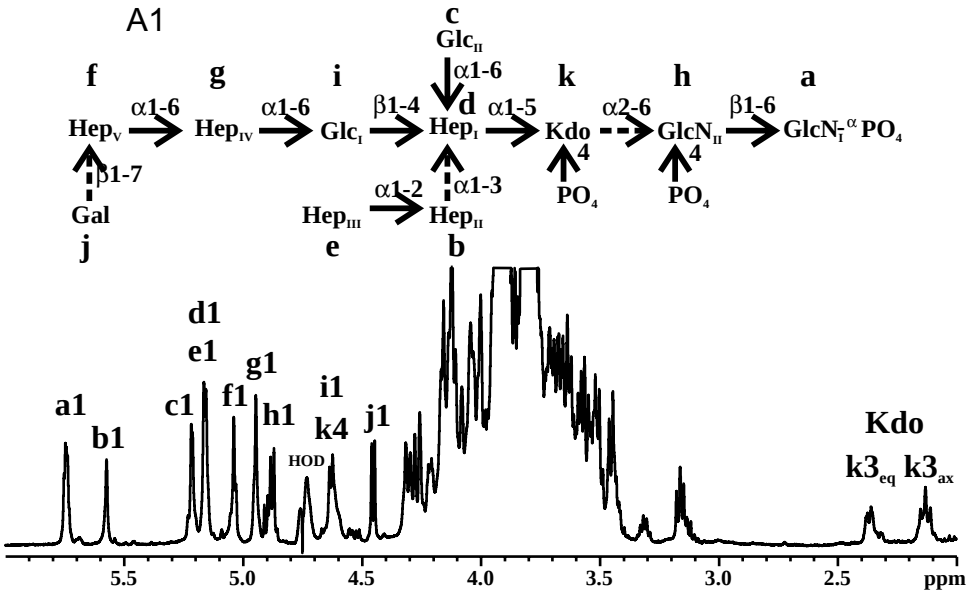
Fig. 1. Proton NMR spectrum at 600 MHz of the core oligosaccharide component from *M. haemolytica* serotype A1 LPS in D_2O (300 K, pH 3). The HOD resonance is at 4.756 ppm. Resonances in the anomeric region up from 4.4 ppm are labelled along with the Kdo methylene resonances. The determined structure designated as A1 and nomenclature for the residues are also shown. Heterogeneity due to partial truncation of the backbone oligosaccharide is indicated by dotted arrows at linkage sites. In the text, the minor component for f due to heterogeneity is indicated by f′. Hep_I, Hep_{II}, and Hep_{III} are L-D-heptose while Hep_{IV} and Hep_V are D-D-heptoses. Other residues have the D-configuration.



An advantage of 1D selective methods is that the multiplet pattern for each resonance in the 1D selective experiments can be clearly observed due to the same digital resolution as a 1D ^1H spectrum. Also, 1D selective experiments are sometimes preferable to 2D methods for the structural analysis of oligosaccharides as was recently demonstrated in the characterization of some enzymatically synthesized oligosaccharides (56, 57). Also, with selective experiments, incursion in the ring region of carbohydrates is possible. The 1D TOCSY-NOESY permits the isolation of spin systems of interests and the detection of NOEs from proton resonances within the ring allowing NOE constraints to be obtained which cannot be otherwise determined from 2D experiments (58, 59). Recently several reviews have dealt with carbohydrate structural determination by NMR spectroscopy (60–64).

Preliminary studies by chemical, ^1H NMR, and mass spectrometric (MS)-based methods have indicated that the LPS core region of *M. haemolytica* A1 has the composition $Hex_{2-3}Hep_5Kdo$. The Hex_2Hep_5Kdo species is the major core oligosaccharide component in the *O*-chain deficient serotype A8 LPS (17). Analyses of the LPS from these serotypes indicate the core oligosaccharide to contain D-glucose, D-galactose and both L-glycero-D-manno-heptose (L-D-heptose) and D-glycero-D-manno-heptose (D-D-heptose) residues. In the present investigation the structure of the core oligosaccharide of *M. haemolytica* serotype A1 LPS was determined in detail. The sequence, linkage positions, and relative stereochemistries of the heptose-containing oligosaccharide were established by NMR spectroscopic techniques. On the basis of NMR analyses and Monte Carlo calculations a conformational model is now proposed for the core oligosaccharide region of the LPS.

Results and discussion

Our previous analysis of the LPS of *M. haemolytica* serotype A1 revealed Hex_3Hep_5Kdo as the major core oligosaccharide component. This was determined by 1D ^1H NMR and FAB-MS analysis of the oligosaccharide fraction obtained following mild acid hydrolysis (1% HOAc, 100°C, 3 h) of the LPS sample (17). The core oligosaccharide was found to contain D-glucose, D-galactose, L-D-heptose, and D-D-heptose in a molar ratio of 2:1:3:2 in the major fraction as determined by GLC–MS analysis of their alditol acetate and 2-butyl glycoside derivatives. The D-Gal residue was found to be a terminal nonreducing moiety from methylation analysis and was absent in the minor component of the core oligosaccharide fraction, that had the composition of Hex_2Hep_5Kdo. The occurrence of Kdo in the LPS was established by colorimetric analysis.

Treatment of *M. haemolytica* LPS with anhydrous hydrazine followed by strong alkali afforded water-soluble, deacylated LPS oligosaccharides. The deacylated LPS sample was representative of the intact backbone oligosaccharide of the native material containing core and lipid A oligosaccharide moieties. This was confirmed by electrospray ionization ESI-MS which gave molecular ions corresponding to $Hex_3Hep_5Kdo_1HexN_2(H_2PO_3)_3$ as the major oligosaccharide component (see *Experimental section*).

From the proton spectrum (Fig. 1) and HMQC and COSY spectra (Fig. 2), 10 anomeric ^1H NMR resonances were observed, as well as methylene proton resonances. The anomeric resonances were labeled a–j in decreasing order of their ^1H NMR chemical shifts and $k3_{eq}$ and $k3_{ax}$ assigned to the methylene protons of Kdo. The integral for the b1 and de1 and j1 anomeric peaks were 40% less than those for the

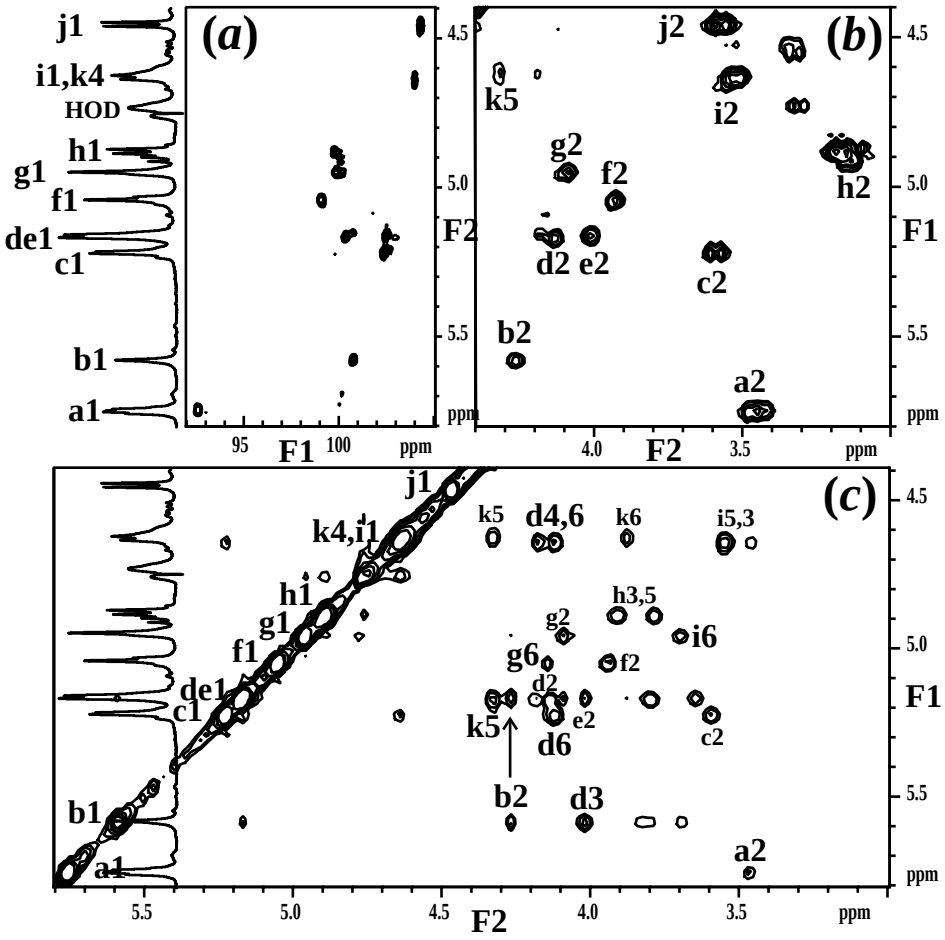
Fig. 2. 2D NMR experiments for A1 showing the HMQC spectrum of the anomeric region (*a*), and the COSY (*b*) and NOESY (*c*) spectra of the anomeric and ring region. The arrow indicates the position of the b2 resonance observed near k5.



other anomeric resonances confirming heterogeneity in the sample. There was also some heterogeneity at h1 with the appearance of a downfield doublet at 4.91 ppm near h1.

Standard homo- and hetero-nuclear 2D-NMR analyses was undertaken. From the COSY spectrum in Fig. 2, the H-2 resonances could be located. It was realized that for residues **b**, **d**, **e**, **f**, and g, $J_{1,2}$ was small, typical of *manno*-heptoses, and that a 2D-TOCSY could not be used to transfer magnetization from H-1 past H-2. From the HMQC spectrum in Fig. 3, the H-2 of the heptose residues overlapped with other resonances making 2D-TOCSY difficult to analyze for these residues. The 2D-NOESY spectrum also showed an unusually high number of NOEs especially for the b1, de1 resonances. Also, there was overlap of several resonances in the anomeric region. Hence, due to the complexity of the spectra and heterogeneity of the sample, 1D selective methods were used to extract spectral parameters that could not be obtained using standard 2D methods, thus permitting the resolution of the structure and conformational analysis. HMQC-TOCSY and HMBC experiments were also very important in determining the complete assignments, especially for the heptose units. Using this approach, the complete assignment for the ^{1}H and ^{13}C NMR chemical shifts for the major backbone oligosaccharide (A1) was possible (Table 1).

The Kdo-$GlcN_{II}$-$GlcN_{I}$ sequence and partial assignments are known from previous studies (65) and are consistent with the assignments made here. The 1D-TOCSYs for residues **a** and **h** permitted assignment of the resonances and measurement of proton coupling constants (Fig. 4*a*, 4*b*). Location of phosphate groups was confirmed from a ^{31}P HMQC experiment as done previously (65). Assignment of the ^{13}C NMR chemical shifts was then made from HMQC, HMQC-TOCSY, and HMBC spectra. This information led to the definition of residues **a** and **h** as the α-D-GlcN and β-D-GlcN pyranosyl units of the lipid A moiety. Most of the proton, ^{31}P and ^{13}C NMR chemical shifts were similar to those previously reported in a similar structural element (65). In the 1D-TOCSY for h1, the h′5 peak at 3.62 ppm is due to hydrolysis of the Kdo-(2-6)-β-D-$GlcN_{II}$ glycosidic linkage. After several months in solution, the linkage was completely hydrolyzed with h′6 and h′6 appearing at 3.82 and 3.92 ppm, respectively. The sharp anomeric signal at 3.91 ppm was also found to be due to h′1 of this disaccharide.

For Kdo, the H-4 and H-5 resonances were assigned from 1D-TOCSY experiments with selective excitation of H-3_{eq} or H-3_{ax}. The H-4 resonance is shifted downfield due to a phosphate group at C-4, confirmed by a ^{31}P HMQC. A small $J_{5,6} < 1$ Hz impeded the TOCSY transfer past H-5 (Fig. 4*c*). However, a strong NOE is observed between k4 and k6 in Fig. 2*c* in accord with the X-ray structure of Kdo (66). 1D NOESY-TOCSY(k4, k6) was used to complete the assignment

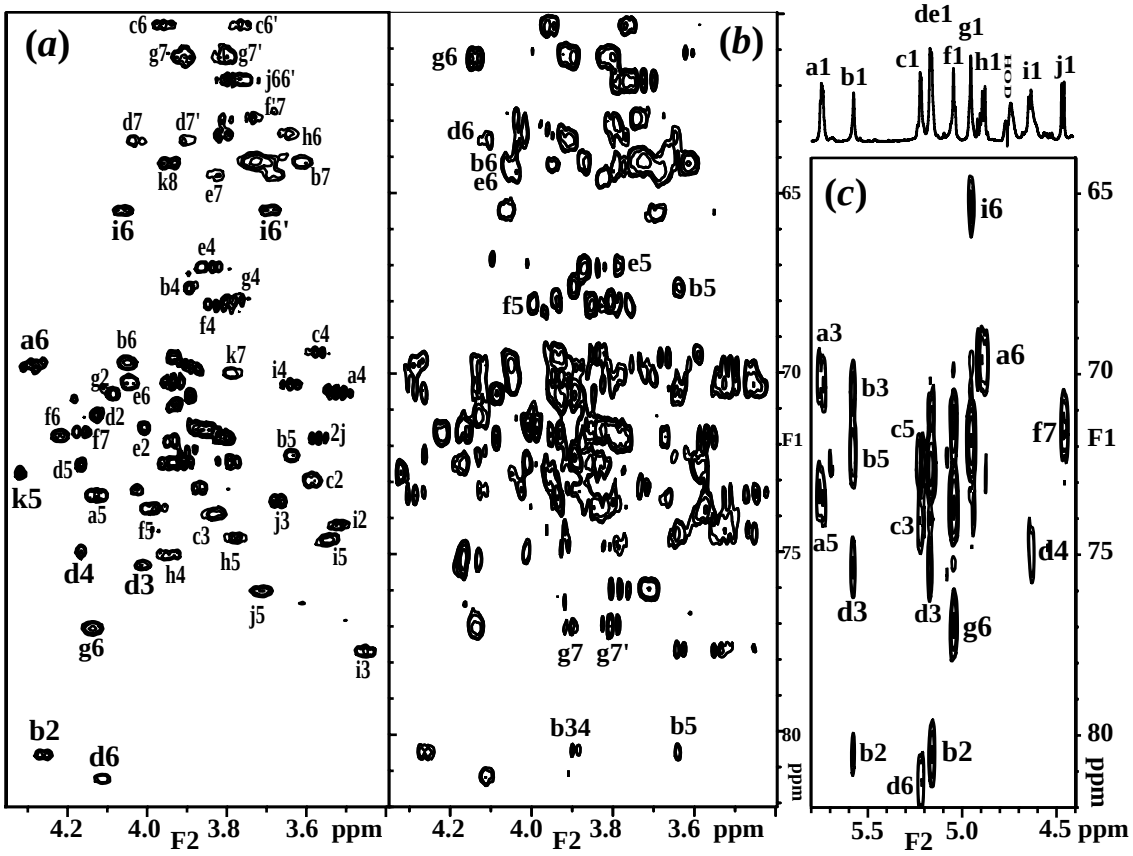
Fig. 3. Selected plots from the heteronuclear ^{1}H-^{13}C 2D NMR spectra of A1. (*a*) In the HMQC spectrum of the ring region some assignments are labelled where possible. (*b*) In the HMQC-TOCSY spectrum, the C7-H7s-C6-H6, C4-H4-C5-H5 TOCSY correlations and those for b2 are labelled. (*c*) In the HMBC spectrum, the H1-C1-O1-C*x* inter-glycosidic correlations are shown for the anomeric proton resonances along with their intra-residue correlations.



(Fig. 4*d*). As shown later, for the HepI-(1-5)-Kdo linkage, the d1-k7 NOE was also observed, typical of a substitution at C-5 of Kdo (67). Using this NOE, the Kdo resonances detected from the 1D-NOESY-TOCSY (de1, k7) (Fig. 4*e*) had the same chemical shifts and similar multiplet patterns as those found in the previous experiment, thus confirming the Kdo ^{1}H NMR assignments. The ^{13}C NMR assignments for Kdo where then obtained from the HMQC spectrum and confirmed from the HMQC-TOCSY spectrum.

Residue **i** was determined to be 6-substituted β-D-glucose denoted as Glc_I. The anomeric resonance for residue **i** overlapped with the H-4 resonance of Kdo. In the 1D-TOCSY for these two overlapping resonances, it was possible to distinguish the resonances for residue **i** because of the small $J_{5,6}$ coupling constant for Kdo (Fig. 4*c*). All resonances up to H-6s could be detected and coupling constants of the multiplets could be measured. Due to its β-D configuration the i1-i3 and i1-i5 NOE were also observed in the NOESY spectrum (Fig. 2 and Fig. 5*f*). ^{13}C NMR assignments for Glc_I were then obtained from the HMQC spectrum and confirmed with the HMQC-TOCSY spectrum. From a comparison with chemical shifts of terminal glucose (68, 69), a glycosidation down-field shift of 3.7 ppm was observed for the C-6 resonance, indicating its substitution at that position. A substantial shift of –2.2 ppm was also observed for C-5. The rotamer distribution about the C-5—C-6 bond could be determined from the H-5 multiplet observed for the i1-i5 NOE in Fig. 5*f*. It was apparent that both $J_{5,6}$ and $J_{5,6'}$ had small values <2 Hz since the H-5 multiple appeared as a doublet dominated by the large $J_{4,5}$ coupling of 10 Hz. This showed that both H-6 and H-6′ were gauche to H-5 with the O6-C6-C5-O5 = –60° rotamer being preferred in solution.

Residue **c** was determined to be a terminal α-D-glucose denoted as Glc_{II}. From the 1D-TOCSY for c1 (Fig. 4*f*) resonances up to H-5 were detected, indicating that residue **c** was an α-glucose based on the measured proton coupling constants. From the HMQC spectra and comparison with chemical shifts of terminal glucose model compounds (68, 69), all the ^{1}H and ^{13}C NMR assignments could be completed.

The terminal galactose, residue **j**, denoted as Gal, was identified from the 1D-TOCSY of j1 and resonances up to H-4 were observed (Fig. 4*j*). To get past the small $J_{4,5}$ coupling constants and identify H-5, the 1D-TOCSY-NOESY (j1, j4) was done (Fig. 4*h*). From the HMQC spectra and comparison with chemical shifts of terminal galactose model compounds (68, 69), all the ^{1}H and ^{13}C NMR assignments were completed.

To assign the heptose residues, model compounds were synthesized to obtain accurate ^{1}H and ^{13}C NMR chemical shifts and $J_{H,H}$ values. These were crucial in assigning the terminal heptose units by chemical shifts comparisons. Also,

Note: Measured at 600 MHz (^1H) in D_2O, 25°C and pH 3 from HMQC and HMBC data with the CH_3 signal of external acetone set at 2.225 ppm for ^1H NMR and 31.07 ppm for ^{13}C NMR. Average error of ±0.2 ppm for δ_C and ±0.02 ppm for δ_H. The minor component for f due to heterogeneity is indicated by f′. The CH_2 spin systems, (H, H′), are in decreasing order of chemical shifts. For Kdo, H-3 and H-3′ are assigned to H-3_{eq} and H-3_{ax}.

upon glycosidation, the ^{13}C NMR resonance of the substituted carbon experiences a substantial down-field glycosidation shift (56, 57). The proton spectra for D-D-heptose and D-L-heptose are shown in Fig. 6. In solution both the α and β forms are present for each compound. Their ^1H NMR spectra were assigned using 1D-TOCSY experiments. To obtain accurate coupling constants and chemical shifts, spin simulations of the proton spectra were done. The simulated spectra are shown in Fig. 6. The simulated spectra reproduced exactly the observed spectra, especially the strong coupling for H-3-H- in D-α-L-heptose (Fig. 6*b*). ^{13}C NMR chemical shifts were assigned using HMQC. The NMR data for the heptose monosaccharides are given in Table 2. The chemical shifts for L-D-heptose are the same as those of D-L-heptose since they are enantiomers of each other.

Residues **b**, **d**, **e**, **f**, and **g** in A1 were identified as heptoses from their narrow anomeric resonance due to the small $J_{1,2}$ coupling and lack of transfer of magnetization beyond H-2 from H-1 in a TOCSY experiment. All the heptoses in A1 had the α-D configuration since the only intra-residue NOE from H-1 was to H-2 (Fig. 2). 1D-TOCSY-TOCSY (H-1, H-2) was used to assign all the heptose residues. The first TOCSY step from H-1 transfers the magnetization to H-2 and further transfer is impeded due to the small $J_{1,2}$ value of 1.8 Hz. However, the second step at H-2 will transfer the magnetization further to higher spins due to the larger $J_{2,3}$ value of 3 Hz. However, for L-D-heptose, transfer of magnetization stops at H-5 due to the small $J_{5,6}$ value of 1.6 Hz. For D-D-heptose, transfer of magnetization is less impeded due to a large $J_{5,6}$ value of 3.2 Hz. However, relaxation

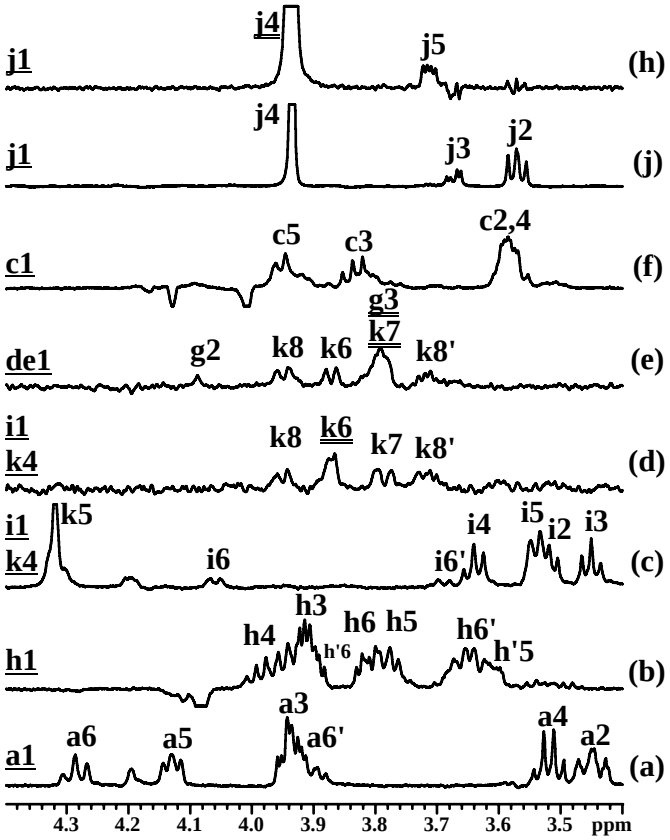
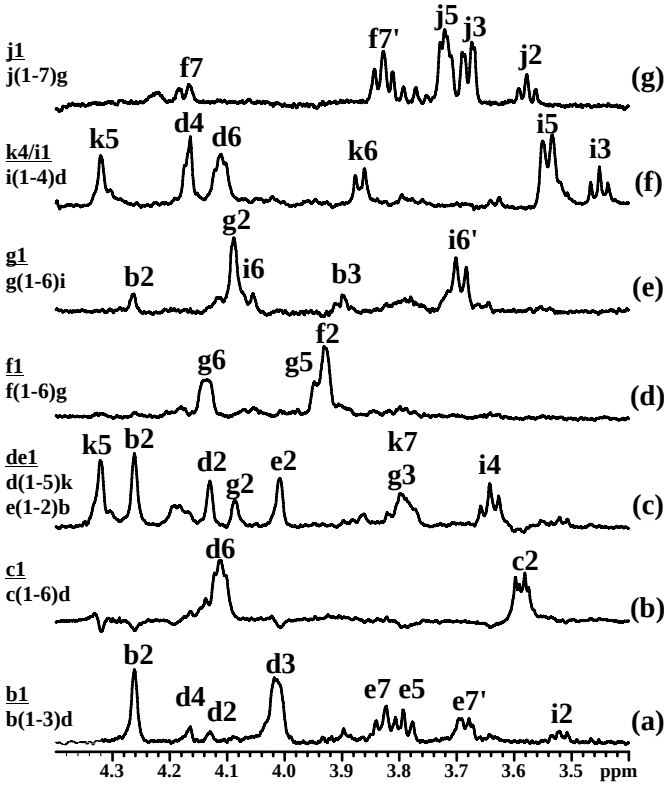
Fig. 4. 1D selective experiments for assignment of the non heptose residues in A1. (*a*) 1D TOCSY (a1, 180 ms); (*b*) 1D TOCSY (h1, 180 ms); (*c*) 1D TOCSY (i1 k4, 180 ms); (*d*) 1D NOESY-TOCSY (i1 k4, 400 ms; k6, 180 ms); (*e*) 1D NOESY-TOCSY (de1, 400 ms; g3 k7, 180 ms); (*f*) 1D TOCSY (c1, 180 ms); (*g*) 1D TOCSY (j1, 180 ms); and (*h*) 1D TOCSY-NOESY (j1, 180 ms; j4, 400 ms). Minor components for f and h due to heterogeneity are indicated by f′ and h′, respectively. The resonance for the first selective step is underlined and the one for second selection step is doubly underlined, where applicable. Selected resonances in the anomeric region are indicated on the left of the spectra.



effects can also impede transfer of magnetization and one cannot use a lack of transfer beyond H-5 as proof of L-D-heptose identification.

Residue **b** was determined to be the 2-substituted L-α-D-heptose denoted as Hep_{II}. The 1D-TOCSY-TOCSY (b1, b2) identified resonances at 3.64 ppm and 3.9 ppm (Fig. 7*a*). The multiplet pattern at 3.64 ppm was indicative of a H-5 resonance while those at 3.9 ppm were similar to the strongly coupled H-3 and H-4 resonances observed in the monosaccharide (Fig. 6*b*). To identify H-6 a 1D-TOCSY-NOESY (b2, b5) was done (Fig. 7*b*). In the first TOCSY step for b2, the a6 resonance was also irradiated but the second step only selected the b5 resonance. NOEs from b2 were observed on b3 and b6 along with an inter-residue NOE on d2. Once b6 was located, the HMQC-TOCSY from the C-7-H-7s-C-6-H-6 was used to assign the H-7 and H-7′ resonances (Fig. 3*b*). Assignments for the other resonances were then obtained from the HMQC spectrum and confirmed from the HMQC-TOCSY and HMBC spectra

Fig. 5. 1D selective experiments to detect dipolar interactions in A1. 1D NOESY spectra of the resonances in the anomeric region with a 200 ms mixing time for b1, c1, de1, f1, g1, i1/k4 and a 1D ROESY (f1, 500 ms) for j1 in (*a*)–(*g*), respectively. The selected anomeric resonances and the linkage are indicated on the left of the spectra.



(Fig. 3). Comparison of chemical shifts with those of L-α-D-heptose indicated a 9 ppm down-field shift for C-2 and an up-field shift of –0.8 ppm for C-3 indicative of a substitution at C-2. The C-4 to C-7 chemical shifts were within 0.6 ppm of those of the monosaccharide.

Residue **e** was determined to be a terminal L-α-D-heptose denoted as Hep_{III}. Although the d1 and e1 resonances overlap, this is of no concern since their H-2 resonances did not overlap. The 1D-TOCSY-TOCSY (de1, e2) identified the e3, e4, and e5 spins (Fig. 7*c*). From the b1 NOE in Fig. 5*a*, the e5 resonance was also observed. The high digital resolution of the 1D selective experiments permits accurate matching of resonances between different experiments due to the observation of their multiplet pattern. In Fig. 5*a*, the b1-e7 and b1-e7′ NOEs were also observed. As seen later, these NOEs are due to the close proximity of b1 proton to the e5 and the e7 and e7′ protons. The H-6 resonance was located in the HMQC-TOCSY from C-7-H-7s-C-6-H-6. ^{1}H and ^{13}C NMR assignments were completed with HMQC and HMQC-TOCSY. ^{1}H and ^{13}C NMR chemical shifts of residue **e** were similar to those of L-α-D-heptose.

Residue **d** was identified as a 3,4,6-trisubstituted L-α-D-heptose denoted as Hep_{I}. The 1D-TOCSY-TOCSY (de1, d2) identified a narrow multiplet at 4.17 and a broader one at 4.01 ppm (Fig. 7*d*). The multiplets at 4.01 ppm and 4.17 ppm (d2) were also observed in the 1D-NOESY for b1 (Fig. 5*a*). The resonance at 4.17 ppm was also observed in

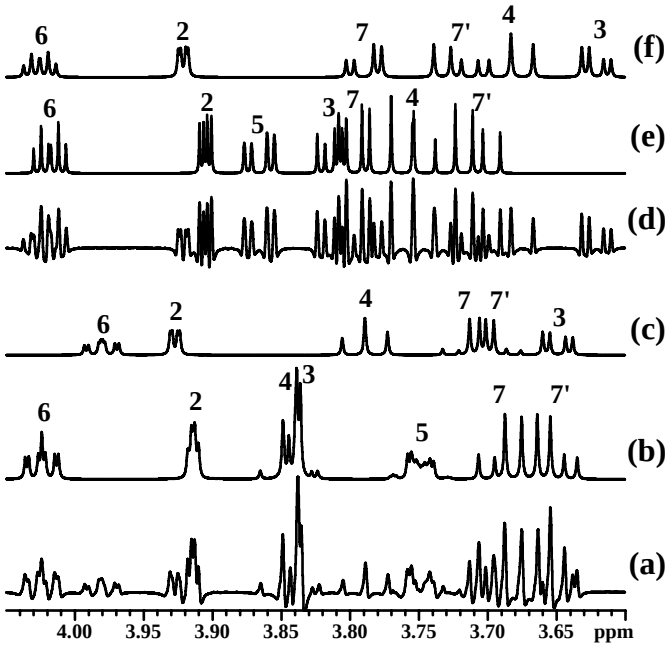
Note: Measured at 600 MHz (^{1}H) in D_2O at 25°C from ^{1}H spin simulations and from the ^{13}C spectra (150 MHz) with the CH_3 signal of acetone set at 2.225 ppm for ^{1}H NMR and 31.07 ppm for ^{13}C NMR. δ_C and δ_H are in ppm with an average error of ±0.005 ppm for δ_C and ±0.003 ppm for δ_H. $J_{H,H}$ values are in Hz with an average error of ±0.2 Hz. H-7 and H-7′ are in decreasing g order of chemical shifts.
[a] $J_{C1,H1}$ = 171 ± 1 Hz.
[b] $J_{C1,H1}$ = 160 ± 1 Hz measured from the undecoupled ^{13}C NMR spectrum.

Fig. 6. Proton spectra of heptose monosaccharides. Resolution enhanced spectrum of D-L-heptose at 600 MHz in D_2O, 300 K (*a*) and its simulated spectrum for the α (*b*) and β forms (*c*). Resolution enhanced spectrum of D-D-heptose at 600 MHz in D_2O, 300 K (*d*) and its spin simulated spectra for the α (*e*) and β forms (*f*). The anomerics and H-5β resonances are not shown. Note that strong coupling for the H-3, H-4 and virtual coupling for H-5 resonances are reproduced correctly for (*b*).



the 1D-NOESY for i1 (Fig. 5*f*). In the HMQC spectrum two narrow crosspeaks at (δc, δh) (74.9, 4.17), (72.5, 4.17) and a broader one at (75.3, 4.01) were identified. HMQC-TOCSY correlations were also observed between these crosspeaks. From a comparison of the ^{13}C NMR chemical shifts with those of the α-D-heptopyranoses in Table 2, it was obvious that the crosspeaks at (74.9, 4.17) and (75.3, 4.01) were subject to a ^{13}C NMR down-field glycosidation shift. Since these three crosspeaks are from d3, d4, or d5, only the d5 crosspeak will not experience a large glycosidation shift since substitutions on heptose cannot occur at C-5. Hence, the crosspeak at (72.5, 4.17) was assigned to (C-5, H-5). The crosspeak at (75.3, 4.01) was assigned to (C-3, H-3) based on the HMBC (d3, d1) and (d3, b1) correlations. The crosspeak at (74.9, 4.01) was thus assigned as (d4, d1), consistent with the observation of the HMBC (d4, i1) correlation and (i1, d4) NOE (Fig. 3 and Fig. 5*f*). The d6 resonance was assigned from the 1D-NOESY from i1, since for the Glc_I-(1-4)-Hep_I linkage, a strong NOE to H-6 is also expected only if residue **d** is L-D-heptose. The d6 resonance was also observed for the 1D-NOESY for c1 (Fig. 5*b*). The H-7 and H-7′ resonances were located from the HMQC-TOCSY (C-7, H-6) crosspeak (Fig. 3) and from 1D-NOESY-TOCSY (i1, d6) (not shown). Comparison of chemical shifts with those of L-α-D-heptose indicated a 3.9, 7.9, and 11.6 ppm down-field glycosidation shift for C-3, C-4, and C-6, respectively.

As shown below, there should be a 4,6-disubstituted L-α-D-heptose (**d′**) present due to heterogeneity on the branching heptose (Fig. 1). From the HMQC and COSY spectra for the anomeric region, no separate signal could be observed either for the H-1 or H-2 due to overlap with other resonances. It is suspected that the proton chemical shifts of d′1 were the same as the one for d1, and that d′2 had a similar chemical shift to e2.

Residue **g** was determined to be a 6-substituted D-α-D-heptose denoted as Hep_{IV}. The 1D-TOCSY-TOCSY (g1, g2) identified the g3, g4, and g5 spins (Fig. 7*e*). The multiplet pattern at 3.94 was indicative of a H-5 resonance. To identify H-6, an 1D-TOCSY-NOESY (g2, g5) was acquired (Fig. 7*f*). NOEs from g2 were observed on g3 and g6 along with a putative inter-residue NOE on i6. Once g6 was located, the HMQC-TOCSY from the C-7-H-7s-C-6-H-6 (Fig. 3*b*) and 1D-NOESY-TOCSY (f1, g6) (Fig. 7*g*) were

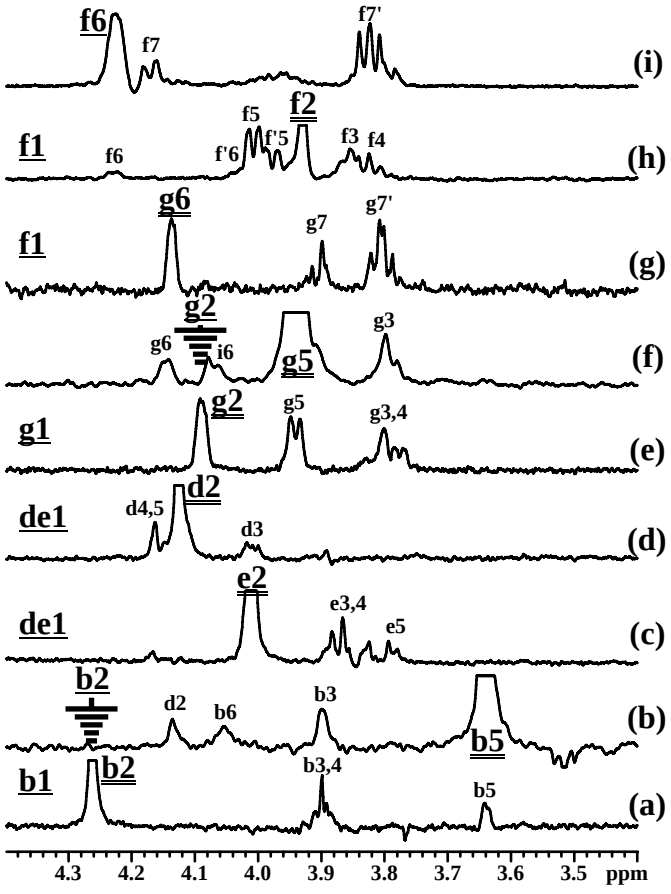
Fig. 7. 1D selective experiments for assignment of the heptose residues in A1. (*a*) 1D TOCSY-TOCSY (b1, 75 ms; b2, 75 ms) to detect b3, b4 and b5; (*b*) 1D TOCSY-NOESY (b2, 150 ms; b5, 400 ms) to detect the b5-b6 and b5-b3 NOEs. Note also the strong b5-d2 NOE due to the b(1-3)d linkage; (*c*) 1D TOCSY-TOCSY (de1, 75 ms; e2, 75 ms) to detect e3, e4 and e5; (*d*) 1D TOCSY-TOCSY (de1, 75 ms; d2, 75 ms) to detect d3, d4 and d5; (*e*) 1D TOCSY-TOCSY (g1, 90 ms; g2, 150 ms) to detect g3 to g5; (*f*) 1D TOCSY-NOESY (g2, 150 ms; g5, 400 ms) showing the g5-g6 and g5-g3 NOEs and g5-i6 NOE in accord with the g(1-6)i linkage; (*g*) 1D NOESY-TOCSY (f1, 400 ms; g6 180 ms) to detect the g7 resonances from the f1-g6 interglycosidic NOE in accord with the f(1-6)g linkage; (*h*) 1D TOCSY-TOCSY (f1, 90 ms; f2, 150 ms) for detection of f and f′ resonances up to H-6. Note the clear multiplet pattern for f5 and f′5; (*i*) 1D TOCSY (f6, 40 ms) to detect the f7 resonances only due to the short spin lock time. The resonance for the first selective step is underlined and the one for second selection step is doubly underlined, where applicable. Selected resonances in the anomeric region are indicated on the left of the spectra.



used to assign the H-7 and H-7′ resonances. Assignments for the other resonances were then obtained from the HMQC spectrum and confirmed with the HMQC-TOCSY spectrum (Fig. 3). In the 1D-NOESY (f1), the g6 and g5 resonances were observed (Fig. 5*d*). The NOE f1-g5 NOE can only be possible if residue **g** is a D-D-heptose from molecular modeling studies (see below). Comparison of chemical shifts with those of D-α-D-heptose indicated a 4.3 ppm down-field shift for C-6.

Residue **f** was determined to be a 7-substituted D-α-D-heptose and denoted as Hep_V. The 1D-TOCSY-TOCSY (f1, f2) identified spins up to f6 indicating that residue **f** was a D-D-heptose. The f5 multiplet pattern was quite clear. From a 1D-TOCSY starting on f6, the f7, and f7′ resonances were identified. The ^{13}C NMR assignments were then obtained from the HMQC spectrum and confirmed with the HMQC-TOCSY spectrum. Comparison of chemical shifts with those of α-D-D-heptose indicated a 8.8 ppm down-field shift for C-7. A terminal D-α-D-heptose, denoted **f′**, was only detected due to heterogeneity at this linkage site. As seen in the 1D-TOCSY-TOCSY (f1, f2), the f′5 and f′6 resonance can be detected, along with crosspeaks in the HMQC and HMQC-TOCSY spectra which correspond to those of a terminal D-α-D-heptose similar to those for D-α-D-heptose in Table 2.

The sequence of the core octasaccharide was established from the 1D-NOESY spectrum for the anomeric resonances presented in Fig. 5 and from the HMBC spectrum of the anomeric proton resonances (Fig. 3*c*). Inter-residue NOEs were also observed in 1D-TOCSY-NOESY experiments in Fig. 7*b* and 7*f*. The results are tabulated in Table 3 and the structure shown in Fig. 1. From integration of the anomeric resonances and appearance of new resonances with time, the linkage sites where heterogeneity occurs were determined. The k(2-6)h linkage and the b(1-3)d linkage hydrolyzed over a period of months in solution at pH 3, while the j(1-7)f linkage was stable.

An unusually large number of long-range NOEs were observed spanning up to five sequential residues. For an α-D sugar, the H-1-H-2 intra-residue NOE is expected. For a β-D sugar, the H-1-H-3 and H-1-H-5 intra-residue NOEs are expected. The H-1-C-1-O-1-C-*x*-H-*x* interglycosidic NOEs are expected for (1-*x*) linkage. Inter-residue anomeric NOEs between two linked sugars on the H-*x* ± 1 and H-*x* ± 2 can also occur. Other inter-residue NOEs, not in the vicinity of the glycosidic linkage, are deemed to be long-range NOEs as listed in Table 3.

To explain the large number of long-range NOEs, conformational analysis was done using the Metropolis Monte Carlo (MMC) method to vary the glycosidic linkage angles and sample the multiple conformations of the molecule. Using this method for the inner core oligosaccharide with Kdo at the reducing end, it was found that all the observed long-range NOEs could be explained by the close proximity of the e-b branch to the g-i branch. These long-range NOEs were possible due to restriction of the inner core residues brought about by the three branching points on Hep_I.

A minimum energy conformer obtained from the calculation is shown in Fig. 8. The various interproton distances measured from these coordinates are given in Table 3. As can be observed the occurrence of most NOEs can be explained by the short inter-proton distances. The long-range NOEs for g1-b2 and g1-b3 are not consistent with distances obtained from the molecular model drawn in Fig. 8. Although there is restriction due to the 3,4,6)-Hep_I substitution pattern, there is flexibility about the glycosidic linkage and this must be taken into account. As shown in Fig. 9 for the g1-b2 and g1-b3 distances, multiple conformations having short inter-proton distances are sampled consistent with the observed NOEs. The same situation was applicable for all

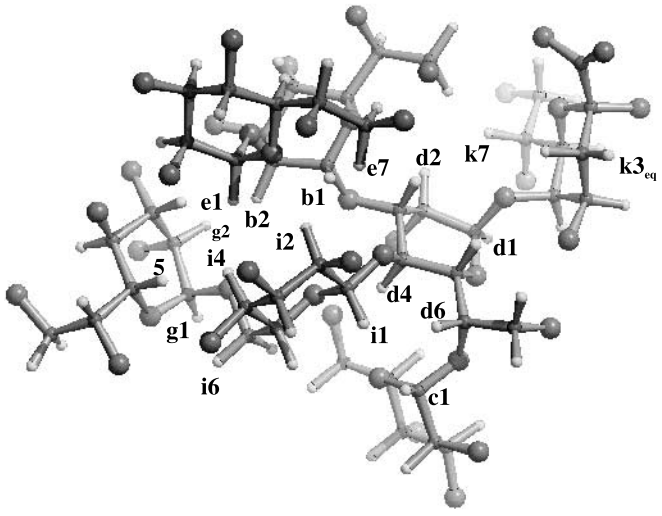
[a]For the j and f residues in the Gal-(1-7)-Hep_V-(1-6)-Hep_{IV} sequence (j-f-g), the average distances from MMC calculations are given.

Fig. 8. Molecular model of a minimum-energy conformer obtained from a MMC calculation of the inner core heptasaccharide of A1. Oxygens are depicted as the larger spheres and hydroxyl protons are removed. Relevant protons are labelled. Note the close proximity of the e-b branch to the g-i branch and the close proximity of the exocyclic chain of residue **e** to the anomeric proton of residue **b** consistent with the long range NOEs observed. Also, note the differences in orientation of the exocyclic chain between L-D heptose (residues **d**, **b**, **e**) and D-D heptose (residue g).



the other long-range and inter-residue NOEs. The long-range NOEs for g1-b2 and g1-b3 and e1-i4 span four residues with mobility about the three glycosidic (ϕ, ψ) angles for a total of 6 df. The long-range NOEs between e1-g2 and e1-g3 that span five residues (e-b-d-i-g) vary even more due to 8 df

Fig. 9. Variation of inter-proton distances (*r*) vs. macro move in a MMC calculation of the inner core heptasaccharide of A1 for b1-e5, b1-e7, e1-i4, e1-g2, g1-b2, g1-b3 in (a)–(g), respectively. Occurrences of interproton distances in the 2–4 Å range are consistent with the observed long range b-e, e-i, and e-g NOEs.

about the glycosidic angles, not counting possible flexibility about the C-5—C-6 bond for the g(1-6)i linkage. The b1-e5, b1-e7, and b1-e7′ are dependent on mobility about the e(1-2)b glycosidic bond and rotation about C-6-C-7 of residue **e**. In all cases, the occurrence of multiple conformations that have short inter-proton distances is consistent with the observed inter-residue and long-range NOEs.

In the present study it was established that the lipid A region of the *M. haemolytica* A1 LPS molecule contains a bis-4,4′-phosphorylated β-1,6 linked D-glucosamine disaccharide moiety. The nature and substitution patterns of the fatty acyl groups attached to this disaccharide have not been reported. The fully acylated LPS molecule makes up the outer most leaflet of the bacterial membrane and is essential for maintaining membrane integrity. The glycose portion of the molecule typically extends out and away from the plane defined by the bacterial membrane. The LPS oligosaccharide portion is important in virulence (70) and is involved in eliciting host immune responses (17). To gain a perspective of the relative sizes and orientation of the core oligosaccharide and membrane-anchoring lipid A regions of this LPS molecule, a molecular model was constructed using the lipid A fatty acid substitution pattern found in a related organism, *Haemophilus influenzae*. This is shown in Fig. 10. The *H. influenzae* lipid A has been reported (71) to have six fatty acyl groups in which the amide group (C-2) and C-3 hydroxyl groups of the reducing glucosamine residue are acylated by 3-hydroxytetradecanoic acid while the C-2′ amide and C-3′ hydroxyl groups of the nonreducing residue are acylated by 3-tetradecanoyloxytetradecanoic acid.[2] As observed in Fig. 10, due to the inner core which provides a fairly rigid structure, the glycose portion projects out from the lipid A moiety which defines the bacterial membrane. More mobility was observed for the terminal residues, especially for the terminal Gal residue. In the NOESY spectrum in Fig. 2, no NOEs for the anomeric resonance were observed consistent with increased mobility of this residue.

The core structures of several LPS have been found to be highly branched (3) and this can result in well-defined conformations for the inner core. In a previous study, the LPS of *Moraxella catharrhalis* was found to adopt an unusual conformation in which a very rare *anti* conformer (72) was observed (73). For a highly branched 3,4,6-trisubstituted D-glucose residue in this LPS molecule, a dihedral angle (C-1′-O-1′-C-4-H-4) near 180° was detected for β-D-Glc*p*-(1–4)-D-Glc*p* linkage to the branched glucose unit.

The results of the present study have provided a detailed picture of the structure of the LPS core oligosaccharide region of *M. haemolytica* serotype A1. We have previously shown that the oligosaccharide region of *M. haemolytica* LPS is immunogenic in mice, sheep, and cattle and that eight of the 12 *M. haemolytica* serotypes (i.e., serotypes A1, A5, A6, A7, A8, A12, A14, and A16) share common core oligosaccharide determinants (17). The core oligosaccharides from serotypes A1 and A8 show almost identical ^{1}H NMR spectra (17) establishing the presence of a common basal structure. Based on the results of the present study it is apparent that the *O*-chain deficient LPS elaborated by *M. haemolytica* serotype A8 lacks the terminal Gal unit in the core oligosaccharide, a residue which possibly provides a site for *O*-chain attachment (16). An understanding of LPS structural differences among *M. haemolytica* serotypes could provide the basis for a vaccine against *M. haemolytica* bovine pasturellosis. Serotype A1 is the principal microorganism responsible for this disease, accounting for 30% of total cattle deaths globally (11). The use of a less virulent serotype or antigens thereof in a vaccine formulation could provide an effective disease management strategy.

Experimental

Preparation of LPS from *M. haemolytica*

Pasteurella (Mannheimia) haemolytica serotype A1 (NRCC 4212) was obtained from the Veterinary Infectious Diseases Organization (VIDO), Saskatoon, SK, Canada. LPS was extracted and purified from fermenter-grown bacteria culture by the hot aqueous phenol method as previously described (16).

Deacylation of LPS to give backbone oligosaccharides

Backbone oligosaccharide was prepared as previously described (74) by modification of the deacylation procedure of Holst et al. (75). Ester-bound fatty acids were removed from the lipid A of the LPS by treatment of a sample (400 mg) with anhydrous hydrazine at ambient temperature (20 mL, 37°C, 30 min). Excess hydrazine was destroyed by addition of acetone (three volumes) to the cooled reaction mixture (0°C). The precipitated *O*-deacylated LPS product was isolated by centrifugation (5000 rpm, 10 min), washed with acetone, and lyophylized from water. Removal of *N*-acyl groups was achieved by heating the *O*-deacylated sample (200 mg) in aq KOH (4 M, 10 mL) at 100°C for 20 h. The reaction mixture was cooled (0°C), neutralized with 4 M HCl, and the precipitated fatty acids removed by centrifugation (12 000 × g, 30 min). The supernatants were filtered in an Amicon concentration cell with a 500-molecular-weight-cutoff membrane (Amicon; YC05) and washed with deionized water until the eluant was free of chloride ions (as determined with aq $AgNO_3$). The dialyzed material was lyophylized to give deacylated LPS (ca. 80 mg). The oligosaccharide was purified by anion-exchange chromatography on DEAE A-25 (74). The backbone oligosaccharide fraction (ca. 50 mg) showed a doubly charged ion at *m*/*z* 1124.8 in the positive ion ESI-MS as the major ion which corresponded to a composition of Hex_3Hep_5 Kdo $HexN_2(H_2PO_3)_3$ (M, 2246.9). MS–MS of the doubly charged ion gave characteristic fragments at *m*/*z* 500 ($HexN_2(H_2PO_3)_2$) and 801 ($KdoHexN_2(H_2\ PO_3)_2$) corresponding to deacylated lipid A and the Kdo-P substituted units, respectively.

D-glycero-L-manno-*Heptose*

The heptose was prepared by the condensation of D-galactose with nitromethane in alkaline methanol (76). The crystalline 1-deoxy-1-nitro-D-*glycero*-L-*manno*-heptitol obtained from the aqueous solution of the deionized products (mp

[2] ES-MS of O-deacylated LPS from *M. heamolytica* serotype A1 is consistant with each glucosamine residue containing an amide-linked 3-hydroxytetradecanoic acid group (data not shown).

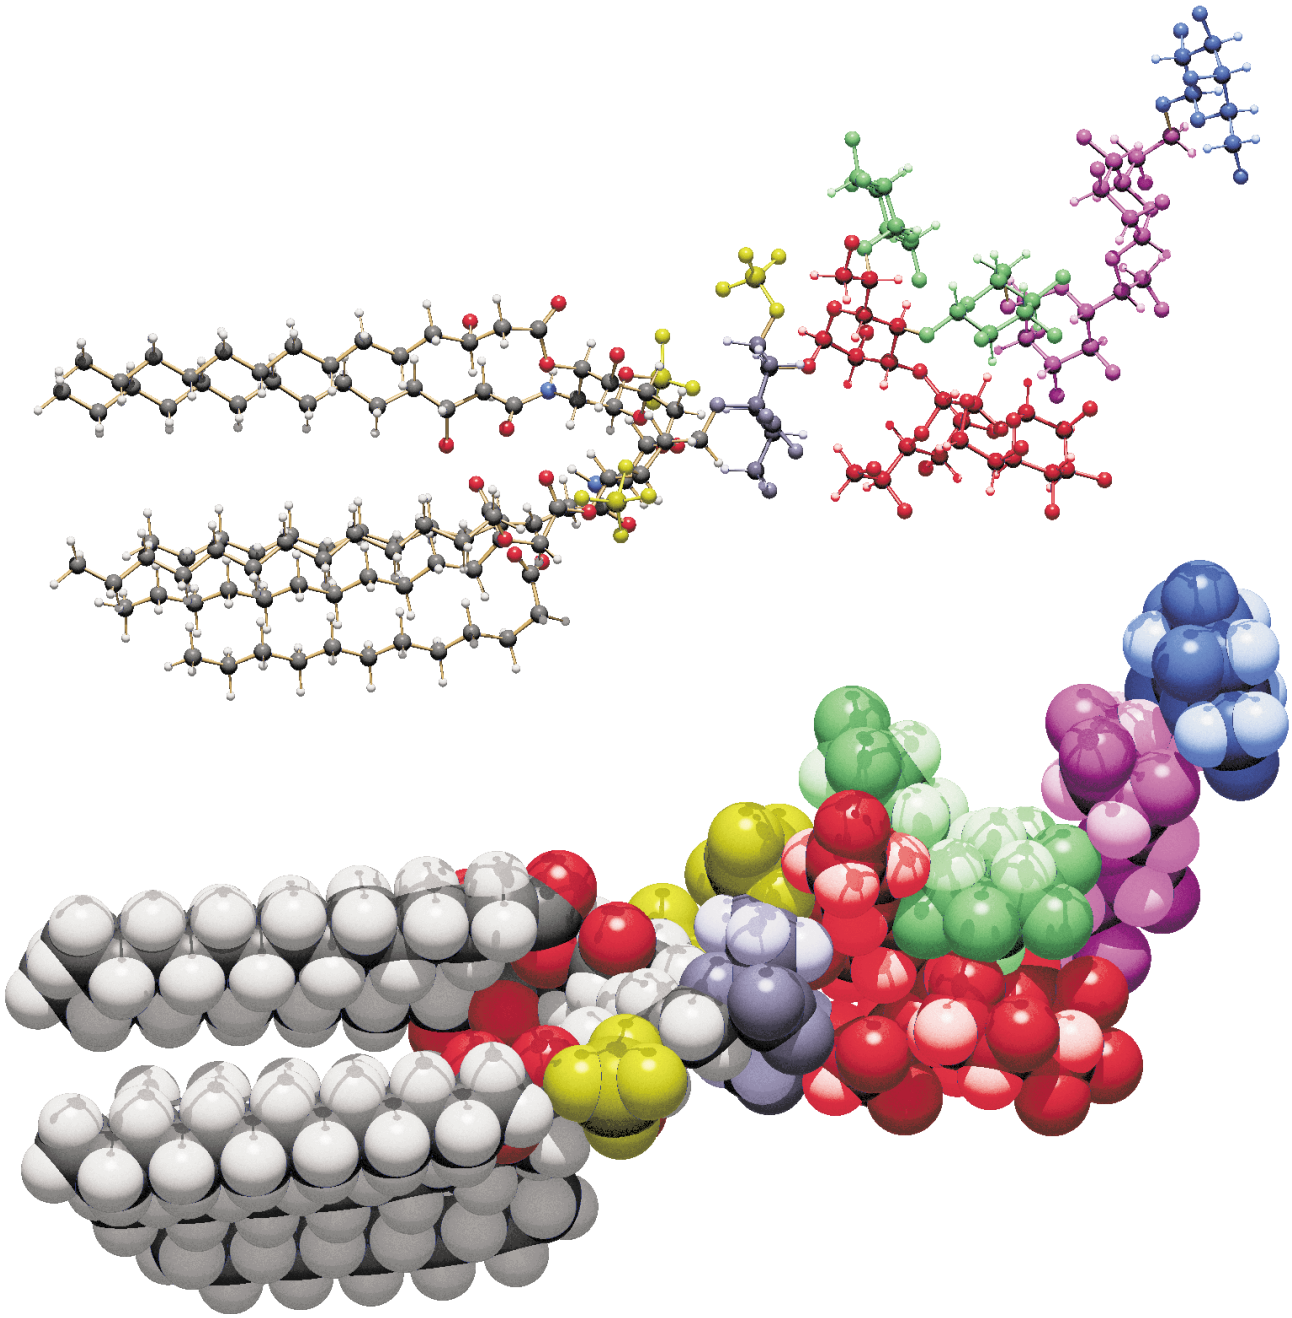
Fig. 10. Molecular model of the LPS of *M. haemolytica* A1 constructed using a lipid A having the fatty acyl substitution patterns reported (71) for LPS from *H. influenzae*. The lipid A moiety is colored with the atoms C in black, O in red, and H in white. The sugar moiety is colored with Kdo in gray, heptoses in red or purple, glucose in green, and galactose in blue. The PO_4 groups are yellow. Hydroxyl protons have been removed.



158°C, 21% yield) was converted to its sodium salt. On treatment with dilute sulphuric acid (35°C), followed by deionization with Rexyn 101(H^+) and Amberlite A4(OH^-) ion-exchange resins, the solution was lyophilized to give the heptose as a syrup (80% yield). The product was fractionated by cellulose column chromatography using butan-1-ol–water (1:10 v/v) as the eluant. Fractions containing the heptose were concentrated to dryness under reduced pressure. The D-*glycero*-L-*manno*-heptose having $[\alpha]_D$ –14° (*c* 0.2, water) was pure by paper chromatography and its reduced ($NaBH_4$) and acetylated product on GLC gave a single peak corresponding in retention time with that of authentic hepta-*O*-acetyl-D-*glycero*-L-*manno*-heptitol, establishing its purity.

D-glycero-D-manno-*Heptose*

The heptose was prepared from D-altrose via its condensation with nitromethane to yield 1-deoxy-1-nitro-D-*glycero*-D-*manno*-heptitol (mp 109°C, $[\alpha]_D$ –7.0° (*c* 1.1, EtOH), 27% yield)) whose aqueous sodium salt solution on slow dropwise addition to stirred 20% (v/v) sulfuric acid maintained at 0°C

© 2002 NRC Canada

was converted to D-*glycero*-D-*manno*-heptose (77). The reaction mixture was neutralized with sat. $Ba(OH)_2$ solution, filtered, passed through Rexyn 101(H^+) and Duolite A4(OH^-) ion-exchange resins to remove residual ionic material, and was concentrated to a syrup (92% yield). The heptose product, as indicated by paper chromatography, was contaminated with altrose and unchanged 1-deoxy-1-nitro-D-*glycero*-D-manno-heptitol (ca. 2 to 3%). The product was purified by cellulose column chromatography using butan-1-ol–water (1:10 v/v) as the mobile phase. The D-*glycero*-D-*manno*-mannose had $[\alpha]_D$ +22° (*c* 2, MeOH). A reduced ($NaBH_4$) and acetylated sample on GLC gave a single peak corresponding to authentic hepta-*O*-acetyl-D-*glycero*-D-*manno*-D-heptitol indicating the identity and purity of the synthesized heptose.

Electrospray mass spectrometry

Samples were analyzed on a VG Quattro triple quadrupole mass spectrometer (Micromass, Manchester, U.K.) fitted with an electrospray ion source. Backbone oligosaccharide was dissolved in acetonitrile–water (approx. 1:2 v/v) containing 0.5% acetic acid. Injection volumes were 10 μL and the flow rate was set at 4 mL min^{-1}. The electrospray tip voltage was typically 2.7 kV and the mass spectrometer was scanned from *m*/*z* 50 to 2500 with a scan time of 10 s. For MS–MS experiments, precursor ions were selected using the first quadrupole and fragment ions formed by collisional activation with argon in the RF-only quadrupole cell, were mass analyzed by scanning the third quadrupole. Collision energies were typically 60 ev (laboratory frame of reference).

Nuclear magnetic resonance

NMR spectra were performed on a Bruker AMX 600, AMX 500, or a Varian Inova 600 spectrometer using standard software. All measurements were made at 300 K and at pH 3, containing 10 mg of sample dissolved in 0.6 mL of D_2O. Measurements were done at pH 3 to improve resolution of the proton spectrum as done previously (65). Acetone was used as an internal or external reference at 2.225 ppm for ^1H spectra and 31.07 ppm for ^{13}C spectra. Standard homo- and heteronuclear correlated 2D techniques were used for general assignments of the core oligosaccharide: COSY, TOCSY, NOESY, triple quantum homonuclear correlated experiment, HMQC, HMQC-TOCSY, and HMBC and ^{31}P HMQC (78). Spin simulations for the heptose monosaccharides were performed with standard Varian software. Accurate chemical shifts and coupling constants were obtained from the parameters used to perform the spin simulation and not from the peak listing of the spectra.

Selective 1D-TOCSY, 1D-NOESY, 1D-TOCSY-TOCSY, 1D-TOCSY-NOESY, and 1D-NOESY-TOCSY experiments were performed for complete residue assignment and for determination of inter-residue ^1H-^1H nuclear Overhauser enhancements. The nomenclature used to describe the use of the 1D selective sequences will be 1D EXP (spin, mixing time) and 1D EXP1-EPX2 (spin1, mixing time; spin2, mixing time), where EXP, EXP1, and EXP2 stand for either TOCSY or NOESY. Also, in the figures, the selected resonances are underlined. A doubly underlined resonance means that this resonance was selected as the second selection step. As shown in Fig. 1, all the residues are labeled by letters and the spins are labeled by the atom number, so that a1 refers to the H-1 resonance of residue **a**.

On the AMX spectrometers, selective excitation was achieved by means of half-Gaussian pulses. The mixing time used for a TOCSY depended on the spin system. Usually a range of mixing times (spin lock times) from 30 to 180 ms was used to assign the spin system. The mixing time for a 1D-NOESY depended on the correlation time of the molecule and internal motion about the glycosidic linkage. NOESY mixing times were in the range from 150 to 400 ms. To detect inter-residue NOEs for the terminal Gal residue, a 1D-ROESY experiment was done with a mixing time of 500 ms. For the doubly selective experiments, the selective pulses were kept as short as possible to avoid loss of signal intensity due to relaxation effects. Each part was optimized one at a time. The 1D-TOCSY could be carried out in a matter of minutes. The 1D-NOESY took from minutes to hours depending on the magnitude of the NOE. Some doubly selective experiments took up to 12 h. The 1D-TOCSY-TOCSY and 1D-TOCSY-NOESY were the most efficient. As the sample degraded with time, some experiments were also performed on an Inova 600 spectrometer making use of pulse field gradients.

Molecular modeling

The conformational analysis was done using the Metropolis Monte Carlo method as previously described (79). The PFOS potential was used (80). Minimized coordinates for the monosaccharides were obtained using MM3 (92) available from the Quantum Chemistry Program Exchange (QCPE). The minimum energy conformation for each disaccharide was used as the starting conformation. Starting from the Kdo at the reducing end, calculations were performed for various oligosaccharides up to the complete structure. For the inner core octasaccharide, 5×10^4 macro moves were used with a step length of 5° for the glycosidic linkage and a temperature of 1×10^3 K resulting in an acceptance ratio of 0.36. The molecular model for the inner core octasaccharide was generated using the minimum energy conformer. Distances were extracted from the saved coordinates at each macro move. The complete LPS with lipid A was generated using the lipid A structure (81) and the minimum energy conformer for the Kdo linkage. Molecular drawings were done using Schakal97 from E. Keeler, University of Freiburg, Germany.

New mannotriosides and trimannosides as potential ligands for mannose-specific binding proteins

Richard H. Furneaux, Zbigniew Pakulski, and Peter C. Tyler

Abstract: The α-D-mannopyranosyl and 3,6-di-*O*-(α-D-mannopyranosyl)-α-D-mannopyranosyl neoglycolipids **3**–**6** and the branched and cluster trimannosidic acids **38** and **41** have been made in connection with studies of liposomes as transporters of antigens to dendritic cells.

Key words: mannotrioside, trimannoside, neoglycoconjugate, glycolipid, synthesis.

Résumé : Dans le cadre d'études sur les liposomes comme transporteurs d'antigènes dans des cellules dendritiques, on a préparé les néoglycolipides α-D-mannopyranosyl- et 3,6-di-*O*-(α-D-mannopyranosyl)-α-D-mannopyranosyle (**3**–**6**) ainsi que les acides trimannosidiques ramifié et en agrégat (**38** et **41**).

Mots clés : mannotrioside, trimannoside, néoglycoconjugué, glycolipide, synthèse.

[Traduit par la Rédaction]

Introduction

Terminal α-D-mannopyranosyl units commonly occur in the glycoproteins of pathogenic bacteria, yeasts, viruses, and various parasites and are recognised by receptors of macrophages (1) and dendritic cells (2, 3). Because the branched trisaccharide 3,6-di-*O*-(α-D-mannopyranosyl)-α-D-mannopyranosyl ligand binds with higher affinity to the mannose receptors of human macrophages and dendritic cells than do mono- and linear oligo-mannosyl ligands (4), we began studies of synthetic neoglycoconjugates and liposomes containing this trimer with a view to using the liposomes to transport antigens to dendritic cells.

In the first report of this work (5), we exploited the earlier finding (6, 7) that various α-D-mannopyranosides could be di-*O*-mannosylated concurrently and with some selectivity at O-3 and O-6 by use of tetra-*O*-acetyl-α-D-mannopyranosyl bromide to give the required branched-chain mannotriose derivatives, and we introduced the new tetra-*O*-benzoyl-α-D-mannopyranosyl trichloroacetimidate as glycosylating agent. By its use 8-(methoxycarbonyl)octyl α-D-mannopyranoside was converted to the 3,6-bis-*O*-(2,3,4,6-tetra-*O*-benzoyl-α-D-mannopyranosyl)-mannopyranoside in 55% yield, and the neoglycolipids **1** and **2** (Scheme 1) were made (5). More recently the 3,6-di-*O*-α-D-mannosylation of *p*-nitrophenyl α-D-mannopyranoside in 42% yield by use of tetra-*O*-acetyl-α-D-mannopyranosyl trichloroacetimidate as glycosylating agent has been described (4).

We now report (Scheme 1) the preparation of the neoglycolipids **3**–**6** which differ from analogues **1** and **2** in having four-carbon (compounds **3** and **5**) and six-carbon (compounds **4** and **6**) as opposed to nine-carbon atom spacer groups. Additionally, and with further neoglycolipids in view, the polyoxyethylene glycosides **30** and **34** and the mannotriose-containing acid **38** were made, as well as the alternative cluster type of trimannosyl glycosidic (8) acid **41** (Scheme 2). Considerable effort has gone into the study of this last kind of trimannoside (9).

Results and discussion

The neoglycolipids **3** and **4** (Scheme 1) were made following glycosylations of methyl 4-hydroxybutanoate and methyl 6-hydroxyhexanoate, respectively, by use of tetra-*O*-benzoyl-α-D-mannopyranosyl trichloroacetimidate. The first products **7** and **11** were converted successively to the required neoglycolipids by the previously used processes (5), that is, via the debenzoylated glycosides **8** and **12**, the carboxylic acids **9** and **13** and the *N*-succinimido derivatives **10** and **14**, respectively. The final step involved coupling of the activated acids **10** and **14** with dipalmitoyl-1-α-phosphatidyl ethanolamine (DPPE) to give products **3** and **4**.

Selective bis-(tetra-*O*-benzoyl-α-D-mannosylation) of glycosides **8** and **12**, by use of the glycosylating agent mentioned above, afforded the trisaccharide derivatives **15** and **21** which were isolated following chromatographic separation of their derived diacetates **16** (23% from **8**) and **22** (33% from **12**), respectively. Compounds **16** and **22** were used to prepare the neoglycolipids **5** and **6**, respectively, by the routes used for compounds **3** and **4**, i.e., **16**→**18**→**19**→**20**→**5** and **22**→**24**→**25**→**26**→**6** as also outlined in Scheme 1. The 1→3-, 1→6-linked trisaccharide

Compound	*n*	R
1	8	H
2	8	Man
3	3	H
4	5	H
5	3	Man
6	5	Man

Man = α–D-mannopyranosyl
Man Bz = tetra-*O*-benzoyl-α-D-mannopyranosyl
Suc = *N*-succinimido

Reagents: i, K_2CO_3, MeOH; ii, NaOH (aq.); iii, *N*-hydroxysuccinimide; DCC; iv, 1,2-hexadecanoyl-sn-glycero-3-phosphoethanolamine, $NaHCO_3$; v, tetra-*O*-benzoyl-D-mannopyranosyl trichloroacetimidate; vi, Ac_2O, Py; vii, NaOMe, MeOH

structures of the products **15** and **21** followed from the ^{1}H NMR characteristics of their diacetates **16** and **22**, the H-2 and H-4 resonances being ca. 1 ppm deshielded with respect to those of H-3, and the $J_{2,3}$ and $J_{3,4}$ coupling constant values being 3.4 and 9.8 Hz, respectively. These data compare closely with those obtained for the corresponding trisaccharide octa-*O*-benzoyl diacetate prepared in the course of making compound **2** (5).

During the isolation of the acetylated trisaccharide derivatives **16** and **22** the (3,4,6-tri-*O*-mannosyl)mannoside by-products **17** and **23**, containing small proportions of other oligosaccharide derivatives, were also obtained. The ^{1}H NMR spectra of monoacetates **17** and **23** showed δ values for the H-2 resonances of the central mannose residues of 5.34 and 5.43, respectively. The less-deshielding acetyl groups are consequently concluded to be substituted at O-2 since, for both of the compounds, the nine protons at the secondary benzoylated ring positions resonated within the range δ 5.79–6.27. The tetrasaccharide by-products are therefore 3,4,6-tris-*O*-(tetra-*O*-benzoyl-mannopyranosyl)-mannopyranosides.

In all the above cases the glycosylation reactions gave no observable orthoester by-products.

En route to alternative types of neoglycolipids the mono- and trisaccharide glycosides **27** and **35** (Scheme 2) were made by standard condensations of tetra-*O*-benzoyl-α-D-mannopyranosyl trichloroacetimidate with the corresponding alcohols whereas, in our hands, the corresponding acetylglycosyl bromide with mercury(II) cyanide was more effective for the preparation of triglycoside **39** from [tris(hydroxymethyl)]methyl-(5-methoxycarbonyl)pentanoamide (8).

From **27** and **35** the acids **30** and **38** were made by standard methods, and from **27** the extended-chain compound **34** was produced via the azide **31**. The dimannosylation of compound **29** gave the 1→3-,1→6-linked trisaccharide derivative **35** in 40% yield, the positions of substitution being determined from the ^{1}H,^{1}H coupling constants of the H-2 and H-4 resonances of the derived diacetate **36**. De-esterification of the substituted triglycoside **39** gave acid **41** via methyl ester **40**.

The biological evaluation of compounds described above will be reported separately.

Man Ac = tetra-*O*-acetyl-α-D-mannopyranosyl.
For other abbreviations see Scheme 1.

Reagents: i, KCN, DMSO; ii, K_2CO_3, MeOH; iii, NaOH (aq.); iv, NaN_3, DMF; v, $NaBH_4$, $NiCl_2$, EtOH; vi, methyl adipate, 2-ethoxy-1-ethoxycarbonyl-1,2-didydroquinoline ; vii, tetra-*O*-benzoyl-D-mannopyranosyl trichloroacetimidate; viii, Ac_2O, Py; ix, NaOMe, MeOH.

Experimental

General methods

All glycosylation reactions were performed under argon in dry CH_2Cl_2. TLC was performed on silica gel HF-254 and column chromatography on silica gel 230–400 mesh (Merck). ^1H NMR spectra were recorded with a Bruker Avance 300 MHz NMR spectrometer equipped with a 5 mm o.d. Quattro nucleus probe or (when indicated) a Varian Unity 500 MHz spectrometer equipped with 5 mm Universe probe. Resonance assignments were by use of DEPT, H,H-COSY, inverse C,H-COSY, and H,H-TOCSY experiments. All spectra were consistent with those expected for the structures assigned to the respective compounds; unresolved resonances and those of substituent groups and carbonyl groups (^{13}C spectra) are frequently not listed. High resolution mass spectra (HR-MS) were measured with a VG70-250S double focussing magnetic sector mass spectrometer or a Mariner 8105 electrospray TOF mass spectrometer. Optical rotations were measured with a PerkinElmer 241 automatic polarimeter. 2-[2-(2-Chloroethoxy)ethoxy]ethanol was purchased from Aldrich.

*3-(Methoxycarbonyl)propyl 2,3,4,6-tetra-*O*-benzoyl-α-D-mannopyranoside (7)*

A solution of 2,3,4,6-tetra-*O*-benzoyl-α-D-mannopyranosyl trichloroacetimidate (5) (4.45 g, 6.0 mmol) and methyl 4-hydroxybutanoate (10) (760 mg, 6.4 mmol) in CH_2Cl_2 (30 mL) was stirred for 30 min at room temperature over molecular sieves (4 Å, 700 mg, finely ground). The solution was cooled in an ice bath and TmsOTf (60 μL) was added. After 20 min the reaction was quenched by addition of Et_3N (0.5 mL), and the solvent was evaporated in vacuo. Column chromatography (hexane–EtOAc, 2:1) gave the title compound **7** (3.60 g, 92%, contaminated with 10% of inseparable methyl 4-hydroxybutanoate): $[\alpha]_D^{20}$ –47 (*c* 1.0, $CHCl_3$, corrected for the impurity). ^1H NMR ($CDCl_3$) δ: 6.10 (t, $J_{3,4}$, $J_{4,5}$ = 10 Hz, 1H, H-4), 5.88 (dd, $J_{2,3}$ = 3.3 Hz, 1H, H-3), 5.69 (dd, $J_{1,2}$ = 1.8 Hz, 1H, H-2), 5.08 (d, 1H, H-1), 4.69 (dd, $J_{5,6}$ = 2.5 Hz, $J_{6,6'}$ = 12.0 Hz, 1H, H-6), 4.50 (dd, $J_{5,6'}$ = 4.4 Hz, 1H, H-6′), 4.42 (m, 1H, H-5), 3.90 (dt, *J* = 9.8, 6.2 Hz, 1H, OC*H*H), 3.73 (s, 3H, Me), 3.61 (dt, *J* = 9.8, 6.3 Hz, 1H, OCH*H*), 2.53 (m, 2H, CH_2), 2.06 (m, 2H, CH_2). ^{13}C NMR ($CDCl_3$) δ: 97.65 (C-1), 70.43, 70.09, 68.93, 67.48 (CH_2), 66.91, 62.87 (CH_2), 51.69 (CH_3), 30.78 (CH_2), 24.73 (CH_2). FAB-HR-MS calcd. for $C_{39}H_{37}O_{12}$ $[M + H]^+$ (*m*/*z*): 697.2285; found: 697.2330.

3-(Methoxycarbonyl)propyl α-D-mannopyranoside (8)

To a solution of compound **7** (3.6 g) in methanol (60 mL) K_2CO_3 (300 mg) was added and the mixture was stirred overnight then neutralized with Amberlyst 15 resin (H^+), filtered and the filtrate was evaporated to dryness. Column chromatography ($CHCl_3$–MeOH, 3:1) of the residue gave

© 2002 NRC Canada

8 (1.03 g, 71% after two debenzoylation treatments): $[\alpha]_D^{20}$ +54.2 (*c* 0.59, MeOH). ^{1}H NMR (CD_3OD) δ: 4.74 (d, $J_{1,2}$ = 1.5 Hz, 1H, H-1), 3.68 (s, Me), 2.44 (t, 2H, CH_2), 1.91 (m, 2H, CH_2). ^{13}C NMR (CD_3OD) δ: 176.03 (C=O), 101.97 (C-1), 75.07, 73.04, 72.56, 69.02, 67.92 (CH_2), 63.33 (CH_2), 52.47 (CH_3), 32.19 (CH_2), 26.40 (CH_2). FAB-HR-MS calcd. for $C_{11}H_{21}O_8$ $[M + H]^+$: 281.1236; found: 281.1243.

3-Carboxypropyl* α-D-*mannopyranoside (9)

NaOH (0.75 mL, 3M aq) was added to a solution of the methyl ester **8** (517 mg, 1.84 mmol) in THF (15 mL) and water (7 mL), The reaction mixture was stirred for 24 h, neutralised with Amberlyst 15 resin (H^+), filtered, concentrated in vacuo and freeze-dried to afford the acid **9** (440 mg, 90%): $[\alpha]_D^{20}$ +46.1 (*c* 0.41, water). ^{1}H NMR (D_2O) δ: 4.78 (d, $J_{1,2}$ = 1.2 Hz, 1H, H-1), 3.46–3.87 (m, 8H), 2.42 (t, 2H, CH_2), 1.86 (m, 2H, CH_2). ^{13}C NMR (D_2O) δ: 178.73 (C=O), 100.11 (C-1), 73.12, 71.00, 70.44, 67.22 (CH_2), 67.15, 61.31 (CH_2), 31.36 (CH_2), 24.55 (CH_2). FAB-HR-MS calcd. for $C_{10}H_{19}O_8$ $[M + H]^+$: 267.1080; found: 267.1084.

3-[Carboxy-2-(1,2-dihexadecanoyl*-sn-*glycero-3-phospho)ethanolamido]propyl* α-D-*mannopyranoside sodium salt (3)

A mixture of acid **9** (119 mg, 0.45 mmol), DCC (248 mg, 1.5 mmol), *N*-hydroxysuccinimide (139 mg, 1.5 mmol) in THF (6.5 mL) – $CHCl_3$ (3 mL) – methanol (6.5 mL) was stirred at room temperature for 24 h. The solvent was removed and column chromatography ($CHCl_3$–MeOH, 4:1) of the residue gave the crude amide **10** (115 mg, 71%). FAB-HR-MS calcd. for $C_{14}H_{12}NO_{10}$ $[M + H]^+$: 364.1244; found: 364.1225.

To a suspension of 1,2-dihexadecanoyl-*sn*-glycero-3-phosphoethanolamine (DPPE, 200 mg, 0.284 mmol) in $CHCl_3$–MeOH (2:1, 6 mL), water (0.4 mL), and $NaHCO_3$ (120 mg, 1.42 mmol) were added, and the mixture was stirred at 30°C for 30 min. A solution of **10** (94 mg, 0.27 mmol) in $CHCl_3$–MeOH (2:1, 6 mL) was added and stirring was continued at 30°C overnight. The solvents were evaporated and column chromatography ($CHCl_3$–MeOH, 3:1) of the residue gave glycolipid **3**, 125 mg (47%): $[\alpha]_D^{20}$ +17.1 (*c* 0.38, $CHCl_3$–MeOH, 3:1). ^{13}C NMR ($CDCl_3$–CD_3OD, 3:1) δ: 174.33, 173.93, 173.61 (C=O), 100.09 (C-1), 72.59, 71.39, 71.15, 70.75, 70.50, 66.55, 66.55 (CH_2), 64.39 (CH_2), 63.80 (CH_2), 62.66 (CH_2), 61.89 (CH_2), 61.18 (CH_2), 60.89 (CH_2), 57.62 (CH_2), 51.60, 40.36 (CH_2), 34.26 (CH_2), 34.11 (CH_2), 31.94 (CH_2), 29.70 (CH_2), 29.36 (CH_2), 29.22 (CH_2), 25.34 (CH_2), 24.94(CH_2), 22.67 (CH_2), 13.96 (CH_3). FAB-HR-MS calcd. for $C_{47}H_{89}NO_{15}P$ $[M]^+$: 938.5970; found: 938.6012.

5-(Methoxycarbonyl)pentyl 2,3,4,6-tetra*-O-*benzoyl*-α-D-*mannopyranoside (11)

Glycosylation of methyl 6-hydroxyhexanoate (11) (0.94 g, 6.4 mmol) was carried out with the glycosylating agent (4.45 g, 6.0 mmol) used in the preparation of compound **7** and gave 5.16 g of crude title compound contaminated with 6-hydroxyhexanoate. A chromatographically purified sample had: ^{1}H NMR ($CDCl_3$) δ: 6.10 (t, $J_{3,4}$, $J_{4,5}$ = 10 Hz, 1H, H-4), 5.92 (dd, $J_{2,3}$ = 3.3 Hz, 1H, H-3), 5.69 (dd, $J_{1,2}$ = 1.8 Hz, 1H, H-2), 5.08 (d, 1H, H-1), 4.69 (dd, $J_{5,6}$ = 2.4 Hz, $J_{6,6'}$ = 12.0 Hz, 1H, H-6), 4.50 (dd, $J_{5,6'}$ = 4.5 Hz, 1H, H-6′), 4.42 (m, 1H, H-5), 3.84 (dt, *J* = 6.6, 6,6, 9.6 Hz, 1H, OC*H*H), 3.68 (s, 3H, CH_3), 3.58 (dt, *J* = 6.6, 6,6, 9.6 Hz, 1H, OCH*H*), 2.36 (t, 2H, CH_2), 1.71 (m, 4H, 2 × CH_2), 1.46 (m, 2H, CH_2). ^{13}C NMR ($CDCl_3$) δ: 98.08 (C-1), 71.02, 70.55, 69.28, 68.83 (CH_2), 67.46, 63.37 (CH_2), 51.87 (CH_3), 34.32 (CH_2), 29.46 (CH_2), 26.08 (CH_2) 25.05 (CH_2). FAB- HR-MS calcd. for $C_{41}H_{41}O_{12}$ $[M + H]^+$: 725.2598; found: 725.2582.

5-(Methoxycarbonyl)pentyl* α-D-*mannopyranoside (12)

Debenzoylation was carried out on compound **11** (5.16 g) as with the ester **7** to give glycoside **12** (1.735 g, 93%, two treatments): $[\alpha]_D^{20}$ +44.1 (*c* 0.76, MeOH). ^{1}H NMR (CD_3OD) δ: 4.74 (d, $J_{1,2}$ = 1.5 Hz, 1H, H-1), 3.84 (dd, $J_{5,6}$ = 2.3 Hz, $J_{6,6'}$ = 11.7 Hz, 1H, H-6), 3.80 (dd, $J_{2,3}$ = 3.2 Hz, 1H, H-2), 3.68–3.77 (m, 3H, H-3, H-6′, OC*H*H), 3.67 (s, 3H, CH_3), 3.62 (t, $J_{3,4}$, $J_{4,5}$ = 9.2 Hz, 1H, H-4), 3.54 (m, 1H, H-5), 3.43 (dt, *J* = 6.6, 6,6, 9.6 Hz, 1H, OCH*H*), 2.35 (t, *J* = 7.4 Hz, 2H, CH_2), 1.64 (m, 4H, 2 × CH_2), 1.44 (m, 2H, CH_2). ^{13}C NMR (CD_3OD) δ: 176.32 (C=O), 101.98 (C-1), 75.02, 73.09, 72.67, 69.08, 68.73(CH_2), 63.36 (CH_2), 52.38 (CH_3), 35.12 (CH_2), 30.62 (CH_2), 27.27 (CH_2), 26.19 (CH_2). FAB-HR-MS calcd. for $C_{13}H_{25}O_8$ $[M + H]^+$: 309.1549; found: 309.1540.

5-Carboxypentyl* α-D-*mannopyranoside (13)

Ester hydrolysis of **12** (785 mg, 2.54 mmol) was carried out as for compound **8** and gave **13** (750 mg, 100%): $[\alpha]_D^{20}$ +53.2 (*c* 0.34, MeOH). ^{1}H NMR (CD_3OD) δ: 4.76 (d, $J_{1,2}$ = 1.5 Hz, 1H, H-1), 3.33–3.89 (m, 8H), 2.28 (t, 2H, CH_2), 1.65 (m, 4H, 2 × CH_2), 1.42 (m, 2H, CH_2). ^{13}C NMR (CD_3OD) δ: 179.48 (C=O), 101.95 (C-1), 74.91, 73.05, 72.65, 69.01, 68.85 (CH_2), 63.17 (CH_2), 36.42 (CH_2), 30.71 (CH_2), 27.43(CH_2), 26.68 (CH_2). FAB-HR-MS calcd. for $C_{12}H_{23}O_8$ $[M + H]^+$: 295.1393; found: 295.1398.

5-(*N*-Succinimidyloxycarbonyl)pentyl* α-D-*mannopyranoside (14)

Amide formation was effected with acid **13** (148 mg, 0.5 mmol) as for analogue **9** and gave amide **14** (170 mg, 89%). ^{13}C NMR (CD_3OD) δ: 101.97 (C-1), 75.00, 73.08, 72.66, 69.09, 68.70 and 63.35 (CH_2), 52.73, 32.55 (CH_2), 30.53 (CH_2), 27.12 (CH_2), 26.92 (CH_2), 25.94 (CH_2). FAB-HR-MS calcd. for $C_{16}H_{26}NO_{10}$ $[M + H]^+$: 392.1557; found: 392.1542.

5-[Carboxy-2-(1,2-dihexadecanoyl*-sn-*glycero-3-phospho)ethanolamido]pentyl* α-D-*mannopyranoside sodium salt (4)

The title glycolipid (170 mg, 87%) was made from amide **14** (77 mg, 0.19 mmol) in like manner to its analogue **3**: $[\alpha]_D^{20}$ +13.1 (*c* 0.58, $CHCl_3$–MeOH, 2:1). ^{13}C NMR ($CDCl_3$–CD_3OD) δ: 101.94, 74.76, 73.12, 72.63, 69.05, 68.82 (CH_2), 63.34 (CH_2), 52.62, 50.11, 35.44 (CH_2), 35.25 (CH_2), 33.51 (CH_2), 31.20 (CH_2), 31.01 (CH_2), 30.92 (CH_2), 30.81 (CH_2), 30.66 (CH_2), 27.22 (CH_2), 26.50 (CH_2), 24.19 (CH_2), 15.09 (CH_3). FAB-HR-MS calcd. for $C_{49}H_{93}NNaO_{15}P$ $[M]^+$: 989.6180; found: 989.6157.

3-(Methoxycarbonyl)propyl 2,4-di-O-acetyl-(2,3,4,6-tetra-O-benzoyl-α-D-mannopyranosyl)-(1→3)-[(2,3,4,6-tetra-O-benzoyl-α-D-mannopyranosyl)-(1→6)]-α-D-mannopyranoside (16) and 3-(methoxycarbonyl)propyl 2-O-acetyl-(2,3,4,6-tetra-O-benzoyl-α-D-mannopyranosyl)-(1→3)-[(2,3,4,6-tetra-O-benzoyl-α-D-mannopyranosyl)-(1→4)]-{[(2,3,4,6-tetra-O-benzoyl-α-D-mannopyranosyl)-(1→6)]}-α-D-mannopyranoside (17)

A solution of glycoside **8** (832 mg, 3.0 mmol) in CH_2Cl_2 (50 mL) was stirred at room temperature over molecular sieves (4 Å, 500 mg, finely ground) for 30 min. The solution was cooled to −40°C and TmsOTf (200 μL) was added, followed by 2,3,4,6-tri-*O*-benzoyl-α-D-mannopyranosyl trichloroacetimidate (4.41 g, 5.95 mmol) in CH_2Cl_2 (30 mL) dropwise over 30 min. The solution was stirred for further 30 min, treated with Et_3N (0.5 mL), and evaporated to dryness. Column chromatography (hexane–EtOAc, 1.5:1, then 1:1) afforded a mixture of trisaccharide (**15**) (FAB-HR-MS calcd. for $C_{79}H_{72}O_{26}Cs$ $[M + Cs]^+$: 1569.3366; found 1569.3367) and tetrasaccharide derivatives (2.863 g). Acetylation of this crude mixture under standard conditions followed by column chromatography (hexane–EtOAc, 1:1) gave the following title compounds.

16:

(1.055 g, 23%): $([\alpha]_D^{20}$ −21.3 (*c* 0.65, $CHCl_3$). ^1H NMR (500 MHz, $CDCl_3$) δ: 6.18 (t, $J_{3'',4''}$, $J_{4'',5''}$ = 10 Hz, 1H, H-4″), 6.13 (t, $J_{3',4'}$, $J_{4',5'}$ = 10 Hz, 1H, H-4′), 5.95 (dd, $J_{2',3'}$ = 3.3 Hz, 1H, H-3′), 5.82 (dd, $J_{2'',3''}$ = 3.2 Hz, 1H, H-3″), 5.75 (dd, 1H, H-2′), 5.53 (dd, 1H, H-2″), 5.44 (m, 2H, H-2,4), 5.37 (d, $J_{1'',2''}$ = 1.7 Hz, 1H, H-1″), 5.16 (d, $J_{1',2'}$ = 1.7 Hz, 1H, H-1′), 4.88 (d, $J_{1,2}$ = 1.7 Hz, 1H, H-1), 4.71 (m, 2H, H-6′a, H-6″a), 4.59 (m, 2H, H-5′, H-5″), 4.52 (m, 2H, H-6′b, H-6″b), 4.37 (dd, $J_{2,3}$ = 3.4 Hz, $J_{3,4}$ = 9.8 Hz, 1H, H-3), 4.02 (m, 2H, H-5,6a), 3.89 (dt, *J* = 6.6, 6,6, 9.6 Hz, 1H, OC*H*H), 3.69 (m, 1H, H-6b), 3.63 (s, 3H, CH_3), 3.57 (dt, *J* = 6.6, 6,6, 9.6 Hz, 1H, OCH*H*), 2.45 (m, 2H, CH_2), 2.32, 2.27 (2s, 2 × 3 H, OAc), 2.00 (m, 2H, CH_2). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 99.46 (C-1″), 97.87 (C-1′), 97.80 (C-1), 75.39 (C-3), 71.39 (C-2), 71.19 (C-2″), 70.86 (C-2′), 70.39 (C-3′), 70.10, 70.07 (C-5, C-5″), 69.78 (C-3″), 69.41 (C-5′), 68.89 (C-4), 67.70 (OCH_2), 67.29 (C-6, C-4′), 66.93 (C-4″), 63.35, 63.02 (C-6′, C-6″), 51.95 (CH_3), 31.19 (CH_2), 25.08 (CH_2), 21.41 (*C*H_3CO), 21.22 (*C*H_3CO). FAB-HR-MS calcd. for $C_{83}H_{76}O_{28}Cs$ $[M + Cs]^+$: 1653.3577; found: 1653.3583.

17:

(1.670 g, 27%, containing small proportions of other oligosaccharide derivatives). ^1H NMR (500 MHz, $CDCl_3$) δ: 6.21 (t, $J_{3'',4''}$, $J_{4'',5''}$ = 10.1 Hz, 1H, H-4″), 6.12, 6.10 (dt, 2H, H-4′, H-4‴), 6.04 (m, 2H, H-2′, H-3′), 5.95 (dd, $J_{2'',3''}$ = 2.7 Hz, 1H, H-3″), 5.91 (dd, $J_{2''',3'''}$ = 3.2 Hz, $J_{3''',4'''}$ = 10.2 Hz, 1H, H-3‴), 5.88 (m, 1H, H-2″), 5.79 (m, 1H, H-2‴), 5.68 (d, $J_{1'',2''}$ = 1.7 Hz, 1H, H-1″), 5.51 (d, $J_{1',2'}$ = 1.5 Hz, 1H, H-1′), 5.34 (dd, $J_{2,3}$ = 3.0 Hz, 1H, H-2), 5.26 (d, $J_{1''',2'''}$ = 1.7 Hz, 1H, H-1‴), 4.83 (d, $J_{1,2}$ = 1.7 Hz, 1H, H-1), 4.43–4.73 (m, 9H, H-5′, 6′a, 6′b, H-5″, 6″a, 6″b, H-5‴, 6‴a, 6‴b), 4.38 (m, 2H, H-3, H-4), 4.23 (dd, $J_{5,6a}$ = 5 Hz, $J_{6a,6b}$ = 12 Hz, 1H, H-6a), 4.18 (dd, $J_{5,6b}$ = 1.5 Hz, 1H, H-6b), 4.00 (m, 1H, H-5), 3.82, 3.48 (2m, 2H, OC$H_2$$CH_2$), 3.58 (s, 3H, CH_3), 2.38 (m, 2H, CH_2), 2.18 (s, 3H, Ac), 1.92 (m, 2H, CH_2). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 100.68 (C-1′), 100.43 (C-1″), 98.53 (C-1‴), 97.14 (C-1), 79.61 (C-3), 76.52 (C-4), 72.29 (C-2), 71.86 (C-2″); 71.66 (C-5), 71.33 (C-2′), 70.78 (C-2‴), 70.48 (C-3‴), 70.27, 70.16, 69.56 (C-5′, C-5″, C-5‴), 69.77, 69.73 (C-3′, C-3″); 68.80 (CH_2), 68.80, 67.25, 67.24 (C-4′, C-4″, C-4‴), 66.97 (C-6), 63.49, 63.08, 62.95 (C-6′, C-6″, C-6‴), 51.95 (CH_3), 31.11 (CH_2), 25.12 (CH_2), 21.38 (*C*H_3CO). FAB-HR-MS calcd. for $C_{115}H_{100}O_{36}Cs$ $[M + Cs]^+$: 2189.5049; found: 2189.5031.

3-(Methoxycarbonyl)propyl (α-D-mannopyranosyl)-(1→3)-[(α-D-mannopyranosyl)-(1→6)]-α-D-mannopyranoside (18)

To a solution of the perester **16** (1.050 g, 0.65 mmol) in MeOH (30 mL) was added NaOMe (8 mmol, 1 M in MeOH), and the mixture was stirred at room temperature for 24 h, taken to pH ~ 5 with Amberlyst 15 (H^+), filtered, and evaporated to dryness to afford the title trisaccharide glycoside **18** (420 mg, 100%): $[\alpha]_D^{20}$ +74.7 (*c* 0.38, H_2O). ^1H NMR (D_2O) δ: 5.07 (d, $J_{1,2}$ = 1.4 Hz, 1H, H-1), 4.86 (d, $J_{1,2}$ = 1.5 Hz, 1H, H-1), 4.77 (d, $J_{1,2}$ = 1.4 Hz, 1H, H-1), 3.43–4.03 (m, 26H), 2.46 (t, 2H, CH_2), 1.93 (m, 2H, CH_2). ^{13}C NMR (D_2O) δ: 177.24 (C=O), 102.77, 100.32, 99.83 (C-1), 79.00, 73.74, 73.11, 71.51, 71.03, 70.81, 70.49, 70.39, 70.08, 67.35 (CH_2), 67.16, 66.12, 65.74 (CH_2), 61.38 (2 × CH_2), 52.65 (CH_3), 31.19 (CH_2) and 24.54 (CH_2). FAB-HR-MS calcd. for $C_{23}H_{41}O_{18}$ $[M + H]^+$: 605.2293; found: 605.2321.

3-Carboxypropyl (α-D-mannopyranosyl)-(1→3)-[(α-D-mannopyranosyl)-(1→6)]-α-D-mannopyranoside (19)

To a solution of glycoside **18** (121 mg, 0.20 mmol) in H_2O (3 mL), NaOH (0.5 mL, 3 M, aq) was added. The reaction mixture was stirred for 2 days, neutralized with Amberlyst 15 resin (H^+), filtered, and freeze-dried to afford the acid **19** (120 mg, 101%): $[\alpha]_D^{20}$ +85.5 (*c* 0.31, MeOH). ^{13}C NMR (CD_3OD) δ: 170.34 (C=O), 104.27, 102.17, 101.81 (C-1), 81.13, 75.32, 74.76, 73.90, 73.06, 72.89, 72.48 (2×CH), 71.81, 69.22, 69.01, 68.17 (CH_2), 67.89, 67.68 (CH_2), 63.29 (2 × CH_2), 32.27 (CH_2), 26.44 (CH_2). FAB-HR-MS calcd. for $C_{22}H_{39}O_{18}$ $[M + H]^+$: 591.2136; found: 591.2159.

3-(N-Succinimidyloxycarbonyl)propyl (α-D-mannopyranosyl)-(1→3)-[(α-D-mannopyranosyl)-(1→6)]-α-D-mannopyranoside (20)

By use of the procedure described for making amide **10**, and using $CHCl_3$ – MeOH – H_2O (5:4:1) as eluent for column chromatography, acid **19** (115 mg, 0.19 mmol) was converted to amide **20** (85 mg, 64%): $[\alpha]_D^{20}$ +87.8 (*c* 0.23, MeOH). ^{13}C NMR ($CDCl_3$) δ: 104.36, 102.28 and 101.81 (C-1, C-1′, C-1″), 81.13, 75.32, 74.76, 73.90, 73.06, 72.89, 72.48, 69.22, 69.01, 67.89, 67.68 (2×CH_2), 63.29 (2×CH_2), 32.27 (CH_2), 30.16, (CH_2), 28.69 (CH_2), 26.17 (CH_2). FAB-HR-MS calcd. for $C_{26}H_{42}NO_{20}$ $[M + H]^+$: 688.2300; found: 688.2317.

3-[Carboxy-2-(1,2-dihexadecanoyl-sn-glycero-3-phospho)ethanolamido]propyl (α-D-mannopyranosyl)-(1→3)-[(α-D-mannopyranosyl)-(1→6)]-α-D-mannopyranoside sodium salt (5)

From amide **20** (83 mg, 0.12 mmol), according to the procedure described for making glycolipid **3**, the analogue **5**

© 2002 NRC Canada

(105 mg, 70%, containing small proportions of 1,2-hexadecanoyl-*sn*-glycero-3-phosphoethanolamine) was obtained following column chromatography with $CHCl_3$–MeOH–H_2O (5:4:1) as eluent: $[\alpha]_D^{20}$ +26.4 (*c* 0.25, $CHCl_3$–MeOH, 3:1). ^{13}C NMR ($CDCl_3$) δ: 106.47, 104.85 and 104.04 (C-1, C-1′, C-1″), 83.33, 77.55, 76.92, 75.90, 75.30, 75.00, 74.65, 71.32, 71.10, 70.17, 69.78, 68.63, 68.04, 66.85, 66.01, 65.27, 44.72, 38.48, 38.33, 36.92, 36.15, 33.93, 33.58, 33.40, 29.53, 29.14, 26.88 and 18.17. FAB-HR-MS calcd. for $C_{59}H_{110}NNaO_{25}P$ $[M]^+$: 1286.7002; found: 1286.6958.

5-(Methoxycarbonyl)pentyl 2,4-di-O-acetyl-(2,3,4,6-tetra-O-benzoyl-α-D-mannopyranosyl)-(1→3)-[(2,3,4,6-tetra-O-benzoyl-α-D-mannopyranosyl)-(1→6)]-α-D-mannopyranoside (22) and 5-(methoxycarbonyl)pentyl 2-O-acetyl-(2,3,4,6-tetra-O-benzoyl-α-D-mannopyranosyl)-(1→3)-[(2,3,4,6-tetra-O-benzoyl-α-D-mannopyranosyl)-(1→4)]-{[(2,3,4,6-tetra-O-benzoyl-α-D-mannopyranosyl)-(1→6)]}-α-D-mannopyranoside (23)

A solution of glycoside **12** (917 mg, 2.97 mmol) in CH_2Cl_2 (50 mL) was mannosylated as for the analogue **8**, and column chromatography (hexane–EtOAc, 1.5:1, then 1:1) afforded two main fractions (692 mg) and (2.73 g) (in order of elution), both as mixtures of products mainly containing trisaccharide derivative **21** and a tetrasaccharide analogue. Acetylation of the second fraction under standard conditions followed by column chromatography (hexane–EtOAc, 1:1) gave the trisaccharide glycoside perester **22** and **23**. The latter contained small proportions of impurities — probably tri- and tetra-saccharide isomers of the main products.

2-[2-(2-Chloroethoxy)ethoxy]ethyl 2,3,4,6-tetra-O-*benzoyl*-α-D-*mannopyranoside (27)*

2-[2-(2-Chloroethoxy)ethoxy]ethanol (1.00 g, 5.95 mmol) was glycosylated according to the procedure described for making glycoside **7**, to give product **27** (4.07 g, 91%): $[\alpha]_D^{20}$ −48.2 (*c* 0.57, $CHCl_3$). ^1H NMR ($CDCl_3$) δ: 6.11 (t, $J_{3,4}$, $J_{4,5}$ = 10.1 Hz, 1H, H-4), 5.94 (dd, $J_{2,3}$ = 3.3 Hz, 1H, H-3), 5.73 (dd, $J_{1,2}$ = 1.8 Hz, 1H, H-2), 5.16 (d, 1H, H-1), 4.70 (m, 1H, H-6), 4.50 (m, 2H, H-5,6′), 4.00–3.61 (m, 12H, spacer protons). ^{13}C NMR ($CDCl_3$) δ: 98.22 (C-1), 71.83 (CH_2), 71.20 (CH_2), 71.14 (CH_2), 70.90, 70.61 (CH_2), 70.47, 69.25, 68.05 (CH_2), 67.39, 63.27 (CH_2), 43.18 (CH_2). FAB-HR-MS calcd. for $C_{40}H_{40}ClO_{12}$ $[M + H]^+$: 747.2208; found: 747.2184.

2-[2-(2-Cyanoethoxy)ethoxy]ethyl 2,3,4,6-tetra-O-*benzoyl*-α-D-*mannopyranoside (28)*

A mixture of chloro-compound **27** (3.98 g, 5.33 mmol), potassium cyanide (3.26 g 50 mmol), and DMSO (40 mL) was stirred under argon at 65°C for 22 h. Water (100 mL) was added, and the mixture was extracted with EtOAc (4 × 50 mL). The combined organic extracts were washed with H_2O (20 mL), dried (Na_2SO_4), and evaporated to dryness. Column chromatography (hexane–EtOAc, 1:1) of the residue gave the nitrile **28** (2.77 g, 70%): $[\alpha]_D^{20}$ –37.2 (*c* 0.78, $CHCl_3$). IR (film) (cm^{-1}): 2253. ^1H NMR ($CDCl_3$) δ: 6.11 (t, $J_{3,4}$, $J_{4,5}$ = 10.1 Hz, 1H, H-4), 5.93 (dd, $J_{2,3}$ = 3.3 Hz, 1H, H-3), 5.72 (dd, $J_{1,2}$ = 1.8 Hz, 1H, H-2), 5.16 (d, 1H, H-1), 4.70 (m, 1H, H-6), 4.50 (m, 2H, H-5,6′), 4.00–3.70 (m, 12H, spacer H), 2.63 (t, *J* = 6.4 Hz, 2H, C*H*$_2$CN). ^{13}C NMR ($CDCl_3$) δ: 118.34 (CN), 98.23 (C-1), 71.19 (2 × CH_2), 70.88, 70.64 (CH_2), 70.47, 69.28, 68.02 (CH_2), 67.39, 66.44 (CH_2), 63.26 (CH_2), 19.28 (CH_2). FAB-HR-MS calcd. for $C_{41}H_{40}NO_{12}$ $[M + H]^+$: 738.2550; found: 738.2573.

2-[2-(2-Cyanoethoxy)ethoxy]ethyl α-D-*mannopyranoside (29)*

De-esterification of tetrabenzoate **28** (320 mg, 0.43 mmol), following the procedure described for making glycoside **8**, gave glycoside **29** (128 mg, 92%): $[\alpha]_D^{20}$ +47.0 (*c* 0.61, MeOH). IR (film) (cm^{-1}): 2252.; ^{13}C NMR (CD_3OD) δ: 120.16 (CN), 102.13 (C-1), 74.99, 72.99, 72.51, 72.02 (CH_2), 71.95 (CH_2), 71.85 (CH_2), 69.03, 68.18 (CH_2), 67.51 (CH_2), 63.35 (CH_2), 19.66 (CH_2). FAB-HR-MS calcd. for $C_{13}H_{24}NO_8$ $[M + H]^+$: 322.1502; found: 322.1500.

*2-[2-(2-*α-D-*Carboxyethoxy)ethoxy]ethyl* α-D-*mannopyranoside (30)*

A mixture of nitrile **29** (79 mg, 0.24 mmol) in NaOH (1 mL, 3 M) was stirred at room temperature for 24 h, neutralized with Amberlyst 15 (H^+) resin, filtered, and freeze-dried to afford acid **30** (81 mg, 100%): $[\alpha]_D^{20}$ +38.0 (*c* 0.41, H_2O). ^{13}C NMR (D_2O) δ: 176.89 (C=O), 100.37 (C-1), 73.16, 72.14 (CH_2), 70.92, 70.37, 69.98 (CH_2), 67.18, 66.87 (CH_2), 61.35 (CH_2), 60.81 (CH_2) 57.80 (CH_2), 37.34 (CH_2). FAB-HR-MS calcd. for $C_{13}H_{25}O_{10}$ $[M + H]^+$: 341.1448; found: 341.1449.

2-[2-(2-Azidoethoxy)ethoxy]ethyl 2,3,4,6-tetra-O-*benzoyl*-α-D-*mannopyranoside (31)*

A mixture of chloro-compound **27** (2.785 g, 3.72 mmol), sodium azide (2.6 g 40 mmol), and DMF (40 mL) was stirred under argon at 65°C for 19 h. Water (60 mL) was added, and the mixture was extracted with EtOAc (3 × 30 mL). The combined organic extracts were washed with water (10 mL), dried (Na_2SO_4), and evaporated to dryness. Column chromatography (hexane–EtOAc, 1:1) of the residue gave of azide **31** (2.655 g, 95%): $[\alpha]_D^{20}$ –43.7 (*c* 0.6, $CHCl_3$). IR (film) (cm^{-1}): 2105. ^1H NMR ($CDCl_3$) δ: 6.11 (t, $J_{3,4}$, $J_{4,5}$ = 10.0 Hz, 1H, H-4), 5.95 (dd, $J_{2,3}$ = 3.3 Hz, 1H, H-3), 5.73 (dd, $J_{1,2}$ = 1.8 Hz, 1H, H-2), 5.16 (d, 1H, H-1), 4.70 (m, 1H, H-6), 4.50 (m, 2H, H-5,6′), 4.0–3.6 (m, 10H, spacer H), 3.38 (t, *J* = 5.0 Hz, 2H, CH_2N_3). ^{13}C NMR ($CDCl_3$) δ: 98.23 (C-1), 71.28 (CH_2), 71.15 (CH_2), 70.90, 70.63 (CH_2), 70.50, 69.25, 68.06 (CH_2), 67.40, 63.26 (CH_2), 51.10 (CH_2), 14.57 (CH_2). FAB-HR-MS calcd. for $C_{40}H_{39}N_3O_{12}Cs$ $[M + Cs]^+$: 886.1588; found: 886.1538.

2-{2-[2-(5-Methoxycarbonylpentanoylamino)ethoxy]ethoxy}ethyl α-D-*mannopyranoside (34)*

To a solution of azide **31** (1.30 g, 1.72 mmol) in EtOH (25 mL), $NaBH_4$ (325 mg, 8.5 mmol) was added followed by a solution of $NiCl_2$ in EtOH (1.5 mL, 0.2 M), and the mixture was stirred at room temperature for 45 min, filtered through a pad of silica gel (thickness ~ 5 cm) and washed with $CHCl_3$–MeOH (2:1). The filtrate and washings were taken to dryness and purified by column chromatography ($CHCl_3$–MeOH, 3:1) to give the amine **32** (660 mg, 53%). ^{13}C NMR (CD_3OD) δ: 99.53 (C-1), 72.15, 71.99 (CH_2), 71.90, 71.64 (CH_2), 71.49 (CH_2), 70.50, 68.91 (CH_2), 68.41, 68.33 (CH_2), 64.00 (CH_2), 41.05 (CH_2). A solution of amine **32** (200 mg, 0.27 mmol), monomethyl adipate (48 mg, 0.3 mmol), and 2-ethoxy-1-ethoxycarbonyl-1,2-dihydroquinoline (12) (74 mg, 0.3 mmol) in EtOH (10 mL) was heated under reflux for 3 h and taken to dryness in vacuo. Column chromatography ($CHCl_3$–MeOH, 50:1) of the residue gave amide **33** (244 mg, 100%). ^{13}C NMR ($CDCl_3$) δ: 98.23 (C-1), 71.04, 70.90 (CH_2), 70.72 (CH_2), 70.55, 70.49 (CH_2), 70.33 (CH_2), 69.28, 68.06 (CH_2), 67.35, 63.26 (CH_2), 51.84 (CH_3), 39.75 (CH_2), 36.51 (CH_2), 34.11 (CH_2), 25.46 (CH_2), 24.81 (CH_2). A mixture of amide **33** (1.615 g, 18.6 mmol) and K_2CO_3 (200 mg) in MeOH (20 mL) was stirred overnight, neutralized with Amberlyst 15 (H^+), filtered, and taken to dryness in vacuo. Column chromatography ($CHCl_3$–MeOH, 3:1) of the residue gave the de-esterified glycoside **34** (530 mg, 63%): $[\alpha]_D^{20}$ +32.1 (*c* 0.57, MeOH). ^{13}C NMR (CD_3OD) δ: 102.17 (C-1), 75.03, 73.01, 72.54, 72.02 (CH_2), 71.82 (CH_2), 71.71 (CH_2), 71.06 (CH_2), 69.07, 68.13 (CH_2), 63.40 (CH_2), 52.43 (CH_3), 40.79 (CH_2), 37.00 (CH_2), 34.86 (CH_2), 26.77 (CH_2), 25.91 (CH_2). Synthesis and in vitro evaluation of substituted aryl- and hetarylmethyl phosphonate and phosphate — UMP derivatives as potential glucosyltransferase inhibitors

Asish K. Bhattacharya, Florian Stolz, Jürgen Kurzeck, Wolfgang Rüger, and Richard R. Schmidt

Abstract: The enzyme β(1→4)-glucosyltransferase (BGT) catalyses the transfer of glucose from uridine diphosphoglucose (UDP-Glc) to 5-hydroxymethylcytosine (5-HMC) bases in double-stranded DNA. Potential inhibitors of BGT were developed by structure-based design and synthesized. The designed inhibitors **1**–**6** provide conformational mimicry of the transition state in glucosyltransfer reactions. The key synthetic steps involve a Michaelis–Arbuzov reaction followed by coupling with uridine-5′-morpholidophosphate as activated UMP derivative. The compounds were tested for in vitro inhibitory activity against BGT and the inhibition kinetics were examined. Three of the designed molecules were found to be potential inhibitors of BGT having IC_{50} values in the micromolar (μM) range. Useful structure–activity relationships were established which provide guidelines for the design of future generations of inhibitors of BGT.

Key words: β-glucosyltransferase, transition state, enzyme inhibitors, structure-based design, synthesis.

Résumé : La transférase de β(1→4)-glucosyle (BGT) est un enzyme qui catalyse le transfert du glucose de l'uridine diphosphoglucose (UDP-Glc) aux bases 5-hydroxyméthylcytosines (5-HMC) de l'ADN à doubles brins. En se basant sur la structure, on a développé et réalisé la synthèse d'inhibiteurs potentiels de la BGT. Les inhibiteurs proposés (**1**–**6**) fournissent une imitation conformationnelle de l'état de transition des réactions de transfert du glucosyle. Les étapes de synthèse clés implique une réaction de Michaelis–Arbuzov, suivie d'un couplage avec un 5′-morpholinophosphate d'uridine sous la forme de dérivé activé UMP. L'activité inhibitrice des composés contre le BGT a été vérifiée in vitro et on a étudié la cinétique de l'inhibition. On a trouvé que trois des molécules synthétisées sont des inhibiteurs potentiels du BGT, avec des valeurs de IC_{50} au niveau micromolaire (μM). On a établi des relations structure–activité intéressantes; elles fournissent des indications générales pour le développement des futures générations d'inhibiteurs de BGT.

Mots clés : transférase de β-glucosyle, état de transition, inhibiteurs d'enzyme, développement sur la base de la structure, synthèse.

Introduction

The biosynthesis of complex carbohydrates, oligosaccharides, and other glycosylated cellular metabolites is of major importance, since these molecules are directly involved in numerous biological and cellular processes (1). The role of glycobiology ranges from storage of photosynthetic products, cell–cell recognition and adhesion, as well as glycosylation of proteins (2–6). Thus, in glycobiology, one of the central questions raised is understanding the fundamental basis of the incredibly diverse set of glycan structures observed in nature (7). What we do know is that there are a myriad of glycosyltransferases, each with its sugar specific donor and with acceptor and linkage specificity, which are responsible for the biosynthesis of these remarkably complex structures. From a medicinal chemist's standpoint, the study of these glycosyltransferases has begun to throw new light onto these areas ranging from bacterial toxicity to mammalian development. Moreover, the role played by glycosyltransferases in the etiology of disease, as well as their potential role as therapeutic targets, are also now being appreciated (8). Despite tremendous progress made in this

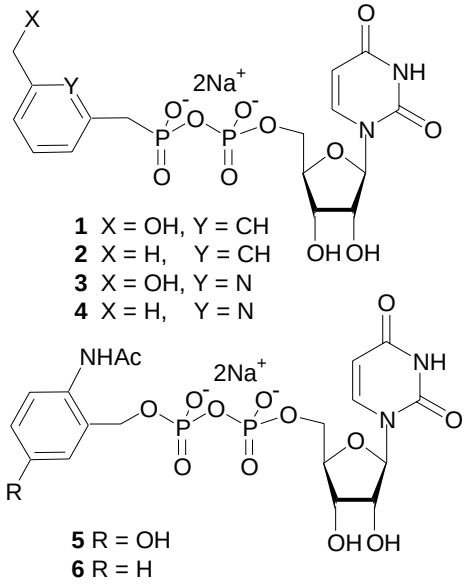
field, the molecular basis of many processes are still uncertain (9). The glycosyltransferases of the Leloir pathway are key catalysts for the synthesis of oligosaccharides and glycoconjugates in vivo (10–14).

β(1→4)-Glucosyltransferase (BGT) is an enzyme encoded by a number of bacteriophages belonging to the T-even group. It catalyses the transfer of glucose from uridine diphosphoglucose (UDP-Glc) to 5-hydroxymethylcytosine (5-HMC) bases in double-stranded DNA (15). Glucosylation protects the infecting viral DNA from host restriction enzymes (16). In addition to its protective role, the glucosylation has also been implicated in the control of phage-specific gene expression by influencing transcripton in vivo and in vitro (17). Another example of DNA modification by glucosylation has been found in *Trypanosoma brucei* (18) where glucosylation is believed to be involved in regulating the expression of variant surface glycoproteins, used by the parasite for protection from immune recognition (19). BGT is one of two enzymes involved in the glucosylation of T4 phage DNA. In contrast to its counterpart α-glucosyltransferase (AGT), which forms α-glycosidic linkages, BGT catalyses the formation of β-glycosidic linkages, between the Glc and the modified 5-HMC base. Recognition specificity resides in the opposite base, namely G, therefore T4 BGT also glucosylates 5-HMU.[2] Regarding this glucosylation of 5-HMU, it does not take place if A or C or even an abasic site face 5-HMU on the opposite DNA strand. Thus, recognition specificity must reside in the hydroxymethyl group and the opposing G (20, 21). Inhibition or modulation of this transfer reaction provides an excellent opportunity for intervention of oligosaccharide biosynthesis and to obtain a more complete understanding of the structure–activity relationship of oligosaccharides on a molecular basis (22). This endeavour is also an interesting excursion to the basis of carbohydrate–protein recognition, which has gained seminal contributions by the late Professor Lemieux (23).

Earlier, we had reported (24) the synthesis of a transition state based analog of galactosyltransferase which exhibited high-inhibition properties towards galactosyltransferases. Encouraged by this, we have recently reported (25) transition-state-based analogs of sialyltransferases which showed very high affinity towards the enzyme in the nanomolar range. However, the aryl analogs mimicking the sugar of CMP-Neu5Ac turned out to be potent inhibitors exhibiting very high binding affinity to α(2→6)-sialyltransferase (26). Herein we describe the design, synthesis, and in vitro inhibiting activities of inhibitors **1**–**6** (27) (Fig. 1), in order to derive requirements for the structure–activity relationship of glucosyltransferases as well as to ascertain essential substituents on aryl and hetaryl moieties.

For the synthesis of sugar mimetics **1**–**4** the appropriate phosphonates **15**–**18** had to be synthesized first. We based our approach essentially on the Michaelis–Arbuzov reaction of bromides **11**–**14** with tris-(trimethylsilyl) phosphite to generate the corresponding phosphonates **15**–**18**. The required benzyl bromide derivatives **11** and **12** (28) were prepared from their corresponding methyl precursors **7** and **8**, respectively, by treating them with *N*-bromosuccinimide

Fig. 1. Structures of designed inhibitors **1**–**6**.



(NBS) in the presence of catalytic amounts of dibenzoyl peroxide (DBP) in refluxing carbon tetrachloride (Scheme 1). The bromides **11** and **12** on Michaelis–Arbuzov reaction with tris-(trimethylsilyl) phosphite in toluene at 95°C for 4 h furnished the respective bis-trimethylsilylphosphonates **15** and **16** based on the ^{1}H NMR spectra in quantitative yield. The bis-trimethylsilylphosphonates are highly labile to moisture and had to be stored under argon. They were used in the next step without further purification. The deprotection of the TMS groups and subsequent preparation of sodium salts were carried out in one pot by treating the phosphonates **15** and **16** with sodium methanolate in methanol at 0°C for 30 min, which after usual work up furnished disodium salts **19** and **20**. They were transformed into their corresponding bis-triethylammonium salts **23** and **24** by ion exchange (Amberlite IR-120, $HNEt_3^+$ form).

The synthesis of mimetics **1**–**6** was performed following a recent procedure (29*a*) which is an improved variant of the Moffat–Khorana phosphomorpholidate coupling method (29*b*). The phosphonophosphates or diphosphates were isolated in 42–52% yield. The ^{1}H NMR and ^{13}C NMR spectra showed the expected signals and total assignment could be performed by 2D NMR experiments. The ^{31}P NMR spectra also showed the characteristic signals associated with the phosphorous atom. Reaction of bis-triethylammonium salts **23** and **24** with uridine-5′-morpholidophosphate as activated UMP derivative in the presence of 1*H*-tetrazole in pyridine for 3 days at room temperature afforded **1** and **2** as white powders, respectively, after isolation and purification by HPLC, ion exchange (Amberlite IR-120 (Na^+ form)), and lyophilization.

In similar fashion, synthesis of **3** and **4** were also carried out (Scheme 1). Treatment of **9** (30) with NBS in the presence of catalytic amounts of α,α′-azo-isobutyronitrile (AIBN) in CCl_4 and irradiation of the reaction mixture for 8 h with a Hg lamp furnished **13** whereas bromide **14** (31, 32) was

[2] A manuscript based on the latest results of recognition specifity of BGT is in preparation by J. Kurzeck and W. Rüger.

prepared by treatment of **10** with CBr_4–Ph_3P–Et_3N in CH_2Cl_2 at 0°C. Subsequent reactions of bromides **13** and **14** with tris-trimethylsilyl phosphite furnished the corresponding phosphonates **17** and **18** which were transformed into their bis-triethylammonium salts **25** and **26** in the usual way. Their reaction with uridine-5′-morpholidophosphate in presence of 1*H*-tetrazole (29) in pyridine for 3 days at room temperature furnished **3** and **4** as white powders, respectively, after isolation and purification by HPLC, ion exchange (Amberlite IR-120 (Na^+ form)) and lyophilization.

The synthesis of compounds **5** and **6** were accomplished as delineated in Scheme 2. The required alcohol **28** was prepared from the readily available aldehyde **27** (33) in 60% yield by treating the latter with $NaBH_4$ in KH_2PO_4 buffer (34) in dry methanol (Scheme 3). The allyl protected phosphates **30** and **31** were synthesized in an one-pot reaction. The alcohols **28** and **29** (35) were coupled with bis(allyloxy)(diisopropylamino)phosphine in dry dichloromethane–acetonitrile (1:1) activated by 1*H*-tetrazole and then the resulting phosphites were oxidized with *tert*-butylhydroperoxide to phosphates **30** and **31** in 76 and 51% yield, respectively. The deprotection of allyl protecting groups were carried out by treating the allylesters **30** and **31** with dimedone in THF at room temperature catalyzed by tetrakis-(triphenylphosphine)-palladium. The bis-triethylammonium salts **32** and **33** were obtained after flash chromatography ($CHCl_3$–MeOH–H_2O, 6:4:1 + 1% Et_3N) in 64 and 72% yield, respectively.

Finally, compounds **5** and **6** were synthesized by the reaction of bis-triethylammonium salts **32** and **33** with uridine-5′-morpholidophosphate as activated UMP derivative in pyridine catalyzed by 1*H*-tetrazole (29) for 3 days at room temperature. Isolation and purification by HPLC followed by ion exchange [Amberlite IR-120 (Na^+ form)] and lyophilization afforded **5** and **6** as white powders in 43 and 45% yield, respectively.

Biological results

The compounds synthesized were tested for in vitro inhibitory activity with β(1→4)-glucosyltransferase which was isolated as previously reported (36). The biological studies reveal a strong structure–activity relationship for the binding of inhibitors **1**–**6** to BGT. The IC_{50} values (concentration of inhibitor at which 50% activity of the enzyme is observed) of inhibitors **1**–**6** were determined and are listed in Table 1. Inhibitor **2** showed an IC_{50} value of 1.9×10^{-3} M whereas compound **1** showed very little inhibition thereby indicating that the potential inhibitor from the substituted aryl group should be lipophilic. However, to our surprise compounds **3** and **4** were totally inactive. Acetamidobenzyl derivative **6** showed an IC_{50} value of 9.6×10^{-5} M ($K_i = 3.2 \times 10^{-5}$ M) whereas the *para*-hydroxy-substituted derivative **5** showed an IC_{50} value of 7.8×10^{-4} M. Thus, **6** exhibits an affinity to the enzyme which is comparable to the natural substrate (UDP-Glc: $K_M = 3.6 \times 10^{-5}$ M). X-ray studies with some of

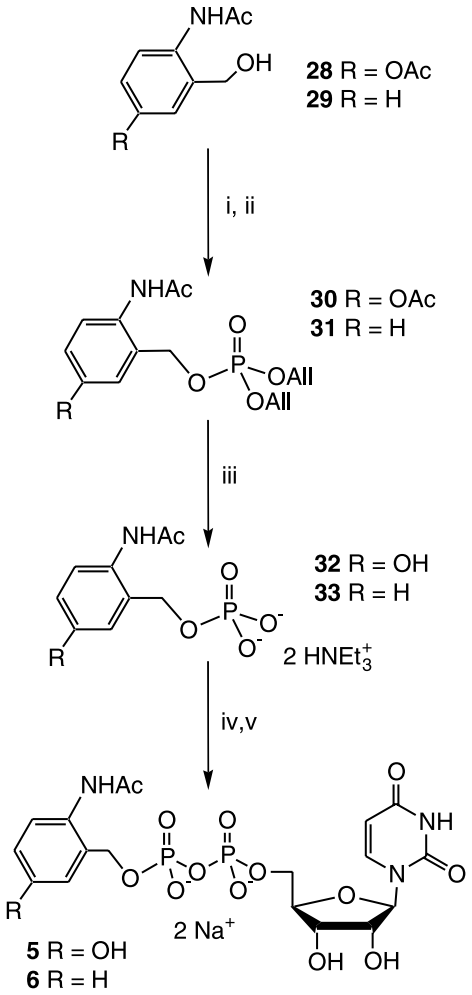
Scheme 2. Reagents and conditions: (*i*) (*i*-Pr_2N)P(OAll)2, 1*H*-tetrazol, CH_2Cl_2–CH_3CN (1:1), rt, 2.5 h; (*ii*) *t*-BuOOH, 0°C, 1.5 h, 76% (for **30**), 51% (for **31**); (*iii*) dimedone, $Pd(PPh_3)_4$, THF, Et_3N, rt, 1.5 h, 64% (for **32**), 72% (for **33**); (*iv*) UMP-morpholidate, 1*H*-tetrazol, py, rt, 3 days, RP-18; (*v*) Amberlite IR-120 (Na^+ form), 43% (for **5**), 45% (for **6**).



these compounds bound to BGT will be reported in due course.

In conclusion, our inhibition studies clearly indicate that: (*i*) phosphates **5** and **6** are better inhibitors than phosphonates **1**–**4** in general; (*ii*) acetamido functionality on the aryl residue greatly enhances the inhibition property; (*iii*) in phosphonates, methyl substitution shows some activity; and (*iv*) substituted pyridyl phosphonates **3** and **4** are not active at all. Our studies have also revealed that benzene rings are accepted by this glucosyltransferase (and presumably by carbohydrate processing enzymes in general) as mimics of carbohydrate residues. Thus, useful structure–activity relationships and further guidelines for the design of future generations of inhibitors of BGT are provided.

Experimental section

Solvents were purified according to the standard procedures. NMR measurements were recorded at 22°C on a Bruker AC250 Cryospec or Bruker DRX 600 spectrometers.

Scheme 3. Reagents and conditions: (*i*) $NaBH_4$, KH_2PO_4, MeOH, 30 min, rt, 60%.

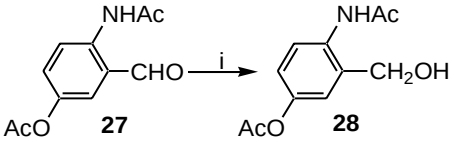


Table 1. IC_{50} values of transition-state analogues **1**–**6**.[a]

Inhibitor	IC_{50} (M)	K_i (competitive) (M)
1	$>5 \times 10^{-3}$	
2	$1.9\ (\pm 0.1) \times 10^{-3}$	
3	$>1 \times 10^{-2}$	
4	$>1 \times 10^{-2}$

[b]K_M of UDP-Glc: 3.6×10^{-5} M.

Tetramethylsilane (TMS) or the resonance of the deuterated solvent was used as an internal standard; solvents: $CDCl_3$ (δ = 7.24), D_2O (δ = 4.63), [D_6]DMSO (δ = 2.49). For ^{31}P NMR, phosphoric acid was used as an external standard; ^{31}P NMR spectra were broadband ^1H-decoupled. MALDI-mass spectra were recorded on a Kratos Kompact Maldi 1 and 2,5-dihydroxybenzoic acid (DHB) or 6-aza-2-thiothymine (ATT) were used as matrices. FAB mass spectra were measured on a Finnigan MAT312/AMD 5000 spectrometer. Thin layer chromatography (TLC) was performed on Merck silica gel plastic plates $60F_{254}$ or Merck glass plates RP-18; compounds were visualized by treatment with a solution of $(NH_4)_6Mo_7O_{24}{\cdot}4H_2O$ (20 g) and $Ce(SO_4)_2$ (0.4 g) in 10% sulfuric acid (400 mL). Flash chromatography was performed on J.T. Baker silica gel 60 (0.040–0.063 mm) at a pressure of 0.3 bar. MPLC was performed at a pressure of 5–10 bar; column: silica gel LiChroprep Si 60 (Merck, 15–25 μm, 28 × 2.5 cm). Preparative HPLC separations were performed on an Autochrom system with a Shimadzu LC8A preparative pump and a Rainin Dynamax UV 1 detector at 260 nm. The column used was a Lichrosorb RP-18, 7 μm, 250 × 16 mm (Knauer, Germany). Mixtures of acetonitrile and 0.05 M triethylammonium bicarbonate (TEAB) (pH 7.0 to 7.2) were used as the mobile phase.

2-Acetoxymethyl-6-methylpyridine (9)

2-Acetoxymethyl-6-methylpyridine (**9**) was synthesized following a procedure by Baker et al. (32). The NMR data were in good agreement with the reported data (30).

General procedure for the synthesis of compounds (11) and (12)

To a solution of **7** or **8** (6–9 mmol) in carbon tetrachloride (CCl_4) (20–60 mL), *N*-bromo succinamide (NBS) (1 equiv) and a catalytic amount of dibenzoyl peroxide (DBP) were added and refluxed for 4 h. Evaporation of the solvent and chromatography (MPLC or flash) of the residue afforded compounds **11** or **12**, respectively.

© 2002 NRC Canada

3-Bromomethylbenzyl acetate (11)

Treatment of 3-methylbenzyl acetate **7** (1.0 g, 6.1 mmol) according to the general procedure afforded **11** (620 mg, 42%) as a colorless oil after MPLC (toluene). R_f = 0.67 (petroleum ether–ethyl acetate, 19:1). ^{1}H NMR (250 MHz, $CDCl_3$) δ: 2.11 (s, 3H, COCH_3), 4.49 (s, 2H, Ar-CH_2Br), 5.10 (s, 2H, Ar-CH_2OAc), 7.34–7.38 (m, 4H, Ar-*H*). MS (EI) (*m*/*z*): 242 (M^+). Anal. calcd. for $C_{10}H_{11}BrO_2$ (243.01): C 49.43, H 4.56; found: C 49.23, H 4.50.

3-Methylbenzyl bromide (12)

Treatment of *m*-xylene **8** (1.0 g, 9.4 mmol) according to the general procedure afforded **12** (780 mg, 45%) as a colorless oil after flash chromatography (petroleum ether–ethyl acetate, 19:1). R_f = 0.60 (petroleum ether–ethyl acetate, 19:1). The physical data were in agreement with the reported (28) data.

2-Acetoxymethyl-6-bromomethylpyridine (13)

A mixture of **9** (1.0 g, 6.0 mmol), NBS (1.1 g, 6.1 mmol) and α,α′-azo-isobutyronitrile (AIBN) (100 mg, 0.61 mmol) in CCl_4 (65 mL) was irradiated with a Hg lamp for 8 h. Flash chromatography (petroleum ether–ethyl acetate, 7:3) afforded **13** (660 mg, 45%) as a colorless oil. R_f = 0.44 (petroleum ether–ethyl acetate, 3:2). ^{1}H NMR (250 MHz, $CDCl_3$) δ: 2.17 (s, 3H, COCH_3), 4.55 (s, 2H, Ar-CH_2Br), 5.23 (s, 2H, Ar-CH_2OAc), 7.28 (d, $J_{3,4}$ = 7.6 Hz, 1H, H-3), 7.40 (d, $J_{5,4}$ = 7.6 Hz, 1H, H-5), 7.72 (dd, $J_{4,3}$ = $J_{4,5}$ = 7.6 Hz, 1H, H-4). MS (EI) (*m*/*z*): 243 (M^+). Anal. calcd. for $C_9H_{10}NO_2Br$ (244.1): C 44.44, H 4.12, N 5.76; found: C 44.34, H 4.18, N 5.66.

2-Bromomethyl-6-methylpyridine (14)

To a stirred solution of 2-(hydroxymethyl)-6-methylpyridine (1.0 g, 8.1 mmol) in dry CH_2Cl_2 (80 mL) at 0°C, carbon tetrabromide (CBr_4) (3.2 g, 9.8 mmol), triphenyl phosphine (PPh_3) (2.6 g, 9.8 mmol), and triethylamine (Et_3N) (1.1 mL, 820 mg, 8.1 mmol) were added successively. After 1 h when the reaction was complete (TLC), the reaction mixture was dried in vacuo and purified by flash chromatography (*n*-pentane–diethyl ether, 9:1) to afford **14** (630 mg, 42%) as a colorless oil. The physical data were in full agreement with the reported data (32). R_f = 0.29 (*n*-pentane–diethyl ether, 4:1). ^{1}H NMR (250 MHz, $CDCl_3$) δ: 2.56 (s, 3H, CH_3), 4.52 (s, 2H, Ar-CH_2Br), 7.07 (d, $J_{3,4}$ = 7.7 Hz, 1H, H-3), 7.25 (d, $J_{5,4}$ = 7.7 Hz, 1H, H-5), 7.58 (dd, $J_{4,3}$ = $J_{4,5}$ = 7.7 Hz, 1H, H-4). MS (EI) (*m*/*z*): 185 (M^+), 106 $(M - Br)^+$. Anal. calcd. for C_7H_8NBr (186.1): C 45.51, H 4.32, N 7.57; found: C 45.36, H 4.34, N 7.48.

General procedure for the synthesis of phosphonates (15–18)

A mixture of **11**, **12**, **13**, or **14** (1 mmol) and tris-(trimethylsilyl) phosphite (2 mmol) in dry toluene (2 mL) was heated under argon to 95°C for 4 h to afford **15**, **16**, **17**, or **18**, respectively, in a quantitative reaction (^{1}H NMR). The formed trimethylsilyl bromide was distilled off under slightly reduced pressure. The mixture was concentrated in vacuo and excess tris-(trimethylsilyl) phosphite was removed under high vacuum (0.01 mbar). The residue to be kept under argon was used as such in the next step without further purification.

Bis-(trimethylsilyl) 3-(acetoxymethyl)benzylphosphonate (15)

A mixture of **11** (160 mg, 0.67 mmol) and tris-(trimethylsilyl) phosphite (420 μL, 2.0 mmol) in dry toluene (2 mL) was treated as described in the general procedure to afford **15** as a colorless oil which was used in the next step without further purification. ^{1}H NMR (600 MHz, $CDCl_3$) δ: 0.27 (d, J = 1.2 Hz, 18H, 6CH_3), 2.08 (s, 3H, COCH_3), 3.06 (d, J = 22.3 Hz, 2H, Ar-CH_2P), 5.07 (s, 2H, Ar-CH_2OAc), 7.22–7.43 (m, 4H, Ar-*H*). ^{13}C NMR (150.8 MHz, $CDCl_3$) δ: 0.9, 1.0 (6C, 6CH_3), 21.0 (1C, COCH_3), 35.5 (d, $J_{C,P}$ = 156.1 Hz, 1C, Ar-CH_2P), 66.1 (1C, Ar-CH_2OAc), 126.6, 128.6, 129.7, 130.0, 132.6, 136.1 (6C, Ar), 170.8 (1C, COCH$_3$). ^{31}P NMR (243 MHz, $CDCl_3$) δ: 21.81. MS (EI) (*m*/*z*): 388 (M^+) for $C_{16}H_{29}O_5PSi_2$ (388.5).

Bis-(trimethylsilyl) 3-methylbenzylphosphonate (16)

A mixture of **12** (195 mg, 1.06 mmol) and tris-(trimethylsilyl) phosphite (600 μL, 2 mmol) in dry toluene (2 mL) was treated as described in the general procedure above to afford **16** as a colorless oil. ^{1}H NMR (600 MHz, $CDCl_3$) δ: 0.30 (d, J = 1.2 Hz, 18H, 6CH_3Si), 2.31 (s, 3H, CH_3), 3.02 (d, J = 22.1 Hz, 2H, Ar-CH_2P), 7.01–7.30 (m, 4H, Ar-*H*). ^{31}P NMR (243 MHz, $CDCl_3$) δ: 22.18. MS (EI) (*m*/*z*): 330 (M^+) for $C_{14}H_{27}O_3PSi_2$ (330.5).

Bis-(trimethylsilyl) 2-[6-(acetoxymethyl)pyridyl]methylphosphonate (17)

A mixture of **13** (360 mg, 1.50 mmol) and tris-(trimethylsilyl) phosphite (950 μL, 3.0 mmol) in dry toluene (2 mL) was treated as described in the general procedure above to afford **17** as a colorless oil. ^{1}H NMR (600 MHz, $CDCl_3$) δ: 0.31 (d, J = 1.2 Hz, 18H, 6CH_3Si), 2.12 (s, 3H, COCH_3), 3.31 (d, J = 22.7 Hz, 2H, Ar-CH_2P), 5.15 (s, 2H, Ar-CH_2OAc), 7.20 (d, $J_{3,4}$ = 7.7 Hz, 1H, H-3), 7.31 (d, $J_{5,4}$ = 7.7 Hz, 1H, H-5), 7.62 (dd, $J_{4,3}$ = $J_{4,5}$ = 7.7 Hz, 1H, H-4). ^{31}P NMR (243 MHz, $CDCl_3$) δ: 12.61. FAB-MS (positive mode, matrix: $CHCl_3$–NBA–NaI) (*m*/*z*): 390 $(M + H)^+$, 412 $(M + Na)^+$ for $C_{15}H_{28}NO_5PSi_2$ (389.5).

Bis-(trimethylsilyl) 2-(6-methylpyridyl)methylphosphonate (18)

A mixture of **14** (360 mg, 1.50 mmol) and tris-(trimethylsilyl) phosphite (950 μL, 3.0 mmol) in dry toluene (2 mL) was treated as described in the general procedure above to afford **18** as a colorless oil. ^{1}H NMR (600 MHz, $CDCl_3$) δ: 0.32 (d, J = 1.2 Hz, 18H, 6CH_3Si), 2.46 (s, 3H, CH_3), 3.24 (d, J = 22.7 Hz, 2H, Ar-CH_2P), 6.95 (d, $J_{3,4}$ = 7.6 Hz, 1H, H-3), 7.12 (d, $J_{5,4}$ = 7.6 Hz, 1H, H-5), 7.45 (dd, $J_{4,3}$ = $J_{4,5}$ = 7.6 Hz, 1H, H-4). MS (EI) (*m*/*z*): 331 (M^+) for $C_{13}H_{26}NO_3PSi_2$ (331.5).

General procedure for the synthesis of disodium salts (19–22)

The crude phosphonate (≅0.35g) was disolved in dry CH_2Cl_2 (3 mL) under argon and the solution added dropwise through a syringe to a sodium methoxide solution (30 mL, 0.2 M) at 0°C. After 30 min, small amounts of Amberlite IR-120 (H^+ form) were added to the solution with stirring till the solution became neutral (pH paper). The solution was

© 2002 NRC Canada

filtered and the resin was washed once with MeOH (5 mL) and added to the filtrate. The filtrate was evaporated and coevaporated with water to furnish a solid. Finally, the solid obtained was lyophilized with water to afford the disodium salt as a white powder.

Disodium 3-(hydroxymethyl)benzylphosphonate (19)

The phosphonate **15** (270 mg, crude material) was disolved in dry CH_2Cl_2 (3 mL) under argon and was treated with sodium methoxide solution (30 mL, 0.2 M) at 0°C as per the general procedure described above to yield **19** as a white powder (166 mg, 98%). ^{1}H NMR (600 MHz, $CDCl_3$) δ: 2.72 (d, J = 19.7 Hz, 2H, Ar-CH_2P), 4.46 (s, 2H, Ar-CH_2OH), 7.04–7.18 (m, 4H, Ar-*H*). ^{13}C NMR (151 MHz, D_2O) δ: 36.2 (d, $J_{C,P}$ = 127 Hz, 1C, Ar-*C*H_2P), 63.6 (1C, Ar-*C*H_2OH), 123.8, 127.9, 128.2, 128.5, 138.0, 139.2 (6C, Ar). ^{31}P NMR (243 MHz, D_2O) δ: 19.01. FAB-MS (negative mode, matrix: DMSO–H_2O–glycerol, 1:1:1) (*m*/*z*): 201 [M – 2Na^+ + H^+]$^-$ for $C_8H_9O_4PNa_2$ (246.1).

Disodium 3-methylbenzylphosphonate (20)

The phosphonate **16** (374 mg, crude material) was dissolved in dry CH_2Cl_2 (3 mL) under argon and was treated with sodium methoxide solution (30 mL, 0.2 M) at 0°C as per the general procedure described above to yield **20** as a white powder (250 mg, 96%). ^{1}H NMR (600 MHz, $CDCl_3$) δ: 2.17 (s, 3H, CH_3) 2.67 (d, J = 19.8 Hz, 2H, Ar-CH_2P), 6.97 (d, $J_{4,5}$ = 7.8 Hz, 1H, H-4), 7.05 (d, $J_{5,6}$ = 7.8 Hz, 1H, H-6), 7.10 (s, 1H, H-2), 7.13 (dd, $J_{5,4}$ = $J_{5,6}$ = 7.8 Hz, 1H, H-5). ^{31}P NMR (243 MHz, D_2O) δ: 19.02. FAB-MS (negative mode, matrix: H_2O–glycerol, 1:1) (*m*/*z*): 185 [M – 2Na^+ + H^+]$^-$ for $C_8H_9O_3PNa_2$ (230.1).

Disodium 2-[6-(hydroxymethyl)pyridyl]methylphosphonate (21)

The phosphonate **17** (580 mg, crude material) was dissolved in dry CH_2Cl_2 (3 mL) under argon and was treated with sodium methoxide solution (30 mL, 0.2 M) at 0°C as per the general procedure described above to yield **21** as a white powder (320 mg, 86%). ^{1}H NMR (250 MHz, $CDCl_3$) δ: 2.97 (d, J = 20.7 Hz, 2H, Ar-CH_2P), 4.96 (s, 2H, Ar-CH_2OH), 7.12 (d, $J_{3,4}$ = 7.8 Hz, 1H, H-3), 7.18 (d, $J_{5,4}$ = 7.8 Hz, 1H, H-5), 7.59 (dd, $J_{4,3}$ = $J_{4,5}$ = 7.8 Hz, 1H, H-4). FAB-MS (positive mode, matrix: H_2O – CH_3CN – 0.1% TFA, 1:1:1) (*m*/*z*): 248 [M + 2Na^+ + H]$^+$ for $C_7H_8NO_4PNa_2$ (247.1).

Disodium 2-(6-methylpyridyl)methylphosphonate (22)

The crude phosphonate **18** (1.11 g) was dissolved in dry CH_2Cl_2 (3 mL) under argon and was treated with sodium methoxide solution (30 mL, 0.2 M) at 0°C as per the general procedure described above to yield **22** as a white powder (693 mg, 90%). ^{1}H NMR (250 MHz, $CDCl_3$) δ: 2.41 (s, 3H, CH_3), 2.95 (d, J = 19.6 Hz, 2H, Ar-CH_2P), 7.15 (d, $J_{3,4}$ = 7.8 Hz, 1H, H-3), 7.28 (d, $J_{5,4}$ = 7.8 Hz, 1H, H-5), 7.74 (dd, $J_{4,3}$ = $J_{4,5}$ = 7.8 Hz, 1H, H-4). FAB-MS (negative mode, matrix: H_2O–glycerol, 1:1) (*m*/*z*): 186 [M – 2Na^+ + H^+]$^-$, 208 [M + Na^+]$^-$ for $C_7H_8NO_3PNa_2$ (231.1).

General procedure for the synthesis of bis-triethylammonium salts (23–26)

The disodium salts of **19**, **20**, **21**, or **22** were dissolved in H_2O and passed through a column (10 × 2.5 cm) containing Amberlite IR-120 ($HNEt_3^+$-form). The column was washed thoroughly with H_2O and all the fractions collected were lyophilized to afford **23**, **24**, **25**, or **26** as a colorless oil.

Bis-triethylammonium 3-(hydroxymethyl)benzylphosphonate (23)

The disodium salt **19** (250 mg, 1.02 mmol) was treated as per the general procedure described above to furnish **23** as a colorless oil (380 mg, 92%). ^{1}H NMR (600 MHz, D_2O) δ: 1.19 (t, J = 7.3 Hz, 18H, NCH$_2$CH_3), 2.96 (d, J = 20.6 Hz, 2H, Ar-CH_2P), (q, J = 7.3 Hz, 12H, NCH_2CH$_3$), 4.54 (s, 2H, Ar-CH_2OH), 7.11 (m, 2H, H-4, H-6), 7.17 (s, 1H, H-2), 7.19 (dd, $J_{5,4}$ = $J_{5,6}$ = 7.6 Hz, 1H, H-5). ^{13}C NMR (151 MHz, D_2O) δ: 7.7 (1C, NCH$_2$CH$_3$), 35.1 (d, $J_{C,P}$ = 128 Hz, 1C, Ar-*C*H_2P), 46.2 (1C, NCH$_2$CH$_3$), 63.4 (1C, Ar-*C*H_2OH), 124.7, 128.1, 128.2, 128.4, 135.0, 139.7 (6C, Ar). ^{31}P NMR (243 MHz, D_2O) δ: 19.49 Hz. FAB-MS (negative mode, matrix: MeOH–glycerol, 1:1) (*m*/*z*): 201 [M – 2$HNEt_3^+$ + H^+]$^-$ for $C_{20}H_{41}N_2O_4P$ (404.5).

Bis-triethylammonium 3-methylbenzylphosphonate (24)

The disodium salt **20** (100 mg, 0.43 mmol) was treated as per the general procedure described above to furnish **24** as a colorless oil (156 mg, 92%). ^{1}H NMR (600 MHz, D_2O) δ: 1.09 (t, J = 7.3 Hz, 18H, NCH$_2$CH_3), 2.14 (s, 3H, CH_3), 2.82 (d, J = 20.7 Hz, 2H, Ar-CH_2P), 3.01 (q, J = 7.3 Hz, 12H, NCH_2CH$_3$), 6.80–7.12 (m, 4H, Ar-*H*). FAB-MS (negative mode, matrix: MeOH–glycerol, 1:1) (*m*/*z*): 185 [M – 2$HNEt_3^+$ + H^+]$^-$ for $C_{20}H_{41}N_2O_3P$ (388.5).

Bis-triethylammonium 2-[6-(hydroxymethyl)pyridyl]methylphosphonate (25)

The disodium salt **21** (320 mg, 1.30 mmol) was treated as per the general procedure described above to furnish **25** as a colorless oil (478 mg, 92%). ^{1}H NMR (250 MHz, D_2O) δ: 1.06 (t, J = 7.3 Hz, 18H, NCH$_2$CH_3), 2.95 (q, J = 7.3 Hz, 12H, NCH_2CH$_3$), 3.09 (d, J = 21.7 Hz, 2H, Ar-CH_2P), 5.04 (s, 2H, Ar-CH_2OH), 7.31 (m, 2H, H-3, H-5), 7.79 (dd, $J_{4,3}$ = $J_{4,5}$ = 7.7 Hz, 1H, H-4). FAB-MS (positive mode, matrix: H_2O – CH_3CN – 0.1% TFA (1:1:1), glycerol) (*m*/*z*): 248 [M – $HNEt_3^+$ + 2Na^+ + H^+]$^+$ for $C_{19}H_{40}N_3O_4P$ (405.5).

Bis-triethylammonium 2-(6-methylpyridyl)methylphosphonate (26)

The disodium salt **22** (428 mg, 1.85 mmol) was treated as per the general procedure described above to furnish **23** as a colorless oil (605 mg, 84%). ^{1}H NMR (250 MHz, D_2O) δ: 1.09 (t, J = 7.3 Hz, 18H, NCH$_2$CH_3), 2.56 (s, 3H, CH_3), 3.02 (q, J = 7.3 Hz, 12H, NCH_2CH$_3$), 3.24 (d, J = 20.8 Hz, 2H, Ar-CH_2P), 7.59 (d, $J_{3,4}$ = 7.9 Hz, 1H, H-3), 7.62 (d, $J_{5,4}$ = 7.9 Hz, 1H, H-5), 8.23 (dd, $J_{4,3}$ = $J_{4,5}$ = 7.9 Hz, 1H, H-4). ^{31}P NMR (243 MHz, D_2O) δ: 13.80 Hz. FAB-MS (positive mode, matrix: CH_3CN – 0.1% TFA (1:1), glycerol) (*m*/*z*): 188 [M – 2NEt_3^+ + H^+]$^-$ for $C_{19}H_{40}N_3O_3P$ (389.5).

General procedure for the synthesis of (1–6)

A mixture of **23**, **24**, **25**, **26**, **31**, or **32** (0.13–0.25 mmol) and 4-morpholine-*N*,*N*′-dicyclohexylcarboxamidinium uridine 5′-monophosphomorpholidate (0.17–0.27 mmol) was evaporated with dry pyridine (3 × 1.5 mL). To this mixture, vacuum-dried 1*H*-tetrazole (0.29–1.10 mmol) and dry pyridine (1 mL) were added under argon and the solution was stirred

© 2002 NRC Canada

at room temperature (rt) for 3 days. The reaction mixture was evaporated and coevaporated with water (2 × 1 mL). The residue was purified by preparative HPLC (0.05 M triethylammonium hydrogencarbonate buffer + 4–8% MeCN, flow rate: 10–18 mL min^{-1}). The fractions containing product were pooled and evaporated. The residue was dissolved in water (2 mL) and passed through a column (2.5 × 12 cm) of Amberlite IR-120 (Na^+ form). The column was washed with water (50 mL) and the collected fractions were evaporated. The residue thus obtained was dissolved in a few drops of water and then precipitated with EtOH (5 mL). The suspended solution was centrifuged and the supernatant was carefully decanted to afford a white solid which was dissolved in water and lyophilized. After lyophilization, **1**, **2**, **3**, **4**, **5**, or **6** was obtained as a white powder in 42–52% yield.

Disodium uridine 5′-phosphono [3-(hydroxymethyl)benzyl]phosphate (1)

A mixture of **23** (86 mg, 0.21 mmol) and 4-morpholine-*N*,*N*′-dicyclohexylcarboxamidinium uridine 5′-monophosphomorpholidate (187 mg, 0.27 mmol) and 1*H*-tetrazole (32 mg, 0.46 mmol) in dry pyridine (1 mL) was treated as per the general procedure described above. After 3 days, the product was purified by HPLC (0.05 M triethylammonium hydrogencarbonate buffer + 6% MeCN, flow rate: 18 mL min^{-1}, t_R 14.0 min). Compound **1** was obtained as a white powder (62 mg, 52%) after ion exchange and precipitation. ^{1}H NMR (600 MHz, D_2O) δ: 3.10 (d, J = 21.4 Hz, H 2H, -1a″, H-1b″), 3.96 (m, 1H, H-5a′), 4.02 (m, 1H, H-5b′), 4.12 (m, 2H, H-3′, H-4′), 4.20 (dd, $J_{2',3'} = J_{2',1'}$ = 4.9 Hz, 1H, H-2′), 4.53 (s, 2H, -CH_2OH), 5.77 (d, $J_{5,6}$ = 8.0 Hz, 1H, H-5), 5.86 (d, $J_{1',2'}$ = 4.9 Hz, 1H, H-1′), 7.14–7.25 (m, 4H, H-3″, H-5″, H-6″, H-7″), 7.75 (d, $J_{6,5}$ = 8.0 Hz, 1H, H-6). ^{13}C NMR (151 MHz, D_2O, assignment by HMQC) δ: 35.06 (d, $J_{C,P}$ = 133.5 Hz, 1C, C-1″), 63.4 (1C, Ar-CH_2OH), 64.0 (1C, C-5′), 68.9 (1C, C-3′), 73.2 (1C, C-2′), 82.4 (1C, C-4′), 88.1 (1C, C-1′), 102.2 (1C, C-5), 124.7, 128.2, 128.3, 128.6, 134.4, 139.7 (6C, Ar), 140.6 (1C, C-6). ^{31}P NMR (243 MHz, D_2O) δ: –9.95 (d, J = 27.6 Hz, $P(O)O_3$), 15.04 (d, J = 27.6 MHz, $CP(O)O_2$). MS (MALDI, negative mode, matrix: ATT, H_2O) (*m*/*z*): 507.5 $[M - 2Na^+ + H^+]^-$ for $C_{17}H_{20}N_2O_{12}P_2Na_2$ (552.28).

Disodium uridine 5′-phosphono (3-methylbenzyl)phosphate (2)

A mixture of **24** (50 mg, 0.13 mmol) and 4-morpholine-*N*,*N*′-dicyclohexylcarboxamidinium uridine 5′-monophosphomorpholidate (116 mg, 0.17 mmol) and 1*H*-tetrazole (20 mg, 0.29 mmol) in dry pyridine (1 mL) was treated as per the general procedure described above. After 3 days, the product was purified by HPLC (0.05 M triethylammonium hydrogencarbonate buffer + 8% MeCN, flow rate: 18 mL min^{-1}, t_R 27.8 min). Compound **2** was obtained as a white powder (29 mg, 42%) after ion exchange and precipitation. ^{1}H NMR (600 MHz, D_2O) δ: 2.22 (s, 3H, CH_3), 3.05 (d, J = 21.4 MHz, 2H, H-1a″, H-1b″), 3.95 (m, 1H, H-5a′), 4.04 (m, 1H, H-5b′), 4.11 (m, 2H, H-3′, H-4′), 4.21 (dd, $J_{2',3'} = J_{2',1'}$ = 4.9 Hz, 1H, H-2′), 5.78 (d, 1H, $J_{5,6}$ = 8.1 Hz, H-5), 5.85 (d, $J_{1',2'}$ = 4.9 Hz, 1H, H-1′), 6.99–7.14 (m, 4H, H-3″, H-5″, H-6″, H-7″), 7.78 (d, $J_{6,5}$ = 8.1 Hz, 1H, H-6). ^{13}C NMR (151 MHz, D_2O) δ: 19.89 (1C, *C*H_3), 35.0 (d, $J_{C,P}$ = 135 Hz, 1C, C-1″), 63.9 (1C, C-5′), 68.8 (1C, C-3′), 73.2 (1C, C-2′), 82.5 (1C, C-4′), 8.0 (1C, C-1′), 102.0 (1C, C-5), 126.2, 127.8, 129.91, 129.95, 133.9, 137.8 (6C, Ar), 140.9 (1C, C-6), 151.3, 165.8 (2C, C-2, C-4). ^{31}P NMR (243 MHz, D_2O) δ: –10.3 (d, J = 27.7 Hz, $P(O)O_3$), 15.1 (d, J = 27.7 MHz, $CP(O)O_2$). MS (MALDI, negative mode, matrix: ATT, H_2O) (*m*/*z*): 491.6 $[M - 2Na^+ + H^+]^-$ for $C_{17}H_{20}N_2O_{11}P_2Na_2$ (536.28).

Disodium uridine 5′-phosphono {2-[6-(hydroxymethyl)pyridyl]methyl}phosphate (3)

A mixture of **25** (100 mg, 0.25 mmol) and 4-morpholine-*N*,*N*′-dicyclohexylcarboxamidinium uridine 5′-monophosphomorpholidate (227 mg, 0.33 mmol) and 1*H*-tetrazole (45 mg, 0.56 mmol) in dry pyridine (1 mL) was treated as per the general procedure described above. After 3 days, the product was purified by HPLC (0.05 M triethylammonium hydrogencarbonate buffer + 5% MeCN, flow rate: 10 mL min^{-1}, t_R 29.5 min). Compound **3** was obtained as a white powder (59 mg, 42%) after ion-exchange and precipitation. ^{1}H NMR (600 MHz, D_2O) δ: 3.28 (d, J = 21.8 Hz, 2H, H-1a″, H-1b″), 3.98 (m, 1H, H-5a′), 4.03 (m, 1H, H-5b′), 4.11 (m, 1H, H-4′), 4.13 (dd, $J_{3'',2''} = J_{3'',4''}$ = 4.9 Hz, 1H, H-3′), 4.20 (dd, $J_{2',3'} = J_{2',1'}$ = 5.0 Hz, 1H, H-2′), 4.59 (s, 2H, Ar-CH_2OH), 5.74 (d, $J_{5,6}$ = 7.8 Hz, 1H, H-5), 5.87 (d, 1H, $J_{1',2'}$ = 5.0 Hz, H-1′), 7.24 (d, $J_{5'',6''}$ = 7.6 Hz, 1H, H-5″), 7.30 (d, $J_{7'',6''}$ = 7.6 Hz, 1H, H-7″), 7.67 (dd, $J_{6'',5''} = J_{6'',7''}$ = 7.6 Hz, 1H, H-6″), 7.72 (d, $J_{6,5}$ = 7.8 Hz, 1H, H-6). ^{31}P NMR (243 MHz, D_2O) δ: –10.00 (d, J = 27.6 Hz, $P(O)O_3$), 12.20 (d, J = 27.6 MHz, $CP(O)O_2$). FAB-MS (positive mode, matrix: H_2O – CH_3CN – 0.1% TFA (1:1:1), glycerol) (*m*/*z*): 532 $[M - Na^+ + 2H^+]^+$ for $C_{16}H_{19}N_3O_{12}P_2Na_2$ (553.27).

Disodium uridine 5′-phosphono [2-(6-methylpyridyl)methyl]phosphate (4)

A mixture of **26** (70 mg, 0.18 mmol) and 4-morpholine-*N*,*N*′-dicyclohexylcarboxamidinium uridine 5′-monophosphomorpholidate (124 mg, 0.18 mmol) and 1*H*-tetrazole (22 mg, 0.31 mmol) in dry pyridine (1 mL) was treated as per the general procedure described above. After 3 days, the product was purified by HPLC (0.05 M triethylammonium hydrogencarbonate buffer + 4% MeCN, flow rate: 10 mL min^{-1}, t_R 14.13 min). Compound **4** was obtained as a white powder (58.5 mg, 42%) after ion exchange and precipitation. ^{1}H NMR (600 MHz, D_2O) δ: 2.46 (s, 3H, CH_3), 3.00 (d, J = 19.6 MHz, 2H, H-1a″, H-1b″), 4.06 (m, 1H, H-5a′), 4.13 (m, 2H, H-5b′, H-4′), 4.21 (m, 2H, H-3′, H-2′), 5.80 (d, $J_{5,6}$ = 8.1 Hz, 1H, H-5), 5.82 (d, $J_{1',2}$ = 4.2 Hz, 1H, H-1′), 7.20 (d, $J_{5'',6''}$ = 7.7 Hz, 1H, H-5″), 7.33 (d, 1H, $J_{7'',6''}$ = 7.8 Hz, H-7″), 7.79 (m, 2H, H-6″, H-6). ^{31}P NMR (243 MHz, D_2O) δ: –9.63 (bd, $P(O)O_3$), 17.14 (bd, $CP(O)O_2$). FAB-MS (positive mode, matrix: H_2O – CH_3CN – 0.1% TFA (1:1:1), glycerol) (*m*/*z*): 516 $[M - Na^+ + 2H^+]^+$ for $C_{16}H_{19}N_3O_{11}P_2Na_2$ (537.27).

2-Acetamido-5-acetoxy-benzaldehyde (27)

2-Acetamido-5-acetoxy-benzaldehyde (**27**) was synthesized as previously described (33).

© 2002 NRC Canada

4-Acetamido-3-hydroxymethylphenyl acetate (28)

To a solution of **27** (220 mg, 1.0 mmol) in dry methanol (25 mL), potassium dihydrogen phosphate (1.36 g, 10 mmol) was added. The reaction mixture was cooled to 0°C and then $NaBH_4$ (94 mg, 2.5 mmol) was added under argon and further stirred for 30 min. Then cold water (20 mL) was poured into the reaction mixture and the solution was acidified to pH 5 with 5% HCl solution. The methanol was distilled off and the aqueous phase was extracted with CH_2Cl_2 (5 × 80 mL). The organic phase was washed with water and dried over $MgSO_4$. Evaporation and flash chromatography (toluene–acetone, 3:1) afforded **28** (130 mg, 60%) as a white solid. R_f = 0.45 (toluene–acetone, 1:1), mp 140–142°C. ^{1}H NMR (250 MHz, [D_6]DMSO) δ: 2.03 (s, 3H, NHCOCH_3), 2.25 (s, 3H, OCOCH_3), 4.45 (d, J = 5.6 Hz, C 2H, H_2-Ar), 5.31 (t, J = 5.7 Hz, 1H, CH_2OH, exchanged with D_2O), 6.95 (dd, $J_{2,6}$ = 2.7 Hz, $J_{5,6}$ = 8.6 Hz, 1H, H-6), 7.15 (d, $J_{2,6}$ = 2.7 Hz, 1H, H-2), 7.41 (d, $J_{5,6}$ = 8.6 Hz, 1H, H-5), 9.29 (s, 1H, NH). Anal. calcd. for $C_{11}H_{13}NO_4$ (223.2): C 59.19, H 5.87; found: C 58.90; H 5.71.

(2-Acetamido-5-acetoxy-benzyl) diallyl phosphate (30)

To a solution of **28** (160 mg, 0.717 mmol) in a mixture of dry CH_2Cl_2 and dry MeCN (each 10 mL) under argon, vacuum-dried 1*H*-tetrazole (135 mg, 1.94 mmol) was added at room temperature. Bis(allyloxy)(diisopropylamino)phosphine (250 μL, 0.95 mmol) was added dropwise to the reaction mixture through a syringe under argon. After stirring at room temperature for 2.5 h, the reaction mixture was cooled to 0°C and 5.5 M *t*-BuOOH solution in Nonan (195 μL, 1.07 mmol) was added dropwise and after completion of the addition, the reaction mixture was further stirred for 1.5 h at room temperature. After completion of the reaction (TLC), $Na_2S_2O_3$ solution (50 mL) was poured into the reaction mixture. The organic phase was washed successively with NaCl solution, $NaHCO_3$ solution, and once again with NaCl solution (each 50 mL). The aqueous solution was extracted with CH_2Cl_2 (2 × 25 mL) and added to the organic phase. The pooled organic phase was dried ($MgSO_4$) and evaporated to dryness. The residue after flash chromatography (toluene–acetone, 4:1) afforded **30** as a colorless oil (210 mg, 76%). R_f = 0.52 (toluene–acetone, 1:1). ^{1}H NMR (250 MHz, $CDCl_3$) δ: 2.24 (s, 3H, NHCOCH_3), 2.30 (s, 3H,OCOCH_3), 4.49 (m, 4H, CH_2=CH-CH_2), 5.03 (d, J = 11.2 Hz, 2H, CH_2Ph), 5.22–5.37 (m, 4H, CH_2=CH-CH_2), 5.81–5.95 (m, 2H, CH_2=CH-CH_2), 7.12 (d, $J_{6,4}$ = 1.8 Hz, 1H, H-6), 7.14 (dd, $J_{4,3}$ = 9.5 Hz, $J_{4,6}$ = 1.8 Hz, 1H, H-4), 8.03 (d, $J_{3,4}$ = 9.5 Hz, 1H, H-3), 9.16 (bs, 1H, NH). MS (MALDI, positive mode, matrix: DHB, THF): 406.5 [M + Na]$^+$. Anal. calcd. for $C_{17}H_{22}NO_7P$ (383.3): C 53.27, H 5.78, N 3.65; found: C 53.16, H 5.87, N 3.45.

Bis-triethylammonium (2-acetamido-5-hydroxy)benzyl phosphate (32)

To a solution of **30** (180 mg, 0.47 mmol) in dry THF (6 mL), dimedone (330 mg, 2.35 mmol) and tetrakis-(triphenylphosphine)-palladium (100 mg, 0.087 mmol) was added and stirred at room temperature protected from light. After 1.5 h when the TLC showed no starting material, Et_3N (0.25 mL) was added and further stirred for 20 min at room temperature. The reaction mixture was evaporated and the residue was purified over flash chromatography ($CHCl_3$–MeOH–H_2O, 6:4:1 + 1% Et_3N) and afforded a mixture of **32** and 5-*O*-acetylated product which was dissolved in MeOH (50 mL). To this solution, Et_3N (4 mL) was added and stirred at 45°C for 20 h. The reaction mixture was evaporated in vacuum and lyophilized in water. After lyophilization, compound **32** was obtained as a colorless oil (140 mg, 64%). R_f = 0.3 ($CHCl_3$–MeOH–H_2O, 6:4:1). ^{1}H NMR (250 MHz, D_2O) δ: 1.08 (t, J = 7.4 Hz, 18H, NCH_2CH_3), 2.01 (s, 3H, COCH_3), 3.00 (q, J = 7.4 Hz, 12H, NCH_2CH$_3$), 4.59 (d, J = 6.4 Hz, 2H, CH_2Ar), 6.67 (dd, $J_{4,3}$ = 8.6 Hz, $J_{4,6}$ = 2.9 Hz, 1H, H-4), 6.87 (d, $J_{6,4}$ = 2.9 Hz, 1H, H-6), 7.04 (d, $J_{3,4}$ = 8.6 Hz, 1H, H-3). MS (MALDI, positive mode, matrix: DHB) (*m*/*z*): 284 [M – 2HEt$_3$N$^+$ + 2H$^+$ + Na$^+$]$^+$ for $C_{21}H_{41}N_3O_6P$ (463.5).

Disodium (2-acetamido-5-hydroxy)benzyl-uridine-5′-diphosphate (5)

A mixture of **32** (32 mg, 0.069 mmol) and 4-morpholine-*N*,*N*′-dicyclohexylcarboxamidinium uridine 5′-monophosphomorpholidate (106 mg, 0.15 mmol) and 1*H*-tetrazole (24 mg, 0.34 mmol) in dry pyridine (1 mL) was treated as per the general procedure described above. After 3 days, the product was purified by HPLC (0.05 M triethylammonium hydrogencarbonate buffer + 5% MeCN, flow rate: 16 mL min^{-1}, t_R 8.5 min). Compound **5** was obtained as a white powder (18.3 mg, 43%) after ion exchange and precipitation. ^{1}H NMR (250 MHz, D_2O) δ: 2.00 (s, 3H, COCH_3), 3.95–4.02 (m, 5H, H-2′, H-3′, H-4′, H-5a′, H-5b′), 4.69 (d, 2H, CH_2Ar), 5.56 (d, J = 8.1 Hz, 1H, 5-H), 5.66 (d, J = 2.9 Hz, 1H, H-1′), 6.61 (dd, $J_{4,3}$ = 8.6 Hz, $J_{4,6}$ = 2.8 Hz, 1H, H-4′′), 6.80 (d, $J_{6,4}$ = 2.8 Hz, 1H, H-6′′), 6.93 (d, $J_{3,4}$ = 8.6 Hz, 1H, H-3′′), 7.62 (d, J = 8.1 Hz, 1H, H-6). ^{31}P NMR (243 MHz, D_2O) δ: –12.2 (bd, 2P). MS (MALDI, negative mode, matrix: ATT, H_2O) (*m*/*z*): 566 [M – 2Na$^+$ + H$^+$]$^-$ for $C_{18}H_{21}N_3O_{14}P_2$ Na$_2$ (611.4).

2-Acetamidobenzyl alcohol (29)

2-Acetamidobenzyl alcohol (**29**) was synthesized from 2-aminobenzyl alcohol by following the procedure reported by Söderbaum and Widman (35*a*) in 95% yield. All the physical data were in agreement with the reported (35*b*) data.

2-Acetamidobenzyl diallyl phosphate (31)

To a solution of **29** (190 mg, 1.15 mmol) in a mixture of dry CH_2Cl_2 and dry MeCN (each 12.5 mL) under argon, vacuum dried 1*H*-tetrazole (220 mg, 3.14 mmol) was added at room temperature. Bis(allyloxy)(diisopropylamino)phosphine (557 μL, 2.18 mmol) was added dropwise to the reaction mixture through a syringe under argon. After stirring for 2.5 h at rt, the reaction mixture was cooled to 0°C, and 5.5 M *t*-BuOOH solution in Nonan (400 μL, 2.2 mmol) was added dropwise and on completion of the addition, the reaction mixture was further stirred for 1.5 h at rt. After completion of the reaction (TLC), $Na_2S_2O_3$ solution (50 mL) was poured into the reaction mixture. The organic phase was washed successively with NaCl solution, $NaHCO_3$ solution, and once again with NaCl solution (each 50 mL). The aqueous solution was extracted with CH_2Cl_2 (2 × 25 mL) and added to the organic phase. The pooled organic phase was

dried ($MgSO_4$) and evaporated to dryness. The residue after flash chromatography (toluene–acetone, 3:1) afforded **31** as a colorless oil (190 mg, 51%). R_f = 0.5 (toluene–acetone, 1:1). ^{1}H NMR (250 MHz, $CDCl_3$) δ: 2.24 (s, 3H, COCH_3), 4.48 (m, 4H, CH_2=CH-CH_2), 5.07 (d, J = 11.0 Hz, 2H, CH_2-Ar), 5.22–5.35 (m, 4H, CH_2=CH-CH_2), 5.80–5.96 (m, 2H, CH_2=CH-CH_2), 7.14 (dd, $J_{5,6}$ = 7.5 Hz, $J_{5,4}$ = 7.4 Hz, 1H, H-5), 7.34 (d, $J_{6,5}$ = 7.5 Hz, 1H, H-6), 7.41 (dd, $J_{4,3}$ = 7.5 Hz, $J_{4,5}$ = 7.4 Hz, 1H, H-4), 8.01 (d, $J_{3,4}$ = 7.5 Hz, 1H, H-3), 9.16 (bs, 1H, NH). MS (MALDI, positive mode, matrix: DHB, THF) (*m*/z): 348.5 $[M + Na^+]^+$, 364.6 $[M + K^+]^+$. Anal. calcd. for $C_{15}H_{20}NO_5P$ (325.3): C 55.38, H 6.20; found: C 55.11, H 6.27.

Bis-triethylammonium-2-acetamidobenzyl phosphate (33)

To a solution of **31** (130 mg, 0.40 mmol) in dry THF (6 mL), dimedone (320 mg, 2.28 mmol) was added and stirred at room temperature protected from light. After 1.5 h when the TLC showed no starting material, Et_3N (0.15 mL) was added and further stirred for 15 min at room temperature. The reaction mixture was evaporated and the residue was purified over flash chromatography ($CHCl_3$–MeOH–H_2O, 6:4:1 + 1% Et_3N). The product obtained after flash chromatography was lyophilized with water to afford **33** as a colorless powder (128 mg, 72%). R_f 0.37 ($CHCl_3$–MeOH–H_2O, 6:4:1). ^{1}H NMR (250 MHz, [D_6]DMSO) δ: 1.09 (t, J = 7.3 Hz, 18H, NCH_2CH_3), 2.07 (s, 3H, COCH_3), 2.89 (q, J = 7.3 Hz, 12H, NCH_2CH_3), 4.64 (d, J = 9.0 Hz, 2H, CH_2Ar), 6.99 (dd, $J_{5,4}$ = $J_{5,6}$ = 8.0 Hz, 1H, H-5), 7.24–7.27 (m, 2H, H-4, H-6), 8.00 (d, J = 8.0 Hz, 1H, H-3), 11.26 (bs, 1H, NH). ^{1}H NMR (250 MHz, D_2O) δ: 1.09 (t, J = 7.3 Hz, 18H, NCH_2CH_3), 2.04 (s, 3H, COCH_3), 3.01 (q, J = 7.3 Hz, 12H, NCH_2CH_3), 4.73 (d, overlapping with D_2O peak, CH_2Ar), 7.19–7.25 (m, 3H, H-4, H-5, H-6), 7.37 (d, J = 7.3 Hz, 1H, H-3). MS (MALDI, positive-mode, matrix: DHB, H_2O) (*m*/*z*): 268.6 $[M - 2HNEt_3^+ + 2H^+ + Na^+]^+$, 284.5 $[M - 2HNEt_3^+ + 2H^+ + K^+]^+$ for $C_{21}H_{41}N_3O_5P$ (447.53).

Disodium (2-acetamidobenzyl)-uridine-5′-diphosphate (6)

A mixture of **33** (100 mg, 0.22 mmol) and 4-morpholine-*N*,*N*′-dicyclohexylcarboxamidinium uridine 5′-monophosphomorpholidate (160 mg, 0.23 mmol) and 1*H*-tetrazole (77 mg, 1.1 mmol) in dry pyridine (1 mL) was treated as per the general procedure described above. After 3 days, the product was purified by HPLC (0.05 M triethylammonium hydrogencarbonate buffer + 5% MeCN, flow rate: 16 mL min^{-1}, t_R 14.0 min). Compound **6** was obtained as a white powder (57.8 mg, 45%) after ion exchange and precipitation. ^{1}H NMR (250 MHz, D_2O) δ: 2.04 (s, 3H, COCH_3), 3.90–4.01 (m, 5 H, H-2′, H-3′, H-4′, H-5a′, H-5b′), 4.74 (d, J = 4.4 Hz, 2H, CH_2Ar), 5.58 (d, J = 8.0 Hz, 1H, H-5), 5.66 (d, J = 3.2 Hz, 1H, H-1′), 7.12–7.19 (m, 3 H, H-4″, H-5″, H-6″), 7.32 (d, J = 6.9 Hz, 1H, H-3″), 7.63 (d, J = 8.0 Hz, 1H, H-6). ^{13}C-NMR (151 MHz, D_2O) δ: 22.3 ($COCH_3$), 64.5 (1C, C-5′), 64.5 (1C, Ar-CH_2), 69.2, 73.8, 83.0 (3C, C-2′, C-3′, C-4′), 88.6 (1C, C-1′), 102.4 (1C, C-5), 126.7–134.4 (6C, C-1″, C-2″, C-3″, C-4″, C-5″, C-6″), 141.4 (1C, C-6), 151.5, 166.0 (2C, C-2, C-4), 173.9 (1C, COCH$_3$). ^{31}P NMR (243 MHz, D_2O) δ: –12.5 (bd, 2P). FAB-MS (negative mode, matrix: glycerin + NBA, DMSO) (*m*/*z*): 594 $[M - H^+]^-$, 572 $[M - Na^+]^-$, 550 $[M - 2Na^+ + H^+]^-$ for $C_{18}H_{21}N_3O_{13}P_2Na_2$ (595.4).

Inhibition studies of β-glucosyltransferase of phage T4

The activity of β-glucosyltransferase was monitored by the transfer of ^{14}C-glucose from the substrate ^{14}C-UDPGlc to 5-hydroxymethylcytosine (HMC) of unglucosylated T4*DNA. T4*DNA was obtained from progeny phage propagating in a UDPGlc$^-$ *Escherichia coli* K host strain (W4597). The reaction mixture used to determine the IC_{50} in the inhibition studies, contained 100 mM Tris–HCl, pH 7.9, 9 μg of T4*DNA, 25 mM $MgC1_2$, 200 μM UDPGlc (Sigma), 5 μL of ^{14}C-UDPGlc (NEN, 330 mCi mmol^{-1} or 1.85 MBq, delivered in a total volume of 2 mL), 0.5 μg BGT and different inhibitors, with concentrations varying between 0.5 and 2.5 mM in a total assay volume of 100 μL. After 15 min of incubation at 30°C, the reaction mixtures were transferred onto DEAE filter disks (Whatman DE81). The filters were washed three times with 5 mL of a buffer containing 0.5 M NaH_2PO_4, pH 7.0, dried and counted in a Beckman scintillation counter, model LS 6000 TA.

K_m and V_{max} values were determined in essentially the same buffer and reaction volume, however, the concentrations of the substrate mixture varied between 1.6 and 200 μM and the inhibitors were added at constant concentrations of 0.5, 1, and 2 mM, respectively. The different substrate concentrations were obtained by the appropriate dilution of a mix containing UDPGlc and ^{14}C-UDPGlc in a ratio of 27.5:1. Radioactivity transferred from the substrate to the T4*DNA, again was measured as described above.

Glycodendrimers based on cellobiosyl-derived monomers[1]

Stacey A. Kalovidouris, W. Bruce Turnbull, and J. Fraser Stoddart

Abstract: Reductive amination of suitably functionalized trisaccharide monomers, based on cellobiosylgalacto residues, has made it possible to construct high-molecular-weight glycodendrons and glycodendrimers for the display of large bioactive oligosaccharides and proteins in a well-defined manner.

Key words: cellobiose, glycodendrimers, reductive amination, trisaccharide monomers.

Résumé : L'amination réductrice de trisaccharides monomères fonctionnalisés de façon appropriée et attachés à de résidus cellobiosylgalactose permet de construire des glycodendrons et des glycodendrimères de masses moléculaires élevées grâce auxquels on peut présenter de grosses molécules d'oligosaccharides et de protéines bioréactifs d'une façon bien définie.

Mots clés : cellobiose, glycodendrimères, amination réductrice, trisaccharides monomères.

Introduction

The incorporation of carbohydrates into dendritic structures continues to be pursued vigorously by a growing number of research groups (1). The driving force behind glycodendrimer research has been the desire to mimic Nature's use of multivalency (2) to enhance both the avidity and selectivity of interactions between oligosaccharide ligands and their corresponding protein receptors. There is a growing appreciation (3) that the structure of the underlying dendritic scaffold is as important to achieving efficient multivalent interactions as presenting multiple copies of the ligand. Thus, developing novel dendritic structures for this purpose may be considered to be a worthy pursuit. We (4, 5) and others (6) have identified that, in addition to the bioactive ligands, oligosaccharides show great potential as building blocks for multivalent and dendritic scaffolds. In this sense, carbohydrates can provide (7) vast diversity in constitution, configuration and conformation in addition to lending themselves well as multifunctional building blocks for constructing branched structures. Small changes in constitution can provide large differences in biological activities, e.g., in the highly selective recognition (8) of α-2,3- and α-2,6-linked sialosides by Siglecs 1 and 2, respectively. But perhaps the most subtle, yet profound, of possible structural changes results from the inversion of configuration at a single carbon atom such as in the repeating unit of the common (1→4)-linked polymers of glucose — i.e., amylose and cellulose (9). The α(1→4)-linkages in amylose promote the adoption of a helical structure by the polymer, in which intramolecular hydrogen bonding between primary and secondary hydroxy groups on adjacent turns of the helix, leads to the formation of channels capable of supramolecular complexation. In contrast, the β(1→4)-linkages of cellulose lead to a more extended structure promoting intermolecular hydrogen bonding between polymer strands and insoluble crystalline fibers. In addition to the changes in overall shape, the spacial distributions of substituent groups (e.g., C-6 hydroxymethyl groups) on the polymers are also different. Whereas, in amylose, all of the primary hydroxy functions point away from the same side of the polymer chain — reminiscent of the primary face of cyclodextrins — the same groups in cellulose are directed in opposing directions from adjacent sugar residues. The graphical representations of maltosyl and cellobiosyl residues shown in Fig. 1 illustrate the background behind our motivation to be able to compare

Received 6 December 2001. Published on the NRC Research Press Web site at http://canjchem.nrc.ca on 15 August 2002.

It was Ray Lemieux who provided intellectual leadership in the field of carbohydrate chemistry during the second half of the 20th century. His contribution to our fundamental knowledge of the nature of the carbohydrates was profound, all-encompassing, and far-reaching. During the last decade or so, our basic understanding of the mechanisms by which carbohydrates are bound by proteins has advanced enormously. These advances were only possible because of the seminal work done by Lemieux in the 1980s. We dedicate this paper to the memory of Ray.

and contrast glycodendrons and glycodendrimers incorporating these two diastereoisomerically related residues.

Recently, we have outlined (5) an approach for the synthesis of dendritic oligosaccharides via reductive amination of a reducing sugar, using a trisaccharide bearing two methylamino groups. Our first choice was to use a maltosylgalactose repeating unit that incorporates the α(1→4)-linkage (associated with amylose) between the branching points of resulting dendrons. Here, we describe the synthesis of analogous compounds that incorporate the corresponding β(1→4)-linkage of cellobiose in a first step toward the general development of oligosaccharide-based dendrimers that exhibit broad structural diversity derived from their constituent building blocks.

Results and discussion

Synthesis of the AB_2 monomers and the dendron

The synthesis of the first-generation cellobiosylgalacto-based dendron **9** is outlined in Scheme 1. Starting from the known (10) peracetylated α-cellobiosyl-trichloroacetimidate **1** as the glycosyl donor and 1,2:3,4-di-*O*-isopropylidene-α-D-galactopyranose (**2**) as the glycosyl acceptor, the protected trisaccharide **3** was obtained in 75% yield using TMSOTf as the promoter. With the ultimate objective being that of introducing protected secondary amino functions at the primary positions of the two glucopyranosyl residues, the *O*-acetyl protecting groups were removed using Zemplén conditions. Thereafter, the two primary hydroxyl groups were protected

as their TBDMS ethers before the secondary ones were reacetylated to afford the fully protected trisaccharide **4**. The last three steps were performed in an overall yield of 50%. The bis-silyl ether was then converted directly into the dibromide **5** in 96% yield with triphenylphosphine and bromine. When **5** was heated with neat benzylmethylamine, the fully protected trisaccharide (**6**) was obtained in 57% yield. One of the required AB_2 monomers, namely the trisaccharide (**7**), carrying two secondary amino functions, was isolated quantitatively following hydrogenolysis of **6** in the presence of Pearlman's catalyst. The other AB_2 monomer (**8**) was obtained in 80% yield following removal of the cyclic acetals in **6** by TFA-catalyzed hydrolysis. The two AB_2 monomers (**7** and **8**) were coupled by reductive amination to give the first-generation dendron (**9**) in 94% yield. DEPT-135 ^{13}C NMR and ES-MS spectra are presented in Figs. 2 and 3, respectively. Of the 11 different methylene carbon atoms present in the dendron, seven can be identified as negative peaks in the ^{13}C NMR spectrum. The ES-MS reveals peaks at 2001.0, 1001.1, 667.8, 500.7, and 400.8 for the $[M + H]^+$, $[M + 2H]^{2+}$, $[M + 3H]^{3+}$, $[M + 4H]^{4+}$, and $[M + 5H]^{5+}$ ions obtained from the dendron (**9**).

Synthesis of the core

The synthesis of the tris[2-(methylamino)ethyl]amine-based core (**13**) is depicted in Scheme 2. A published procedure (11) was followed to obtain **13** in two steps, starting from tris(2-aminoethyl)amine (**11**). In the first step, the triscarbamate (**12**) was prepared by reacting **11** with ethylchloroformate under basic conditions. In the second step, **12** was reduced with lithium aluminum hydride to afford the tris[2-(methylamino)ethyl]amine core (**13**).

Synthesis of the glycodendrimers

The syntheses of the zero-generation glycodendrimer (**14**) and the first-generation glycodendrimer (**16**) are summarized in Scheme 3. The graphical representations of molecular structures employed in this scheme are defined in Schemes 1 and 2. The zero-generation glycodendrimer (**14**) was isolated in 69% yield following coupling by reductive amination of the AB_2 monomer (**8**) with the tris[2-(methylamino)ethyl]amine core (**13**). This glycodendrimer was easily soluble in water. However, upon its acetylation (Scheme 4), the resulting peracetylated derivative (**15**) was soluble in polar organic solvents, e.g., methanol and dimethylformamide, but not in chlorinated solvents, e.g., dichloromethane and chloroform. The MALDI-TOF mass spectrum (Fig. 4) of **15** exhibited an $[M + H]^+$ peak at *m*/*z* 3407 with an isotope distribution that matches well with that of the calculated one. Employing reductive amination once again to couple the dendron (**10**) with the tris[2-(methylamino)ethyl]amine core (**13**) results in the formation of the first-generation glycodendrimer (**16**) in 56% yield. This glycodendrimer (**16**) and its peracetylated derivative (**17**) (see Scheme 5) exhibit solubility characteristics similar to those already described for the zero-generation counterparts **14** and **15**. The MALDI-TOF mass spectrum (Fig. 5) of **17** exhibited an $[M + H]^+$ peak at *m*/*z* 9078 along with fragmentation peaks at *m*/*z* 8062, 7159, 6227, 5153, 4305, 3017, and 1987. These fragmentations

result from cleavages of glycosyl linkages and β-elimination on the amine linkages at the positions indicated by open arrows in Fig. 5. These types of cleavages in oligosaccharide derivatives are well precedented in the literature (12).

Experimental section

General methods

Chemicals were purchased from Aldrich and were used as received except for sodium cyanoborohydride (Aldrich), which was purified by the published procedure (13). Reactions were carried out under a dry argon atmosphere and the solvents were dried prior to use according to literature procedures (14). Thin-layer chromatography (TLC) was carried out on aluminum sheets precoated with silica gel 60F (Merck 5554). The plates were inspected by UV light and developed either with iodine vapor or by treatment with 5% H_2SO_4 in EtOH, followed by heating. Column chromatography was carried out using silica gel 60F (Silicycle). Preparative reversed phase chromatography was performed on fully endcapped C-18, or on C-8 silica gel 100 (230–400 mesh, Fluka), and gel permeation chromatography (GPC) was performed using a 25 × 900 mm column of Sephadex LH20 resin (Sigma), eluting with MeOH. Analytical reversed

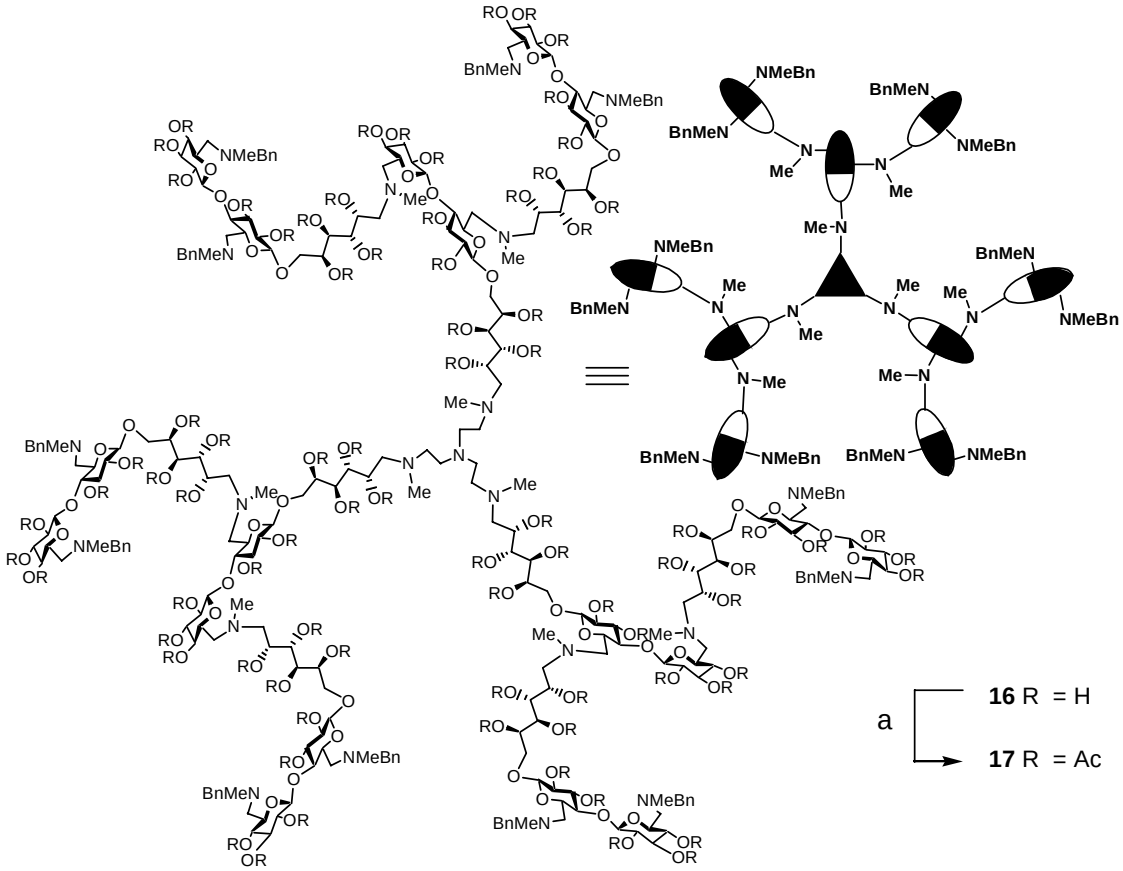

Fig. 4. MALDI-TOF mass spectrum of a zero-generation dendrimer **15**.

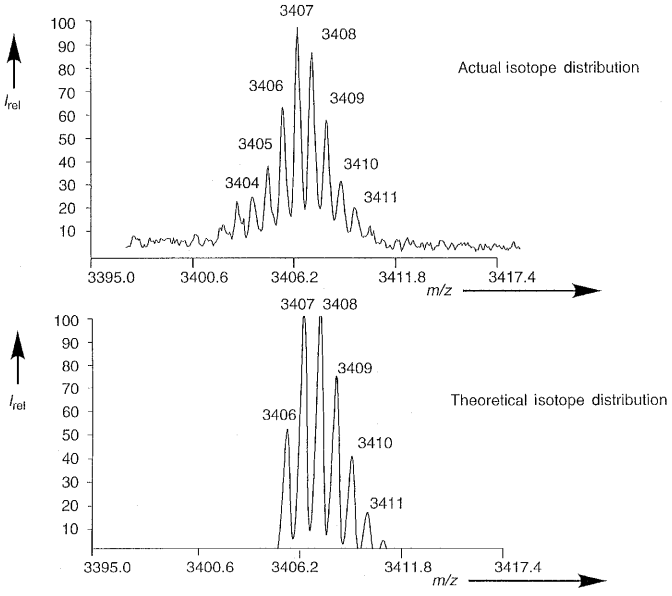

phase HPLC was conducted using a Hypersil 5 μm BDS C-18 silica column (ThermoQuest, 4.6 × 250 mm) under isocratic elution (MeOH–H_2O–TFA, 65:35:0.0001) with UV detection using a Dynamax PDA-2 diode array detector. Matrix-assisted laser desorption ionization time-of-flight mass spectra (MALDI-TOF-MS) and fast atom bombardment mass spectra (FAB-MS) were performed on either Perceptive Biosystems Voyager RP (MALDI) or VG SAB-SE (FAB) mass spectrometers. Electrospray mass spectrometry (ES-MS) was recorded on a Sciex API IIIR triple quadrupole electrospray mass spectrometer using H_2O–MeCN–HCOOH (50:50:0.1) as the mobile phase. ^1H and ^{13}C NMR spectra were recorded using Bruker ARX400, ARX500, and Advance 500 spectrometers with the residual solvent or TMS as the internal standard. The chemical shifts are expressed on the δ scale in parts per million (ppm). The following abbreviations are used to explain the observed multiplicities: s (singlet), d (doublet), dd (doublet of doublets), t (triplet), m (multiplet), br (broad).

*2,3,4,6-Tetra-*O*-acetyl-*β*-D-glucopyranosyl-(1→4)-2,3,6-tri-*O*-acetyl-*β*-D-glucopyranosyl-(1→6)-1,2:3,4-di-*O*-isopropylidene-*α*-D-galactopyranose (3)*

The glycosyl donor **1** (13.4 g, 17 mmol) and the glycosyl acceptor **2** (6.7 g, 26 mmol) were stirred with powdered 4 Å molecular sieves (13.0 g) in CH_2Cl_2 (250 mL) for 2 h under an argon atmosphere. The mixture was then cooled to 0°C and trimethylsilyl trifluoromethanesulfonate (610 μL, 3.4 mmol) was added and stirring was continued at 0°C for 30 min. The reaction was then quenched by the addition of Et_3N (0.47 mL, 3.4 mmol). The solution was filtered through Celite and the filtrate was concentrated. Column chromatography (SiO_2, CH_2Cl_2:EtOAc (8:2)) gave **3** (11 g, 75%) as a solid foam. $[\alpha]_D^{20}$ –11.6 (*c* = 1 in $CHCl_3$). HR-MS (FAB)

calcd. for $C_{38}H_{54}O_{23}Na$ (M + Na): 901.2954; found: 901.2976. ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 1.36, 1.42, 1.43, 1.53 (4 × s, 12H, 2 × CMe_2), 1.91, 1.94, 1.96, 1.98, 2.02, 2.06 (7 × s, 21H, 7 × Ac), 3.57–3.59 (m, 1H, H-5b), 3.59–3.61 (m, 2H, H-6a, H-5c), 3.68 (t, J = 9.3 Hz, 1H, H-4b), 3.80–3.85 (m, 1H, H-5a), 3.91 (dd, $J_{5,6}$ = 3.8 Hz, $J_{6,6'}$ = 11.4 Hz, 1H, H-6a′), 3.98 (br d, $J_{6,6'}$ = 12.5 Hz, 1H, H-6c), 4.04 (dd, $J_{5,6}$ = 5.0 Hz, $J_{6,6'}$ = 12.1 Hz, 1H, H-6b), 4.10 (d, J = 7.84 Hz, 1H, H-4a), 4.22 (m, 1H, H-2a), 4.28 (dd, $J_{5,6}$ = 4.6 Hz, $J_{6,6'}$ = 12.5 Hz, 1H, H-6c′), 4.42–4.47 (m, 2H, H-1c, H-6b′), 4.55 (m, 2H, H-1b, H-3a), 4.82–4.87 (m, 2H, H-2c, H-2b), 4.99–5.14 (m, 3H, H-4c, H-3c, H-3b), 5.42 (d, $J_{1,2}$ = 4.9 Hz, 1H, H-1a). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 20.6 (3C), 20.7, 20.8, 20.9, 21.0, 24.4, 25.0, 25.9, 26.0, 59.1, 59.2, 60.0, 60.3, 68.4, 68.5, 68.6, 68.7, 69.0, 69.3, 69.5, 69.8 (2C), 70.0 (2C), 72.0 (2C), 75.0, 95.0, 101.0 (2C), 169.4, 169.8, 169.9, 170.1, 170.4, 170.5, 170.6.

*2,3,4-Tri-*O*-acetyl-6-*O*-tert-butyldimethylsilyl-*β*-D-glucopyranosyl-(1→4)-2,3-di-*O*-acetyl-6-*O*-tert-butyldimethylsilyl-*β*-D-glucopyranosyl-(1→6)-1,2:3,4-di-*O*-isopropylidene-*α*-D-galactopyranose (4)*

The acetyl protecting groups in **3** were removed under standard Zemplén conditions (NaOMe–MeOH) and then *tert*-butyldimethylsilyl chloride (3 g, 20 mmol) was added to a stirred solution of the deacetylated trisaccharide **3** (3 g, 5.1 mmol) in C_5H_5N (15 mL) at 0°C. After 1 h, additional *tert*-butyldimethylsilyl chloride (1 g, 6.6 mmol) was added, and stirring was continued at room temperature overnight before quenching the reaction with MeOH. The mixture was concentrated and redissolved in CH_2Cl_2 and washed with 1 M HCl, sat. $NaHCO_3$, and H_2O, before drying over anhyd Na_2SO_4, and concentrating to an oil. This oil was treated with Ac_2O (20 mL) and C_5H_5N (20 mL) and the solution was left to stir at room temperature overnight. Following concentration and coevaporation with PhMe, the mixture was dissolved in EtOAc (500 mL) and washed consecutively with 1 M HCl, sat. $NaHCO_3$, and sat. NaCl solutions, before drying (Na_2SO_4), and concentrating to a foam. Column chromatography (SiO_2, CH_2Cl_2:EtOAc (9:1)) gave **4** (2.69 g, 50%) as a foamy semisolid. $[\alpha]_D^{20}$ –17.9 (c = 1 in $CHCl_3$). HR-MS (FAB) calcd. for $C_{46}H_{78}O_{21}Si_2Na$ (M + Na): 1045.4472; found: 1045.4501. ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 0.00, 0.01, 0.08, 0.09 (4 × s, 12H, 4 × SiMe), 0.80, 0.91 (2 × s, 18H, 2 × $SiCMe_3$), 1.30 (s, 6H, CMe_2), 1.40, 1.49 (2 × s, 6H, CMe_2), 1.96, 1.99, 2.03, 2.04, 2.07 (5 × s, 15H, 5 × Ac), 3.28 (m, 1H, H-5b), 3.43–3.44 (m, 1H, H-5c), 3.61 (m, 1H, H-6a′), 3.67–3.73 (m, 2H, H-6c, H-6c′), 3.87 (m, 4H, H-4b, H-5a, H-6b, H-6b′), 3.96 (dd, $J_{5,6}$ = 4.1 Hz, $J_{6,6'}$ = 11.2 Hz, 1H, H-6a), 4.16 (br d, J = 7.9 Hz, 1H, H-4a), 4.27 (m, 1H, H-2a), 4.49 (d, J = 8.0 Hz, 1H, H-1b), 4.56 (dd, $J_{2,3}$ = 2.0 Hz, $J_{3,4}$ = 7.9 Hz, 1H, H-3a), 4.66 (d, $J_{1,2}$ = 8.0 Hz, 1H, H-1c), 4.80–4.85 (m, 2H, H-2b, H-2c), 4.98 (t, $J_{3,4} \approx J_{4,5}$ = 9.5 Hz, 1H, H-4c), 5.02–5.15 (m, 2H, H-3b, H-3c), 5.50 (d, $J_{1,2}$ = 4.9 Hz, 1H, H-1a). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: –5.5, –5.4, –5.3, –4.9, 18.4, 18.6, 20.6, 20.7, 20.8, 20.9, 21.0, 24.4, 25.0, 25.8 26.9, 26.0 (3C), 26.1 (3C), 60.4, 63.0, 67.5, 68.3, 68.5, 70.1, 70.4, 70.5, 70.6, 70.7, 71.0, 71.1, 72.1, 75.1, 75.3, 94.9, 100.2, 100.6, 108.6, 109.3, 169.2, 169.9, 170.2, 170.3, 170.4.

Conclusion

The research we have reported in this short paper has established that we can not only synthesize glycodendrons containing cellobiosylgalacto residues but we can also attach these glycodendrons to a trivalent core. These glycodendrons and glycodendrimers add further diversity to the carbohydrate scaffolds we are currently constructing to display large bioactive oligosaccharides (15) and proteins (16) in a predetermined and reasonably precise way on the peripheries of such glycodendrons and glycodendrimers.

The reactions of 3-alkylindoles with cyclopropanes: An unusual rearrangement leading to 2,3-disubstitution

Dylan B. England, Tom K. Woo, and Michael A. Kerr

Abstract: Indoles that bear an alkyl substituent in the 3-position, when treated with cyclopropanediesters, typically undergo a [3 + 2]-annulation reaction in a kinetically controlled process (**1**→**4**). If the reaction is performed at elevated temperatures for a longer period of time, a rearrangement of the putative intermediate **3** occurs in which the alkylating species undergoes a migration to the 2-position followed by loss of a proton to reform the benzopyrrole ring. The yields range from 78 to 10%. If a 3-allylindole is used in combination with a cyclopropanediester, which is further substituted with an alkenyl moiety, the product is an effective ring closing metathesis substrate and can be converted to the 1,3,3*a*,4,5,6-hexahydro-1*H*-pyrido[3,2,1-*jk*]carbazole system. A mechanistic discussion of the rearrangement process is presented.

Key words: indole, cyclopropanediester, Lewis acid, ytterbium triflate, rearrangement.

Résumé : Les indoles porteurs d'un substituant alkyle en position 3, traités par des cyclopropanediesters, conduisent généralement à une réaction d'annellation [3 + 2] par un processus sous contrôle cinétique. Si on effectue la réaction à température élevée, pour une période prolongée, il se produit un réarrangement de l'intermédiaire putatif (**3**) au cours duquel l'espèce qui provoque l'alkylation subit une migration vers la position 2 qui est suivie d'une perte d'un proton pour reformer un noyau benzopyrrole. Les rendements varient de 78 à 10%. Si l'on utilise un 3-allylindole en combinaison avec un cyclopropanediester substitué par une portion alcényle, le produit est un substrat résultant d'une réaction effective de métathèse conduisant à une formation de cycle; ce substrat peut être transformé en un système 1,3,3*a*,4,5,6-hexahydro-1*H*-pyrido[3,2,1-*jk*]carbazole. On présente une discussion du mécanisme du processus de réarrangement.

Mots clés : indole, cyclopropanediester, acide de Lewis, triflate d'ytterbium, réarrangement.

Introduction

The importance of the indole moiety in biological and medicinal chemistry is unarguably significant. An enormous fraction of the bioactive alkaloids known are based on the indole nucleus (1). Medicinal chemists have repeatedly turned to indole-based compounds for inspiration and indeed many indole-containing compounds are marketed as therapeutic agents (2). It should come as no surprise, then, that there continues to be considerable emphasis on new methods for the formation and the elaboration of the benzopyrrole ring system (3). Such methods add to the toolbox of the synthetic chemist and aid in the chemical synthesis of indole alkaloids (4).

For some time now, our research group has been interested in the elaboration of the indole nucleus for the purposes of natural products synthesis. In particular we have focussed on new ways to take advantage of the natural nucleophilic character of indoles. We have found, for example, that lanthanide triflates (in particular ytterbium triflate) are effective in promoting the nucleophilic addition of indoles to electron-deficient olefins (5) and cyclopropanes (6, 7). In addition, we (5*a*, 6) and others (8) have reported that high pressures are effective in further amplifying the nucleophilic behaviour of indoles. In our more recent work (6) we have shown that indoles with no substituents are efficiently alkylated with cyclopropanediesters producing 2-carboalkoxy-4-indolyl butanoate esters **5** (Scheme 1). Indoles which bear substitution at the 3-position, upon treatment with the cyclopropanediester, yield the cyclopentannulation product **4** (7). It was noted, that if the reactions (**1**→**4**) of substrates where where R^2 = H was performed under high-temperature conditions, a by-product **6** (a formal 2-alkylation) was formed in small amounts (<5%) and in some cases (R^4 = Ph) in significant amounts.

Driven by curiosity, we subjected one example (Scheme 2) to forcing conditions (refluxing acetonitrile, 4 days) and were able to produce **8** as the sole identifiable product in 76% yield. By comparison, if the reaction was

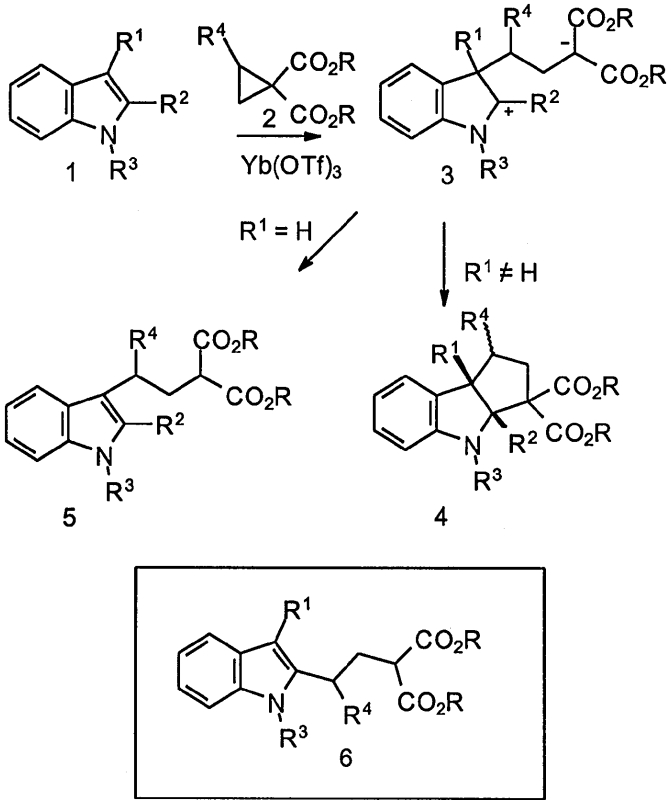
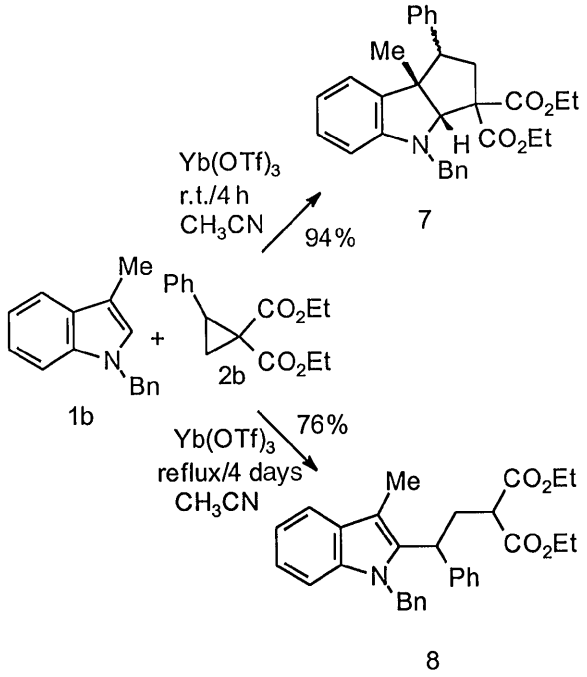
Scheme 1.



Scheme 2.



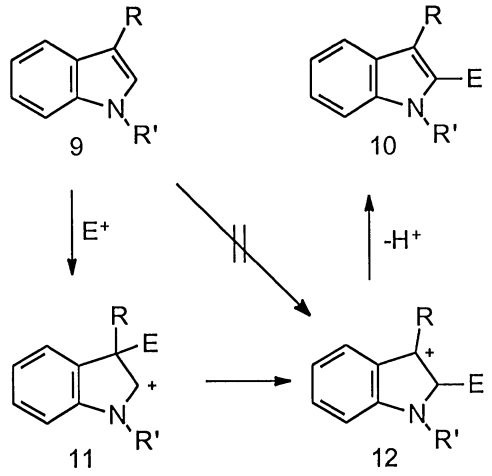
performed under milder conditions (rt, 4 h), the annulation product **7** was formed in 94% yield. Herein we detail a mechanistic picture which explains the formation of the 2-alkylated indoles and the factors which favour its formation over cyclopentannulation. In some select cases the process is synthetically useful and products can be intermediates for the synthesis of more complex indole systems.

Results and discussion

Indoles which bear a substituent at the 3-position often undergo further electrophilic substitution at the 2-position (9) (Scheme 3). While appearing as a direct electrophilic attack, it is widely accepted that substitution at the 2-position of 3-substituted indoles such as **9** proceeds via further 3-alkylation to form intermediate **11** followed by a rearrangement to **12** and subsequent loss of a proton to form **10**. Naidoo and co-workers (10) suggest that the direct formation of the cationic intermediate **12** would be a higher energy process than via intermediate **11.**

A mechanistic scenario for our observations, which illustrates the rearrangement, is shown in Fig. 1. Intuitive relative energies were born out by density functional theory calculations at the B3LYP level of theory[2] on **I** through **V** using R^1 = R^2 = Me and R^3 = H. In a first step common to the formation of both products, the indole may react with the cyclopropanediester to produce intermediate immonium ion **II,** which can suffer two fates. In a kinetic process, ring closure

Scheme 3.



of the malonic enolate can occur to produce cyclopentannulation product **IV**. Alternatively **II** may rearrange to produce the 3° benzyllic carbocation **III**. Transfer of a proton in **III** yields the thermodynamic product **V**. Although the potential energy surfaces linking the structures in Fig. 1 were not studied in detail, the geometry optimization of **II** often led to the formation of **IV**. This suggests that a small energetic barrier for the rearrangement process (**II**–**IV**) exists. Similarly, geometry optimization of **III** often lead directly to **V**, again suggesting a small barrier for this process. It is interesting that the heating of compounds of type **IV** for extended periods of time leads to the formation of **V** as well as a small amount of the starting indole, illustrating the reversibility of the annulation.

[2] Energies refer to those resulting from a global geometry optimization protocol. For a description of the theoretical methods employed see the *Experimental* section.

Fig. 1. Putative mechanistic scenario for the formation and rearrangement of **IV** and **V**. Energies shown are relative to *I*, calculated at the B3LYP/6-31G** level of theory using $R^1 = R^2 = Me$ and $R^3 = H$. Relative energies include zero-point vibrational energy corrections.

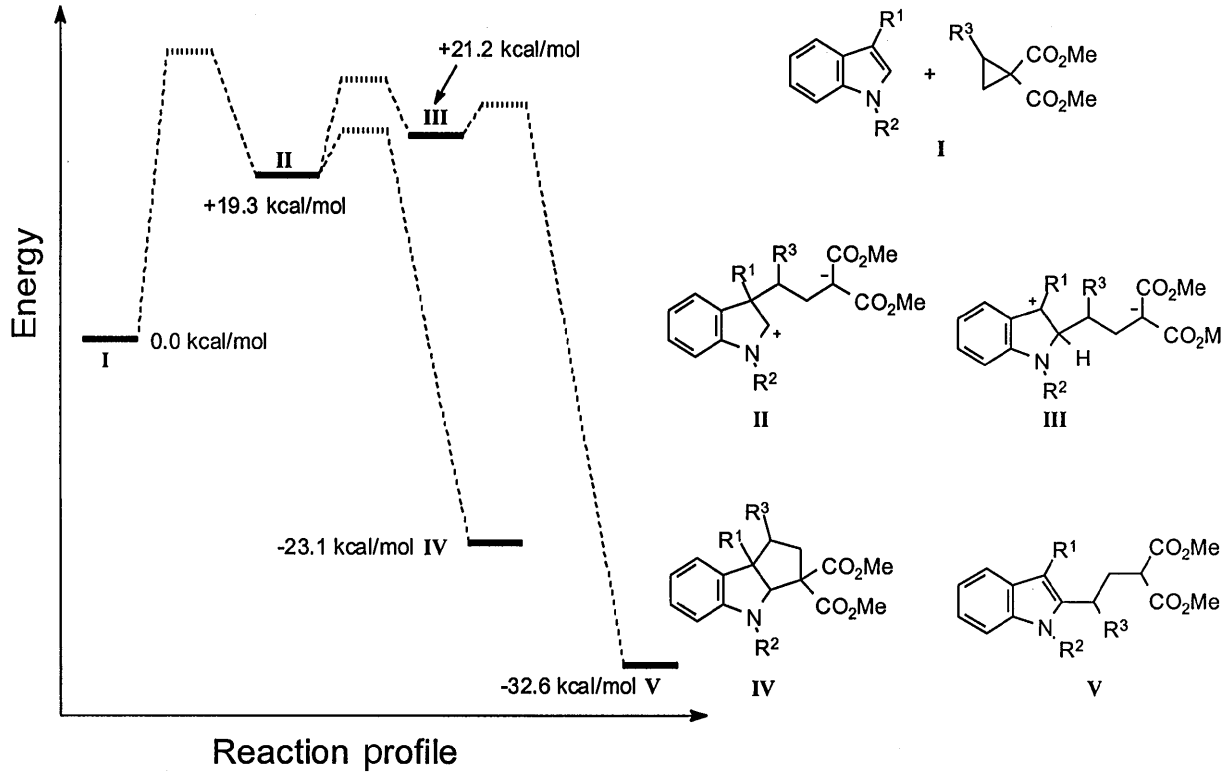

Table 1.

	R^1	R^2		R^3	R^4
1a	Me	Me	2a	$CH=CH_2$	Me
1b	Me	Bn	2b	Ph	Et
1c	$CH_2CH=CH_2$	Bn	2c	CH=CHPh	Me

To probe the synthetic utility of the rearrangement, a series of indoles (11) and cyclopropanes (12) were prepared according to literature procedures (Table 1). In general the reactions of the indoles with the cyclopropanes were performed in refluxing acetonitrile. The results are shown in Table 2. In most cases the annulation product was formed first and soon disappeared (by TLC) to yield the product resulting from 2-alkylation. Phenyl cyclopropane **2b**, upon reaction with **1a** gave **13** in quite acceptable yield (78%). Other cyclopropanes were less well behaved, undergoing rearrangements in yields that would be of questionable synthetic utility. Our interest in having a vinylcyclopropane **2a** undergo this reaction stemmed from our desire to have a pendant double bond in the product that could be a useful handle for further functionalization (vide infra). To exploit the beneficial effects of the phenyl group while retaining this exploitable functionality, we employed the styrenyl cyclopropane **2c**. In the reaction with 1,3-dimethylindole, **14** was produced in acceptable yield, while the product of the reaction with 3-allyl-1-benzylindole produced **18** in 31% yield. A variety of reaction conditions were explored to optimize the yields. Alternative Lewis acid catalysts, solvents, times, and temperatures offered no improvement in the yields of the alkylation products.

In all reactions involving cyclopropane **2a** and **2c**, a significant amount of compound **24** was formed (Scheme 4). This observed product likely originates from what could be described as a vinylogous Wagner–Meerwein rearrangement of the intermediate immonium ion (**19** or **20**) to **21** or **22** which occurs in competition with the predicted rearrangement.

Compounds such as **17** and **18** were prepared with an eye towards ring closing metathesis (RCM) (13). Treatment of **17** or **18** with the commercially available Grubb's catalyst (13) **28**, resulted in the formation of the dihydrocarbazole **25** in 85 and 96% yield, respectively (Scheme 5). Hydrogenation of the double bond gave the tetrahydrocarbazole **26**. Treatment of **25** with a metallic palladium catalyst in the presence of oxygen yielded the carbazole **27** in 67% yield.

In summary we have detailed an interesting rearrangement reaction which results in the 2-alkylation of 3-substituted indoles. The products may be further elaborated by ring closing metathesis to yield tetrahydrocarbazoles which may be of synthetic utility for the preparation of a large variety of indole alkaloids. Efforts are underway to improve the

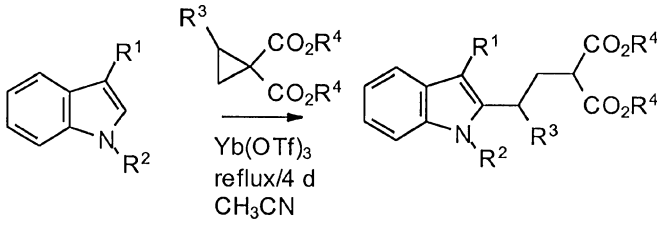
Table 2.



Indole	Cyclopropane	Product (yield)	
1a	2b	 13	(78%)
1a	2c	 14	(44%)
1a	2a	 15	(22%)
1b	2a	 16	(16%)
1c	2a	 17	(18%)
1c	2c	 18	(27%)

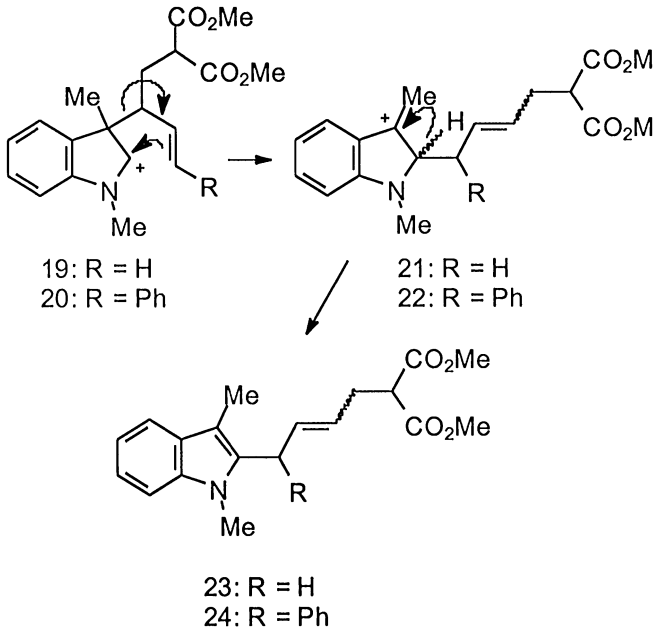
efficiency of the rearrangement protocol so that it may be of general utility. Results of our efforts will be reported in due course.

Experimental

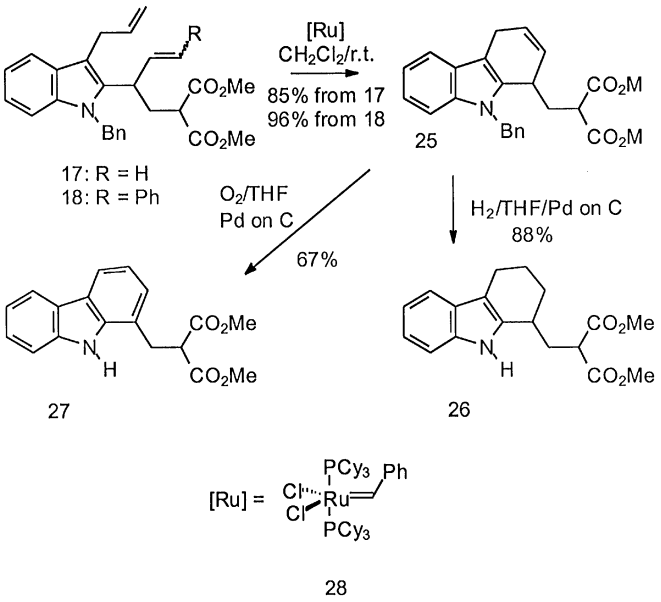
General considerations (energy calculations)

Due to the conformational variability of the structures of interest, the following global optimization protocol was utilized to estimate relative energies. To generate a large

Scheme 4.



Scheme 5.



number of conformations that might lead to a global minimum, a high-temperature molecular dynamics simulation was performed for each of **II**–**V** using the SYBYL molecular mechanics force field. Partial atomic charges for the SYBYL calculations were obtained using the Merz–Singh–Kollman (17) electrostatic potential charge fitting procedure as implemented in the Gaussian 98 suite of programs (19) from a fully optimized structure at the B3LYP/6-31G** level (15, 16). For the purpose of generating the point charges for the SYBYL calculations, an arbitrary conformation was utilized. Using the SYBYL potential, a 10 ns molecular dynamics simulation was performed with a time step of 1 fs where the temperature was approximately maintained at 1300 K by velocity rescaling every 50 000 time steps.

© 2002 NRC Canada

Two hundred structures were generated from this MD simulation by sampling every 50 ps. These 200 structures were then fully optimized at the PM3 (18) semi-empirical level with the Gaussian 98 package. The five lowest energy structures were then fully optimized at the B3LYP/6-31G** level with Gaussian 98. The geometry optimization of some complexes often resulted in the formation of another. Consequently, we report on the lowest energy structures consistent with structures **II** through **V**. For each of the lowest energy structures, harmonic vibrational frequency analysis at the B3LYP/6-31G** level was performed with no constraints for the purpose of estimating the zero-point vibrational energy. The relative energies reported in Fig. 1 are zero-point energy corrected. It is important to note that the high-temperature molecular dynamics was used only to generate structures for the global optimization protocol and that the relative energies are approprate to the zero K limit. Furthermore, the calculations have been performed on the gas-phase molecules such that that solvation effects have been neglected.

General considerations (preparative chemistry)

All reactions were performed in anhydrous acetonitrile either as purchased from VWR (DriSolv) or distilled from CaH_2. $Yb(OTf)_3$ was used as the hydrate as purchased from Aldrich. TLC analysis was performed on E. Merck glass plates precoated with silica gel 60 F254. Flash column chromatography (FCC) was performed on silica gel purchased from Silicycle. ^{1}H NMR spectra were recorded at 400 or 600 MHz. ^{13}C NMR spectra were recorded at 100 or 125 MHz. Mass spectra (EI) were recorded using an ionizing voltage of 70 eV.

General procedure for the Yb(OTf)3-catalyzed 2-alkylation of indoles with cyclopropanediesters

The indole (2 equiv), cyclopropane (1 equiv), and $Yb(OTf)_3$ (5 mol%) were charged into a dry flask equipped with a stirring bar. Acetonitrile was added via syringe and the mixture stirred under argon for the indicated time at reflux. The solvent was removed in vacuo and the residue purified by FCC on silica using mixtures of EtOAc–hexanes.

Diethyl 2-[2-(1,3-dimethyl-1H-indol-2-yl)-2-phenyl ethyl] malonate (13)

The general procedure above was followed using indole **1a** (0.290 g, 2.0 mmol), cyclopropane **2b** (0.262 g, 1.0 mmol), and $Yb(OTf)_3$ (0.031 g, 0.05 mmol) in 3 mL acetonitrile. The mixture was refluxed for 1.5 days to give, after purification, 318 mg of **13** (78%) as an oil. IR (thin film on NaCl plates υ) (cm^{-1}): 1747, 1730, 1601, 1472, 1447. ^{1}H NMR ($CDCl_3$) δ: 7.57 (d, *J* = 8.1 Hz, 1H), 7.31–7.17 (m, 7H), 7.13–7.09 (m, 1H), 4.59–4.55 (m, 1H), 4.26–4.16 (m, 2H), 4.03–3.95 (m, 1H), 3.91–3.85 (m, 1H), 3.41 (s, 3H), 3.31–3.28 (m, 1H), 3.02–2.94 (m, 1H), 2.81–2.74 (m, 1H), 2.33 (s, 3H), 1.26 (t, *J* = 7.2 Hz, 3H), 1.13 (t, *J* = 7.2 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ: 169.3, 169.2, 141.4, 137.1, 135.0, 128.5, 128.3, 127.3, 126.5, 121.3, 118.7, 118.4, 109.3, 108.7, 61.5, 61.5, 50.2, 38.7, 31.6, 30.5, 14.0, 13.9, 9.3. EI-HR-MS for $C_{25}H_{29}NO_4$ calcd.: 407.2097; found: 407.2097.

Dimethyl 2-[(3E)-2-(1,3-dimethyl-1H-indol-2-yl)-4-phenyl-3-butenyl] malonate (14)

The general procedure above was followed using indole **1a** (0.290 g, 2.0 mmol), cyclopropane **2c** (0.260 g, 1.0 mmol), and $Yb(OTf)_3$ (0.031 g, 0.05 mmol) in 3 mL acetonitrile. The mixture was refluxed for 6 h to give, after purification, 178 mg of **14** (44%) as an oil. IR (thin film on NaCl plates υ) (cm^{-1}): 1751, 1734, 1472, 1435. ^{1}H NMR ($CDCl_3$) δ: 7.54 (d, *J* = 7.8 Hz, 1H), 7.34–7.18 (m, 7H), 7.11 (dt, *J* = 6.9, 1.2 Hz, 1H), 6.44 (dd, *J* = 16.2, 4.7 Hz, 1H), 6.37 (dd, *J* = 16.2, 4.7 Hz, 1H), 4.06 (ddd, *J* = 8.8, 4.9, 4.9 Hz, 1H), 3.72 (s, 3H), 3.69 (s, 3H), 3.51 (s, 3H), 3.32 (dd, *J* = 8.2, 6.0 Hz, 1H), 2.71–2.55 (m, 2H), 2.30 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 169.7, 169.5, 137.1, 136.8, 134.3, 130.7, 129.9, 128.6, 128.3, 127.7, 127.5, 126.2, 121.3, 118.8, 118.3, 108.8, 52.7, 52.6, 49.8, 37.2, 32.4, 30.7, 9.3. EI-HR-MS for $C_{25}H_{27}NO_4$ calcd.: 405.1940; found: 405.1933.

Dimethyl 2-[2-(1,3-dimethyl-1H-indol-2-yl)-3-butenyl] malonate (15)

The general procedure above was followed using indole **1a** (0.290 g, 2.0 mmol), cyclopropane **2a** (0.184 g, 1.0 mmol), and $Yb(OTf)_3$ (0.031 g, 0.05 mmol) in 3 mL acetonitrile. The mixture was refluxed for 1.5 days to give, after purification, 72 mg of **15** (22%) as an oil. IR (thin film on NaCl plates υ) (cm^{-1}): 1751, 1734, 1472, 1434. ^{1}H NMR ($CDCl_3$) δ: 7.51 (d, *J* = 7.9 Hz, 1H), 7.25 (d, *J* = 7.9 Hz, 1H), 7.19 (t, *J* = 7.9 Hz, 1H), 7.09 (t, *J* = 7.9 Hz, 1H), 6.06 (ddd, *J* = 17.2, 10.2, 5.4 Hz, 1H), 5.17 (dd, *J* = 10.4, 1.2 Hz, 1H), 5.07 (dd, *J* = 17.2, 1.2 Hz, 1H), 3.91–3.85 (m, 1H), 3.72 (s, 3H), 3.65 (s, 3H), 3.49 (s, 3H), 3.27 (t, *J* = 8.3, 6.2 Hz, 1H), 2.60–2.46 (m, 2H), 2.25 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 169.6, 169.5, 138.1, 137.1, 134.2, 128.3, 121.2, 118.7, 118.2, 115.7, 108.7, 108.5, 52.6, 52.5, 49.7, 37.8, 31.7, 30.6, 9.1. EI-HR-MS for $C_{19}H_{23}NO_4$ calcd.: 329.1627; found: 329.1628.

Dimethyl 2-[2-(1-benzyl-3-methyl-1H-indol-2-yl)-3-butenyl] malonate (16)

The general procedure above was followed using indole **1b** (0.442 g, 2.0 mmol), cyclopropane **2a** (0.184 g, 1.0 mmol), and $Yb(OTf)_3$ (0.031 g, 0.05 mmol) in 3 mL acetonitrile. The mixture was refluxed for 1.5 days to give, after purification, 73 mg of **16** (18%) as an oil. IR (thin film on NaCl plates υ) (cm^{-1}): 1751, 1734, 1636, 1466, 1453. ^{1}H NMR ($CDCl_3$) δ: 7.57–7.55 (m, 1H), 7.26–7.09 (m, 6H), 6.93 (d, *J* = 7.4 Hz, 2H), 5.94 (ddd, *J* = 17.2. 10.3, 5.9 Hz, 1H), 5.33 (AB, 2H), 5.03 (d, *J* = 10.3 Hz, 1H), 4.87 (d, *J* = 17.2 Hz, 1H), 3.76–3.71 (m, 1H), 3.68 (s, 3H), 3.51 (s, 3H), 3.27 (dd, *J* = 8.4, 6.0 Hz, 1H), 2.50–2.42 (m, 1H), 2.37–2.27 (m, 1H), 2.31 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 169.6, 169.4, 138.1, 137.6, 136.8, 134.5, 128.8, 128.6, 127.0, 125.8, 121.6, 119.1, 118.2, 115.8, 109.4, 108.8, 52.6, 52.4, 49.4, 46.8, 38.1, 31.8, 9.4. EI-HR-MS for $C_{25}H_{27}NO_4$ calcd.: 405.1940; found: 405.1937.

Dimethyl 2-[2-(3-allyl-1-benzyl-1H-indol-2-yl)-3-butenyl] malonate (17)

The general procedure above was followed using indole **1c** (0.247 g, 1.0 mmol), cyclopropane **2a** (0.184 g,

1.0 mmol), and $Yb(OTf)_3$ (0.031 g, 0.05 mmol) in 3 mL acetonitrile. The mixture was refluxed for 1.5 days to give, after purification, 69 mg of **17** (16%) as an oil. IR (thin film on NaCl plates υ) (cm^{-1}): 1751, 1734, 1636, 1465, 1453, 1435. ^1H NMR ($CDCl_3$) δ: 7.59 (d, *J* = 6.8 Hz, 1H), 7.27–7.08 (m, 6H), 6.93 (d, *J* = 7.2 Hz, 2H), 6.05–5.90 (m, 2H), 5.38 (AB, 2H), 5.11–5.01 (m, 3H), 4.91 (d, *J* = 17.5 Hz, 1H), 3.79–3.73 (m, 1H), 3.70 (s, 3H), 3.53 (s, 3H), 3.59–3.49 (m, 2H), 3.28 (dd, *J* = 8.5, 6.0 Hz, 1H), 2.53–2.42 (m, 1H), 2.32–2.25 (m, 1H). ^{13}C NMR ($CDCl_3$) δ: 169.6, 169.3, 137.9, 137.9, 137.3, 137.1, 135.2, 128.6, 128.1, 127.0, 125.8, 121.7, 119.2, 118.8, 116.0, 114.8, 111.0, 109.6, 52.6, 52.4, 49.4, 47.0, 37.9, 32.0, 29. EI-HR-MS for $C_{27}H_{29}NO_4$ calcd.: 431.2097; found: 431.2101.

*Dimethyl 2-[(3**E**)-2-(3-allyl-1-benzyl-1**H**-indol-2-yl)-4-phenyl-3-butenyl] malonate (18)*

The general procedure above was followed using indole **1c** (0.400 g, 1.6 mmol), cyclopropane **2c** (0.443 g, 1.7 mmol), and $Yb(OTf)_3$ (0.050 g, 0.08 mmol) in 7 mL acetonitrile. The mixture was refluxed for 1 day to give, after purification, 255 mg of **18** (31%) as an oil. IR (thin film on NaCl plates υ) (cm^{-1}): 1750, 1734, 1495, 1466, 1453. ^1H NMR ($CDCl_3$) δ: = 7.59 (d, *J* = 7.2 Hz, 1H), 7.28–7.04 (m, 11H), 6.93 (d, *J* = 7.7Hz, 2H), 6.26 (dd, *J* = 15.7, 6.4 Hz, 1H), 6.10 (d, *J* = 15.7 Hz, 1H), 6.06–5.97 (m, 1H), 5.42 (AB, 2H), 5.10–5.02 (m, 2H), 3.95–3.90 (m, 1H), 3.68 (s, 3H), 3.66–3.49 (m, 2H), 3.55 (s, 3H), 3.32 (dd, *J* = 8.5, 6.0 Hz, 1H), 2.58–2.50 (m, 1H), 2.40–2.33 (m, 1H). ^{13}C NMR ($CDCl_3$) δ: 169.6, 169.3, 137.9, 137.3, 137.1, 136.7, 135.6, 131.1, 129.5, 128.7, 128.4, 127.4, 127.1, 126.1, 125.9, 121.7, 119.3, 118.8, 115.0, 111.0, 109.7, 109.5, 52.7, 52.5, 49.5, 47.1, 37.6, 32.8, 29.2. EI-HR-MS for $C_{33}H_{33}NO_4$ calcd.: 507.2410; found: 507.2413.

*Dimethyl 2-[(9-benzyl-4,9-dihydro-1**H**-carbazole-1-yl)methyl]malonate (25)*

Indole **18** (0.255 mg, 0.50 mmol) and Grubbs' catalyst **28** (21 mg, 0.025 mmol) were charged into a dry flask equipped with a stirring bar. Dichloromethane was added via syringe and the mixture stirred under argon at room temperature for 4 h. The mixture was then concentrated in vacuo and purified by column chromatography (EtOAc–hexanes as the eluent) to yield 0.195 g (96%) of **25** as a an oil. IR (thin film on NaCl plates υ) (cm^{-1}): 1751, 1733, 1466, 1453, 1435. ^1H NMR ($CDCl_3$) δ: 7.52 (d, *J* = 8.2 Hz, 1H), 7.26–7.07 (m, 6H), 6.95 (d, *J* = 7.8 Hz, 2H), 6.17–6.15 (m, 1H), 5.77–5.73 (m, 1H), 5.45 (d, *J* = 17.2 Hz, 1H), 5.32 (d, *J* = 17.2 Hz, 1H), 3.68 (s, 3H), 3.68–3.63 (m, 2H), 3.48–3.44 (m, 1H), 3.36 (t, *J* = 7.0 Hz, 1H), 3.14 (s, 3H), 2.47 (ddd, *J* = 12.9, 6.6, 6.6 Hz, 1H), 2.36 (ddd, *J* = 14.1, 7.0, 3.3 Hz, 1H). ^{13}C NMR ($CDCl_3$) δ: 170.2, 169.2, 138.1, 137.2, 133.3, 128.7, 127.5, 127.1, 126.6, 126.5, 125.9, 121.6, 119.1, 118.1, 109.6, 109.3, 52.6, 52.2, 47.5, 46.7, 34.0, 32.0, 23.7. EI-HR-MS for $C_{25}H_{25}NO_4$ calcd.: 403.1784; found: 403.1787.

*Dimethyl 2-[(9-benzyl-2,3,4,9-tetrahydro-1**H**-carbazole-1-yl)methyl]malonate (26)*

Dihydrocarbazole **25** (0.089 g, 0.22 mmol) was dissolved in dry THF in a flask equipped with a stirring bar. 10% Pd/C (5 wt%) was added quickly and the flask was purged with H_2 gas. The mixture was then stirred under a balloon of H_2 at ambient temperature for 3 h. The reaction mixture was then filtered over a pad of Celite, rinsed with THF, and subjected to flash chromatography on silica gel (EtOAc–hexanes as the eluent) to yield 0.079 g (88%) of **26** as an oil. IR (thin film on NaCl plates υ) (cm^{-1}): 1750, 1734, 1480, 1453, 1435. ^1H NMR ($CDCl_3$) δ: 7.51 (d, *J* = 8.3 Hz, 1H), 7.27–7.06 (m, 6H), 6.91 (d, *J* = 7.9 Hz, 2H), 5.43 (s, 2H), 3.69 (s, 6H), 3.56 (dd, *J* = 11.3, 3.8 Hz, 1H), 2.88–2.83 (m, 1H), 2.77–2.65 (m, 2H), 2.35 (ddd, *J* = 13.5, 11.4, 1.6 Hz, 1H), 2.06 (ddd, *J* = 15.2, 11.7, 1.6 Hz, 1H); 1.93–1.78 (m, 4H). ^{13}C NMR ($CDCl_3$) δ: 169.7, 169.6, 138.4, 137.4, 137.0, 128.5, 127.2, 126.9, 125.8, 121.3, 118.9, 118.0, 110.1, 109.6, 52.7, 52.6, 49.5, 45.9, 32.3, 29.5, 25.8, 20.9, 18.1. EI-HR-MS for $C_{25}H_{27}NO_4$ calcd.: 405.1940; found: 405.1954.

Towards high affinity carbohydrate-binding proteins: Directed evolution of murine galectin-3

Joseph J. Lundquist, Brendan M. Kiburz, Jeffrey K. Wu, Kenneth D. Gibbs, Jr., and Eric J. Toone

Abstract: Towards a better understanding of the molecular basis of affinity, a directed evolution of murine galectin-3 (G3) was initiated to produce mutants with improved affinity for lactose and *N*-acetyllactosamine relative to the wild-type protein. A series of *N*-terminal truncations were developed to facilitate incorporation of the 35 kDa protein into a phage-display construct. Analysis of the various assemblies revealed that all such deletions produced protein unsuitable for use in directed evolution studies. Following fusion of the full-length galectin to p3 of filamentous phage, three libraries were constructed and biopanned for increased affinity for lactose. The first two libraries, of 1×10^5 and 1×10^6 members, respectively, were assembled through a combination of error-prone PCR and DNA shuffling. A third library was constructed using a modified staggered extension protocol (StEP), but contained only 10 members. Mutants were also engineered site-specifically to test the role of key residues in or near the binding pocket. Analysis of the mutants by ITC identified one mutation (R158G) that produces a twofold increase in affinity for lactose and another that results in a sixfold increase in affinity for *N*-acetyllactosamine. Solid-phase binding analysis of phage for nonexpressing proteins indicated that two other mutants demonstrated increased binding to β-methyllactose relative to the wild-type protein. Together these studies validate the evolutionary approach and set the stage for the development of novel carbohydrate-binding proteins.

Key words: phage display, directed evolution, galectin, thermodynamics, carbohydrates.

Résumé : Dans le but de mieux comprendre les bases moléculaires de son affinité, on a initié une évolution dirigée de la murine-galectine-3 (G3) afin de produire des mutants ayant une meilleure affinité que la protéine naturelle pour le lactose et la *N*-acétyllactosamine. On a développé une série de produits tronqués au niveau *N*-terminal qui permettent de mieux incorporer la protéine de 35 kDa dans un assemblage présentant le phage. Une analyse de divers types d'assemblage a permis de découvrir que de tels tronquaqes conduisent à une protéine qui n'est pas appropriée pour un usage dans des études d'évolution dirigée. À la suite d'une fusion de la galectine complète à un p de 3 à un phage filamenteux, on a préparé trois banques et dont on a évalué d'un point de vue biologique le degré d'affinité pour le lactose. Les deux premières banques qui comprennent respectivement 1×10^5 et 1×10^6 membres ont été assemblées par le biais d'une combinaison PCR et de réarrangement d'ADN qui est sujette à erreur. La troisième bibliothèque a été obtenue en faisant appel à un protocole d'extension décalé modifié (« StEP »), mais elle ne comportait que 10 membres. On a aussi préparé des mutants à spécification de site pour évaluer le rôle des résidus clés dans ou près de la poche de fixation. L'analyse des mutants par ITC a permis d'identifier une mutation (R158G) qui permet de doubler l'affinité pour le lactose et une autre qui multiplie par six cette affinité pour la *N*-acétyllactosamine. Une analyse de la fixation du phage en phase solide pour des protéines qui ne donnent pas d'expression indique que deux autres mutants possèdent un pouvoir de fixation accru pour le β-méthyllactose par rapport à la protéine naturelle. Ces études considérées ensemble permettent de valider l'approche évolutionnaire et de mettre tout en place le développement de nouvelles protéines pouvant se lier à des hydrates de carbone.

Mots clés : mise en évidence du phage, évolution dirigée, galectine, thermodynamique, hydrates de carbone.

[Traduit par la Rédaction]

Introduction

Protein-carbohydrate interactions play important roles in myriad biological events. Bacterial infections, fertilization, host entry by viruses, and inflammatory responses are all mediated by specific interactions between carbohydrate-binding proteins and their cognate cell-surface carbohydrate receptors (1–12). Although protein–carbohydrate interactions

are vital to many biological events, they are uniformly weak: dissociation constants range from millimolar to micromolar (13).

The molecular basis of affinity and specificity in aqueous association phenomena in general is poorly understood. Although structural data reveal favorable interactions, such as hydrogen bonds and salt bridges, they offer no understanding of the extent to which these interactions stabilize the bound complex. Water is a unique medium, both in bulk and in detail, that provides energetically favorable contacts with a wide range of solutes. Under such conditions, a binding event is necessarily a cycle during which energetically favorable contacts between solute and solvent are lost and replaced by a corresponding set of interactions between solutes. A better understanding of the energetic consequences of these cycles is prerequisite to the rational construction of molecular motifs with a priori predictable properties.

Considering the complexity of association phenomena in general, it is not surprising that the basis for the weak affinity of protein–carbohydrate interactions is unclear. On one hand, the structure of carbohydrates might mandate that binding cycles cannot provide a favorable energetic increment greater than about 6 kcal mol^{-1}. On the other hand, the observed affinities may simply reflect the requirements for biological activity, where dissociation is frequently as important as binding. The long-term goals of our research are to understand the molecular basis of affinity in aqueous solution and the maximum affinity with which a carbohydrate can be bound by a protein. Considerable effort has been expended towards the synthesis of carbohydrates with enhanced binding behavior relative to native epitopes; with few exceptions, these studies have universally failed to yield high-affinity ligands (14–35). Work towards modification of the protein partner has shown some promise (36–40). Here, we present initial results on the enhancement of lectin affinity through random protein modification.

We selected murine galectin-3 (G3), a 35-kDa monomeric member of the galectin family of proteins that bind β-galactosides, for directed evolution (41–45). The function of galectin-3 is not fully understood, although it appears to posses a number of interesting attributes that include pre-mRNA splicing and anti-apoptotic signaling (46–48). The expression of various galectins also correlates with a number of cancer states (49–51). The protein is found in the cytosol and nucleus of several cell types in a temporally regulated fashion depending on developmental phase (52). In some cases the protein is secreted into extracellular spaces through a non-classical pathway (52).

Galectin-3 is a chimeric galectin, characterized by an *N*-terminal domain connected to a *C*-terminal domain through a short linker. The *N*-terminal region consists of a 12-amino-acid cell-directing sequence that includes a phosphorylation site followed by a series of glycine- and proline-rich repeats that vary in number and composition (53–57). The *C*-terminal domain consists of the canonical galectin fold, comprising 12 β-sheets, and contains the carbohydrate-binding site. No crystal structure is available for murine galectin-3, although a structure has been determined for the *C*-terminal domain of the human homolog with which the murine galectin shares greater than 90% sequence identity (58, 59).

Using murine galectin-3 as our starting point, we have engineered and isolated truncated forms of the protein and tested their utility for phage display. We have also incorporated the full-length protein into filamentous phage. Concurrently, a new expression system was developed to facilitate expression. This new system also greatly reduces the time necessary for protein purification. Following these preliminary studies, random mutations were introduced into the protein via a combination of error-prone PCR and DNA shuffling techniques. Increased affinity mutants were selected from these libraries by biopanning. These mutants, as well as chimeric proteins and site-directed mutants, were analyzed for ligand binding by isothermal titration calorimetry. Several galectin-3 mutants could not be expressed; the binding of those mutants was tested by a phage-based binding assay. Here we report the prelimary results of these studies.

Experimental

General

Ampicilin, tetracycline, kanamycin, lactose, β-methyllactose, and *N*-acetyllactosamine were purchased from Sigma. Restriction enzymes *Bam*HI, *Bgl*II, *Sph*I, *Eco*RI, and *Sfi*I, as well as Deep Vent DNA polymerase were obtained from New England Biolabs. T4 ligase and dNTPs were obtained from Boehringer–Mannheim. Plasmid prCBP35s was obtained from Dr. J. L.Wang, Department of Biochemistry, Michigan State University. Plasmid fUSE5 and *Escherrichia coli* strain K91 were obtained from Dr. G. P. Smith, Division of Biological Science, University of Missouri. K91 starved cells were prepared by the procedure of Pratt and co-workers (60). Protein concentrations were determined by the method of Edelhoch (61). Unless stated otherwise, all transformations are carried out by chemical transformation.

Assembly of truncated G3

Using plasmid prCBP35s as a template, polymerase chain reaction (PCR) amplification was carried out with the appropriate *N*-terminal primer (Table 1) and a reverse primer (5′-CGG TAT TTA GTA GCC ATG TTG-3′) that corresponds to a randomly selected downstream sequence. Thirty PCR cycles were conducted (94°C for 30 s, 50°C for 30 s, and 74°C for 60 s). The amplified section was digested with *Eco*RI and ligated into the vector pIN-III-*Omp*A1. The final plasmid was transformed into XL-10 Gold cells (Stratagene). Isolated DNA was analyzed for insert orientation by repeating the PCR; clones containing the correct orientation were sequenced for verification of the coding frame.

Expression and isolation of the G3 and truncations

Plasmids containing insert corresponding to either wild-type or truncated G3 were transformed into BL21 Codon Plus RP cells (Stratagene). A starter culture was prepared from a single colony transferred into 5 mL Luria broth supplemented with 100 μg mL^{-1} ampicilin and incubated at 37°C overnight. Terrific broth (1 L) supplemented with 100 μg mL^{-1} of ampicilin was inoculated with the starter culture and allowed to grow at room temperature for 2 h before the addition of isopropyl-1-thio-β-galactopyranoside (IPTG) to a final concentration of 50 μM. The culture was incubated with shaking (300 rpm) for 20 h at room temperature. Cells were

harvested by centrifugation (5000 × *g*, 15 min) and the cell-pellet was resuspended in 25 mL of 1 M tris buffer (pH 7.0) containing 10 mM β-mercaptoethanol, 1 mM phenylmethylsulfonyl fluoride (PMSF), 10 μg mL^{-1} soybean trypsin inhibitor, 0.5 μg mL^{-1} leupeptin, and 5 trypsin inhibition units (TIU) L^{-1} aprotinin and stored at 4°C. After 4 h, the resultant mixure was centrifuged (18 000 × *g*, 30 min) and the supernatant was fractionated at 65% ammonium sulfate. The crude protein precipitate collected by centrifugation (12 000 × *g*, 20 min), resuspended in 75 mM tris buffer containing 75 mM NaCl, 2 mM EDTA, 1 mM β-mercaptoethanol, 1 mM PMSF at pH 7.5 and applied to a lactosylsepharose column (approx. 25 mL resin) pre-equilibrated in the same buffer. The resin was washed with 20 column volumes of loading buffer then eluted with five column volumes of buffer supplemented with 0.3 M lactose. Fractions were checked for purity by SDS-PAGE under denaturing conditions and positive fractions were concentrated using a YM-3 filter in an Amicon stirred cell.

Construction of plasmid for pET expression

Using the appropriate template (prCBP35s for wild-type, phage plasmid from biopanning, or assembled insert for chimeric constructs), 30 PCR cycles (94°C for 30 s, 53°C for 30 s, and 74°C for 60 s) were carried out with the primers EcoG3 and BamG3 (Table 1). The amplified section was digested with *Eco*RI (4 h at 37°C) and purified with a Qiagen PCR purification kit. The purified DNA was digested with *Bam*HI (4 h at 37°C) and purified by extraction from a 1% agarose gel using a Qiagen gel extraction kit. Ligation into a similarly prepared pET28b vector gave the final plasmid that was transformed into XL-10 Gold cells (Stratagene). Plasmids from resultant colonies were isolated and analyzed for insert by PCR. Colonies that tested positive were sequenced for verification of the coding frame.

Expression and isolation of His-tagged G3 and mutants

Plasmids containing insert for either wild-type or mutant G3 were transformed into BL21 Codon Plus RP cells (Stratagene). A starter culture was prepared by transfer of a single colony into 5 mL Luria broth supplemented with 50 μg mL^{-1} kanamycin and incubated at 37°C overnight. Terrific broth (TB, 1 L) supplemented with 50 μg mL^{-1} of kanamycin was inoculated with starter culture and allowed to grow at 37°C for 3 h before adding IPTG to a final concentration of 1 mM. The resultant culture was incubated with shaking (300 rpm) for 3.5 h. Cells were harvested by centrifugation (5000 × *g*, 15 min) and the cell-pellet was subjected to partial disruption by a freeze–thaw cycle. The cell-pellet was resuspended in binding buffer (5 mM imidazole, 0.5 M NaCl, 20 mM tris, pH 7.9) and sonicated using a Fisher Model 550 probe sonicator (three 2-min pulses at power level 4). Lysed cells were centrifuged (23 000 × *g*, 30 min) and the supernatant was applied to a column containing 7 mL His Bind resin pre-equilibrated according to the manufacturer's instructions. The column was washed with six column volumes of binding buffer followed by 10 column volumes of wash buffer (25 mM imidazole, 0.5 M NaCl, 20 mM tris, pH 7.9). Protein was eluted with six column volumes of elution buffer (0.5 M imidazole, 0.5 M NaCl, 20 mM tris, pH 7.9). Fractions containing the desired protein were pooled and concentrated using an Amicon stirred cell fitted with a YM-3 filter.

Site-directed mutagenesis of G3

Using plasmid prCBP35s as a template, PCR (30 cycles of 94°C for 30 s, 45°C for 30 s, and 68°C for 17 min) was carried out with primers W195Ffor and W195Frev (Table 1) and *Pfu*Turbo polymerase (Strategene). The reaction mixture was digested with *Dpn*I, purified with a Qiagen PCR purification kit, and transformed into XL-10 Gold cells (Stratagene). Plasmids from the resultant colonies were isolated and sequenced. Plasmids containing the W195F mutation were transformed into BL21-Codon Plus cells and protein was expressed as described above. This protocol was repeated using primers S251Afor and S251Arev to provide the S251A mutant.

Construction of plasmid for phage display of G3 (pf5G3)

PCR (30 cycles of 94°C for 30 s, 53°C for 30 s, and 74°C for 60 s) was carried out from prCBP35s with the primers

© 2002 NRC Canada

PDfor and PDrev (Table 1). The amplified section was digested with *Sfi*I (4 h at 37°C) and purified with a Qiagen PCR purification kit (Qiagen). Ligation into similarly prepared fUSE5 vector gave the complete plasmid (pf5G3) that was transformed into DH10B MAX competent cells (Gibco) and plated on to LB/agar media supplemented with tetracycline (40 μg mL^{-1}). Plasmids from the resultant colonies were isolated and analyzed for insert by PCR. Colonies that tested positive by PCR were sequenced for verification of the coding frame.

Test for infectious phage

A single colony of the transformed DH10B MAX cells was used to inoculate a 5 mL aliquot of Luria broth (LB) supplemented with tetracycline (40 μg mL^{-1}). Growth proceeded for 12 h at 37°C prior to centrifugation (2 × 10 000 *g*, 30 min). Starved K91 *E. coli* cells (10 μL) were mixed with 10 μL of phage-containing supernatant and the medium was incubated for 10 min at 25°C. Luria broth was added and the infection was incubated at 37°C for 1 h prior to plating on LB/agar plates containing tetracycline (40 μg mL^{-1}) and kanamycin (100 μg mL^{-1}). The presence of colonies indicates the presence of infectious phage in the original growth medium.

Phage assay for lactose binding

A modified microtiter plate displaying either β-lactose (Calbiochem) or an *N*-acetyl cap was washed with PBS (2×) and blocked with 1% BSA in PBS (100 μL) for 2 h at room temperature. The plate was washed (3×) with PBS containing 0.05% v/v Tween-20 (PBST), then 100 μL phage solution (a dilution of medium in PBS that produced 10 colony forming units per μL) was added to the plate prior to incubation for 2 h at 37°C. The plate was washed with PBST (3×). Lactose (0.3 M in PBS) was added and the plates were incubated for 1 h at 37°C. Lactose solutions were transferred to a sterile microtiter plate and an infection was carried out as above. The number of colonies obtained from the lactose and control plates were then compared.

Library construction and isolation

PCR (45 cycles of 94°C for 30 s, 52°C for 30 s, and 74°C for 120 s) was carried out on prCBP35s with Taq polymerase and the primers PDfor and PDrev (Table 1). Amplification was conducted in buffer supplemented to final concentrations of 6.8 mM $MgCl_2$, 400 μM dITP, 200 μM dCTP, 200 μM dTTP, 80 μM dGTP, and 20 μM dATP. The generated insert library was purified with a Qiagen PCR purification kit and digested with deoxyribonuclease I (0.24 U mL^{-1} reaction) in a buffer of 33 mM tris, 0.67 mM $MgCl_2$, pH 7.4. The digestion proceeded at 25°C for 10 min before being heated to 94°C for 15 min. The DNA fragments were purified with a MERmaid spin kit (Bio101). Reassembly of the DNA fragments was accomplished by PCR using Taq polymerase in the supplied buffer but without additional primers (45 cycles of incubation at 94°C for 30 s, 50°C for 30 s, and 74°C for 30 s). The reassembled material was purified with a Qiagen PCR purification kit and subject to PCR amplification (30 cycles of incubation at 94°C for 30 s, 50°C for 30 s, and 68°C for 60 s) using PDfor and PDrev primers. Amplified DNA was purified using a Qiagen PCR purification kit and subject to digestion with *Sfi*I (4 h at 37°C) followed by a second purification. Ligation into similarly prepared fUSE5 vector resulted in plasmid that was purified as before and eluted with MilliQ Ultrapure water. The ligated material was electroporated into DH10B MAX electrocompetent cells (Gibco) using a MicroPulse electroporator (BioRad) with 0.2 cm cuvettes at 2.7 kV (5.2 ms decay). Cultures of electroporated cells were prepared in 5 mL LB broth supplemented with tetracycline and incubated for 1 h at 37°C. After incubation, the cultures were used to inoculate 1 L of TB supplemented with tetracycline (40 μg mL^{-1}). A 0.5 mL aliquot was removed from the medium for the estimation of electroporation efficiency by determining the number of transformants yielded; the remaining broth was incubated with shaking for 24 h. The electroporation efficiency provided an estimate of the library size.

After 24 h, phage-containing media was isolated by centrifugation (8000 × *g*, 15 min) and the supernatant was mixed with 0.15 volumes of PEG–NaCl (16.7% PEG 8000 in 3.3 M NaCl) by gentle inversion (100×). The phage were allowed to precipitate over 16 h at 4°C. The solution was centrifuged (8000 × *g*, 20 min) and the pellets were resuspended in a total volume of 30 mL PBS. This solution was centrifuged (20 000 × *g*, 15 min) to remove insoluble material. The supernatant was transferred to another centrifuge tube, 0.167 volumes of PEG–NaCl was added, and, after mixing by several inversions, the solution was centrifuged (20 000 × *g*, 15 min). The phage pellet was resuspended in 15 mL PBS and cleared of insoluble material as before. The supernatant was then transferred to another centrifuge tube containing 0.25 volumes of PEG–NaCl, mixed and centrifuged (20 000 × *g*, 10 min). The phage pellet was resuspended in 4 mL PBS and shaken at 25°C for 1 h before being cleared of insoluble material. The resultant solution containing the purified phage library was used as a stock; 1:10 – 1:100 dilutions were used for biopanning assays.

Error-prone modification of staggered extension protocol

StEP (64) (90 cycles of incubation at 94°C for 30 s and 50°C for 5 s) was conducted on prCBP35s using the primers PDfor and PDrev (Table 1). Taq polymerase was used in the supplied reaction buffer supplemented to final concentrations of 6.8 mM $MgCl_2$, 400 μM dITP, 200 μM dCTP, 200 μM dTTP, 80 μM dGTP, and 20 μM dATP. The amplified material was purified using a Qiagen PCR purification kit, digested with *Sfi*I, and utilized as a library of inserts.

Biopanning of G3 displaying phage

Diluted phage library (100 μL) was added to two wells of a β-lactose displaying microtiter plate (Calbiochem). The plate was incubated with gentle shaking for 1 h at 25°C then washed with PBST supplemented with 200 mM lactose (15×). The elution solution (50 μL; 100 μM glycine, 1 mg mL^{-1} BSA, 300 mM lactose, pH 2.2) was added to the wells and the plate was allowed to incubate at 25°C for 1 h with gentle shaking. Lactose solutions were subsequently transferred to wells in a sterile microtiter plate containing 10 μL neutralization solution (1 M tris, pH 9.1). After a 5 min incubation, 10 μL of K91 starved cells were added, initiating transfection as above. Plasmids from individual

© 2002 NRC Canada

colonies were isolated and sequenced to determine the position and nature of mutations.

Solid-phase analysis of binding

Prior to each assay, the concentration of phage required to give a maximum of 10–100 colonies upon binding to lactose-displaying plates in the absence of inhibitor was determined. A series of wells on a microtiter plate were blocked overnight with 1% BSA in PBS. After blocking, the wells were washed three times with assay buffer (10 mM tris, 1 mM EDTA, 1 mM β-mercaptoethanol, pH 8.5) and 40 μL of serial fourfold dilutions of β-methyllactose were added to each well followed by 10 μL of galectin-displaying phage. After incubating for 1 h at 25°C, the solutions were transferred to a series of wells on a lactose plate and allowed to incubate with gentle shaking at 25°C for another hour. The wells were washed three times with assay buffer containing 0.05% (v/v) Tween-20 before 50 μL elution buffer (100 μM glycine, 1 mg mL^{-1} BSA, 300 mM lactose, pH 2.2) was added. The plates were incubated with gentle shaking at 25°C for 1 h, then elution solution was transferred to a series of wells on a sterile microtiter plate containing 10 μL of neutralization solution (1 M tris, pH 9.1). After 5 min, 10 μL of K91 starved cells were added, initiating infection as described above. Using the number of colonies obtained in the absence of inhibitor as 0% inhibition, the colony number was plotted as a function of inhibitor concentration and the IC_{50} was determined from the best-fit sigmoidal curve (Origin 2.9).

Assembly of chimeric protein inserts

Inserts corresponding to mutant and wild-type galectin-3 were obtained by PCR as before. Following amplification, the inserts were digested with *Sph*I, producing fragments corresponding to the *N*- and *C*-terminal halves of the protein separated at amino acid 143. The fragments were separated on a 1.3% agarose gel and extracted using a Qiagen Gel extraction kit. The chimeric inserts were assembled by ligating one half of the wild-type insert to the complementary half of the mutant insert under standard conditions. The resultant product was amplified by PCR as described above, purified with a Qiagen PCR purification kit, and sequenced before further use as a template for the assembly of the chimeric plasmid.

Isothermal titration microcalorimetry for galectin-3

Calorimetric experiments were carried out on a MicroCal Omega isothermal titration microcalorimeter; details on the instrument and mathematical analyses are described elsewhere (63, 64). The reaction cell (volume = 1.3678 mL) contained a solution of 0.12–0.05 mM galectin-3 in buffer (10 mM tris, 1 mM EDTA, 1 mM β-mercaptoethanol). A series of 30 injections of carbohydrate solution (2–10 mM) were made. The volume of each injection was 8 μL, the duration of injection was 8 s, and the time between injections was 3 min. The data from the resulting injections were integrated to generate a titration curve. A non-linear least-squares fit of the data was used to determine the binding constant (K), the enthalpy of binding (ΔH), and the stoichiometry of binding (n).

Table 2. Galectin-3 truncations from this study.

Protein	Size (kDa)	Size of bacterial pellet from 1 L TB growth[a]	Lactose affinity
Full-length	30.0	+	Yes
d50	25.1	+	Yes
d91	20.4	+	Yes
d96	20.9	—	No

d116	19.0	+	No

[a](—) Represents a pellet size of less than 1 g, (–) a pellet of ~3 g, (+) a pellet of ~7 g.

Results and discussion

Truncation of galectin-3

We initially sought to produce a truncated version of galectin-3; such a protein was attractive for two reasons. First, the size of the native protein is close to the size limit for stable incorporation into p3 of filamentous phage. Although phage can typically tolerate inserts of approximately 30–35 kDa, larger inserts hamper both assembly and infectivity of the phage (65–68). Second, the library size required for complete examination of single mutants grows exponentially with the number of residues in the protein (69, 70). Since the *N*-terminal domain of galectin-3 does not appear to participate in carbohydrate binding, mutations in this region increase the library size through mutation of residues that are presumably uninvolved in binding. By eliminating this domain, even partially, the number of neutral mutations is reduced.

Initial truncation of galectin-3 was attempted at position 116. The selection of this position was based on Wang et al.'s (53) observation that a post-translational digest at position 118 produced protein that retained lactose-binding activity. It was reported in the same paper that a recombinant construct beginning at position 145 failed to produce active protein. A new restriction site was introduced upstream of the DNA corresponding to position 116 in the protein. Digestion of the PCR product with *Eco*RI followed by ligation into the plasmid pIN-III-*Omp*A2 and transformation into *E. coli* provided the appropriate DNA. All attempts at isolating protein from this construct were unsuccessful. A series of truncations were next designed at positions 50, 91, 96, and 101 in the *N*-terminus of galectin-3 (referred to as d50, d91, d96, and d101, respectively). Using the established protocols developed for d116, assembly of the corresponding plasmids was readily accomplished allowing the production of d50, d91, d96, and d101. Table 2 details the various proteins and expression characteristics.

Deletion mutant d101 was initially utilized for study. Although the bacteria grew sluggishly, a small amount (<1 mg) of purified d101 was isolated from 2 L of growth. Attempts to optimize growth conditions failed to improve protein yields, and our attention turned to d96. This construct was apparently toxic, and cells failed to grow following induction. Both d91 and d50 yielded protein expression at roughly the same level as full-length galectin-3. Both proteins aggregate at concentrations above 20 μM, a level too dilute for calorimetry experiments. Based on these data, we chose to

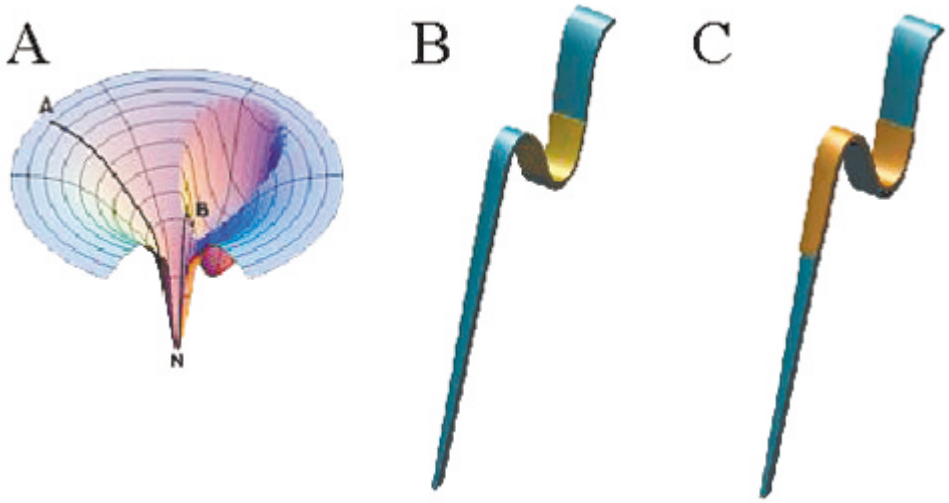
Fig. 1. (*a*) Graphical representation of protein folding and ligand binding (90). Possible sequences are represented on the *x* and *y* axes with the overall free energy of folding or binding represented by the *z*-axis. Both methods are successful along path A. (*b*) Cross-section of energy funnel across path B. Exhaustive sequence search can only be carried out in a small region (depicted in yellow) and results in trapping the search in the energy minimum. (*c*) Cross-section of energy funnel across path B. Random sampling along the path depicted in orange will find members outside the local minimum, allowing global minimum to be eventually discovered.



proceed with directed evolution studies using full-length galectin-3.

Phage display of murine galectin-3

The primary goal of this research is to prepare high affinity mutants of galectin-3 to better understand the structural basis of affinity. We propose to generate these mutants randomly through a directed evolution approach. Relative affinity is usefully assayed by a phage display and biopanning approach; accordingly, we next set out to present G3 on the surface of filamentous phage. The insert for galectin-3 was readily cloned from pET28b and inserted between *Sfi*I sites in the phage display vector fUSE5, allowing display of G3 as the *N*-terminal fusion to the phage protein p3. As G3 is close to the size limit for proteins stably displayed on p3, several tests were undertaken to ensure active protein was present on the phage surface. The phage construct was electroporated into DH10B cells for phage production, and isolated phage were tested for the ability to infect cells and bind lactose.

Phage were initially tested for infectivity since large proteins fused to p3 are known to inhibit infection efficiency (66). Phage mixed with K91 starved cells under standard conditions yielded lawns when plated on LB/agar supplemented with kanamycin and tetracycline indicating that phage were infectious. For a qualitative determination of lactose affinity, dilute phage were incubated for 1 h in microtiter plates capped with either *N*-acetyl (control) groups or lactose. After washing, the phage were eluted and infections carried out. No colonies were generated from capped wells, while lactose-displaying wells gave approximately 200 colonies. We thus conclude that galectin-3 displayed as a p3 fusion retains lactose affinity, enabling a biopanning selection strategy.

Directed evolution of galectin-3

With methods for selection established, construction of libraries could now proceed. Two conceptual strategies for library generation were contemplated: an exhaustive search of a small area of sequence space or a partial search of a much larger area of sequence space (Fig. 1). In the former case, a mutagenesis technique is utilized to prepare all possible single, double, or triple mutants. In the latter case, mutagenesis techniques are used that produce a large number of multiple mutants separated widely in sequence space. The appropriate choice between these two approaches requires knowledge of the "shape" of the energy landscape between wild-type and optimum proteins. In addition, assumptions are necessarily made regarding the uniqueness of both the optimum protein and the path along the landscape toward the optimum. Local minima too deep for escape by a small number of mutations are the bane of in vitro and, presumably, in vivo evolutionary expeditions.

In the first strategy, a library of inserts designed to vary two to three random positions within the protein is prepared. For a 200-amino-acid protein, varying three positions results in a library of less than 1×10^9. A library size of 1×10^{10} provides every possible double and triple mutant to be analyzed at 95% confidence, and is near the limit of that available with phage display (65, 69). However, if a local energy minimum for ligand binding is realized by a mutation at a small number of positions, these mutations will dominate the selection. Subsequent rounds of mutation will fail to achieve further enhancement in binding, since the space searched is too small to escape the minimum. In the second case, a library of inserts containing three to six positions varied randomly is constructed, but not all such mutants are generated simultaneously since the total number is prohibitive. This library samples a larger nonrelated population and thus avoids problems of a dominant local energy minimum by allowing access to mutants that are sufficiently different to escape the local minimum. Previous work by Arnold and co-workers (71) regarding the directed evolution of subtilisin indicated that a saturation approach may prove beneficial in selecting particularly active enzymes, and we chose to follow this suggestion.

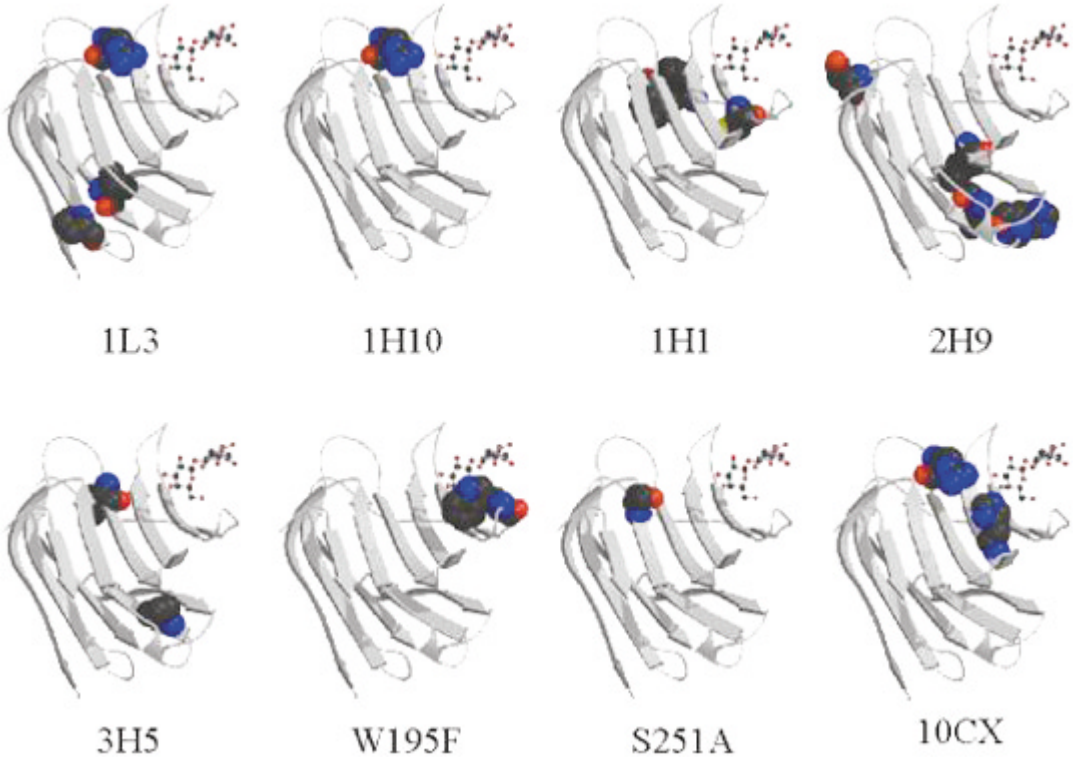
Fig. 2. Ribbon diagrams based on human galectin-3 (PDB accession 1A3K) highlighting residues changed in the mutants based in the mouse homologue. Images were created with MOLSCRIPT and rendered with RASTER3D (91, 92).



Libraries of random mutants can be constructed using error-prone PCR and DNA shuffling as a source of diversity (72–78). In many respects, error-prone PCR replicates the evolutionary process of asexual organisms and, as such, is potentially limited in the same manner as these organisms. Specifically, the "Muller's ratchet" phenomenon ultimately limits both the degree and rate of evolution of such species (79). In theory, shuffling obviates these limitations by introducing the essential element of sexual reproduction: the production of unique hybrid genes as a random combination of related parental sequences. To maximize the mutational frequency, both techniques were used here in series. Starting with DNA corresponding to native galectin-3, a set of mutants was generated via error-prone PCR and then shuffled. The resultant library was digested with *Sfi*I and ligated into fUSE5 vector prior to electroporation into DH10B cells. After growth for 24 h, the phage were isolated and purified. This procedure was utilized to create two libraries of 1×10^5 and 1×10^6 members, respectively.

A third library was created using a modification of the staggered extension process (StEP) developed by Arnold and co-workers (62). In this protocol, PCR is carried out on mutagenized DNA under conditions where the temperature is rapidly cycled between the annealing and denaturing temperatures. During the heating phase, the reaction briefly passes through the extension temperature, allowing a short extension before the complex is disrupted. By repeating this cycle numerous times, mutations from multiple parental genes are incorporated into the final hybrid. We attempted modification of this protocol by utilizing native DNA and error-prone PCR conditions; we thus imagined the process might introduce and shuffle mutations simultaneously allowing rapid creation of a large, diverse library. Although the process produced DNA that was successfully incorporated into phage, sequencing of random phage from the library indicated that the final library size was less than 10. The failure to generate a large library is likely due to the nature of the random mutant introduction. Presumably the short extension time, in conjunction with the low efficiency of misincorporation under error-prone PCR conditions, provides few mutants.

Table 3. Mutants isolated from various libraries.

Protein name	Deletions and (or) mutations
WTG3	Wild-type murine galectin-3
1L3	Δ92–96, P137L, R158G,V216A
1H1	Δ84–92, C187R, F204L, F206S
1H10	Δ92–96, R158G
2H9	Δ52–69, P84S, Y109H, F163L, H222R, K224E, L255P
3H5	I159T, F223S
3L1	L145P, R182G
3L2	A47T, S110G M149T, I214M, E219D, S251G

All three libraries were selected for high-affinity mutants by biopanning against lactose. Briefly, purified phage were incubated in wells on a lactose-displaying microtiter plate for 1 h at room temperature. After incubation, plates were washed with PBST supplemented with 200 mM lactose (0–3 times for low stringency selection, 15 times for high stringency), then an acidic (pH 2.2) elution buffer containing 0.3 M lactose was added. After 1 h, the solution was neutralized and K91 *E. coli* were infected with the isolated phage.

Plasmids were isolated from the resultant colonies and sequenced were to determine the nature of the mutations present (Table 3).

Following sequence identification, high-stringency library members were cloned and ligated into pET28b for protein production and isolation. The low stringency library member from the first library (1L3) was also inserted into pET28b to determine the difference in affinity required to produce high and low stringency "hits". Figure 2 shows mutated residues obtained by this selection strategy and the position of the mutations in the structure of the human homolog.

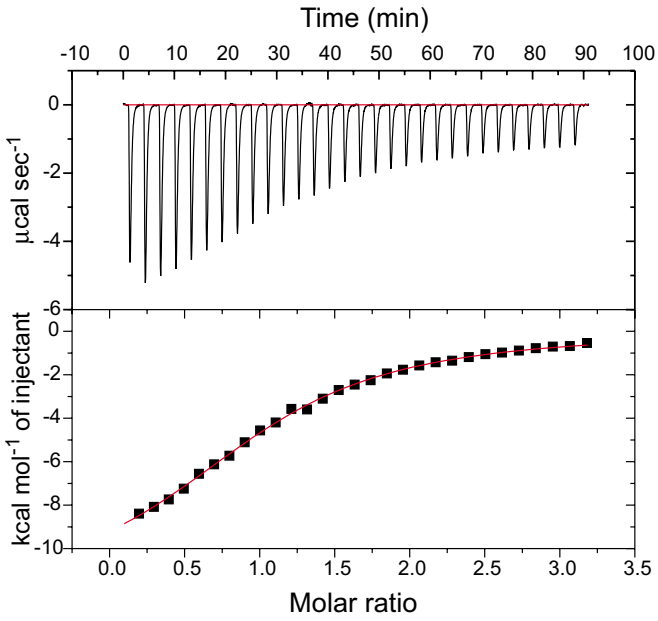
Assembly of chimeric proteins and site-directed mutants

Analysis of the sequences isolated in the first and second libraries revealed an unusual pattern: all mutants demonstrated some form of deletion in the *N*-terminal domain. Because this domain is not involved in carbohydrate binding, it was of interest to determine the relative contributions of *N*-terminal and *C*-terminal mutations to carbohydrate binding. Toward this goal, chimeric proteins were prepared by digesting wild-type G3 and mutants with *Sph*I, separating the two domains at position 143. Following agarose gel purification, the domains were recombined and amplified via PCR to form wild-type/mutant chimeras (Table 4). During the course of chimeric protein assembly, an additional spontaneous mutation within the binding site (H172Y) was created and analyzed. In addition, site-directed mutants were initially assembled as a possible line of investigation failing directed evolution. These mutants would better establish the roles of residues at the periphery of and within the binding site (W195F, S251A). As progress towards evolved proteins was realized, engineering of further site-directed mutants was abandoned as unlikely to result in enhanced binding. As before, the various inserts were cloned into pET28b for protein expression.

Expression and analysis of galectin-3 proteins

Following transformation of the various plasmids into BL21(DE3)-RP Codon Plus cells, expression was carried out under standard conditions. Unfortunately, expression was not realized with 1H1, 2H9, 3H5, any of their *C*-terminal chimeras, or S251A. Decreased growth temperature coupled with increased incubation times failed to improve expression. No inclusion bodies were detected, suggesting either digestion of misfolded protein or lack of expression as a source of the problem. Use of an *E. coli* strain that supplements all rare codons in galectin-3 also failed to produce protein, indicating that rare codon usage is not the source of the observed phenomena. All other proteins were stable at concentrations required for calorimetry. In calorimetry buffer (10 mM tris, 1 mM EDTA, 1 mM β-mercaptoethanol, pH 8.5), 1H10 was soluble at 0.5 mM, an almost fivefold increase in maximum solubility over wild-type protein. Isothermal titration microcalorimetry was carried out with all soluble mutants against βMeLac and LacNAc. A representative titration is shown in Fig. 3; data are summarized in Table 5.

Fig. 3. Representative example of isothermal titration calorimetry data. Thirty injections of *N*-acetyllactosamine (1.6 mM) were made into 0.1 mM 1H10 mutant in 10 mM tris, 1 mM EDTA, 1 mM β-mercaptoethanol, pH 8.5. Raw data for the titration (upper panel) is integrated with the individual points (■) and the best-fit curve (–) displayed (bottom panel).



Data from Table 5 both validate the biopanning selection and provide initial information regarding the role of various residues for ligand binding in the protein. High-stringency mutant 1H10 binds β-methyllactose with greater affinity than does low stringency mutant 1L3, validating the biopanning selection strategy. Interestingly, 1L3 binds β-MeLac with *lower* affinity than wild-type. Since no phage displaying the wild-type protein were recovered in the low stringency wash, this observation suggests that no wild-type is present in the library. In addition, the increased solubility of 1H10 allowed calorimetric evaluation of monosaccharide binding, a process not feasible with wild-type protein. While no enhancements of greater than threefold are observed in the first three libraries, this is not surprising since they are all first-generation libraries. Frequently, first-generation directed evolution libraries appear to have modest gains (approximately two- to 10-fold) in activity (80–82).

The chimeric proteins also provide insight into the contributions of specific mutations to overall affinities. First, the increased affinity of 1H10 is also observed in WN10C — the *C*-terminal half of 1H10 — suggesting that the majority

of the increase in affinity of 1H10 arises from the R158G mutation. The observed increase in affinity might arise from an increased flexibility of the binding site as the arginine side chain by the C_α proton of glycine. All *N*-terminal deletions and mutations produced no significant change in binding β-methyllactose. On the other hand, all *N*-terminal deletions and mutations resulted in at least some increase in affinity for *N*-acteyllactosamine, with a sixfold increase observed for 2NWC. The deletions might alter the flexibility of this domain, in turn allowing more favorable interactions between the protein and the *N*-acetyl moiety. NMR and modeling studies suggest that the *N*-terminal domain, while largely unstructured, may interact with the binding site (83, 84). The *N*-terminal domain of galectin-3 is also known to modulate galectin dimerization (85–88), a process that could be coupled to ligand binding. Because thermodynamic parameters are state functions, a change in *any* contributing process leads to changes in the overall measured parameters. If deletions in the *N*-terminal domain shift the monomer and dimer equilibrium, an alteration in *apparent affinity* is observed. Previous studies have failed to observe dimer by either gel filtration or analytical ultracentrifugation, implying that the dimerization interaction is weak (83, 84, 89). In the absence of additional data, it is difficult to discern which of these factors contribute to the observed phenomena.

Site-directed mutations in or near the binding site provide little useful information regarding binding. The mutation at the periphery of the binding pocket (S251A) failed to express. No significant formation of inclusion bodies was detected, and we assume that the protein failed to fold. Mutation of the key tryptophan (W195F) residue resulted in a protein that was readily expressed, but yielded calorimetric traces with either β-methyllactose or *N*-acetyllactosamine identical to control titrations, indicating a complete lack of binding activity. This tryptophan indole is located directly beneath the galactose moiety in crystal structure and provides a hydrophobic interaction with the apolar carbohydrate face (59). The spontaneous mutant 10CX is modified at position 172, replacing a histidine that donates a hydrogen bond to the axial O-4 of the galactose moiety with tyrosine (59). This residue is also located directly above tryptophan 195 and may preorganize the protein for ligand binding. 10CX is also interesting in that it contains the positive mutation R158G, a residue proximal to position 172. As with W195F, this mutant fails to bind either β-methyllactose or *N*-acetyllactosamine. Presumably, the favorable impact of the R158G mutation is more than offset by the tyrosine at 172 that prevents either hydrogen bonding or interaction of the tryptophan residue with the apolar face of the carbohydrate ligand.

Table 6. Solid-phase quantification of phage binding.

Protein displayed	IC_{50} (μM) of βMeLac
WT	20
H1	30
2H9	10
3H5	<8

Because protein could not be isolated for several high-stringency mutants, quantification of the relative binding affinity was determined by a solid-phase plate-binding assay. This assay is similar to a typical ELISA, but utilizes phage infectivity to quantify the extent of binding (Table 6).

© 2002 NRC Canada

All mutant phage show IC_{50} values against β-methyllactose equivalent to, or better than, wild-type protein. One mutant, 3H5, demonstrated a greater than threefold increase in inhibitory activity despite arising from a small library. This observation suggests that many galectin-3 mutations increase affinity for lactose ligands; additional mutants will presumably not be difficult to discover. Continued progress toward higher-affinity galectins is quite likely, although the ultimate extent of available enhancement is unclear. Bundle and coworkers (40) isolated mutant anti-serogroup B *O*-polysaccharide antibodies by biopanning serogroup B lipopolysaccharide. While ELISA analysis of mutants selected from the relatively small (1×10^6) library showed IC_{50} values of approximately 20 nM, ITC demonstrated that the mutants had association constants similar to wild-type (~1×10^5 M^{-1}). This result implies that either the number of mutants that produce increased affinity are few or that $1 \times 10^5 - 1 \times 10^6$ M^{-1} represents a fundamental limit in binding constant for this protein scaffold. Arguing against this latter conclusion, Marvin and Hellinga (36) recently modified maltose-binding protein (MBP) from *E. coli*, introducing a number of natural and unnatural side chains at position 324. These studies produced a mutant with an apparent binding constant of 1.2×10^8 M^{-1}, suggesting that enhancements well beyond 1×10^6 M^{-1} can be realized for other protein–carbohydrate interactions.

The dose-dependent response behavior of phage binding to β-methyllactose indicates that galectin-3 fused to p3 behaves similarly to the native protein. Directed evolution can result in the discovery of phage that have affinity for the solid support of the microtiter plate rather than the ligand of interest resulting in false positive hits. From the phage-binding assay, we can eliminate the possibility of protein affinity for the support as a confounding issue. The question remains as to the source of the protein expression difficulty. Protein fused to p3 is apparently folded and competent; the data indicate that fusion of the mutant protein to p3 allows stabilization. In the absence of the p3 fusion, the mutant protein might fail to fold properly, resulting in protein digestion.

Conclusions

Several conclusions arise from this work. First and foremost, galectin-3 can be displayed on the surface of filamentous phage and used in a biopanning selection strategy. The biopanning assay has been validated by a number of different means, and has been used for the discovery of mutants with increased binding affinity. Second and of equal importance to our long-term goals, the number of mutations available for galectin-3 that result in the increased affinity for ligands must be large since even small libraries contain adventitious mutations. Based on this observation, we are confident that further mutations will result in higher affinity carbohydrate-binding proteins. Finally, modification of the *N*-terminal domain of galectin-3 clearly affects expression of the protein and its affinity for ligands. We are continuing our efforts in this area, and the results will be reported in due course.

Examination of the structural basis for O(H) blood group specificity by *Ulex europaeus* Lectin I

Gerald F. Audette, Douglas J.H. Olson, Andrew R.S. Ross, J. Wilson Quail, and Louis T.J. Delbaere

Abstract: The structural basis for carbohydrate specificity of the first lectin from *Ulex europaeus* (UE-I) is reported. UE-I is a dimeric metalloglycoprotein that binds the H-type 2 human blood group determinant (α-L-Fucα(1→2)-β-D-Galβ(1→4)-β-D-GlcNAcα-), the blood group determinant present on the surface of O-type erythrocytes. The structural characteristics of UE-I involved in carbohydrate recognition have been examined using mass spectrometry (MS) and X-ray diffraction analysis. MS analysis allowed for discrimination between the different primary structures reported for UE-I. To examine the binding of the H-type 2 blood group determinant by UE-I, the methyl glycosides of the fucose monosaccharide (α-L-Fuc-OMe), known to exhibit primary binding specificity, and the H-type 2 trisaccharide (H-type 2-OMe) were, in two separate experiments, co-crystallized into the binding site of UE-I. The UE-I:α-L-Fuc-OMe complex crystallizes in the monoclinic space group $P2_1$, with unit cell dimensions a = 71.81, b = 69.00, and c = 119.02 Å, and β = 106.76°. Two UE-I dimers are observed to be present within the asymmetric unit, and the model has been refined to a R-value and R_{Free} of 0.202 and 0.289, respectively, to 2.3 Å resolution. The preliminary model of the UE-I:H-type 2-OMe complex has been refined at 3.0 Å resolution. The UE-I:H-type 2-OMe complex crystallizes in the orthorhombic space group $C222_1$, with unit cell dimensions a = 88.80, b = 164.75, and c = 77.42 Å, and a single UE-I dimer is present within the asymmetric unit. The carbohydrate recognition domain of UE-I has been identified to be comprised of residues Glu44, Thr86, Asp87, Arg102, Ala103, Gly104, Gly105, Tyr106, Ile129, Val133, Asn134, Trp136, Tyr219, and Arg222. Several critical protein–carbohydrate interactions have been identified, including the role of the hydrophobic interaction between the Thr86 side chain and C-5-CH_3 of the α-L-Fuc-OMe. The role of these interactions in carbohydrate recognition–binding by UE-I, as well as differences between the observed and previously modeled complexes, are discussed.

Key words: *Ulex europaeus* lectin I, H-type 2 human blood group determinant, protein–carbohydrate interactions, X-ray crystallography, chemical mapping.

Résumé : On a établi les bases structurales de la spécificité de l'hydrate de carbone de la première lectine provenant d'Ulex europaeus (EU-I). EU-I est une métalloglycoprotéine dimère qui se lie au déterminant du groupe sanguin humain H de type-2 (α-L-Fucα(1→2)-β-D-Galβ(1→4)-β-D-GlcNAcα-), le déterminant du groupe sanguin présent à la surface des érythrocytes de type-O. Les caractéristiques structurales de UE-I impliquées dans la reconnaissance du carbohydrate ont été examinées en faisant appel à la spectrométrie de masse (SM) et à la diffraction des rayons X. L'analyse par SM a permis de distinguer entre les différentes structures primaires proposées pour UE-I. Afin d'étudier le site de fixation du déterminant du groupe sanguin humain H de type-2 par UE-I, on a procédé à deux expériences séparées au cours desquelles on a procédé à la cocristallisation dans le site de fixation de UE-I des glycosides de méthyle d'une part du monosaccharide du fucose (α-L-Fuc-OMe), reconnu pour présenter une spécificité pour le site de fixation primaire, et d'autre part du trisaccharide H de type-2 (H de type-2-OMe). Le complexe UE-I:α-L-Fuc-OMe cristallise dans le groupe d'espace $P2_1$ avec a = 71,81, b = 69,00 et c = 119,02 Å et β = 106,76°. On a observé la présence de deux dimères de UE-I dans l'unité asymétrique et on a affiné le modèle jusqu'à des valeurs de R et R_{libre} de 0,0202 et 0,289 respectivement à une résolution de 2,3 Å. Le modèle préliminaire du complexe UE-I:H-type-2-OMe a été affiné jusqu'à une résolution de 3,0 Å. Ce complexe cristallise dans le groupe orthorhombique $C222_1$, avec a =

88,80, *b* = 164,75 et *c* = 77,42 Å et on n'observe la présence que d'un seul dimère UE-I dans l'unité asymétrique. On a établi que le domaine de reconnaissance du carbohydrate du UE-I comprend les résidus Glu44, Thr86, Asp87, Arg102, Ala103, Gly104, Gly105, Tyr106, Ile129, Val133, Asn134, Trp136, Tyr219 et Arg222. On a identifié plusieurs interactions protéine–carbohydrate critiques, y compris le rôle de l'interaction hydrophobe entre la chaîne latérale du Thr86 et le C-5-CH_3 du α-L-Fuc-OMe. On discute du rôle de ces interactions dans la reconnaissance/fixation du carbohydrate par UE-I ainsi que des différences entre les complexes modélisés antérieurement et les complexes observés.

Mots clés : lectine I d'*Ulex europaeus*, déterminant du groupe sanguin humain H de type-2, interactions protéine–carbohydrate, diffraction des rayons X, carte chimique.

[Traduit par la Rédaction]

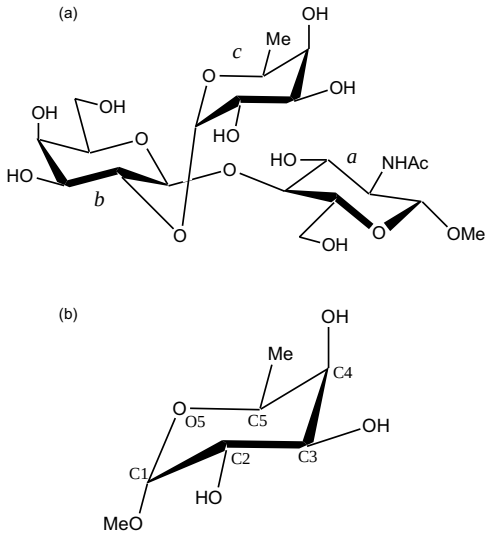
Introduction

Protein–carbohydrate interactions are involved in a wide range of important biological processes. These processes include, but are not limited to, cellular infection by invading microorganisms, the subsequent cellular defense and immune response to the invading pathogen, fertilization, leukocyte trafficking and infiltration, and cancer metastasis (1–3). The lectins are a class of proteins that exhibit a polyvalent affinity for carbohydrates; this polyvalency arises from the association of monomeric subunits into mainly dimeric and tetrameric molecules (3). A wide variety of different lectins are present in living cells and tissues. Their carbohydrate specificity is akin to antigenic recognition by antibodies (4) and enzymatic substrate specificity (5), yet lectins are neither products of the immune system nor do they exhibit enzyme-like catalytic properties. The role of lectins appears limited to specific cross-linking interactions, which allow lectins to serve as recognition molecules for various biological events (1, 2).

Extracts from the seeds of *Ulex europaeus* (common gorse), a leguminous shrub native of Western Europe, have been shown to agglutinate type O erythrocytes (6); the first lectin present in these extracts, *U. europaeus* lectin I (UE-I), was the agglutinating agent, with a carbohydrate specificity for α-L-fucose (7). The classical ABO blood-group in humans was initially identified by Landsteiner (8) at the turn of the 20th century. Landsteiner identified three classes of blood, based upon the agglutination of erythrocytes from one individual when mixed with the serum of another. He labeled these blood-groups in terms of antigenic substances as groups A and B, based on this agglutinating activity. The third group, O, was thus labeled for its lack of agglutinating activity (9). The ABO blood group determinants were subsequently identified as being carbohydrate in nature (10). The O blood group determinant, identified as the H-type 2 trisaccharide (α-L-Fucα(1→2)-β-D-Galβ(1→4)-β-D-GlcNAcα-) (Fig. 1*a*), was also the precursor of the A and B blood group determinants, which are tetrasaccharides (10). It is this trisaccharide that is recognized by UE-I. Though classified as an α-L-fucose-specific legume lectin, UE-I binds α-L-fucose with an affinity that is approximately 100-fold less than the binding of the complete H-type 2 determinant (11).

In the absence of crystallographic information, a method has been developed to probe the interactions between protein and carbohydrate. This method, known as chemical mapping (12), was developed based on the interactions between the Lewis b blood group determinant and the fourth lectin from *Griffonia simplicifolia* (GS-IV) observed in the crystal structure (13). The chemical mapping method employs the generation of monodeoxy and mono-*O*-methyl derivatives of the carbohydrate to generate a chemical map of the carbohydrate epitope, which is recognized by the protein. Application of this method to the binding of the H-type 2 blood group determinant by UE-I has been reported (11, 14–16). These inhibition studies into the binding of the H-type 2 determinant by UE-I have revealed several key interactions between protein and carbohydrate (Table 1) (16), and allowed for the generation of the chemical map for the epitope of the H-type 2 trisaccharide recognized by UE-I (Fig. 1*a*).

Fig. 1. The human H-type 2 blood group determinant. (*a*) The β-methyl glycoside of the H-type 2 trisaccharide (α-L-Fucα(1→2)-β-D-Galβ(1→4)-β-D-GlcNAcα-) (H-type 2-OMe). Structural units *a*, *b*, and *c* are β-D-GlcNAc-OMe, β-D-Gal, and α-L-Fuc, respectively. (*b*) The methyl glycoside of α-L-fucose (α-L-Fuc-OMe) shown in a perspective representation with atomic numbering for clarity.



The lectins from leguminous plants have contributed significantly to our understanding of the structural nature of carbohydrate specificity exhibited by proteins (17–20) — the majority of knowledge about lectins and their interactions with carbohydrate is from crystallographic analysis of the Glc/Man, Gal/GalNAc and complex specific legume lectins (20). Very little structural information is available regarding the carbohydrate specificity of the α-L-fucose-specific lectins, though the structure of the native UE-I has been recently reported to 2.2 Å resolution (21). This study revealed

Fig. 2. MALDI-TOF MS spectra of trypsin-digested UE-I. Several peaks were found to correspond to peptide fragments of an in silico digestion of UE-I, and are indicated in the spectra and in Table 2. The horizontal axis represents the observed *m*/*z* ratios for the UE-I peptide fragments, and the vertical axes represent the percent relative intensity (left) and measured peak height of the most intense or base peak (right). The peak at *m*/*z* 1889.01 confirmed the presence of Thr in the X86-Asp87 *cis*-peptide, and the peak at *m*/*z* 2097.13 allowed for discrimination between the Konami et al. (22) and Audette et al. (21) primary structures of the UE-I peptide Glu204–Arg222. The peak at *m*/*z* 842.51 is due to the autolysis of trypsin.

[b]By radioimmunoassay, setting the potency of H-type 2-OMe at 100 (11).

several differences between other legume lectins, and included the modeling of the β-methyl glycoside of the H-type 2 trisaccharide (H-type 2-OMe) within the carbohydrate binding site to predict the interactions between protein and carbohydrate in correlation with the available chemical mapping data (21).

The present study examines the structural nature of the recognition of the H-type 2 blood group determinant by UE-I through mass spectrometry and X-ray diffraction analysis of the complex of UE-I and the methyl glycoside of α-L-fucose (α-L-Fuc-OMe; Fig. 1*b*) at 2.3 Å resolution. Also, a preliminary analysis of a low resolution structure of the UE-I:H-type 2-OMe complex allows for the identification of the interactions between protein and carbohydrate at the periphery of the binding site, which confer extended carbohydrate specificity to the lectin. The interactions observed between protein and carbohydrate are in correlation with the observed chemical mapping data; however, these observed interactions differ from those predicted in the previous modeling studies. The observed interactions, carbohydrate specificity of UE-I, and differences from the modeling studies are discussed.

Results and discussion

Mass spectrometry

Electrospray ionization mass spectrometric (ESI-MS) analysis of UE-I indicates that the molecular weights of the two monomeric UE-I subunits are 30 049.0 and 31 243.0 Da (data not shown). These values correlate well with observations made during SDS-PAGE analysis of UE-I, in which the dimer separates as two distinct bands of approximately 30 kDa molecular weight (data not shown). It was noted, however, that the molecular weight of the UE-I monomer, based on the primary structure observed in the electron density is 26 606 Da (21). This apparent difference in molecular weight between UE-I monomers may be attributed to differential glycosylation states of each subunit.

Examination of the crystal structure of the native UE-I (21) revealed several differences between the reported primary structure of UE-I (22) and that observed in the electron density. To verify the crystallographically observed amino acid sequence of UE-I (21) vs. that of the published primary structure (22), matrix-assisted laser desorption/ionization-time of flight mass spectrometric (MALDI-TOF MS) analysis was performed on a tryptic digest of UE-I. Both the upper and lower bands of SDS-PAGE separated UE-I were subjected to identical digestion and MALDI-TOF MS protocols; a representative mass spectrum is shown in Fig. 2. The *m*/*z* ratios for each peptide peak were compared with those predicted for a theoretical (in silico) tryptic digest. Peaks at *m*/*z* 842.51, 1045.56, 2211.10, and 2383.93 can be attributed to autolysis of trypsin, and were thus excluded from analysis.

Several peaks were found to correspond to those predicted from the theoretical digest (Table 2). Of particular interest was the peak observed at *m*/*z* 2097.13. This peak corresponds to the residues between Glu204 and Arg222, and allowed for discrimination between the differing primary

Table 2. MALDI-TOF analysis of trypsinized UE-I.

$[M + H]^+$ (*m/z*)		Residue range
Predicted	Observed	
689.36	689.35	Ser152–Arg157
1412.71	1412.74	Val37–Arg50
1888.98	1889.01	Ala84–Arg101
2045.08	2045.12	Ala84–Arg102
1984.00	1984.06	Tyr162–Lys179
2097.07	2097.13	Glu204–Arg222
2140.10	2140.17	Arg161–Lys179

sequences. Within this region, a Gly → Ser change was required to account for the electron density observed at residue 217 (21). The corresponding $[M + H]^+$ ion for this region (with the Gly → Ser change) has a predicted *m*/*z* of 2097.07, which matches closely the observed MS peak. The peptide fragment with a Gly at position 217 would have an *m*/*z* of 2067.03; no corresponding peak was observed in the mass spectrum.

No other peaks were observed that would correspond to peptides containing expected differences in the UE-I sequence. It is possible that glycosylation of the protein may prevent correlation between observed and predicted *m*/*z* values for glycosylated peptides. Also, non-specific cleavage by trypsin may result in peptide fragments that will not correlate with an in silico trypsin digest of the target protein. Nevertheless, the available MS data suggests that the primary structure determined via X-ray analysis (21) is indeed correct. This, together with the fact that Asn116 was not observed in the structure of native UE-I, indicates that continuous numbering of UE-I residues can be applied throughout the sequence (Ser1–Ser242). For native UE-I (21), however, discontinuous residue numbering (Ser1–Cys115 and Asp117–Ser243) was retained to coincide with the published amino acid sequence of Konami and co-workers (22).

Quality of the crystallographic models of the UE-I–carbohydrate complexes

The final model of the UE-I:α-L-Fuc-OMe complex consists of two UE-I dimers within the asymmetric unit, related by non-crystallographic symmetry (NCS). The structure was refined to 2.3 Å resolution (diffraction data summarized in Table 3). The final model consists of 240 amino acid residues in three of the four UE-I monomers; the fourth UE-I monomer contains 239 amino acid residues. No electron density was observed for the final two C-terminal residues in UE-I subunits A, B, and C, nor for the final three C-terminal residues for UE-I subunit D. Four calcium and four manganese ions are present in the model (one Ca^{2+} and one Mn^{2+} per subunit). There are four bound α-L-Fuc-OMe molecules in the final model, with one α-L-Fuc-OMe molecule located in the predicted carbohydrate recognition domain (CRD) of each UE-I monomer. Electron density was observed at Asn23 and Asn111 of all UE-I monomers, which correspond to *N*-linked oligosaccharide at these positions; however, the observed density was not sufficiently resolved to allow for modeling of the *N*-linked carbohydrate. There are 266 solvent (water) molecules present in the final model, and a single MPD molecule was observed adjacent to Cys60 of the third UE-I monomer.

The stereochemical quality of the final model was analyzed using the program PROCHECK (23). A total of 80.6% of the amino acid residues are within the most favored regions of the Ramachandran plot (24); 18.7% of the residues are located in the additional allowed regions, and six residues (0.7%) are located in generously allowed regions. The mean coordinate error from Luzzatti plot analysis (25) is 0.15 Å. The final refinement statistics are summarized in Table 3.

The model of the UE-I:H-type 2-OMe complex consists of a single UE-I dimer within the asymmetric unit refined to 3.0 Å resolution (Table 3). The model consists of 240 amino acid residues in both UE-I subunits, two calcium and two manganese ions (one Ca^{2+} and Mn^{2+} per subunit), and a single bound H-type 2-OMe is present in the final model, located in the predicted CRD of the UE-I subunit A. Electron density was observed at Asn23 and Asn111 of both UE-I monomers, which correspond to *N*-linked oligosaccharide at these positions; however, the observed density was not sufficiently resolved to allow for modeling of the *N*-linked carbohydrate. Because of the resolution of the data, no solvent (water) molecules were included in the model. The stereochemical quality of the model was analyzed using the program PROCHECK (23). A total of 68.4% of the amino acid residues are within the most favored regions of the Ramachandran plot (24); 27.8% of the residues are located in the additional allowed regions, and the remaining residues (3.8%) are located in generously allowed regions. The mean coordinate error from Luzzatti plot analysis (25) is 0.20 Å; refinement statistics are summarized in Table 3.

Overall structure of UE-I

The tertiary and quaternary structure of UE-I have been discussed previously (21). Both the UE-I:α-L-Fuc-OMe and UE-I:H-type 2-OMe complexes of UE-I exhibit a similar overall structure to that of the native protein (Fig. 3). A comparison between the UE-I molecules indicates only slight differences; the average root mean square differences (rmsd) between C^α atoms of the native UE-I and the first and second dimers of the UE-I:α-L-Fuc-OMe complex are 0.63 and 0.68 Å, respectively. The average rmsd between the native UE-I and the UE-I:H-type 2-OMe complex is 0.96 Å, and between the UE-I:H-type 2-OMe complex and the first and second dimers of the UE-I:α-L-Fuc-OMe complex are 0.93 and 0.87 Å, respectively.

Examination of the monomeric subunits of UE-I in both complexes also indicate that differences between subunits are minimal. In the UE-I:α-L-Fuc-OMe complex, the overall average rmsd between C^α atoms is 0.46 Å. The B-factors are also similar between the UE-I subunits, with average B-factors (main-chain/side-chain) of 20.4 $Å^2$/20.5 $Å^2$, 22.6 $Å^2$/22.2 $Å^2$, 22.1 $Å^2$/22.3$Å^2$, and 19.4 $Å^2$/19.8 $Å^2$ for UE-I subunits A–D, respectively. Side chains of several residues were observed to have little electron density: Lys83 of subunit A, Asn40 of subunit B, Thr240 of subunit C, and Asn39, Lys83, and Asn239 of subunit D. These residues were replaced with alanines during refinement. In the UE-I:H-type 2-OMe complex, the average rmsd between C^α atoms of subunit A and B is 0.20 Å, and the average B-factors

are (main-chain/side-chain) 19.1 Å^2/17.9 Å^2 and 19.7 Å^2/20.4 Å^2 for subunits A and B, respectively. In all subunits of both UE-I complexes no electron density was observed for residues 241 and 242, sequenced as Asn and Ser by Konami and co-workers (22).

The carbohydrate binding site of UE-I

Carbohydrate specificity in the legume lectins is based upon the monosaccharide that exhibits the highest binding affinity, even though monosaccharide binding is weaker than the binding of the complete oligosaccharide, which the lectin recognizes (20). Examination of the native UE-I identified the UE-I CRD as a small depression at the surface of the lectin (22), comprised of residues Glu44, Thr86, Asp87, Gly104-Gly105, Ile129, Val133, Asn134, Trp136, Tyr219, and Arg222 (21). A molecule of α-L-Fuc-OMe was observed in the CRD of each UE-I subunit (Fig. 4*a*). Each α-L-Fuc-OMe molecule fit the observed electron density well; the average B-factor for the four α-L-Fuc-OMe molecules is 27.8 Å^2. The α-L-Fuc-OMe molecules make several hydrophilic and hydrophobic interactions with UE-I, which are summarized in Table 4 and illustrated in Fig. 4*b*. Of particular interest is the hydrophobic interaction between C6 of the bound α-L-Fuc-OMe and $C^{\gamma 2}$ of Thr86, with an average interatomic distance of 3.4 Å. This interaction likely plays a significant role in the carbohydrate specificity of UE-I, and will be discussed in greater detail in the following section. A stacking interaction, as is commonly observed in the carbohydrate complexes of legume lectins (20), is provided by Tyr219 to the hydrophobic back face of the bound α-L-Fuc-OMe. Also, the residues involved in carbohydrate binding by UE-I must be updated to include Arg102, due to an observed hydrogen bond between the N^{H2} and O2 of α-L-Fuc-OMe, as well as Ala103 and Tyr106, which make van der Waals contacts. Indeed, it was observed that the Arg102 side chain moved an average of 1.1 Å (measured via the C^{ζ} atom of the side chain) towards the carbohydrate upon binding to make the observed hydrogen bond with the O2 of α-L-Fuc-OMe (Fig. 5). Arg222 also exhibited movement towards the CRD upon carbohydrate binding, with an average movement of 0.7 Å (measured via the C^{ζ} atom of the side chain); no other residues of the CRD exhibited appreciable movement upon carbohydrate binding (Fig. 5). The UE-I CRD is, therefore, comprised of Glu44, Thr86, Asp87, Arg102, Ala103,

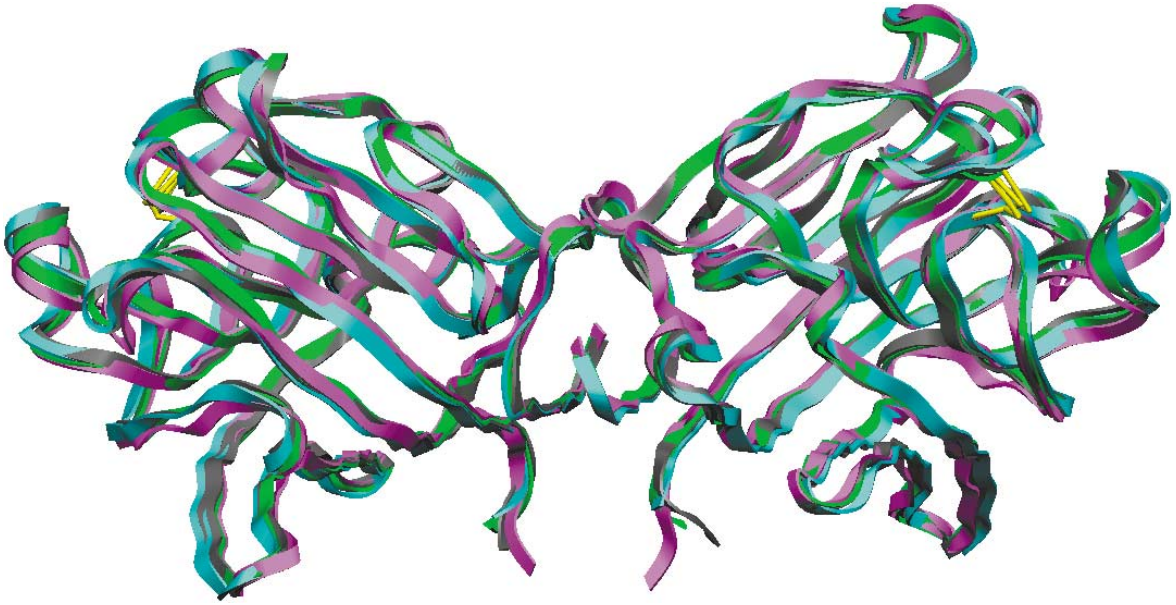
Fig. 3. The UE-I dimer. Shown above is the ribbon representation of the superposition of the C^{α} trace of the various UE-I dimers. The first and second UE-I dimer of the UE-I:α-L-Fuc-OMe complex are shown in gray and green, respectively, the native UE-I (21) is in cyan, and the UE-I:H-type 2-OMe complex is in magenta. Figures 3 through 5 were produced using the program SETOR (53).



Gly104, Gly105, Tyr106, Ile129, Val133, Asn134, Trp136, Tyr219, and Arg222.

A single H-type 2-OMe molecule was found in the UE-I:H-type 2-OMe CRD, and is present in the CRD of subunit A; the electron density in the CRD of subunit B was insufficiently resolved to allow for modeling of the bound carbohydrate. The galactose and *N*-acetylglucosamine moieties of the H-type 2-OMe fit the observed electron density, however, the fucose moiety of the trisaccharide was not as well resolved. It is thought that the fucose moiety of the bound H-type 2-OMe will indeed appear as is observed in the UE-I:α-L-Fuc-OMe complex due to similar positions of the C1, O1, and C7 atoms of α-L-Fuc-OMe and the C1*c*, O2*b*, and C2*b* atoms of H-type 2-OMe (structural unit designations as in Fig. 1*a*); this shall be confirmed upon examination of the UE-I:H-type 2-OMe complex at higher resolution.

Carbohydrate specificity of UE-I

The development of methodologies for complex oligosaccharide synthesis have greatly aided the study of protein–carbohydrate interactions (26); these methodologies are particularly useful when crystallographic data of the complex is unavailable. Indeed, the identification of the effects of slight structural changes to the carbohydrate on the efficacy of binding allows for the prediction of the chemical map of the carbohydrate epitope (12).

The chemical mapping method was applied to the systematic investigation of the interaction between UE-I and the H-type 2 blood group determinant (15), which resulted in the generation of a chemical map of the H-type 2 epitope (Fig. 1) (16). Several conclusions were made upon examination of the results of inhibition studies into the binding of H-type 2-OMe by UE-I (Table 1). In particular, when both deoxygenation and *O*-methylation of hydroxyl groups of the epitope abolish binding, these hydroxyls are identified as being deep within the CRD making critical hydrogen bonds with the protein. When deoxygenation significantly decreases but *O*-methylation exhibits little effect on binding, these hydroxyl groups are interpreted as being closer to the periphery of the binding site. Finally, when neither deoxygenation nor *O*-methylation significantly affect binding, these groups are identified as remaining in the aqueous phase upon complexation.

The observed interactions that occur between UE-I and the bound carbohydrate in the UE-I:α-L-Fuc-OMe complex correlate well with the observed chemical mapping data. In particular, O2, O3, and O4 of α-L-Fuc-OMe make several hydrogen bonds to residues of the UE-I CRD (Fig. 4*b*, Table 4). These interactions occur deep within the CRD. For example, O4 of the α-L-Fuc-OMe was observed to make hydrogen bonds with Asp87 $O^{\delta 2}$ (2.8 Å), Gly105 N (3.0 Å), and Asn134 $N^{\delta 2}$ (3.0 Å). Both Asp87 and Gly105 are located at the bottom of the UE-I CRD, and Asn134 is located close to the bottom of the CRD (Fig. 4*b*). Deoxygenation of the group would result in removal of the hydrogen bonding capacity of that group, while *O*-methylation would prevent interaction through steric interference between the carbohydrate and protein. Disruption of one or all of these interactions would prevent stabilization of the fucose moiety within the CRD as observed in inhibition studies (Table 1) (14).

The presence of a Thr at the X86–Asp87 position is a unique feature of the α-L-Fuc-specific legume lectins; the residue at this position is generally Ala (20). Chemical mapping of the H-type 2-OMe indicated that alteration of the C-5-CH_3 group of the fucose moiety results in significantly reduced binding (Table 1). The authors noted, however, that the effect of replacing this group with a hydrogen atom may have an effect on the conformational preference of the carbohydrate (14). The examination of the UE-I:α-L-Fuc-OMe complex reveals that the C-5-CH_3 group of the α-L-Fuc-OMe makes a significant hydrophobic interaction with $C^{\gamma 2}$ of the Thr86 side-chain as well as several van der Waals

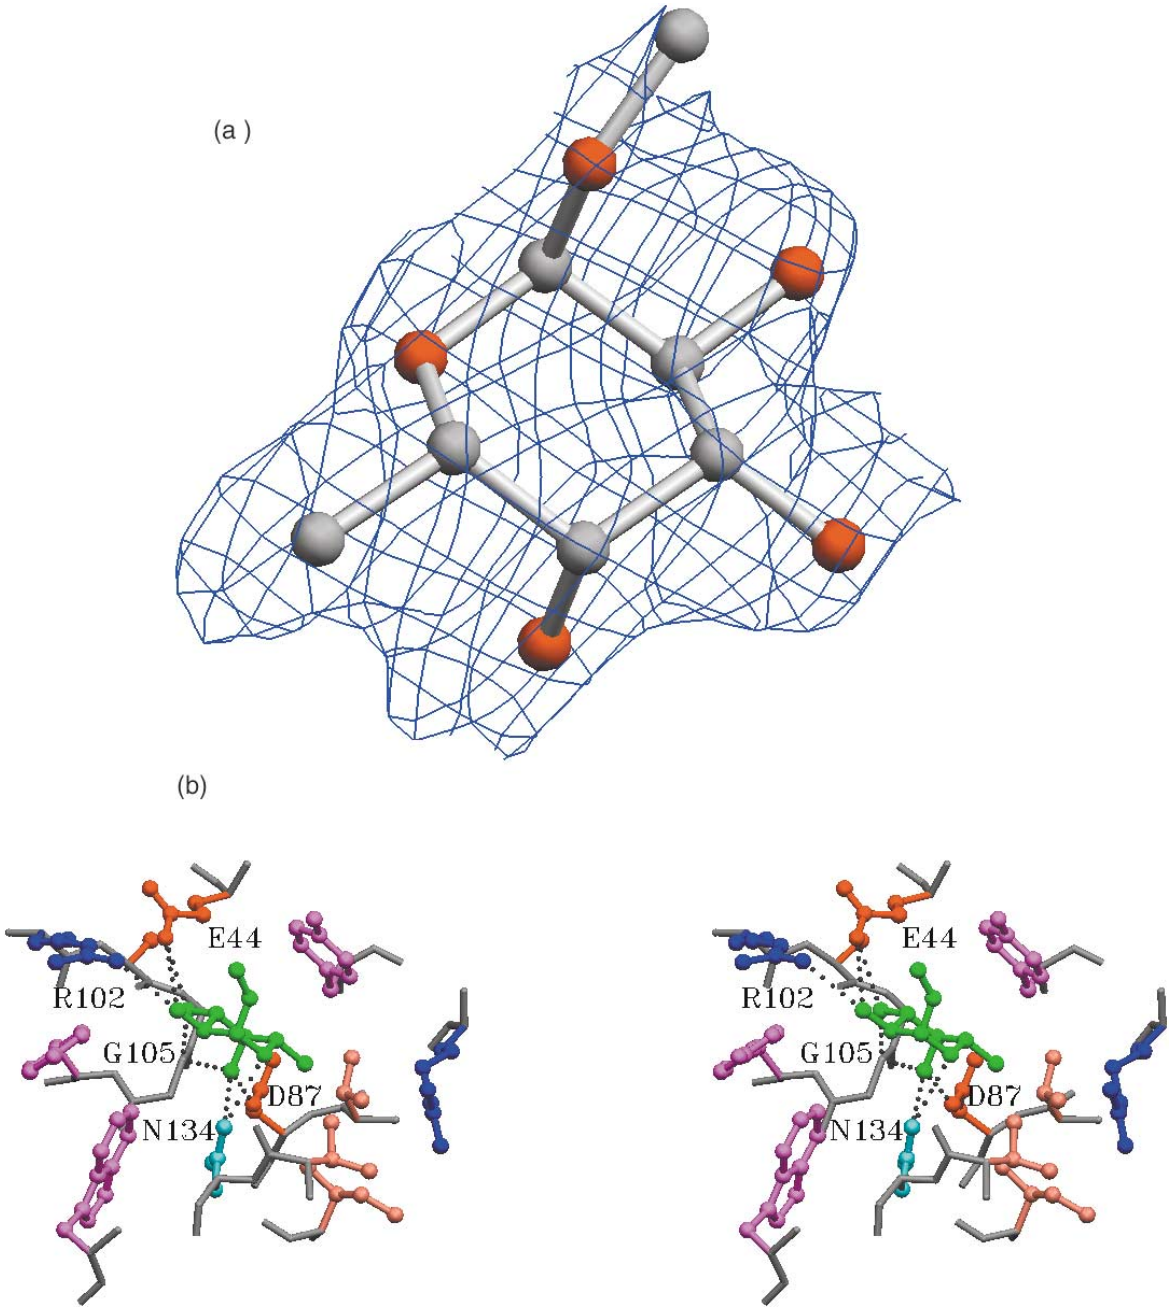
Fig. 4. The bound carbohydrate within the UE-I CRD. (*a*) The bound α-L-Fuc-OMe. Shown is the α-L-Fuc-OMe found in the CRD of the UE-I subunit A of the UE-I:α-L-Fuc-OMe complex in the electron density from an $\boldsymbol{F}_o$-$\boldsymbol{F}_c$ omit electron density map of the final refined structure contoured at the 1σ contour level. The α-L-Fuc-OMe is coloured according to standard element colours (as per SETOR; 53), and the electron density is shown in blue. (*b*) Stereographic representation of the bound α-L-Fuc-OMe within the CRD of the first UE-I subunit in the UE-I:α-L-Fuc-OMe complex. Backbone atoms are in gray, side-chains are in standard colours, and bound carbohydrate is in green. Interactions between the bound α-L-Fuc-OMe and UE-I are listed in Table 4, and hydrogen bonds between the protein and carbohydrate are highlighted.



contacts with hydrophobic residues of the UE-I CRD (Table 4; Fig. 4*b*). These hydrophobic interactions provide stability to the UE-I:α-L-Fuc-OMe complex, and arise from the orientation of the α-L-fucose within the UE-I CRD, in which the hydroxyl groups of the fucose moiety make the most favorable hydrogen bonds with the protein. Thus, disruption of this interaction through replacement with a hydrogen atom (14) would result in significantly reduced binding, as observed in the decreased potency of the congener during inhibition studies (Table 1) (16).

While carbohydrate specificity of the legume lectins is classified based upon which monosaccharide exhibits greatest binding affinity (20), the true specificity for the lectins is for oligomeric structures; this extended specificity arises from interactions between protein and carbohydrate at the periphery of the CRD. Two possible interactions were

O1	Tyr219	
O2	Glu44, Arg102, Tyr106	
O3	Glu44, Ala103, Gly104, Gly105	
O4	Asp87, Gly104, Gly105, Asn134	
O5	Val133, Asn134	

[a]Hydrogen bond distances are averaged over all four bound α-L-Fuc-OMe molecules.

[b]van der Waals contacts were identified through visual inspection with a maximum distance of 4.0 Å.

observed between UE-I and the H-type 2-OMe — hydrogen bonds between O3 of Gal and Arg102 N^{H2} (3.1 Å) and between O6 of GlcNAc and N^{H1} of Arg222 (2.8 Å). Both interactions correlate with the chemical mapping data (Table 1); both interactions are located at the periphery of the binding site, and disruption of these interactions would result in a slight decrease in binding of the trisaccharide by the protein.

The presence of calcium and manganese ions in the legume lectin has been proposed to induce electron delocalization in the binding site and thus increase the strength of the hydrogen bonds between protein and bound carbohydrate (27). Asn134 both hydrogen bonds to O4 of the α-L-Fuc-OMe through $N^{\delta2}$ (3.0 Å) as well as coordinates the Ca^{2+} through $O^{\delta2}$. Thus, it is likely that the proposed electron delocalization occurs, which results in increasing the strength of the hydrogen bonds between protein and carbohydrate upon complexation.

Finally, an ordered water structure has been identified as playing a role in carbohydrate binding by legume lectins (20, 28–32). The identification of the high entropy barrier to binding of H-type 2-OMe by UE-I ($T\Delta S$ = –20.5 kcal mol^{-1}), as well as a high enthalpy of binding (–29 kcal mol^{-1}), led to the inference that an ordered water structure played a role in H-type 2-OMe binding by UE-I, and to the coining of the term "hydraphobic effect" (33) to describe this role of water in the binding of hydrophilic surfaces in the presence of large molar excesses of water as is found on the surface of proteins. No ordered water molecules were observed in the CRD of UE-I in either UE-I:carbohydrate complex. Indeed, the α-L-Fuc-OMe fits snugly within the UE-I CRD, making

© 2002 NRC Canada

numerous hydrophobic and hydrophilic interactions (Table 4; Fig. 4*b*). It can therefore be inferred that the role of ordered water molecules in carbohydrate binding is in the coordination of calcium and manganese ions, which results in stabilization of the protein–carbohydrate complex through the above noted electron delocalization of binding site residues. It is unlikely that ordered water molecules are present within the CRD after formation of the protein–carbohydrate complex, and the observed entropic and enthalpic effects are due, at least in part, to release of water from the CRD upon carbohydrate binding.

Comparison of modeling and crystallographic studies

The modeling of the H-type 2-OMe in the CRD of the native UE-I (21) predicted several interactions between protein and carbohydrate, which would correlate with the observed chemical mapping data (Table 1). The interactions observed between UE-I and the α-L-Fuc-OMe in the UE-I:α-L-Fuc-OMe complex (Fig. 4*b*; Table 4), and those between UE-I and the bound H-type 2-OMe in the UE-I:H-type 2-OMe complex, also correlate with the chemical mapping data. The observed interactions do not, however, correspond with those predicted from the modeling studies.

The differences between modeled and crystallographically observed binding of the H-type 2 epitope may be understood as follows. During the modeling studies, the roles of Thr86 and Arg102 in carbohydrate binding were not initially apparent. Also, an ordered water structure was thought to play a role in carbohydrate binding; this was found to not be the case upon examination of the CRD in the UE-I:α-L-Fuc-OMe complex (Fig. 4*b*). Finally, the starting orientation of the H-type 2-OMe during modeling was based upon the overlap of the carbohydrate on to the R-MPD observed within the CRD (21). These factors resulted in the minimization of a complex (21) that correlated well with the chemical mapping data but does not correlate with the bound carbohydrate observed in the CRD of UE-I.

Materials and methods

Protein and carbohydrate sources

UE-I was purchased from EY Laboratories (San Mateo, CA, U.S.A., lot No's 141216H0529–30, 150604H0808–30, and 150902J0514–30) in pure form; no further purification was performed. Both α-L-Fuc-OMe and H-type 2-OMe were prepared according to previously reported procedures (14, 16, 34) and provided by Professor R.U. Lemieux (University of Alberta, deceased) in pure form; no further purification was performed.

Mass spectrometric analysis of UE-I

Molecular mass analysis of the two monomeric UE-I subunits was performed by ESI-MS using a Quattro LC triple-quadrupole mass spectrometer (Micromass, Manchester, U.K.) operating in the positive ion mode. An aqueous solution of UE-I (2 μL at 9.4 μM) was introduced by flow injection at 15 μL min^{-1}, using water–acetonitrile (50:50) as the carrier. Electrospray conditions were as follows: capillary 3.78 V; cone 25 V; source temperature 85°C. The first quadrupole was scanned in the *m*/*z* range 600–2000 at 3.95 s per scan. Scans corresponding to the sample elution profile were combined and processed using the MaxEnt software algorithm (MassLynx, version 3.5, Micromass) to obtain molecular weight information for the two UE-I subunits.

Information on the primary structure of UE-I was obtained by MALDI-TOF MS analysis of tryptic digests from SDS-PAGE separated subunits. Approximately 2.5 μg protein were applied to each of three separate lanes on a 12% SDS-PAGE gel in the presence of β-mercaptoethanol as described by Laemmli (35). The separate UE-I bands were excised from the gel, cut into 1 mm squares, and placed in 1.5 mL microcentrifuge tubes for destaining, reduction, alkylation, and tryptic digestion.

Digestion and MS analysis of the SDS-PAGE purified subunits were performed at the National Research Council's Plant Biotechnology Institute in Saskatoon. Tryptic digestion of the excised bands proceeded according to reported protocols (36), after which the peptides were resuspended in 10 μL of 0.1% TFA and desalted by solid-phase extraction using disposable pipette tips ($ZipTip_{C18}$, Millipore) according to the manufacturer's instructions. Peptides were eluted in 1–2 μL of 0.1% TFA/75% acetonitrile directly onto a MALDI target plate. An equal volume of matrix solution (5 mg mL^{-1} α-cyano-4-hydrocinnamic acid in 0.1% TFA/50% acetonitrile) was applied to the sample and allowed to dry. A 1:1 mixture of matrix and mass calibrant was also placed beside the sample for close external calibration. MALDI-TOF MS analysis was performed on a Voyager-DE STR (Applied Biosystems, Framingham, MA) operating in the positive ion, delayed extraction, and reflectron modes and using the following parameters: accelerating voltage 20 000 V; grid voltage 72.5%; guide wire voltage 0.001%; delay 100 ns; laser power 2290. Spectra were obtained by combining 400 scans and applying mass calibration, baseline correction, noise filtering, and de-isotoping procedures using the spectrometer software (Data Explorer v. 4.0, Applied Biosystems).

Crystallization UE-I:carbohydrate complexes

Crystallization of the carbohydrate complexes of UE-I proceeded as follows. The UE-I complexes were produced by adding α-L-Fuc-OMe or H-type 2-OMe to UE-I with a final protein concentration of 10 mg mL^{-1} and carbohydrate concentrations of 0.34 or 0.64 mg mL^{-1} for α-L-Fuc-OMe or H-type 2-OMe, respectively, in 0.1 M sodium cacodylate buffer (pH 7.0), 0.1 mM calcium chloride, and 0.1 mM manganese chloride. These solutions were allowed to stand for at least 1 h on ice prior to crystallization. Crystals were grown by the vapour diffusion method from 4 μL drops containing 5 mg mL^{-1} UE-I:α-L-Fuc-OMe or UE-I:H-type 2-OMe complex, 0.05 M sodium cacodylate buffer (pH 4.0), 0.05 M sodium acetate buffer (pH 4.0), 5 mM calcium chloride, 5 mM manganese chloride, 25–30% (v/v) R,S-MPD, and 0.5% (v/v) PEG 550 MME ether were equilibrated over 1 mL reservoirs containing 0.1 M sodium acetate buffer (pH 4.0), 10 mM calcium chloride, 10 mM manganese chloride, 50–60% (v/v) R,S-MPD and 1% (v/v) PEG 550 MME at 287 or 293 K. These crystallization conditions are similar to those previously reported for the native UE-I (21, 37).

Crystals of both complexes took over 6 months to appear. Crystals of the UE-I:α-L-Fuc-OMe were generally clear plates of average dimensions 0.35 × 0.15 × 0.10 mm that were not suitable for X-ray diffraction analysis due to

© 2002 NRC Canada

disordered stacking of the plates during crystal growth. A single clear, rod-like crystal of α-L-Fuc-OMe complex suitable for X-ray diffraction analysis was, however, produced. The UE-I:α-L-Fuc-OMe complex crystallized in the monoclinic space group $P2_1$, with unit cell dimensions a = 71.81, b = 69.00, and c = 119.02 Å, and β = 106.76°. Two UE-I dimers are present within the asymmetric unit, with a Matthews coefficient (38) of 2.67 $Å^3$ Da^{-1} and an estimated 53.6% (v/v) solvent content. Crystals of the UE-I:H-type 2-OMe complex were generally clear plates of average dimensions 0.30 × 0.15 × 0.10 mm. The UE-I:H-type 2-OMe complex crystallizes in the orthorhombic space group $C222_1$, with unit cell dimensions a = 88.89, b = 164.75, and c = 77.42 Å. A single UE-I dimer is present within the asymmetric unit, with a Matthews coefficient (38) of 2.66 $Å^3$ Da^{-1} and an estimated 52.7% (v/v) solvent content. Crystals of both UE-I complexes were flash cooled for X-ray diffraction analysis in 0.35-mm cryoloops (Hampton Research, Laguna Niguel, CA) by direct immersion in liquid nitrogen. The crystals were then stored in liquid nitrogen prior to X-ray diffraction analysis.

Data collection of the UE-I:α-L-Fuc-OMe complex

X-ray diffraction data of the UE-I:α-L-Fuc-OMe complex were collected by Dr. M. Becker at beamline X12-C of the National Synchrotron Light Source (NSLS) at Brookhaven National Laboratory (Upton, NY) under the remote access (courier based) data collection program.[4] Data were collected in 180 images from a single crystal at 100 K on a Brandeis 1.2 CCD detector (39), using a wavelength of 1.0 Å, an exposure time of 50 s, and a 1° rotation per image. The diffraction data were indexed using the OneButton interface (40) for DENZO and scaled using the SCALEPACK software package (41). Diffraction data were collected to 2.00 Å resolution, however, the data were truncated to 2.30 Å resolution as it was observed that the mean $I/\sigma(I)$ of the data dropped below 2.0 at resolutions above 2.30 Å. A summary of the data collection statistics is shown in Table 3.

Structure solution and model refinement of the UE-I:α-L-Fuc-OMe complex

The molecular replacement method was used to solve the structure of the UE-I:α-L-Fuc-OMe complex using the program AMoRe of the CCP4 software package (42, 43). The search model was the native UE-I dimer (protein only; PDB accession code 1FX5) (21). To determine the initial positions of the two molecules within the asymmetric unit, the top six peaks from the rotation search were used in the translation search. The top peak from the initial translation search was interpreted as the first UE-I dimer, and was then fixed. With the first UE-I dimer fixed, the translation search was repeated to determine the position of the second UE-I dimer with respect to the first. After obtaining the initial coordinates for both molecules, rigid body refinement in AMoRe resulted in a correlation coefficient and R-value of 0.762 and 0.415, respectively.

The molecular replacement solution was subjected to an initial rigid-body, positional, and B-factor refinement followed by the generation of an electron density map using the X-PLOR software package (44, 45). It was observed that the two UE-I:α-L-Fuc-OMe complex molecules within the asymmetric unit were related by non-crystallographic symmetry (NCS) rotation and translation operations. During the initial rounds of structure refinement, the backbone atoms of both the UE-I:α-L-Fuc-OMe complex molecules were, therefore, restrained by the NCS operations. The R-value at the end of this initial round of refinement was 0.288 at 2.5 Å resolution.

Upon examination of the initial $2\boldsymbol{F}_o - \boldsymbol{F}_c$ electron density map using TURBO-FRODO (46), electron density was observed to correspond to a bound α-L-Fuc-OMe within the binding site of each UE-I subunit. The α-L-Fuc-OMe was placed into the electron density using coordinates obtained from hard sphere exo-anomeric (HSEA) calculations (47). Also, electron density was observed that would represent a calcium ion and a manganese ion in each UE-I monomer, known to be present adjacent to the binding sites of legume lectins (20); these ions were placed in the electron density during model building. Electron density was also observed near Cys60 of the third UE-I monomer, which would represent a molecule of the crystallization precipitant, R-MPD. Finally, electron density was observed at residues Asn23 and Asn111 of the UE-I monomers, which would correspond to *N*-linked oligosaccharide. This electron density was not sufficiently resolved, however, to allow for modeling of the *N*-linked carbohydrate.

Rounds of model building were followed by simulated annealing refinement, B-factor refinement, and new σ_A weighted (48, 49) electron density map generation using X-PLOR. Of the 44 883 unique reflections, 5% of the reflections were randomly selected to evaluate R_{Free} (50, 51); a total of 1419 reflections were chosen for the R_{Free} test set. All cycles of structure refinement, with exception of the final cycle, used a working set consisting of 95% of the unique reflections and a test set consisting of the 5% randomly chosen reflections. The final cycle of refinement used all data. The simulated annealing refinements consisted of a prepstage of 160 cycles of minimization followed by a slow-cooling stage starting at 3000 K and decreasing to 300 K in steps of 50 K and a time step of 0.5 fs (1 fs = 10^{-15} s). Slow-cooling was followed by 120 cycles of conjugate gradient minimization and 40 cycles of B-factor refinement. Engh and Huber (52) bond and angle parameters and a bulk solvent correction were employed throughout refinement; weighting was obtained from the CHECK procedure in X-PLOR. Water molecules were placed into the structure manually using a difference ($\boldsymbol{F}_o - \boldsymbol{F}_c$) electron density map. Upon refinement, some water molecules developed large B-factors (>40 $Å^2$). These were removed from the structure and new water molecules added as they were located in subsequent difference maps.

The space group of the UE-I:α-L-Fuc-OMe complex was determined to be $P2_1$, with two UE-I dimers within the

[4] Diffraction data for the UE-I:α-L-Fuc-OMe complex were collected at the single-crystal diffraction facility at beamline X12-C of the National Synchrotron Light Source at Brookhaven National Laboratory. This facility is supported by the United States Department of Energy Offices of Health and Environmental Research and of Basic Energy Sciences under prime contract DE-AC02–98CH10886, by the National Science Foundation, and by National Institutes of Health Grant 1P41 RR12408–01A1.

© 2002 NRC Canada

asymmetric unit. The two UE-I:α-L-Fuc-OMe complex molecules within the asymmetric unit were related by non-crystallographic symmetry (NCS) rotation and translation operations. The NCS rotation angle between the two molecules is 179.18°, and the NCS rotation axis is almost parallel to the *b*-axis. This relation between UE-I dimers is such that the crystal exhibits pseudo-C centering, which results in the intensities of the $h + k$ odd reflections being weak in comparison to the $h + k$ even reflections. This distribution of reflection intensities results in a large number of the reflections which are weak. It is known that pseudo-centering of a crystal, with this large number of weak reflections, results in abnormally high R and R_{Free} values. For this reason, the refinement of the UE-I:α-L-Fuc-OMe complex employed a low amplitude cut-off. The final R-value and R_{Free} of the UE-I:α-L-Fuc-OMe complex are 0.202 and 0.289, respectively.

Data collection of the UE-I:H-type 2-OMe complex

X-ray diffraction data for the UE-I:H-Type 2-OMe complex were collected at BioCARS beamline 14-BM-D of the Advanced Photon Source (APS) at Argonne National Laboratory (Argonne, IL).[5] Data were collected in 179 images from a single crystal at 100 K on a ADSC Quantum 4 CCD detector (Area Detector Systems Corporation, Poway, CA), using a wavelength of 1.00 Å, an exposure time of 15 s, a 1° rotation per image, and a crystal-to-detector distance of 168.5 mm. The diffraction data were indexed and scaled using the DENZO/SCALEPACK software package (41). A summary of the data collection statistics is shown in Table 3.

Structure solution and model refinement of the UE-I:H-type 2-OMe complex

The molecular replacement method was used to solve the structure of the UE-I:H-type 2-OMe complex using the program AMoRe of the CCP4 software suite (42, 43). The search model was the native UE-I dimer (PDB accession code 1FX5) (21). To determine the initial position of the UE-I dimer within the asymmetric unit, the top five peaks from the rotation search were used in the translation search. Rigid body refinement in AMoRe of the initial coordinates for the UE-I dimer resulted in a correlation coefficient and R-value of 0.561 and 0.447, respectively.

Upon examination of the initial $2\boldsymbol{F}_o - \boldsymbol{F}_c$ electron density map using TURBO-FRODO (46), density was observed to correspond to a bound H-Type 2-OMe within CRD of the first UE-I subunit. The electron density was not sufficiently resolved at this stage, however, to allow for fitting of the H-Type 2-OMe within the carbohydrate binding site. Also, electron density was observed that would represent a calcium and a manganese ion in each UE-I monomer, and electron density was observed at residues Asn23 and Asn111 of the UE-I monomers, which would correspond to *N*-linked oligosaccharide. The calcium and manganese ions and bound H-Type 2-OMe were added to the model in a similar fashion as that described for the UE-I:α-L-Fuc-OMe complex during subsequent rounds of model building; electron density was insufficiently resolved to allow for addition of *N*-linked oligosaccharide.

Refinement was performed as described for the UE-I:α-L-Fuc-OMe complex. During refinement, 5% of the unique reflections (493) were randomly chosen to evaluate R_{Free}, and the backbone atoms of the UE-I subunits were restrained by the NCS operators by which the subunits were related. The final R-value and R_{Free} of the structure are 0.284 and 0.421, respectively. At the resolution of the crystallographic data for the UE-I:H-Type 2-OMe complex (30–3.0 Å), it was not possible to locate solvent (water) molecules.

Protein data bank accession numbers

The coordinates and structure amplitudes for the UE-I:α-L-Fuc-OMe complex have been deposited in the RCSB Protein Data Bank (accession codes RCSB014305 and 1JXN). The coordinates and structure factor amplitudes for the UE-I:H-type 2-OMe complex have not been deposited in the PDB due to the low resolution of the crystallographic data; deposition shall be done upon refinement of the model against higher resolution diffraction data.

Acknowledgments

The authors wish to express their gratitude to Professor R.U. Lemieux, who provided both the carbohydrates for this study and insightful discussions prior to his death. The authors also wish to thank Dr. L. Prasad for helpful discussions, and Dr. M. Becker (NSLS) and Mr. G. Navrotsky (BioCARS) for their assistance during data collection. G.F.A. gratefully acknowledges financial assistance from the Colleges of Graduate Studies and Medicine from the University of Saskatchewan. This work was supported by a Canadian Institutes for Health Research operating grant to L.T.J.D. (MT-10162) and a Natural Sciences and Engineering Research Council of Canada (NSERC) operating grant to J.W.Q.

^{1}H NMR studies on the solution conformation of contulakin-G and analogues

Lill Kindahl, Corine Sandström, A. Grey Craig, Thomas Norberg, and Lennart Kenne

Abstract: The conformation of contulakin-G, a bioactive 16 amino acid *O*-linked glycopeptide (ZSEEGGSNAT*KKPYIL) with the disaccharide β-D-Gal(1→3)α-D-GalNAc attached to the threonine residue in position 10, has been investigated by ^{1}H NMR spectroscopy. The ^{1}H NMR data for the non-glycosylated peptide and for two glycopeptide analogues, one with the monosaccharide α-D-GalNAc at Thr^{10} and one with the disaccharide β-D-Gal(1→3)α-D-GalNAc at Ser^7, all of lower bioactivity than contulakin-G, have also been collected. The chemical shifts, NOEs, temperature coefficients of amide protons, and $^3J_{NH,\alpha H}$-values suggest that all four compounds exist mainly in random coil conformations. Some transient populations of folded conformations are also present in the glycopeptides and turns, probably induced by the sugars, are present in the peptide chain around the site of glycosylation. In the two peptides *O*-glycosylated at Thr^{10}, the rotation of α-D-GalNAc around the linkage between the sugar and the peptide is restricted. There is evidence for a hydrogen bond between the amide proton of α-D-GalNAc and the peptide chain that could contribute to this torsional rigidity. An intramolecular hydrogen bond between the carbohydrate and the peptide chain does not exist in the peptide *O*-glycosylated at the Ser^7 residue.

Key words: conformation, contulakin-G, NMR, *O*-linked glycopeptide.

Résumé : Faisant appel à la RMN du ^{1}H, on a étudié la conformation de la contulakine-G, un glycopeptide (ZSEEGGSNAT*KKPYIL) bioactif comportant seize acides aminés *O*-liés au disaccharide β-D-Gal(1→3)α-D-GalNAc attaché à un résidu de thréonine en position 10. On a aussi recueille les données de RMN du ^{1}H pour le peptide non-glycosylé et pour deux glycopeptides analogues, l'un comportant le monosaccharide α-D-GalNAc au niveau Thr^{10} et l'autre comportant le disaccharide β-D-Gal(1→3)α-D-GalNAc au niveau Ser^7 dont la bioactivité est toujours inférieure à celle de la contulakine-G. Les déplacements chimiques, les effets Overhauser nucléaires, les coefficients de température des protons de l'amide et les valeurs de $^3J_{NH,\alpha H}$ suggèrent que les quatre composés existent principalement dans des conformations en spirales aléatoires. Dans les glycoprotéines, il existe aussi des populations transitoires de conformations repliées et, dans la chaîne peptidique autour du site de glycosylation, il existe aussi des inversions qui sont probablement induites par les sucres. Dans les deux peptides *O*-glycosylés au niveau Thr^{10}, la rotation du α-D-GalNAc autour de la liaison entre le sucre et le peptide est restreinte. Il y a des indications à l'effet qu'une liaison hydrogène entre le proton de l'amide du α-D-GalNAc et la chaîne peptidique pourrait contribuer à cette rigidité conformationnelle. Il n'existe pas de liaison hydrogène intramoléculaire entre l'hydrate de carbone et la chaîne peptidique du peptide *O*-glycosylé au niveau du résidu Ser^7.

Mots clés : conformation, contulakine-G, RMN, glycopeptide *O*-lié.

[Traduit par la Rédaction]

Introduction

Contulakin-G is a *Conus* venom peptide initially isolated and purified from the marine snail *Conus geographus* based on its ability to induce sluggishness in mice. Contulakin-G was found (1) to be a 16 amino acid *O*-linked glycopeptide with the sequence ZSEEGGSNAT*KKPYIL, where the *N*-terminus was blocked with a pyroglutamic acid residue (Z) and the disaccharide β-D-Gal(1→3)α-D-GalNAc(1→ was attached to the threonine residue in position 10 (see Scheme 1).

There is significant sequence identity between the carboxy-terminus of contulakin-G and members of the neurotensin family of neurotransmitters. Although the binding affinity of contulakin-G for cloned neurotensin receptors in vitro proved to be significantly lower than neurotensin, contulakin-G was shown to be a neurotensin receptor agonist at physiologically relevant concentrations (1). Recently, contulakin-G was shown to be an extremely potent broad spectrum analgesic in a number of models of acute pain when administered intrathecally. When compared with the non-glycosylated contulakin-G and with neurotensin, which is known to be an analgesic, contulakin-G was two orders of

magnitude more potent in vivo (2). Furthermore, the behavioural toxicity of contulakin-G appears to be much lower than neurotensin, giving contulakin-G a considerably more favourable therapeutic index than neurotensin. In recognition of these properties, contulakin-G has entered preclinical trials for short-term management of post-operative pain (3).

The mechanism by which the sugar residues affect the biological activity is not yet understood but several possibilities exist to explain the significantly increased potency of glycosylated contulakin-G. It might be due to an alternative mode of action, or to a modulation of the kinetics of the interaction between ligand and receptor. It might also be due to an enhanced supply of the substance to the site of action due to inhibition of proteolytic degradation by the glycan. The enhanced supply can also be a consequence of more desirable pharmacokinetic profile and enhanced uptake through the blood brain barrier (4). Also, glycosylation may alter the conformation of the peptide, or the binding to the receptor in a way which is favourable for activity. Previous NMR studies on *O*-linked glycopeptides have suggested that one consequence of *O*-glycosylation in small peptides is to limit the number of conformations available to an otherwise flexible peptide (5–12). In most cases, the peptide backbone tends to bend away from the sugar residue. In addition, evidence for a hydrogen bond between the sugar and the glycosylated threonine residue that helps in forming a glyco-turn has been obtained (13–15). However, a recent study has also shown that glycosylation is not always turn-inducing, but can in some cases result in local straightening of the peptide backbone (16). Thus, the effect of glycosylation on conformation appears to depend on the nature of the sugar, and on the amino acid residues at and around the glycosylation site.

In this paper, as a first step towards understanding the effect of glycosylation on the biological activity of contulakin-G, we have carried out an NMR study on the solution conformation of contulakin-G (**2**), its unglycosylated counterpart (**1**), and two analogues, one with the monosaccharide α-D-GalNAc at Thr[10] (**3**), and one with the disaccharide β-D-Gal(1→3)α-D-GalNAc at Ser[7] (**4**) (Scheme 1). The potency of **1**–**4** has been determined using the tail flick assay of antinociception (17). The data showed that shifting the position of the glycosylation from residue 10 to 7, and reducing the size of the glycan decrease the activity compared with the native contulakin-G (17). In relative terms, **2** is the most potent, **3** is more potent than **4**, which has approximately the same potency as **1** (17). Thus, one of the primary goals of this work was to compare the conformations of glycosylated and non-glycosylated versions of contulakin-G to investigate if differences in conformation could be correlated to the observed differences in biological activity.

Experimental

Sample preparation

The synthesis of the non-glycosylated form of contulakin-G (**1**) and of contulakin-G (**2**) has been previously described

© 2002 NRC Canada

(1). The synthesis of **3** and **4** was performed in a similar fashion as described in (1). The full experimental details will be reported elsewhere.

The samples were prepared by dissolving ~1 mg of (glyco)peptide in 50 μL 99.98% D_2O, H_2O–D_2O (95:5), or a buffer containing H_2O–D_2O (95:5), 100 mM sodium chloride, 13.5 mM sodium acetate, pH 5.6. The solutions were then transferred into 1.7- or 2.1-mm NMR capillaries. NMR spectra were also recorded in trifluoroethanol (TFE)–H_2O (1:1).

NMR spectroscopy

All NMR experiments were performed on a Bruker DRX-600 spectrometer equipped with a 2.5-mm microprobe. The NMR spectra unless specified were recorded at 5, 15, or 25°C. The temperature coefficients were calculated for the amide protons in H_2O–D_2O and H_2O–TFE solutions using ^{1}H NMR chemical shift data measured by variation of the temperature from 5 to 45°C in steps of 5°C. The two-dimensional NMR spectra were recorded in the phase-sensitive mode using the TPPI method (18). For experiments in D_2O, the residual HDO peak was suppressed by pre-irradiation at low decoupler power. For experiments in 95% H_2O – 5% D_2O, the WATERGATE pulse sequence (19) was used for water suppression. The DQF-COSY and TOCSY spectra were typically acquired with 4K data points in t_2 and 512 points in t_1 and a repetition delay of 1.5 s. In TOCSY, mixing times of 60 and 100 ms were used. NOESY and ROESY spectra were recorded with mixing times (τ_m) from 100 to 600 ms for NOESY and 100 to 300 ms for ROESY. 256 Spectra of 4K data points were acquired and a repetition delay of 2.5 s was used. The ^{1}H NMR chemical shifts were measured relative to the resonance of the methyl signal of acetone (δ 2.225) added as an internal reference.

Results and discussion

Assignment of ^{1}H NMR resonances

The assignment of the proton resonances of **1**–**4** was done from a combination of two-dimensional DQF-COSY, TOCSY, and NOESY experiments, and the chemical shifts are given in Tables 1 and 2.

^{1}H NMR chemical shifts

The ^{1}H NMR chemical shifts, measured for the amino acid residues in the glycosylated peptides **2**–**4**, are similar to those in the corresponding non-glycosylated peptide **1**, with the exception of signals from NH and αH protons of the residues at and around the glycosylation sites (Table 1, Fig. 1). Thus, the NH and αH signals of Thr^{10} in **2** and **3** show large downfield shifts upon glycosylation at Thr^{10}. Also, the αH signal of the preceding residue, Ala^9, shows a large downfield shift, whereas the αH signal of the second residue from the glycosylation site (αH Lys^{12}) shows a large upfield shift. In a similar way, the NH and αH signals of Ser^7 in **4** are deshielded upon glycosylation. Small effects are also seen on the chemical shifts of Asn^8 and Ala^9 signals. Apart from the effect of glycosylation, the ^{1}H NMR chemical shifts for the signals of αH from the amino acids in the peptide **1** and the glycosylated peptides **2**–**4** are similar to those reported for peptides with random coil conformations (20).

NOEs in the peptide chain

NOEs (Fig. 2) observed in NOESY and ROESY spectra recorded at several mixing times identified the presence of some transient secondary structures. Sequential $d_{NN}(i,i+1)$ NOEs in flexible peptides are representative of folded conformations in terms of turn or helical structures with d_{NN} = 2.3–3.4 Å (21–23). In an extended conformation, the average d_{NN} is 4.5 Å, while the $d_{\alpha N}(i,i+1)$ is ~ 2.2 Å (21–23). In the non-glycosylated peptide **1**, sequential $d_{\alpha N}(i,i+1)$ NOEs, characteristic of extended backbone conformations were observed along the whole peptide chain. In addition, a $d_{NN}(i,i+1)$ NOE was also observed between Asn^8 and Ala^9 and between Ile^{15} and Leu^{16} (Fig. 3*a*).

In contulakin-G, **2**, the sequential $d_{\alpha N}(i,i+1)$ NOE pattern characteristic of extended conformations was also observed along the whole peptide chain. Additional sequential $d_{NN}(i,i + 1)$ NOEs were observed for Ser^7/Asn^8, Asn^8/Ala^9 and Ala^9/Thr^{10} (Fig. 3*b*). A $d_{NN}(i,i + 1)$ NOE was also found between Tyr^{14} and Ile^{15} and between Ile^{15} and Leu^{16}. These $d_{NN}(i,i + 1)$ NOEs are indicative of local structures in terms of folded conformations, but the sites of local structure most likely occur in a subpopulation of the predominantly disordered solution ensemble of conformers. The existence of the proline residue at position 13 led us to probe for β-turn structures. The NOEs that are diagnostic of turns (where Pro = i + 1) include $d_{NN}(i + 2,i + 3)$, $d_{\alpha N}(i,i + 2)$, and either $d_{\alpha N}(i + 1,i + 2)$ for type II or $d_{\delta N}(i + 1,i + 2)$ for type I turns. We observed cross-peaks at $d_{NN}(Tyr^{14}, Ile^{15})$ and $d_{\alpha N}(Pro^{13}, Tyr^{14})$, but no cross-peaks at $d_{\alpha N}(Lys^{12}, Tyr^{14})$ or $d_{\delta N}(Lys^{12}, Tyr^{14})$ were found.

In the glycopeptide monoglycosylated at Thr^{10} (**3**) the sequential $d_{\alpha N}(i,i + 1)$ NOE pattern characteristic of extended conformations was also observed along the whole peptide chain. Sequential $d_{NN}(i,i + 1)$ NOEs were found from Gly^5 to Thr^{10}. Isolated $d_{NN}(i,i + 1)$ NOEs were also found between Ser^2 and Glu^3 and between Tyr^{14} and Ile^{15}. In **4**, where the disaccharide is attached at Ser^7, sequential $d_{\alpha N}(i,i + 1)$ NOEs were found along the whole peptide chain, with the exception for the $d_{\alpha N}(i,i + 1)$ NOE between Lys^{11} and Lys^{12}. $d_{NN}(i,i + 1)$ NOEs were observed for Gly^5/Gly^6, Ser^7/Asn^8, Asn^8/Ala^9, Thr^{10}/Lys^{11}, and Tyr^{14}/Ile^{15}. The presence of local structures in **1**–**4** was supported by the observation of weak $d_{\alpha N}(i,i + 2)$ NOEs (Fig 2).

Sugar-peptide NOEs

Five NOEs between the Thr^{10} and Lys^{11} residues and the directly attached α-D-GalNAc residue were observed for **2** and **3**: NH(Thr^{10})-NH(α-D-GalNAc), NH(Lys^{11})-H-1(α-D-GalNAc), NH(Thr^{10})-H-3(α-D-GalNAc), H-β(Thr^{10})-H-1(α-D-GalNAc), H-γ(Thr^{10})-H-1(α-D-GalNAc) (Fig. 4). The fact that the NOEs from the peptide are to only one side of the sugar indicates a relatively persistent interaction between the peptide and the sugar, and a restricted rotation of the sugar around the sugar–peptide linkage. This restricted rotation is also supported by the small $^3J_{\alpha,\beta}$-value (1.5 Hz in **2** and 2 Hz in **3**) measured for the Thr^{10} residue. Such a small value indicates a preference for an orthogonal orientation between the Thr^{10} α- and β-protons (14). If the α-D-GalNAc residue was undergoing motion relative to the peptide backbone through rotation around the C(α)—C(β) bond of Thr^{10}, a value of ~5 Hz, as measured in the non-glycosylated peptide (**1**) would be expected. In **4**, three NOEs were found

[b]$^3J_{NH,\alpha H} + {}^3J_{NH,\alpha' H}$.

between the peptide chain and the sugars, namely NH(Ser[7])-NH(α-D-GalNAc), H-β(Ser[7])-H1(α-D-GalNAc), and Hβ′(Ser[7])-H1(α-D-GalNAc). The αH signal of Ser[7] appears in the NMR spectrum as a triplet of 9.9 Hz ($^3J_{\alpha H,\beta H} + {}^3J_{\alpha H,\beta' H}$), as in the non-glycosylated peptide (**1**) suggesting a free rotation of the sugar around the sugar–peptide linkage.

$^3J_{NH,\alpha H}$ Values

The $^3J_{NH,\alpha H}$ values for each amino acid in the peptide chain are similar in the non-glycosylated **1** and glycosylated peptides **2**–**4**. The $^3J_{NH,\alpha H}$ values are in the range 5.7–9.0 Hz in **1**–**4**, (Table 3) suggesting random coil or extended conformations. It is sometimes difficult to distinguish between random and extended structures since they can give similar chemical shifts and J values. Extended conformations are identified by both sequential $d_{\alpha N}(i,i+1)$ NOEs and backbone $^3J_{NH,\alpha H}$ values > 8 Hz on a stretch of sequential residues. Thus, the existence of sequential $d_{\alpha N}(i,i+1)$ NOEs along the peptide chain would indicate extended conformations. However, most $^3J_{NH,\alpha H}$ values are lower than 8 Hz. An increase in the $^3J_{NH,\alpha H}$ value from 7.5 to 8.6 Hz can be observed for Thr[10] in **2** and **3** compared to **1** and **4**. This

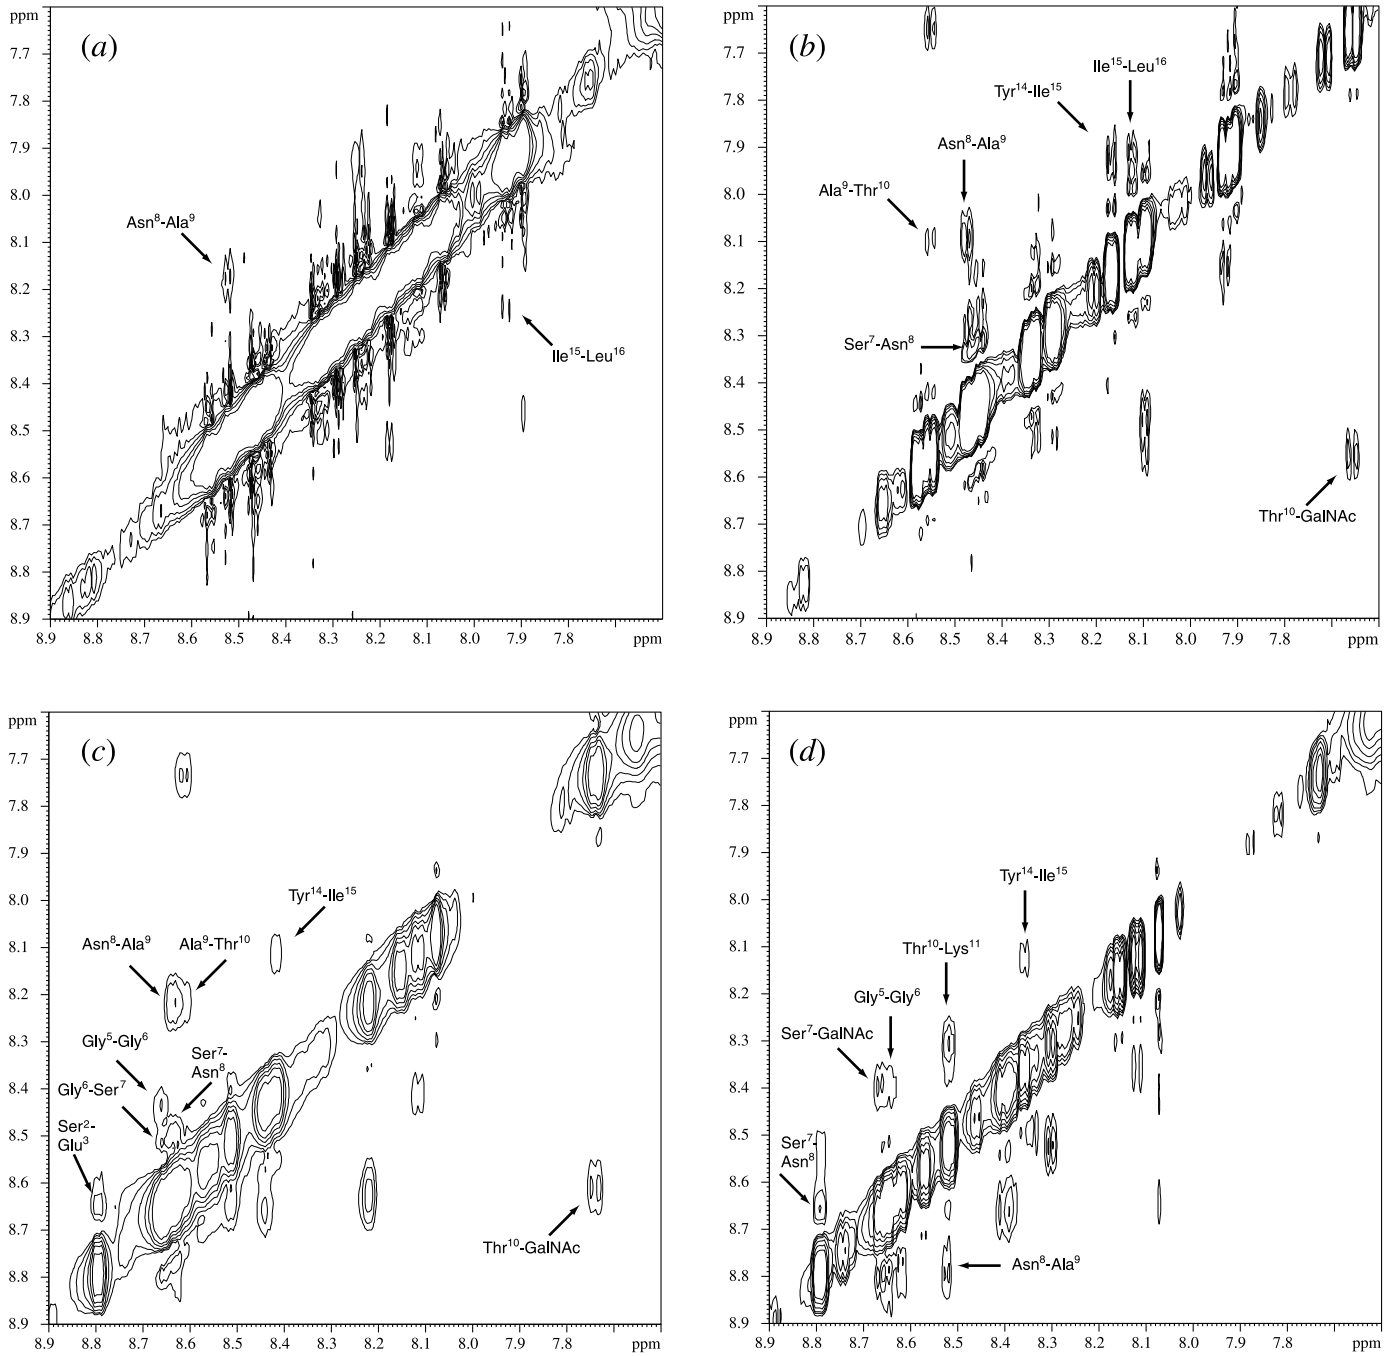
larger value of $^3J_{NH,\alpha H}$ in **2** and **3** is in agreement with the existence of some populations of ordered secondary structures (18). The $^3J_{NH,H2}$ of 10.1 Hz measured for GalNAc demonstrates a *trans* orientation of NH and C(2)H.

Temperature coefficients for the NH protons

The extent to which an amide proton is exposed to the solvent is reflected in the dependence of its chemical shift on temperature (22, 24). Thus, signals from exposed amides shift more than those from an ordered structure. The temperature dependence of NH chemical shifts is a useful way to detect the presence of hydrogen bonds. Signals from NH involved in hydrogen bonds show less temperature dependence ($d\delta/dT < -6$ ppb/°C) than those from NH protons exposed to the solvent. The temperature coefficients ($d\delta/dT$) for the NH proton signals from **1**–**4** were measured in H_2O–D_2O (95:5) solution from a series of one-dimensional spectra recorded between 5° and 45°C (Table 3). The signals from NH protons in the peptide chain show $d\delta/dT$ above –6.0 ppb/°C confirming than the peptide chain in **1**–**4** adopts mainly extended conformations. Of particular interest is the low value of the temperature coefficient of NH of

© 2002 NRC Canada

Fig. 3. The NH–NH region of the 2D NOESY spectra of the (glyco)peptides **1**–**4** in H_2O–D_2O (95:5) recorded at 600 MHz. (*a*) **1**, ROESY, 25°C, mixing time 200 ms; (*b*) **2**, NOESY, 25°C, mixing time 300 ms; (*c*) **3**, NOESY, 5°C, mixing time 300 ms; (*d*) **4**, NOESY, 5°C, mixing time 300 ms.



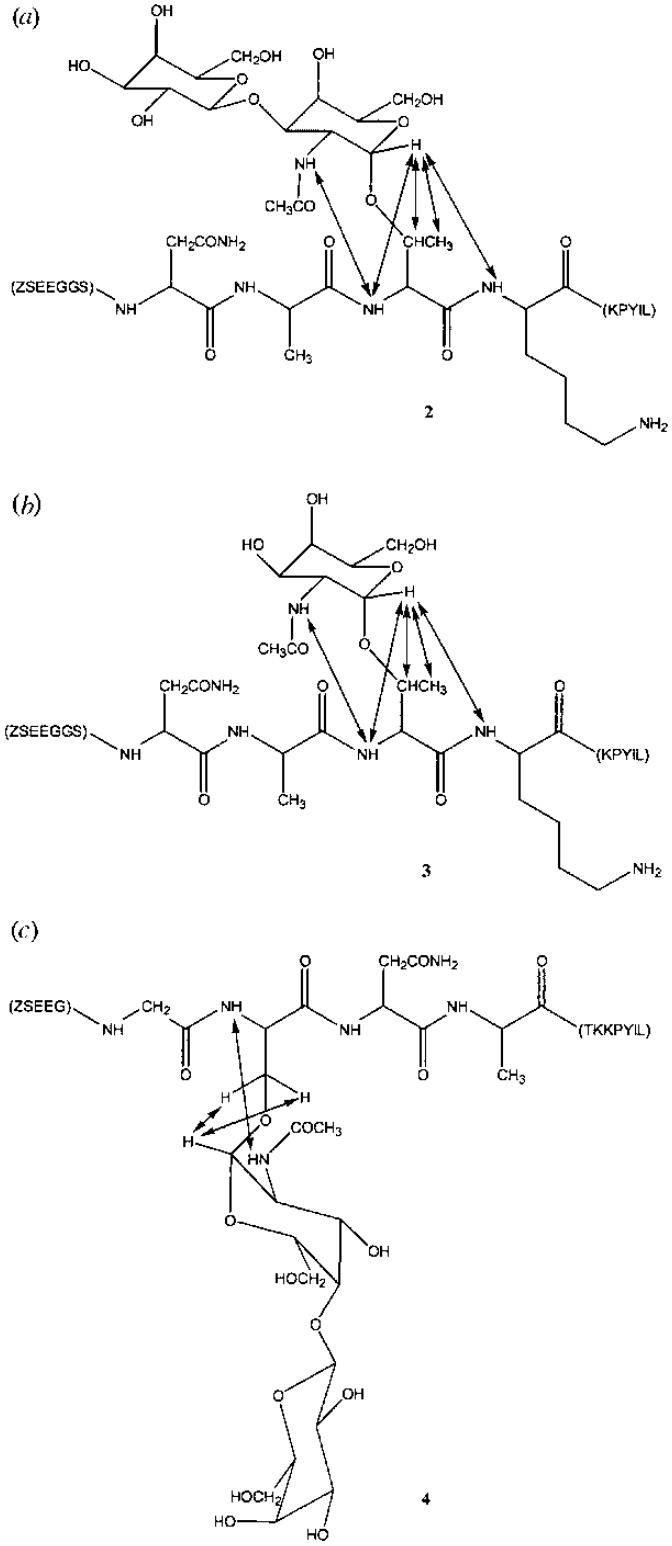
α-D-GalNAc in **2** and **3** (–5.8 and –5.7 ppb/°C, respectively, in water solution). These values indicate that the torsional rigidity between the sugar and the peptide, suggested by the NOEs and by the value of the $^3J_{\alpha,\beta}$ (Thr^{10}) coupling constant (vide infra), may be enforced by a hydrogen bond interaction between NH of α-D-GalNAc and Thr^{10}. In contrast, the large value for the temperature coefficient of NH of α-D-GalNAc in **4** (–11.1 ppb/°C) indicates that this proton is not protected from exchange with the solvent through hydrogen bond formation.

Studies in TFE–H_2O

Since a large number of NMR studies on peptides (16, 25) have shown that the use of TFE as a solvent can induce helix formation in some peptides, NMR spectra were also recorded in 50% TFE – 50% H_2O. When the peptides **1**–**4** were ana-

© 2002 NRC Canada

Fig. 4. Schematic representation of interresidual NOEs observed at the junction between the peptide and the saccharides in **2**–**4**.



lysed in TFE–H_2O solutions, similar ^1H NMR chemical shifts of the amino acids in the glycosylated and non-glycosylated peptides were observed, except for the residues at the junction site. The shifts due to glycosylation were, however, not as large as in water. The $^3J_{NH,\alpha H}$ values were very similar to those measured in water. The temperature coefficients ($d\delta/dT$) were slightly smaller than those obtained for the compounds in water. Most of the NH protons in the peptide chain had $d\delta/dT$ values above –6.0 ppb/°C, with the exception of Ala^9 in **1**, **2**, and **3**, and of Thr^{10} and Ile^{15} in **1** and **2**. As in water, the $d_{\alpha N}(i,i+1)$ NOEs characteristic of extended conformations were observed all along the peptide chains in the glycosylated and non-glycosylated peptides. The $d_{NN}(i,i+1)$ NOEs present in water were also present in TFE–H_2O, but additional $d_{NN}(i,i+1)$ NOEs were also found. The hydrogen bond interaction between Thr^{10} and α-D-GalNAc found for **2** and **3** in water is also present in TFE–H_2O solution.

Conclusion

This NMR study shows that the four analogues mainly exist in random coil conformations. Interestingly, in the glycosylated peptides, some transient populations of folded conformation are also present. In **2** and **3**, which are *O*-glycosylated at the Thr^{10} residue, the rotation of the α-D-GalNAc residue around the bond between the sugar and the peptide is restricted. An intramolecular hydrogen bond between the amide proton of α-D-GalNAc and probably the carbonyl oxygen of the *O*-linked Thr^{10} residue, stabilises the structure. In peptide **4**, *O*-glycosylated at Ser^7, there is no hydrogen bond between the sugar residue and the peptide chain. Since **2** and **3**, which are *O*-glycosylated at the Thr^{10} residue, are more active than the non-glycosylated peptide **1** and the peptide *O*-glycosylated at Ser^7 (**4**), it is possible that the stabilization of conformation by hydrogen bonding to the sugar could be a key factor for the biological activity. It should be noted that in an NMR study of human salivary mucin derived *O*-linked glycopeptides, a hydrogen bond was also found in threonine-glycosylated peptides, but not in serine-glycosylated peptides (15).

The presence of sequential NH–NH NOEs from Ser^7 to Thr^{10} in **2**, from Gly^5 to Thr^{10} in **3**, and from Ser^7 to Ala^9 in **4** indicates that the glycopeptides have a folded structure in these regions. In contulakin-G (**2**), NH–NH NOEs from Tyr^{14} to Leu^{16} suggest that an additional turn is also formed at the *C*-terminal end of the peptide chain. This shows that glycosylation leads not only to local changes in conformations at the junction site, but also induces long distance conformational changes. In **3** and **4**, only the NH–NH Tyr^{14}–Ile^{15} NOE was observed. Since the six *C*-terminal amino acids of contulakin-G are similar to several members of the neurotensin class of peptides, it might be that the terminal turn at the Tyr^{14}–Leu^{16} residues, which exists only in contulakin-G, the most active of the four analogues, and which is induced by glycosylation at Thr^{10} with the disaccharide, is an additional conformational feature important for the biological activity.

An effective strategy for structural elucidation of oligosaccharides through NMR spectroscopy combined with peracetylation using doubly ^{13}C-labeled acetyl groups

Brad Bendiak, Tammy T. Fang, and David N.M. Jones

Abstract: The use of NMR spectroscopy for the elucidation of larger carbohydrate structures isolated from natural sources is principally limited by severe overlap of ^{1}H signals, poor sensitivity when experiments involve ^{13}C nuclei, and difficulties in conclusively establishing linkage positions. Peracetylation of oligosaccharides with doubly ^{13}C-labeled acetyl groups provides several major advantages for their structural elucidation when combined with specifically tailored NMR pulse sequences. The 2.5–4.7 Hz *J*-coupling constants between acetyl carbonyl-^{13}C nuclei and protons of the sugar ring at the sites of acetylation enables these sites to be readily assigned. By inference, glycosidic linkage positions on monosaccharides can be unambiguously determined. *This can be used in lieu of permethylation* analysis, yet does not require degradation of oligosaccharides. Spectral dispersion in the directly detected (^{1}H) dimension is increased ~2.6–2.7-fold due to the downfield shifting of sugar-ring protons at the positions of acetylation. Peracetylation also introduces three new frequency dimensions for NMR studies, namely the ^{13}CO, ^{13}C^{Me}, and ^{1}H^{Me} frequencies of the acetyl groups. These frequencies can be correlated to sugar protons, either independently or in combination, in alternative 2-, 3-, or 4-D experiments. The use of Hartmann–Hahn coherence transfer combined with zero-quantum dephasing periods permits purely absorptive in-phase multiplets to be extracted and enables accurate scalar couplings between ring protons to be measured, even in multidimensional experiments. Results are illustrated on a nonasaccharide-alditol derived from *N*-linked glycoproteins and on some smaller structures containing sialic acids and *N*-acetylhexosamines. Methods for small-scale sample acetylation using the superacylation catalyst, 4-dimethylaminopyridine, are described. A brief historical perspective pertinent to the fundamental contributions of Dr. R.U. Lemieux to the field of carbohydrate NMR is also presented.

Key words: NMR, oligosaccharides, peracetylation, doubly ^{13}C-labeled acetyl groups, tailored pulse sequences, heteronuclear Hartmann–Hahn.

Résumé : L'utilisation de la spectroscopie RMN pour l'élucidation des structures de grosses molécules d'hydrates de carbone isolées de sources naturelles est limitée principalement par les importants recouvrements des signaux du ^{1}H, de la faible sensibilité des expériences impliquant le noyau ^{13}C et par les difficultés à établir de façon concluante les positions de liaisons. Le peracétylation des oligosaccharides par des groupes acétyles doublement marqués au ^{13}C apporte de nombreux avantages importants à l'élucidation de leur structure, surtout lorsqu'on combine cette technique à la RMN avec des séquences pulsées sur mesure. La constante de couplage, *J*, de 2,5 à 4,7 Hz entre les noyaux de ^{13}C du groupe carbonyle des acétyles et les protons du cycle du sucre aux points d'acétylation permet d'assigner facilement ces sites. Par déduction, les positions des liaisons glycosidiques sur les monosaccharides peuvent être déterminées facilement. À cette fin, *on peut utiliser cette technique à la place de l'analyse par perméthylation* et elle ne requière pas de dégradation des oligosaccharides. La dispersion spectrale dans la dimension directement détectée (^{1}H) est augmentée par un facteur de 2,6 à 2,7 en raison d'un déplacement vers les bas champs des protons du cycle du sucre aux positions d'acétylation. La peracétylation introduit aussi trois nouvelles dimensions de fréquence pour les études RMN, soit les fréquences ^{13}CO, ^{13}C^{Me} et ^{1}H^{Me} des groupes acétyles. On peut établir des corrélations entre ces fréquences et les protons du sucre, de façon indépendante ou en combinaison, dans des expériences alternatives en 2-D, 3-D ou 4-D. L'utilisation de transfert de cohérence de Hartmann–Hahn, combiné aux périodes de déphasage à quantum zéro, permet d'extraire des multiplets en phase strictement absorbants et de mesurer des couplages scalaires précis

Introduction

Historical perspective and Dr. R.U. Lemieux

It is fitting in an article dedicated to the memory of Dr. Raymond Lemieux that NMR spectroscopy of carbohydrates is at least one research topic. It is now taken for granted that measurement of ^1H–^1H J couplings provides important dihedral angle information for structural determination of molecules by NMR, according to the Karplus (1) approximation of 1963 ($J_{H,H'} = A + B \cos \phi + C \cos 2\phi$), where for sp^3-hybridized carbons, A, B, and C are numerical constants and ϕ represents the three-bond dihedral angle. Less well known is that this equation was a modified equation related to a wavefunction that, in 1959, Karplus showed could be fitted approximately by two curves, $8.5 \cos^2\phi - 0.28$ (Hz) where $0° \leq \phi \leq 90°$, and $9.5 \cos^2\phi - 0.28$ (Hz) where $90° \leq \phi \leq 180°$ (2). Even less well appreciated is that in the 1959 paper, the only experimental NMR evidence that Karplus cited to verify the theoretical relationship (Table 1 of that article) was a publication by Lemieux et al. (3), who had presented the 40 MHz ^1H NMR spectra of various six-membered ring compounds in 1956 and 1957 (4, 5) and 1958 (3, 6, 7). In the 1957 paper, Lemieux et al. reported their discovery that spin–spin coupling constants would likely be useful for determination of configuration of organic molecules (in general) because, they stated "It was also observed that configuration has an effect on spin-coupling constants as well as on chemical shift. Analysis of the spectra for the acetyl derivatives of glucose, galactose, xylose, and arabinose showed that the spin coupling between hydrogens on neighboring carbon atoms is 2 to 3 times greater when both the hydrogens are in axial orientation than when one or both of the hydrogens are in equatorial orientation." In their 1958 papers (3, 6, 7), they examined additional peracetylated monosaccharides having different anomeric configurations, including a series of chlorinated cyclohexanes, isomeric trichloromethyltrioxanes, and other cyclohexane derivatives. A crucial and very convincing demonstration of the relationship between ^1H–^1H J couplings and configuration was presented for two isomers of 1,3-dimethoxy-2-acetoxycyclohexane, where the ring proton signal at the acetoxy position resonated well downfield (6). Even at 40 MHz, the multiplet pattern of the ring proton having the acetoxy substitution was clearly observable and showed two large couplings when the proton was located diaxially with respect to both vicinal protons (a triplet) and one large and one small coupling when one vicinal proton was diaxially positioned and one located equatorially (a quartet, Fig. 2 of ref. 6). These papers were not only the first reports of carbohydrate NMR spectra, they were the seminal papers that experimentally established a relationship between spin–spin couplings and the three-bond dihedral angle. In a somewhat prophetic statement in one 1958 paper (7), Dr. Lemieux commented that "an almost endless number of such applications of high-resolution nuclear magnetic resonance spectroscopy can be envisaged for gaining information on the immediate environment of atoms in organic molecules."

It is safe to say that the NMR tapestry contributed to by so many investigators since that statement shows no sign of becoming threadbare. The past 10–15 years alone have seen major improvements in coherence transfer–selection methods, the widespread adoption of pulsed-field gradients, the extensive development of adiabatic pulses, and the development of methods for subspectral accumulation and (or) editing. Although Dr. Lemieux could not have foreseen many of these important developments, it is a tribute to his instinct that NMR would evolve explosively. Finally, of course, his many important contributions to synthetic carbohydrate chemistry and control of anomeric configuration were crucial to the success it now enjoys, which will no doubt be the topic of many contributions to this volume.

Introduction proper

Complex carbohydrates represent an extremely variable repertoire of molecules, and have been the target of NMR studies directed along two general lines, primary structural elucidation and conformation and (or) dynamics (8–12). In isolated oligosaccharides from any source, there may be hundreds of monomers or potential monomers having alternate stereo- or regiochemistries that need to be identified. This includes various amino sugars (13–15), deoxy sugars (14, 16, 17), branched-chain sugars (14, 18), uronic acids (14, 15), and unusual sugars having more than six carbons or more than one modification, or the presence of both types of enantiomers in the same oligosaccharide (15, 19). In addition, the vast majority of oligosaccharides are still isolated from natural sources having a natural abundance of ^{13}C. In some cases, as in carbohydrates generated by bacterial or cell cultures, incorporation of ^{13}C into the sugar backbone can be achieved, which is important for conformational and (or) dynamic studies using NMR spectroscopy (20–24). However, this is simply not possible for carbohydrates isolated from most multicellular organisms.

Traditionally, permethylation analysis (25–28) has played a very important role in the structural determination of oligosaccharides. The success of this method is based on the

© 2002 NRC Canada

logic that all free hydroxyl groups are converted to a derivative (a methyl ether) that permits the positions of the formerly free hydroxyl groups to be identified. These methods rely on depolymerization, either solvolytic (25) or reductive (28), to generate methylated monomers. After further appropriate reduction and (or) acetylation, monosaccharide derivatives are produced that can be compared, both by GC retention time and electron-impact mass spectra, to those of standards, thereby enabling glycosidic linkage positions to be inferred.

NMR spectroscopy of oligosaccharides peracetylated with doubly ^{13}C-labeled acetyl groups provides the same information given by permethylation analysis, and is based on precisely the same logic — that all free hydroxyl groups are converted to a derivative (in this case, an acetyl ester), which permits the positions of the formerly free hydroxyl groups to be identified. In this case, however, the information is extracted by identifying a ^{13}C–^{1}H three-bond *J* coupling between the acetyl carbonyl carbon and the ring proton at the position of acetylation.

We have now measured approximately 650 such couplings in 40 different oligosaccharides, with the observation that these $^{3}J_{C,H}$ coupling constants range from 2.5–4.7 Hz (based on initial observations of this range, see ref. 29). All four-bond couplings between acetyl carbonyl carbons and ring protons at adjacent positions on the sugar ring are small and within linewidth (less than 0.5–1 Hz). Sites that are not acetylated do not show these $^{3}J_{C,H}$ couplings. These include the anomeric position, the position of cyclization, and the *position of a glycosidic linkage*. In addition, sites having other pre-existing substituents, such as phosphate monoesters, would not be acetylated. Three major advantages of peracetylation–NMR over classical permethylation analysis are first, that depolymerization is not required — the data is derived from intact oligosaccharides. Second, a series of standards are not necessary to compare GC retention times for determination of stereochemistry. Third, acetyl groups are both easy to remove to recover the initial oligosaccharide (30, 31) or can be easily replaced with methyl ethers under permethylation conditions, if so desired, for permethylation or other mass spectral analyses.

In this report, methods are described that are specialized for primary structural elucidation of oligosaccharides. They focus on the specific advantages provided through peracetylation of oligosaccharides with doubly ^{13}C-labeled acetyl groups. An explicit NMR strategy is outlined that describes new pulse sequences tailored to the benefits of the introduced acetyl groups. The key advantages provided by these methods are (*i*) they permit glycosidic linkage positions of monosaccharides within larger carbohydrates to be unambiguously assigned. (*ii*) They result in a marked increase in spectral resolution, both in the directly detected (^{1}H) dimension and three indirectly detected dimensions provided by the acetyl-group nuclear frequencies. The increased spectral dispersion in the directly detected dimension results in far fewer strong couplings between protons. These advantages are unique to ^{13}C-acetylation and are not available to underivatized oligosaccharides ^{13}C-labeled in the sugar backbone. (*iii*) They make it possible to resolve purely absorptive in-phase multiplets that permit accurate measurement of ^{1}H–^{1}H *J*-coupling constants and enable stereochemistries of individual sugars in oligosaccharides to be determined. (*iv*) They take advantage of the fact that ^{13}CO, $^{13}C^{Me}$, and $^{1}H^{Me}$ frequencies fall within narrow isolated spectral ranges. Selective excitation and decoupling pulses can be applied to eliminate the effects of *J*-coupling so that the signals approach their natural linewidths in the indirect dimensions.

While experiments are illustrated using a few oligosaccharides derived from glycoproteins to demonstrate important advantages, this strategy is entirely general and its potential application to carbohydrates from all sources is emphasized.

Results and discussion

Strategy for elucidation of carbohydrate structures using ^{13}C-acetylation and tailored pulse sequences

A flow chart is shown (Fig. 1) outlining the basic strategy behind the use of doubly ^{13}C-labeled acetyl groups for structural determination of oligosaccharides. The approach involves (*i*) initial assignment and accurate measurement of ring proton scalar couplings. This defines each spin system and enables sugar stereochemistries to be confidently determined. (*ii*) Unambiguous identification of substitution sites on each sugar ring, as revealed by assignment of *O*-acetyl positions. (*iii*) Determination of which specific sugars are linked to each other, as established by interresidue correlations.

Assignment of signals and measurement of ^{1}H–^{1}H *J* couplings of monosaccharide spin systems

Gradient COSY (gCOSY) and carbonyl ^{13}C-decoupled gCOSY

^{1}H–^{1}H Gradient COSY experiments are now routine, and the additional spectral dispersion induced by acetylation of an oligosaccharide results in many more resolved cross-peaks as compared with the same spectrum of the underivatized structure recorded in D_2O. The experiment is performed both with and without ^{13}CO decoupling during the evolution time and free induction decay. Comparison of these two spectra reveals the sites of acetylation based on the additional acetyl-^{13}CO/sugar-^{1}H couplings observed in the multiplet patterns. A standard ^{13}CO-decoupled gCOSY of the typical *N*-linked "biantennary" oligosaccharide-alditol (**1**, Scheme 1) containing nine sugars in D_2O-saturated $CDCl_3$ is shown in Fig. 2A. Figure 2B shows an expansion of the fully ^{13}CO-decoupled gCOSY spectrum and Fig. 2C shows the same region without ^{13}CO decoupling. In the fully ^{13}CO-decoupled experiment the cross-peak multiplet patterns are determined solely by ^{1}H–^{1}H couplings. The presence of a ^{13}CO–$^{1}H^{sugar}$ coupling within this multiplet in the non-decoupled spectrum identifies this ^{1}H as a site of acetylation. The magnitude of these ^{13}CO–$^{1}H^{sugar}$ couplings as measured in other experiments ranges from 2.5–4.7 Hz. This is a sensitive experiment as it is homonuclear and noise is minimized through the use of gradients (32). Collection of a larger number of increments (1000–2000) provides good resolution in F_1, which is useful if multiplets partially overlap. Where there is significant overlap of two or more cross-peaks, additional experiments are required to obtain complete assignments.

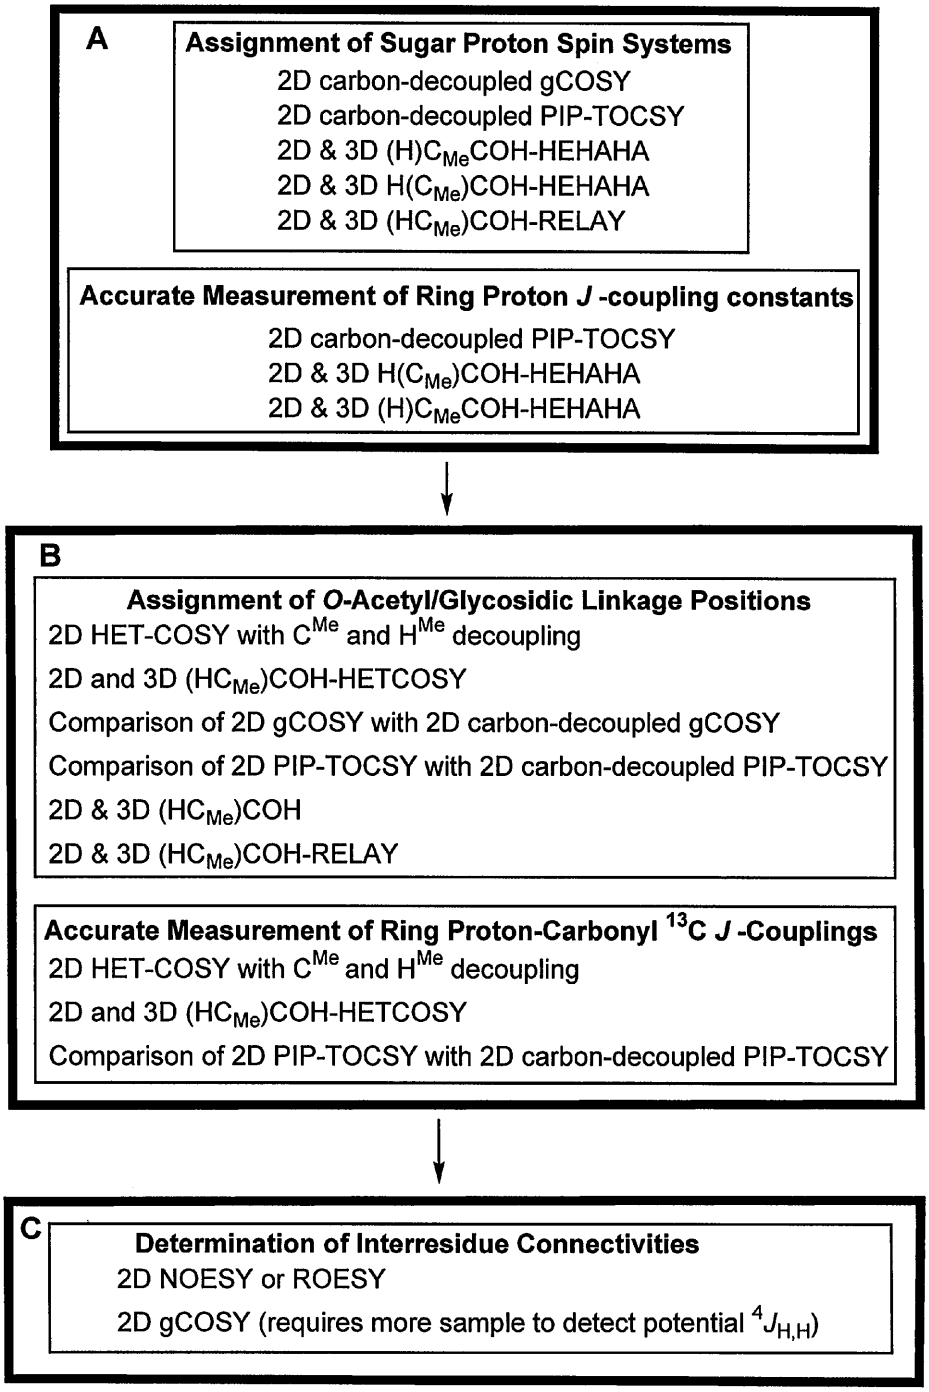
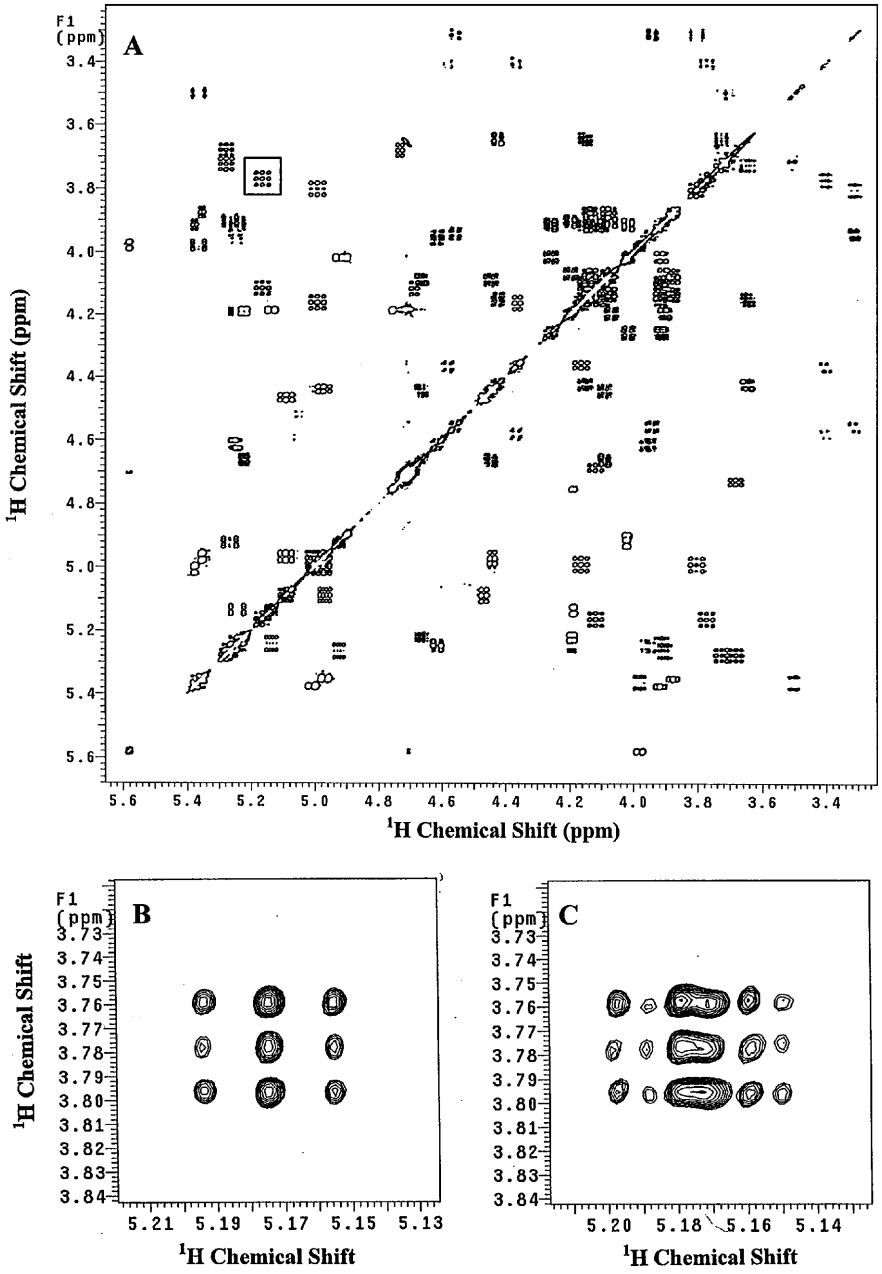
Fig. 1. Flow chart showing of the strategy for structural elucidation of oligosaccharides peracetylated with doubly ^{13}C-labeled acetyl groups. Tailored pulse sequences were designed for (A) definition of individual spin systems, (B) identification of linkage substitutions via assignment of all acetylation sites, and (C) identification of specific interresidue connectivities.



Measurement of scalar couplings directly from COSY-type cross-peaks is not generally applicable for many combinations of coupling constants due to overlap and interference of in-phase and antiphase components. Although homonuclear E.COSY or P.E.COSY methods (33, 34) have been described for measuring such coupling constants, specific difficulties in certain situations have been pointed out for these (35, 36) and their more selective variants, STRIPE or SUPERSTRIPE COSY (37). Recently, Delaglio et al. (38) have developed an interactive computer program that enables coupling constants to be determined in regular COSY spectra by amplitude-constrained multiplet evaluation (ACME). We have found, however, that ^1H–^1H *J*-couplings can be measured directly and accurately from pure-absorption in-phase multiplets in "pure in-phase" TOCSY (PIP-TOCSY) experiments and in novel NMR experiments designed to correlate acetyl nuclear frequencies to ring proton frequencies, as described below.

© 2002 NRC Canada

Fig. 2. (A and B) Carbonyl-decoupled gCOSY spectra of structure **1** (Scheme 1, where acetyl groups shown in bold type are doubly ^{13}C-labeled). This spectrum was accumulated with elimination of the GlcNAc N-H:H-2 couplings by deuterium exchange using D_2O layered on the $CDCl_3$ (27°C). Detailed NMR parameters were previously described (29). The boxed multiplet in (A), assigned to the H-3/H-4 cross peak of GlcNAc2, is shown expanded in (B), with the H-3 frequency along the horizontal axis. (C) The same region of the spectrum of the same compound run under identical conditions, except that the carbonyl frequencies were not decoupled. The additional coupling of a 3-*O*-acetyl ^{13}CO nucleus is clearly observed along the horizontal axis, but the 4-position is substituted with a β-Man, hence shows no additional splitting of the multiplet pattern along the vertical axis.



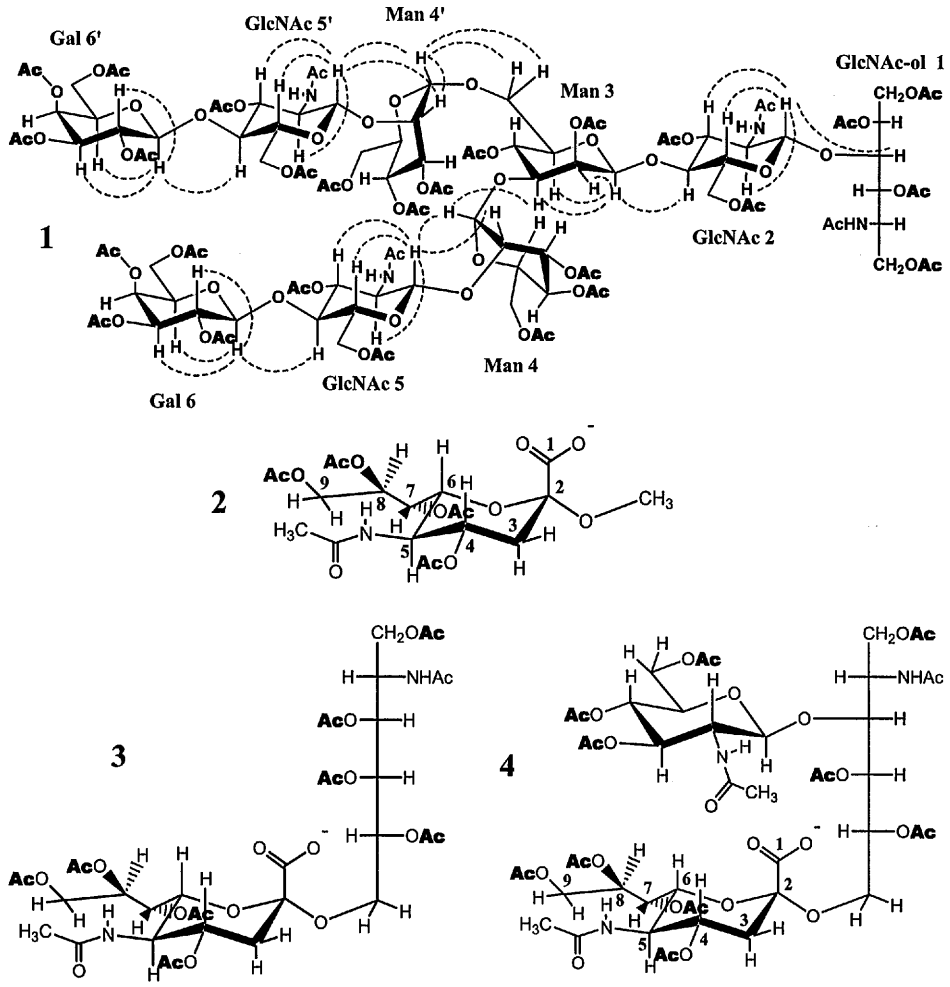
Carbonyl ^{13}C-decoupled pure in-phase TOCSY (PIP-TOCSY)

The accurate measurement of ring proton *J*-coupling constants in carbohydrates is crucial to define the stereochemistry of each monosaccharide. TOCSY experiments are attractive for this purpose because they connect complete individual spin systems and coherence transfer occurs in-phase (39–41). However, zero-quantum coherences of the type $I_yS_x - I_xS_y$ develop during Hartmann–Hahn mixing periods that, if not suppressed, can result in phase distortions of cross-peak multiplets. Methods to suppress zero-quantum coherences have been discussed in some detail (39–41). One effective solution to this problem are the zero-quantum dephasing schemes of Davis et al. (39), which use a spin-lock pulse applied during application of a B_0 gradient. This eliminates the effects of zero-quantum coherences in a single accumulation, which is in contrast to *z*-filters that require repetitions with varying delays. These schemes yield near perfect multiplet patterns in the directly detected dimension.

The basic PIP-TOCSY pulse sequence is shown in Fig. 3A. Although Davis et al. (39) applied dephasing

© 2002 NRC Canada

Scheme 1.



periods before and after the TOCSY mixing period, practically we have found that a single dephasing scheme applied after the mixing period is sufficient to suppress zero-quantum coherences in almost all cross-peaks except those very near the diagonal, where the difference in the frequency offset is small (~15–30 Hz). A PIP-TOCSY spectrum of ^{13}C-acetylated oligosaccharide **1** is shown in Fig. 4A, recorded using the pulse sequence of Fig. 3A where ^{13}CO was decoupled during t_1 and t_2. A trace of the boxed multiplet in Fig. 4A taken parallel to the F_2 axis is shown in Fig. 4B, and the same multiplet is shown in Fig. 4C without ^{13}CO-decoupling in the t_2 dimension. The positions of acetylation again are immediately assignable based on the additional splitting seen in the spectrum without ^{13}C decoupling during t_2. Multiplets are pure-absorption in-phase and the decoupled spectrum yields accurate values of ^{1}H–^{1}H coupling constants. A key point is that the experiment usually yields a series of multiplet patterns at different F_1 frequencies that can be used for additional measurements of the same ^{1}H–^{1}H *J* couplings. This is particularly important if overlap in some regions of the spectrum is an issue. The limits of peak resolution are approximately 1.5–2.0 Hz. The experiment is sensitive as it is homonuclear. Another point worthy of mention is that the GlcNAc amide N–H protons resonate downfield (~5.8 to 7.0 ppm) and couple (8.0–9.6 Hz) to H-2 protons, enabling these spin systems to be straightforwardly identified (Fig. 4A).

(H)C$_{Me}$COH-HEHAHA and H(C$_{Me}$)COH-HEHAHA

Homonuclear 2-D ^{1}H–^{1}H experiments are normally insufficient to adequately resolve all cross-peaks in larger oligosaccharide structures. To extend NMR studies to larger carbohydrates, additional methods to reduce spectral overlap are required. The introduction of ^{13}C-labeled acetyl groups provide additional frequency dimensions that can be used to improve overall spectral dispersion. The frequencies of the ^{13}CO, ^{13}C^{Me}, and ^{1}H^{Me} nuclei are well separated from each other and other signals in the spectrum and can be independently manipulated through selective excitation and (or) decoupling schemes. The (H)C$_{Me}$COH-HEHAHA and H(C$_{Me}$)COH-HEHAHA experiments were designed to correlate sugar-ring ^{1}H frequencies with the acetyl ^{13}CO, ^{13}C^{Me}, and ^{1}H^{Me} frequencies to provide increased spectral dispersion. At the same time these experiments were designed to retain the pure-absorption in-phase nature of the cross-peak multiplets so that accurate sugar ^{1}H–^{1}H *J* couplings could be measured in a single experiment

Correlation of the acetyl ^{13}C and ^{1}H frequencies with the sugar-ring protons is made by coherence transfer from magnetization originating on acetyl ^{1}H^{Me}, rather than an out-and-back

Fig. 3. Pulse sequences used to record (A) the PIP-TOCSY and carbon-decoupled PIP-TOCSY; (B) the H^{Me}, C^{Me}-decoupled HET-COSY; (C) the $HC_{Me}COH$-HEHAHA; and (D) the $HC_{Me}COH$-HETCOSY. In all sequences wide solid bars represent hard 180° pulses and narrow bars represent hard 90° pulses. Shaped 180° pulses are represented as solid filled curves and shaped 90° pulses are represented as gray shaded curves. (A) Homonuclear Hartmann–Hahn mixing uses a DIPSI-3 matching period (76) with a field strength of 4.03 kHz for 35.7 ms. The spin-lock pulse (SLx) was applied for periods of 30–60 ms (usually 60 ms) at the same time as the trapezoidally shaped gradient pulse (gz-trap) (39). This gradient had a maximum strength of 4 G cm^{-1} and the period used to ramp the gradient up to its maximum field strength (and subsequently back down to zero) was 25% of the total gradient duration (30–60 ms). Experiments were conducted with or without GARP (77) decoupling of ^{13}CO frequencies during the direct detection period. (B) The selective 90° pulse acting on ^{13}CO was applied for 600 μs with an e-burp-2 profile (78). The selective 180° pulses (*a*) applied at the $^{13}C^{Me}$ and $^{1}H^{Me}$ frequencies during the middle of the evolution time were seduce–1 180° pulses (79) applied for 250 μs on $^{13}C^{Me}$ (phase modulated by 150 ppm) and 1.4 ms on $^{1}H^{Me}$ (phase modulated by 1.52 ppm). In (C), the pulse sequence was identical to the $(H)C_{Me}COH$-HEHAHA pulse sequence (43) except that an additional incremented evolution time was included within the initial $^{1}H^{Me}$–$^{13}C^{Me}$ INEPT transfer. The $^{13}C^{Me}$ nuclei were inverted using a hyperbolic secant pulse (*d*) and quadratic phase errors were refocused by applying the same pulse at (*e*) but the direction of the frequency sweep was reversed (80–82). In (D), the first part of the pulse sequence is identical to that of (C) up to the time of the broken line marked with a *. The final portion containing the t_3 period was identical to the evolution time period and pulses described in (B). For (B–D), selective ^{13}C 90° pulses acting on *z* magnetization were applied for 600 μs with an e-burp-2 profile (78) and selective ^{13}C 90° pulses acting on transverse magnetization were applied for 600 μs as a Q5 Gaussian pulse (83). Pulse (*b*) was a hyperbolic secant pulse (80, 81), and (*c*) a hyperbolic secant pulse to refocus the quadratic shift, with durations and phase modulations as previously described (43). Gradient strengths and durations were also as previously described (43).

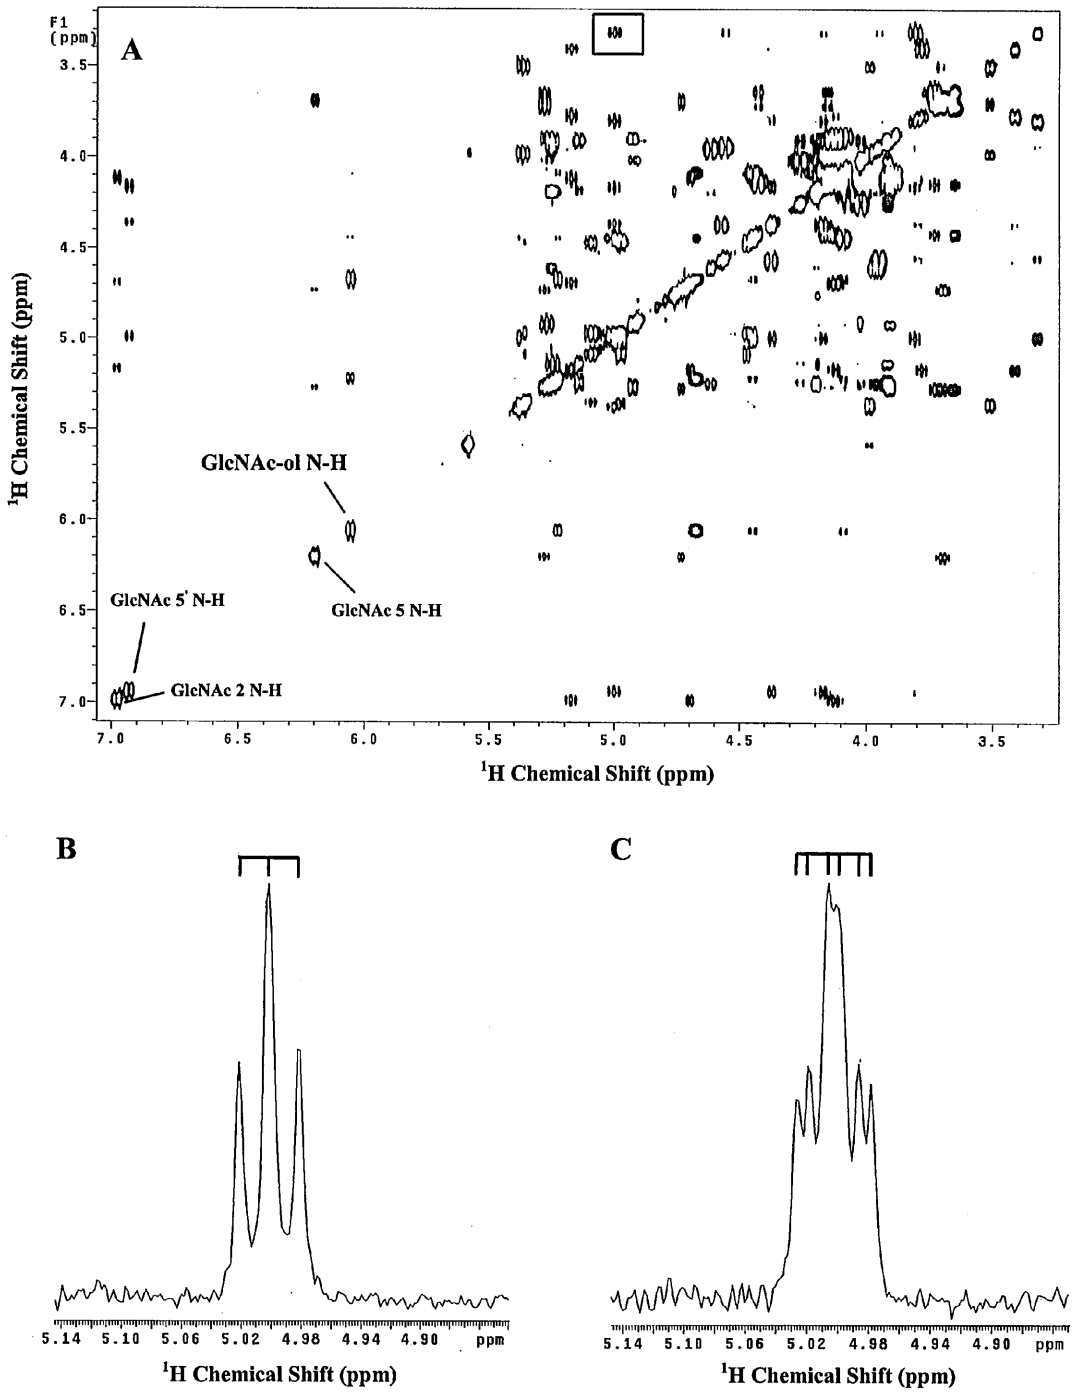
Fig. 4. (A) A PIP-TOCSY spectrum of peracetylated oligosaccharide **1** having doubly ^{13}C-labeled acetyl groups. The spectrum (A) was accumulated with inclusion of the GARP decoupling scheme (77) to decouple ^{13}CO frequencies in the directly detected dimension. It was accumulated in H_2O-saturated $CDCl_3$ at 27°C. The magnetization transferred from GlcNAc N-H signals to other ring protons is readily observable along both frequency axes (the N-H diagonal peaks are indicated). A trace through the boxed multiplet in (A) is shown in (B), representing the sugar backbone H-3 multiplet of GlcNAc5′. The same multiplet is shown in (C) in an otherwise identical spectrum accumulated without ^{13}CO decoupling during the detection period.



approach starting with magnetization on the sugar-ring protons. The one-bond ^{1}H–^{13}C and ^{13}C–^{13}C couplings within the acetyl spin system are large, and INEPT-type transfers (42) permit efficient coherence transfer through the acetyl system to the acetyl ^{13}CO (43). This results in a significant time saving (total time 16 ms) as compared with an HMBC-type transfer from a sugar-ring proton to an acetyl ^{13}CO (about 125 ms). In addition, each step in the direct INEPT transfer through the acetyl system is dependent on a single *J* coupling, and not a range of *J* couplings so coherence transfer can be optimized and arranged so that it occurs pure in-phase to the acetyl ^{13}CO. Subsequent coherence transfer

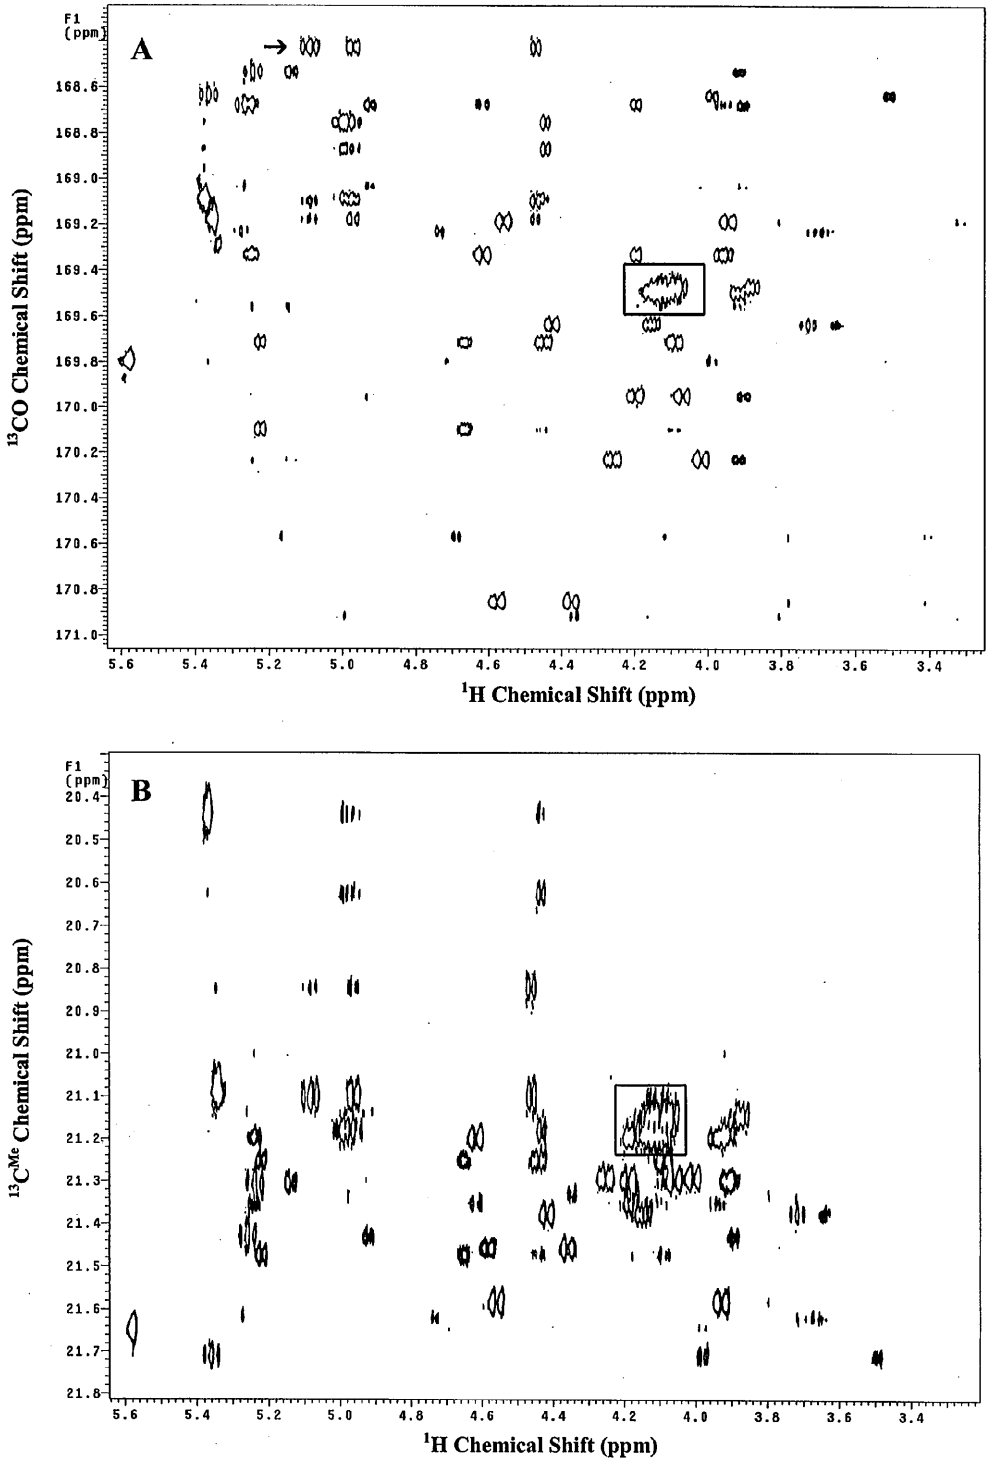
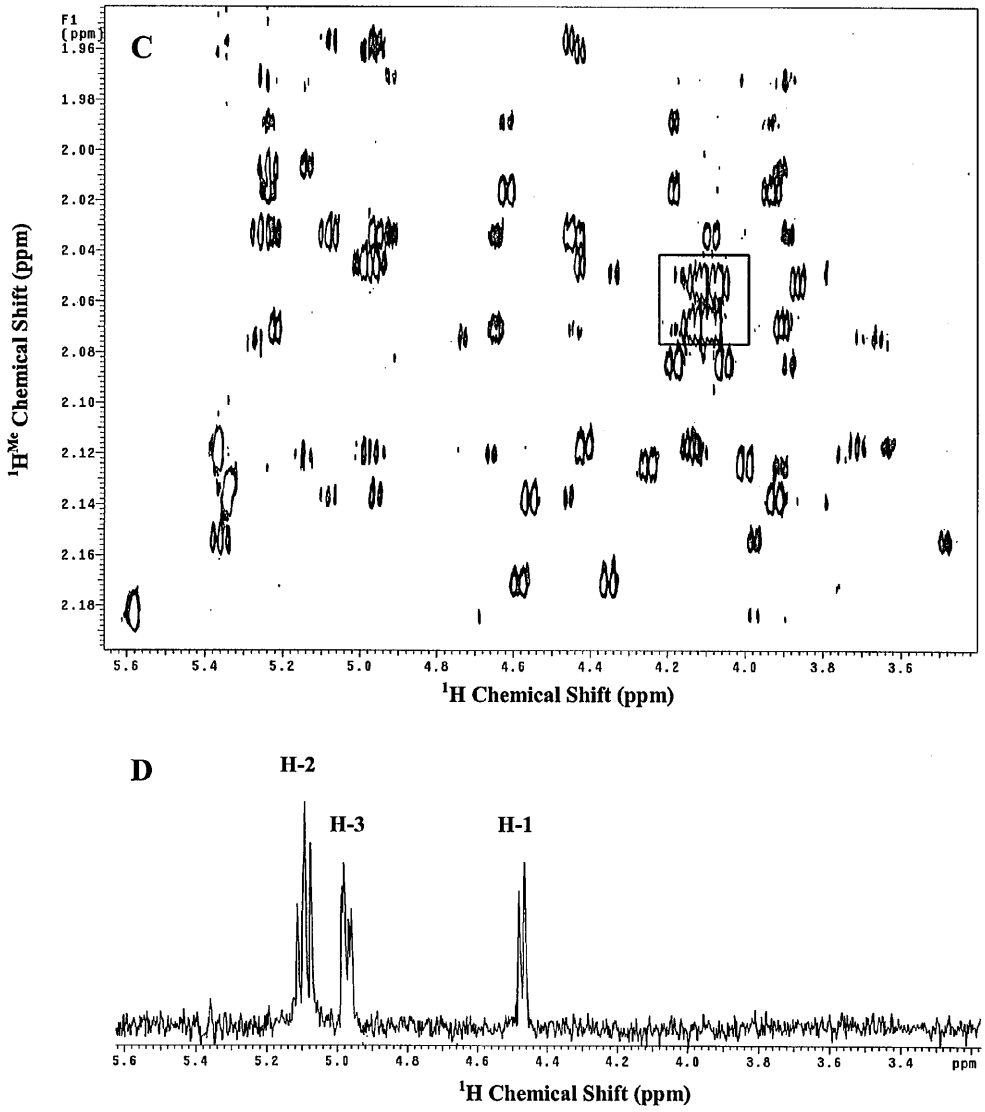
Figs. 5A,B. Correlations of sugar-ring proton frequencies to acetyl group ^{13}CO (A), $^{13}C^{Me}$ (B), and $^{1}H^{Me}$ (C) frequencies using the $HC_{Me}COH$-HEHAHA pulse sequence of Fig. 3C. Spectra were all acquired using peracetylated oligosaccharide **1** having doubly ^{13}C-labeled acetyl groups. The pure-absorption in-phase nature of the multiplets is shown in panel (D), which represents a trace taken parallel to the ^{1}H axis at the arrow shown in panel (A). These multiplets arise from protons of the Gal6 residue that correlate to the acetyl ^{13}CO at the 2-position of the sugar. Spectra were all recorded in D_2O-saturated $CDCl_3$ at 27°C.



from the ^{13}CO to the sugar-ring protons may be achieved through different methods but in-phase transfer is best achieved through the use of heteronuclear Hartmann–Hahn matching (HEHAHA, 44–46). The HEHAHA transfer step to a sugar proton is accompanied by homonuclear Hartmann–Hahn (HOHAHA) transfer of magnetization within the sugar spin system (44–46). This is unavoidable but is advantageous as additional sugar–proton correlations are observed to a single ^{13}CO frequency (43). When combined with suppression of zero-quantum effects as described

© 2002 NRC Canada

Figs. 5C,D.



above (39) these experiments result in cross-peak multiplet patterns that are in-phase and purely absorptive. From these multiplets, scalar couplings between ring protons can be accurately measured and used to define sugar stereochemistries (43). The pulse sequence shown in Fig. 3C can be used to establish correlations from the sugar protons to any combination of the acetyl-group nuclei in 3-D or 4-D experiments at the investigator's discretion.

Shown in Figs. 5A–C are 2-D spectra of peracetylated nonasaccharide-alditol **1**, where sugar protons were separately correlated to the ^{13}CO, $^{13}C^{Me}$, and $^1H^{Me}$ frequencies of the acetyl groups using the $HC_{Me}COH$-HEHAHA pulse sequence of Fig. 3C. The $(H)C_{Me}COH$-HEHAHA pulse sequence correlating $^{13}C^{Me}$, ^{13}CO, and $^1H^{ring}$ was described earlier (43). The more general pulse sequence (Fig. 3C) also achieves correlations to $^1H^{Me}$ frequencies by including an incremented evolution period in the first $^1H^{Me}$–$^{13}C^{Me}$ transfer step. For oligosaccharide **1**, this particular correlation (Fig. 5C) was useful for resolution of some sugar-proton signals that did not resolve with correlation to either the ^{13}CO or $^{13}C^{Me}$ frequencies (boxed in Figs. 5A–C). In the oligosaccharides we have examined to date, the different acetyl-group frequencies appear to correlate randomly to sugar-ring protons. Hence, for any given oligosaccharide, it is difficult to predict which correlations to the ^{13}CO, $^{13}C^{Me}$, or $^1H^{Me}$ frequencies will provide the best spectral dispersion for a 2-D experiment. In practice, performing all three 2-D variants first is useful and consumes less NMR time than 3-D experiments (Figs. 5A–C). A 1-D trace at the F_1 frequency shown with the arrow in Fig. 5A is presented in Fig. 5D. From a series of similar traces at different F_1 frequencies and from different 2-D subspectra, many of the ^1H–^1H J couplings can be extracted. So far, in combination with PIP-TOCSY experiments, these 2-D spectra have resulted in assignments and measurements of almost all ^1H–^1H J coupling constants for oligosaccharides that we have examined containing up to 15 sugars.

Taken together, the above correlations provide a powerful combination for assignment of sugar-proton frequencies, for resolution of cross-peaks in multiple dimensions, and for

Note: Data were extracted from spectra accumulated in H_2O-saturated $CDCl_3$ at 27°C, relative to internal TMS. Chemical shifts were primarily determined from traces of purely absorptive in-phase multiplets in the directly detected dimension of 2-D PIP-TOCSY or HC_{Me}COH-HEHAHA experiments. All multiplets were first-order, except for a minor second-order effect observed for Gal6′ H-2 and H-3 signals.

measurement of ^1H–^1H *J* couplings. As an example, the complete assignment of the chemical shifts and coupling constants of nonasaccharide-alditol **1** is presented in Table 1.

Assignment of *O*-acetyl and glycosidic linkage positions

Both the gCOSY and PIP-TOCSY experiments described above can be used to identify the sites of acetylation in cases where cross-peak multiplets are well resolved. In larger oligosaccharides, however, spectral overlap occurs and the detail in cross-peak multiplets that indicates the presence of an additional ^{13}CO–$^1H^{ring}$ coupling may be obscured. In these instances additional experiments are required to establish sites of acetylation.

We have used two different methods to correlate the acetyl ^{13}CO frequencies with the sugar protons *directly at the site of acetylation*. The first was heteronuclear COSY (HET-COSY) with detection of ^1H signal and the second was $H(C_{Me})COH$ (43). Figure 6 shows the HET-COSY spectrum of nonasaccharide-alditol **1** recorded with the pulse sequence shown in Fig. 3B, where the $^{13}C^{Me}$ and $^1H^{Me}$ were decoupled during t_1. All three-bond correlations between ^{13}CO and $^1H^{ring}$ were observable and permitted measurement of the $^3J_{C,H}$ for ring protons based on the single splitting along the ^{13}C axis. For the exocyclic methylene protons (-CH_2OAc), ^{13}CO is coupled to two protons resulting in two splittings along the ^{13}C dimension, and which often results in cancellation in the middle of the multiplet along that axis. These are easily discernable from the cross-peak multiplets of ring (-CH(OAc)-) protons for two reasons. First, two proton frequencies correlate to a single ^{13}C frequency, which are both seen in traces at specific ^{13}C (F_1) frequencies (Fig. 6). Second, the chemical shifts of acetylated exocyclic (-CH_2OAc) sugar protons are found from 3.8 to 4.7 ppm, always upfield of acetylated sugar-ring (-CH(OAc)-) protons, which occur in the region from 4.8 to 5.8 ppm (Fig. 6).

The HET-COSY correlation (Fig. 3B) begins with the intrinsic magnetization of the ^{13}CO nuclei. We have also examined another related pulse sequence shown in Fig. 3D termed (HC_{Me})COH-HETCOSY, where the magnetization originates in $^1H^{Me}$ protons and is transferred to ^{13}CO nuclei through two INEPT steps via the $^{13}C^{Me}$ nuclei. This pulse sequence resulted in comparable cross-peak intensities (^{13}CO-sugar ^1H cross-peaks) to those observed for the direct pulse on ^{13}CO nuclei of the pulse sequence shown in Fig. 3B. The (HC_{Me})COH-HETCOSY experiment will, however, be important for measuring these coupling constants in larger oligosaccharides, where spectral resolution in additional dimensions is necessary. The implementation of incremented evolution times in both INEPT transfers is straightforward, as shown in Fig. 3C.

The $H(C_{Me})$COH pulse sequence (43) may be used to observe ^{13}CO–$^1H^{sugar}$ correlations with higher sensitivity than the HET-COSY. This experiment completely collapses multiplets in the indirect dimension and results in better resolution and sensitivity than the HET-COSY-based experiment. The cross-peaks in this spectrum are more complex and are not pure in-phase. The intensity of the cross-peaks are dependent both on ^{13}CO–$^1H^{ring}$ and $^1H^{ring}$–$^1H^{ring}$ coupling constants. Consequently, it may be necessary to acquire a series of spectra with different delays in the final

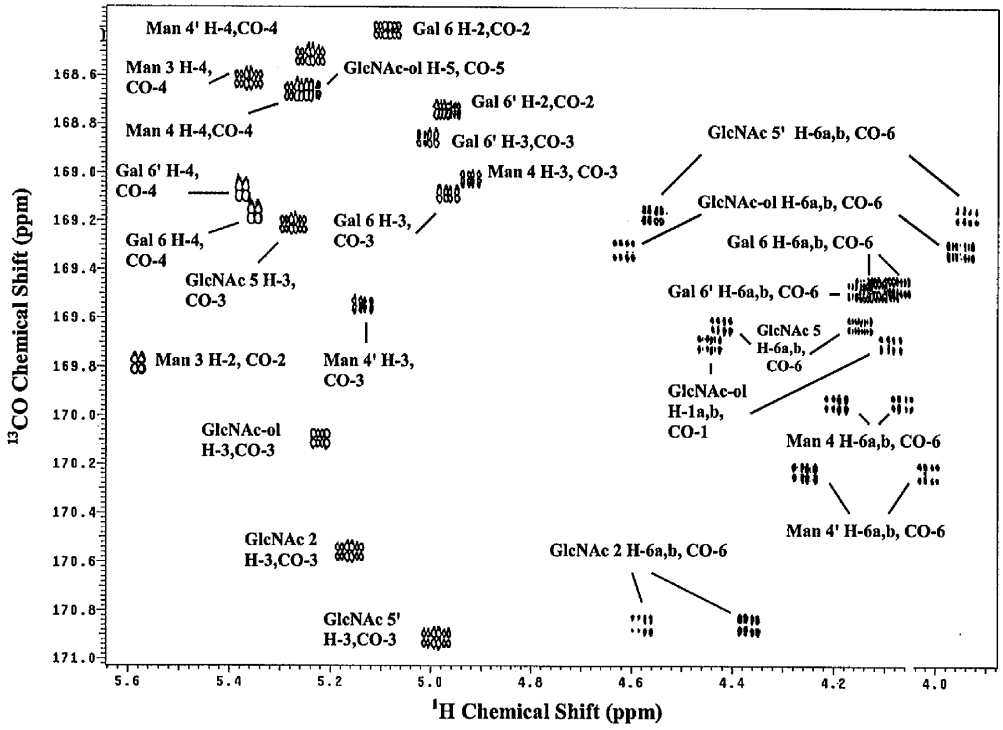
Fig. 6. Direct sugar-^{1}H/acetyl-^{13}CO couplings as revealed by the $^{13}C^{Me}$, $^{1}H^{Me}$-decoupled HET-COSY spectrum (pulse sequence of Fig. 3B). The spectrum was accumulated using peracetylated oligosaccharide **1** having doubly ^{13}C-labeled acetyl groups. Cross-peaks of all correlations are indicated. This spectrum was recorded in H_2O-saturated $CDCl_3$ at 27°C.



INEPT period to observe all of the correlations (43). From a practical perspective, if enough material is available to perform the HET-COSY-type experiment in a reasonable time period (8–10 h) it provides all the ^{13}CO-sugar ^{1}H correlations and enables measurement of their couplings in one experiment. If some of the cross-peaks (usually the ^{13}CO-6/H-6 cross-peaks) prove more difficult to observe in a reasonable time period, they will be observable using the H(C_{Me})COH pulse sequence (discussed in detail in ref. 43). Again, if necessary, additional dimensions can be added in the H(C_{Me})COH experiment (ie., during the $^{1}H^{Me}$–$^{13}C^{Me}$ or $^{13}C^{Me}$–^{13}CO transfers) as shown in Fig. 3C.

The above experiments result in correlations that reveal all the sites of acetylation. By inference, the positions of glycosidic linkages can be assigned, as they can never be acetylated. The positions of glycosidic substitutions are readily distinguished because the H-1 signal shows only one $^{3}J_{H,H}$ coupling (to H-2), the H-5 (of hexopyranosides) shows three $^{3}J_{H,H}$ couplings (to H-4, H-6a, and H-6b), and a glycosidic substitution site shows just two $^{2\text{ or }3}J_{H,H}$ couplings, enabling a glycosidic linkage position to be unambiguously determined.

For all oligosaccharides that we have so far examined, a combination of gCOSY, PIP-TOCSY, (H)C_{Me}COH-HEHAHA, and H(C_{Me})COH-HEHAHA pulse sequences have proven adequate to assign all sugar-ring protons and measure all their ^{1}H–^{1}H *J* couplings. The HET-COSY and H(C_{Me})COH experiments have enabled all acetylated positions to be assigned. An additional experiment, the H(C_{Me})COH-RELAY (described in ref. 43) may be used to correlate acetyl ^{13}CO to sugar ^{1}H frequencies both at the site of acetylation and to additional protons immediately adjacent to those sites. This experiment may prove useful for larger oligosaccharides as an independent method to establish sugar-proton assignments or to confirm them.

Interresidue adjacencies via NOESY and ROESY experiments, and occasional scalar couplings

NOESY and ROESY correlation experiments (47–50) can be used to establish interresidue adjacencies after the positions of glycosidic linkages have been unambiguously established using through-bond correlations between acetyl ^{13}CO and sugar protons. These experiments were actually demonstrated some time ago in peracetylated structures examined without ^{13}C in the acetyl groups (51, 52). Nonasaccharide-alditol **1** yielded reasonably strong NOESY cross-peaks. A number of cross-peaks from the anomeric protons were assignable in this structure and the interproton NOE interactions are shown in Scheme 1. These assignments permitted monosaccharide adjacencies to be established, which, along with the through-bond assignments of the linkage sites via acetylation positions, enabled the overall structure to be deduced *from first principles.* Based on observations so far, assignment of 2-D NOESY or ROESY cross-peaks is the most difficult aspect of overall structural assignment. The use of ROESY is required for structures where $\omega\tau_c$ approaches 1, where ω is the angular Larmor frequency and τ_c is the motional correlation time. For acetylated oligosaccharides this is in the range of 4–6 sugars. To improve resolution in additional dimensions, we are currently developing methods to correlate acetyl ^{13}C nuclei to ring protons prior to the NOESY transfer step.

As was highlighted by Otter and Bundle (53), four- or five-bond *interresidue* ^{1}H–^{1}H *J* couplings may be observed

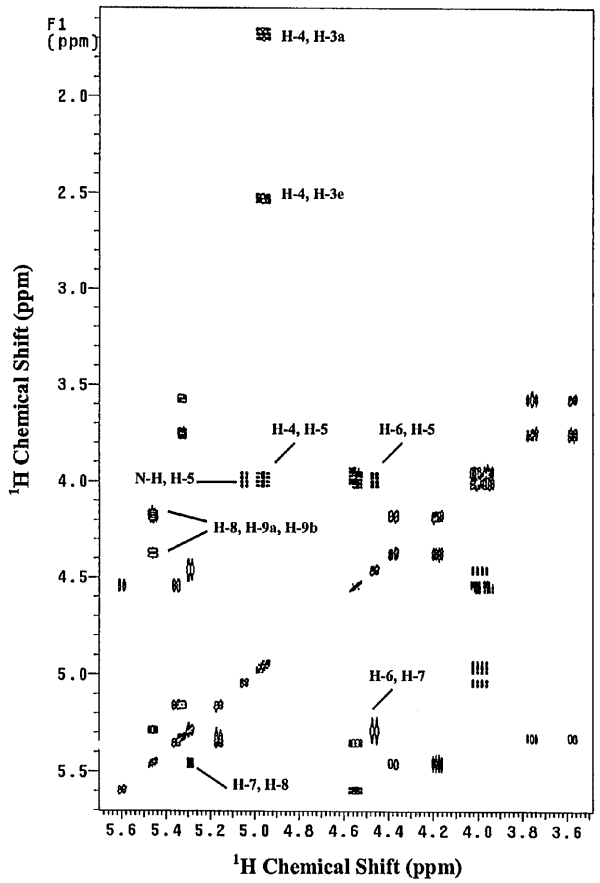
Fig. 7. A gradient COSY spectrum (^{13}CO-decoupled) of doubly ^{13}C-labeled, peracetylated 2-acetamido-2-deoxy-6-*O*-α-(5-*N*-acetylneuraminyl)-D-galactitol (**3**). Spectra were recorded in water-saturated $CDCl_3$. Individual cross-peaks of the *N*-acetylneuraminic acid residue are indicated.



between residues across glycosidic linkages in COSY experiments. We have also observed these correlations, which are much less intense than $^{2\text{ or }3}J_{H,H}$. The ability to observe these long-range couplings depends on whether enough sample is available for the signals to be detected above the noise in the time selected to run the experiment. If observed, they provide corroborative information to NOESY or ROESY data.

Results with sialylated oligosaccharides

Oligosaccharides having *N*-acetylneuraminic acid are straightforward to peracetylate with minor modifications of the method. The basic pattern of the acetylated NeuNAc spin system and some salient points for assigning and measuring ^{1}H–^{1}H *J* couplings can be illustrated with a few examples of smaller structures (**2**–**4**). The protons on the acetylated positions 4, 7, and 8 are found downfield with respect to those on the acetylated position 9, *N*-acetylated position 5, and cyclization position 6. The amide proton overlaps approximately with the downfield *O*-acetylated protons. The H-3e/H-3a protons are both found well upfield, between 1.5–2.7 ppm. A ^{13}CO-decoupled gCOSY experiment with doubly ^{13}C-labeled *O*-peracetylated structure **2**, as its deuterated triethylammonium salt, permitted full assignment of the spin system. The ^{1}H–^{1}H *J* couplings (Hz) were extracted from a 1-D spectrum and are as follows: $J_{3e,3a}$ = –12.0; $J_{3a,4}$ = 11.9; $J_{3e,4}$ = 4.6; $J_{4,5}$ = 10.3; $J_{NH,5}$ = 10.2; $J_{5,6}$ = 10.6; $J_{6,7}$ = 2.2; $J_{7,8}$ = 7.3; $J_{8,9a}$ = 2.9; $J_{8,9b}$ = 6.4; $J_{9a,9b}$ = –12.3. These coupling constants were similar for sialic acids in all oligosaccharides we have examined so far. For example, a ^{13}CO-decoupled gCOSY spectrum of disaccharide-alditol **3** (Fig. 7) shows minor chemical shift differences from **2**, but the sialic acid coupling networks are straightforward to clarify starting with the H-3a/H-3e signals. Using trisaccharide-alditol **4**, the ^{13}CO-decoupled PIP-TOCSY spectrum (Fig. 8A) reveals the three independent spin systems. Traces taken at the arrows shown in Fig. 8A reveal the crucial couplings of all the ring protons for the sialic acid and β-GlcNAc residue (Figs. 8B and C). Magnetization starting from H-4 of the sialic acid proceeds to H-3a, H-3e, H-5, N-H, and H-6 (Fig. 8B). The pure in-phase nature of all these multiplets permitted accurate measurement of ^{1}H–^{1}H *J* couplings and an immediate identification of the sialic acid spin system. Similarly, magnetization starting from N-H of the β-GlcNAc residue proceeded to H-2, H-1, H-3, and H-4 of the sugar ring, and the measurable coupling constants of these multiplets enabled an unambiguous determination of the stereochemistry of this residue within the larger molecule. In a similar manner, the pure-absorption in-phase correlations of sugar-ring protons to acetyl ^{13}CO, $^{13}C^{Me}$, or $^1H^{Me}$ frequencies observed in $HC_{Me}COH$-HEHAHA experiments enabled sugar ^{1}H–^{1}H *J* couplings to be measured directly (spectra not shown).

Comparisons with other derivatives or correlations to sugar hydroxyl protons

As was indicated earlier (29), in theory, any functional group having magnetically susceptible nuclei could be used to identify the positions of free hydroxyl groups, which includes the protons of hydroxyl groups themselves (54–56) prior to derivatization. In consideration of derivatives in general, one key issue is whether the majority of oligosaccharides can actually be fully derivatized. We have examined acetylation, methylation, and trimethylsilylation as potential derivatives for NMR studies as they are the most commonly used to fully derivatize carbohydrate structures.

The protons of hydroxyl groups in underivatized oligosaccharides correlate to sugar-ring protons in predominantly H_2O solutions (54–56) or in polar aprotic solvents such as deuterated dimethylsulfoxide or *N*,*N*-dimethylformamide. Three major advantages of peracetylation are evident over direct correlation of sugar-ring protons to hydroxyl protons. First, spectral dispersion of the sugar-ring protons is not significantly altered in H_2O–co-solvent mixtures or in polar aprotic solvents, and hence these protons are still crowded within a 1.0 ppm region. Second, there are difficulties in limiting fast exchange of hydroxyl protons in water to the point where reasonably narrow linewidths can be observed. This requires the use of co-solvents that permit temperatures to be lowered below 0°C and the careful deionization of solutions (56). These lower temperatures also affect motional correlation times and broaden linewidths by other mechanisms. In polar organic solvents, very dry conditions are important. For example, we have examined the use of *N*,*N*-dimethylformamide-d_7 (Isotec) well dried over molecular sieves (Sigma, product M-0133, 1/16 inch pellets). Exchange was negligible in the complete absence of water and measurable

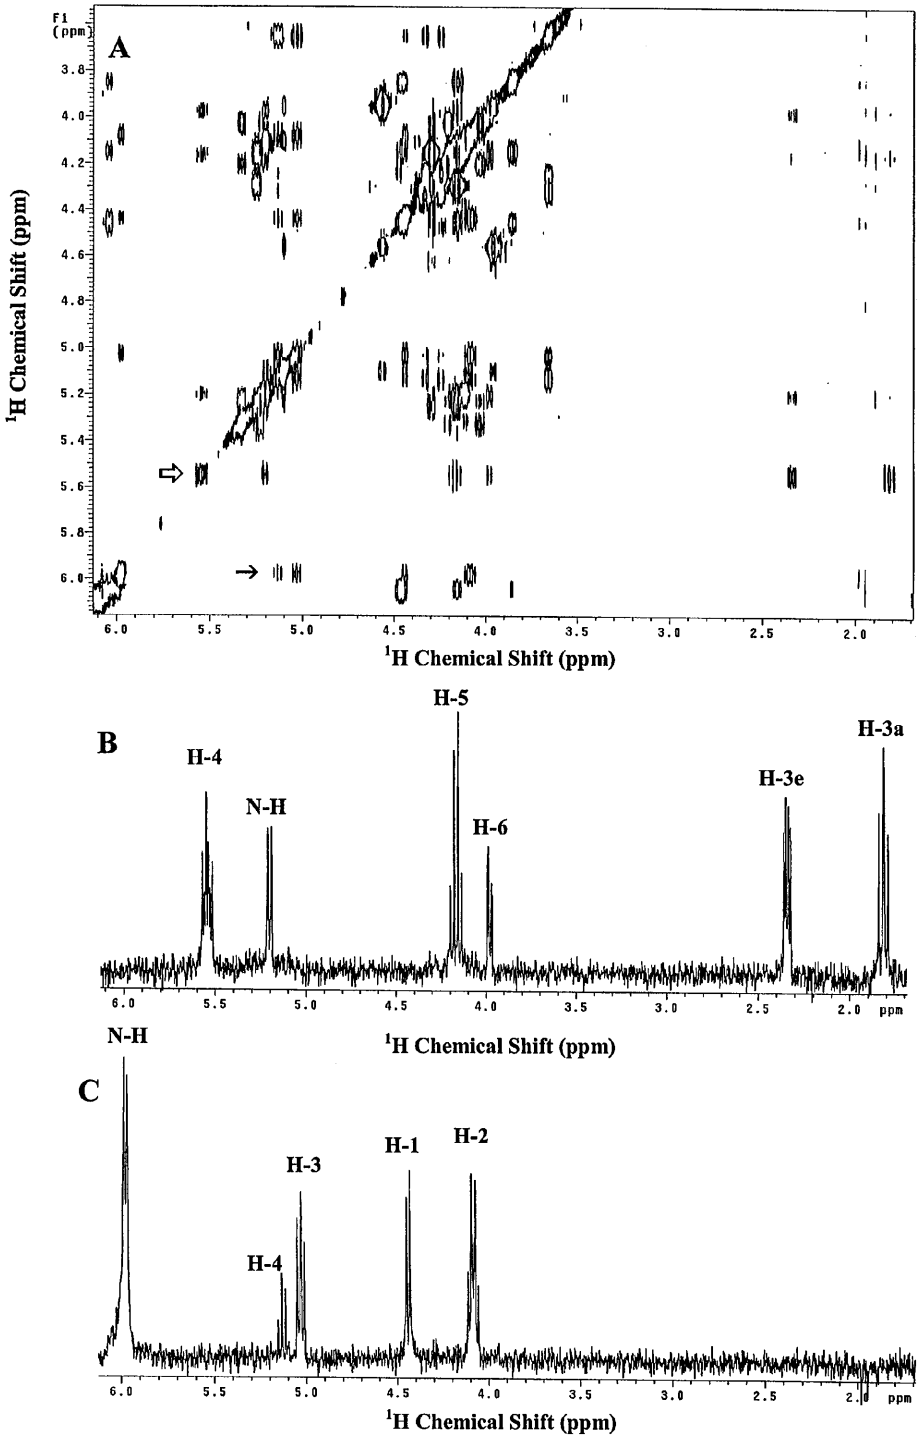
Fig. 8. (A) A PIP-TOCSY spectrum of peracetylated oligosaccharide **4** having doubly ^{13}C-labeled acetyl groups, derived from bovine submaxillary mucin. The spectrum was performed with GARP decoupling in the directly detected dimension, in water-saturated $CDCl_3$ at 27°C. Traces parallel to the F_2 (horizontal axis) are shown, representing signals at the F_1 frequencies pointed out with the large, open arrow (in B), and the smaller arrow (in C). The trace in (B) reveals part of the spin system of the *N*-acetylneuraminic acid. Magnetization derived from H-4 is transferred through the spin system from the H-3's to H-6 and these correlations were observable as purely absorptive in-phase multiplets. Similarly, the trace in (C) shows the coupling network of the β-GlcNAc residue. Magnetization derived from the N-H proton is transfered from H-1 to H-4. These traces enabled all sugar-ring ^1H–^1H *J*-coupling constants to be measured for these monosaccharides.



sugar-^{1}H/hydroxyl-^{1}H coupling constants can be extracted *at room temperature*. The hydroxyl proton signals resonate downfield of sugar-ring protons as well-resolved doublets of narrow linewidth (data not shown). Third, unlike acetylation,

© 2002 NRC Canada

where three independent frequencies may be correlated, hydroxyl protons permit only one additional frequency domain to be correlated to ring protons.

The use of methylated derivatives also proved to have specific drawbacks. Most importantly, permethylation does not result in any appreciable downfield shifting of sugar-ring proton signals, so overlap of these multiplets is essentially the same for derivatized sugars as for the underivatized structures. Added to this difficulty, methyl proton signals almost completely overlap with the sugar-ring proton multiplets, which prevents any selective excitation or decoupling of methyl proton frequencies. Pulses on the methyl carbon result in the vast majority of coherence transfer to methyl protons through the large $^1J_{C,H}$ coupling, which cannot be selectively decoupled. With peracetylation, the availability of three different frequency domains that can be independently manipulated using selective decoupling and (or) excitation pulses is far superior for multidimensional experiments.

We also attempted trimethylsilylation of smaller di- and trisaccharide-alditols, based on a report by Uhrin et al. (57) that correlated ^{29}Si to sugar protons at the site of trimethylsilylation. In reactive reagents for derivatization such as trimethylsilyl chloride, ^{29}Si is, however, commercially limited to natural abundance (5.1%). Also, trimethylsilylation does not induce an appreciable downfield shift of protons at trimethylsilylated positions (see ref. 57 and preliminary experiments, not shown). TMS ethers, being prone to hydrolysis, are also less stable than acetyl groups — rendering further chromatography of such derivatives essentially impossible, should minor initial oligosaccharide contaminants be present in the sample. Hence, we suggest that for the purposes of structural elucidation of oligosaccharides, the use of doubly ^{13}C-labeled acetyl esters have several important advantages over the use of either methyl or trimethylsilyl ethers, or over the use of protonated hydroxyl groups themselves.

Practical aspects of peracetylation and sample preparation for NMR

The use of the superacylation catalyst 4-dimethylaminopyridine in a pyridine–acetic anhydride solution markedly accelerates acylation and all solvent components can be almost entirely removed by volatilization. Additional partitioning between chloroform and a deuterated triethylammonium sulfate solution completely eliminates the catalyst and additional washes of the chloroform phase results in essentially pure peracetylated product. There are two crucial issues in the acylation process worthy of note. First, any salts in a sample prior to drying can result in poor solubility in the pyridine–acetic anhydride solution. Both sonication and prior concentration in vacuo in the presence of glycerol can help to alleviate this problem, but the best solution for neutral oligosaccharides is to ensure they are free of salt by passage through small well-washed columns (in Pasteur pipettes having a glass wool plug) of Dowex AG50W-X8 (H^+ form, 100–200 mesh) and AG1-X8 (OAc^- form, 100–200 mesh) prior to concentration. Second, sialylated oligosaccharides must be converted to triethylammonium or tripropylammonium salts, as described in the *Experimental* section. It is crucial to observe full solubility of the sample prior to heating. We have found the described conditions are required to completely acetylate without the need for chromatography. NMR is the best tool to check for completion of acetylation, where any minor components will be evident and where the heteronuclear COSY experiment permits a count of the acetyl ^{13}CO/sugar ^{1}H correlations. It should be noted that these acetylation conditions were determined for oligosaccharides containing fewer than ~20 monomers, and should be applicable to a majority of structures in this size range. Methods were designed for volatility of solvents and other components to permit immediate analysis by NMR. For large polysaccharides, a number of other acylation methods have been reported, especially in the peracylation of cellulose, which is of commercial importance (reviewed in ref. 58). The conditions reported are especially effective in initial solubilization of larger polymers, and may be applicable if solubilization in the system reported herein is ineffective.

Regarding NMR spectroscopy, the chemical shifts of the samples in $CDCl_3$ alone are not reproducible. The addition of water or D_2O to saturate the solvent has significant effects on chemical shifts and is mandatory for reproducible results. Presumably by saturating the $CDCl_3$ phase, hydrogen-bonding and other (electrostatic) dipole–dipole interactions are limited within and between molecules. Relative to internal tetramethylsilane, chemical shifts are reproducible to within ±0.002 ppm whether obtained from 1-D experiments or from traces in the directly detected dimension of 2-D or 3-D experiments where purely absorptive in-phase multiplets are recorded with the same Hz per point ratio as 1-D experiments. Depending on the experiments that need to be performed to extract all pertinent data, approximately 35–250 nmol of sample is required, and can take from about 1 to 4 days of NMR time to complete.

Conclusions

Major advantages to peracetylation with doubly ^{13}C-labeled acetyl groups

Compared to the typical acquisition of NMR data of oligosaccharides in D_2O, any one of the advantages below would be an important reason to peracetylate with doubly ^{13}C-labeled acetyl groups. Together, they provide a powerful justification for use of this strategy for carbohydrate structural elucidation. The combined acetylation–NMR approach provides new tools for the extraction of detailed structural information of larger oligosaccharides.

(*i*) Enables linkage sites to be determined — The ability to assign the sites of acetyl-group substitution is based on the 2.5–4.7 Hz through-bond coupling ($^3J_{C,H}$) observed between acetyl ^{13}CO carbons and ring protons at the positions of acetylation (29, 43). The position of a glycosidic linkage can therefore be unambiguously assigned. With underivatized structures in D_2O, this information cannot be sensitively obtained. Observation of through-bond ^{13}C–^{1}H couplings across glycosidic linkages is very insensitive in natural abundance structures. The strongest interresidue ^{1}H–^{1}H NOE's may not be between two protons directly across the glycosidic linkage (59), and the same conclusion was reached for long-range interresidue correlations sometimes seen in gCOSY experiments (53).

© 2002 NRC Canada

(*ii*) Increased spectral dispersion in the sugar ^{1}H dimensions — Underivatized oligosaccharides in D_2O display a spectral range for ring protons between ~3.2 and 4.2 ppm and anomeric signals from ~4.4 to 5.4 ppm. Hence, six out of seven signals for a typical hexose reside in a range of 1.0 ppm, resulting in severe overlap and frequent strong coupling effects. In peracetylated structures, sugar-ring proton signals range from ~3.2 to 5.8 ppm, approximately 2.6–2.7-fold greater than in D_2O. This is almost a sevenfold increase in the area where cross-peaks are found in ^{1}H–^{1}H correlated experiments, an enormous advantage for solving larger structures. In addition, far fewer strong couplings occur. These are both important advantages over biosynthetic ^{13}C labeling of the sugar backbone, where ^{1}H dispersion is unchanged.

(*iii*) Markedly improves the ability to prove stereochemistry of monosaccharides within oligosaccharides, through combined use of indirect dimensions and pure in-phase coherence transfer — Based on the orientation of hydroxyl groups with respect to the sugar ring, each monosaccharide has its own characteristic pattern of *J*-couplings. Measurement of ring ^{1}H–^{1}H *J* values by extraction of purely absorptive in-phase multiplets (39) is crucial for delineation of individual spin systems. Resolution of ring proton multiplets is markedly improved through their correlation to the ^{13}CO, $^{13}C^{Me}$, or $^{1}H^{Me}$ dimensions. From these multiplets, $J_{1,2}$, $J_{2,3}$, $J_{3,4}$, and $J_{4,5}$ may be accurately measured, which defines the stereochemistry, anomeric configuration, and ring form of an individual sugar. For pyranosides, the ring conformations are relatively rigid and appear essentially the same after acetylation. We have not yet examined oligosaccharides containing furanosides, but expect that acetylated furanosides will be more flexible, and that more information regarding the *J*-coupling patterns of acetylated furanosides with specific substitutions will need to be amassed from model structures prior to confident identification of their stereochemistries in unknown molecules.

(*iv*) Greatly increases sensitivity in experiments using ^{13}C frequencies — Experiments designed to correlate acetyl ^{13}C frequencies with sugar-ring protons, or that compare ^{13}C–^{1}H coupled multiplets vs. carbon-decoupled spectra, can be performed at ~90-fold greater sensitivity than any natural abundance spectra. This would simply not be possible without the introduction of the ^{13}C acetyl groups. These advantages apply to oligosaccharides isolated from virtually any source, and are not limited to oligosaccharides prepared by biosynthetic ^{13}C-labeling of sugar backbone carbons.

(*v*) Provides flexibility in the type of NMR experiments that are possible — The widely separated frequencies of the ^{13}CO, $^{13}C^{Me}$, and $^{1}H^{Me}$ nuclei permit independent manipulation through band-selective excitation and (or) decoupling schemes. This provides a powerful means for controlling magnetization transfers and for elimination of unwanted couplings during evolution or direct-detection periods, thereby simplifying cross-peak multiplet structures in the different dimensions as desired.

(*vi*) Amide protons in HexNAc residues resonate downfield — The NH protons of HexNAc residues resonate well downfield in water-saturated $CDCl_3$ (5.9–7.0 ppm), and these protons selectively identify HexNAc spin systems via pure in-phase homonuclear Hartmann–Hahn transfer. In D_2O, these protons are quickly exchanged in underivatized structures, although it is possible to correlate them in predominantly H_2O solutions (60).

(*vii*) Advantages over other functional groups we have examined — These were pointed out in the *Results and discussion* section; major advantages of acetylation over methylation or trimethylsilyation were evident, as well as over the use of hydroxyl protons themselves.

Information not obtained by these methods

Regarding information that cannot be extracted with these methods, the determination of specific enantiomers (D or L forms) of monosaccharides within oligosaccharides is currently not possible. Also, unambiguous identification of inorganic substituents having magnetically susceptible nuclei at low natural abundance is not possible, although a substitution site would be evident. The presence of non-protonated carbons, as occurs in uronic acids, or novel branched-chain monosaccharides, for example, would also warrant use of additional methods. In these cases, degradation to monosaccharides (61, 62) or mass spectrometry (63, 64) would be either advantageous or necessary. Mass spectrometry of intact oligosaccharides should always be performed as it provides a completely independent vantage for structural evaluation. We use it routinely because it readily reveals any substituents, such as sulfates, unobservable by NMR, and because it provides important confirmatory information regarding branch patterns and potentially linkage positions when cross-ring cleavages occur. Although peracetylated oligosaccharides can be examined by mass spectrometry, direct losses of ketenes are abundant and permethylated structures yield more detailed structural information. Prior peracetylation is however fully compatible with latter permethylation, as acetylation of carbohydrate structures increases their initial solubility in dimethylsulfoxide during the permethylation procedure. The acetates are rapidly cleaved and the sites are then available for methylation.

The strategy reported here of combining tailored NMR pulse sequences with ^{13}C-acetylation of oligosaccharides provides a great deal more structural information than can be garnered by other NMR methods. The advantages so outweigh conventional NMR spectroscopy of underivatized structures in D_2O that for the purposes of primary structural elucidation we currently peracetylate routinely. It is interesting to note that back at a time when 40 MHz was considered a "high-field" instrument, the very first spectra of carbohydrates happened to be obtained from sugar peracetates, which showed just enough resolution to decipher details of their fine structure. In what appears to be the very first report of carbohydrate NMR, Lemieux and Kullnig (5) stated that "The proton resonance spectra of a variety of fully acetylated sugars and sugar alcohols were determined in chloroform solution in order to gain an appreciation of the possible use of this new physical method in the field of carbohydrate chemistry. Well-resolved signals were produced by the various kinds of hydrogen atoms found in these compounds, except for the C_5-hydrogen of a hexopyranose acetate, in which case the band is overlapped with that of the C_6-methylene hydrogens."

With the current benefits enjoyed at markedly higher field strength instruments, much larger structures should be possible

to elucidate as ^{13}C-labeled peracetates. Regarding the size of oligosaccharides that might be examined by these new methods, reports from the literature indicate that peracetylated polysaccharides, such as cellulose acetate having >100 monomers (65), display very narrow linewidths when examined in $CDCl_3$ at 50°C, a somewhat higher temperature than reported here. This suggests that some polysaccharides, although very high in molecular weight, have internal mobilities about glycosidic bonds that will render them amenable to these procedures. The often-used approach to polysaccharide elucidation, by internal site-selective cleavage to substructures and fractionation by some means, should enable their structures to be solved by these techniques where such subunits are less than ~20 monomers in size. The upper size limits of oligosaccharides to which these methods may be applicable could be significantly larger at higher temperatures.

Experimental

Oligosaccharides were isolated from bovine fibrin, fetuin, and submaxillary mucin (66–71), and those presented in detail here were illustrative of 40 peracetylated oligosaccharides studied to date having doubly ^{13}C-labeled acetates. All were examined after borohydride reduction (72) to avoid anomeric mixtures at the reducing end. 2-*O*-Methyl-α-D-5-*N*-acetylneuraminic acid was from Sigma.

Peracetylation

Peracetylation was carried out using the superacylation catalyst 4-dimethylaminopyridine, which has been reported to catalyze acylation reactions approximately 10^5 times faster than pyridine alone (73). A dried oligosaccharide (between ~100 μg to 2 mg, in a 1.5 mL vial with Teflon cap) was dissolved in a solution (175 μL) containing 4-dimethylaminopyridine (25 mM, Aldrich, 99+%) in pyridine (99.9+%, HPLC grade, Sigma-Aldrich). To the solution was added acetic anhydride (25 μL, 1,1′,2,2′-$^{13}C_4$, Isotec or Cambridge Isotopes), the vial capped under argon or nitrogen, and the sample heated at 50°C for 5 h. For larger structures, full dissolution accompanied gentle warming, which was carried out at 30–35°C usually up to about 1 h, with occasional brief (about 5 s) sonication periods in a sonication bath being necessary for some oligosaccharides prior to heating to 50°C for 5 h. It was important to observe complete solubilization of the sample prior to heating. Occasional sonication at lower temperatures must be continued for as long as necessary for dissolution. The sample was then concentrated to dryness on a Speed-Vac concentrator (~3–4 h). Most of the 4-dimethylaminopyridine is volatilized under good vaccuum (<50 milliTorr) and residual quantities were subsequently extracted. The product was taken up in 1 mL chloroform and extracted 3 times with 0.5 mL of a solution containing 0.1 M triethylammonium sulfate, pH 6.5 (prepared from triethylammonium-d_{15}, Cambridge Isotopes or Isotec, and dilute sulfuric acid), then 3 times with 0.5 mL water. The chloroform phase was concentrated as above, and the sample was again concentrated in $CDCl_3$ prior to being taken up in 0.7–1.0 mL $CDCl_3$ for NMR, with a trace of tetramethylsilane added as an internal standard. For samples of less than 100 μg, the sample was initially concentrated from 100 μL water containing 1% glycerol, which dried the material in a glycerol phase. This prevented losses due to sticking on glass, and enabled rapid dissolution of structures in the pyridine — superacylation catalyst — acetic anhydride phase. The peracetylated glycerol was volatile, and was completely removed by concentration twice from $CHCl_3$ under vacuum. Sialylated oligosaccharide-alditols were converted to their triethylammonium salts prior to acetylation by inclusion of 10 mM triethylammonium acetate, pH 7, as a buffer during their chromatography on Sephadex G-10 or G-15 columns (used for final desalting after HPLC with NaCl gradients). Sialylated oligosaccharides were peracetylated much more readily as such, rather than as Na^+ salts, due to increased solubility during acetylation. Tripropylamine salts may also be used; they ultimately are replaced during extraction with deuterated triethylammonium sulfate. With small sialylated structures (fully *O*-acetylated structures **2** and **3**) some of the product entered the water phases and needed to be back-extracted in chloroform for further recovery. With larger structures, this was not an issue. After peracetylation, all sialylated molecules were exposed to water during the chloroform–water extraction procedure to ensure hydrolysis of any potential mixed anhydride at the carboxyl group.

Where samples contained a minor oligosaccharide contaminant prior to peracetylation, reversed-phase HPLC was performed to separate products according to Hall and Patrick (74) on a column of Spherisorb ODS-2, 3 μm bead size (Alltech). Peracetylated oligosaccharides are very sensitive to UV detection at 200 nm using acetonitrile–water to elute. With sialylated oligosaccharides, inclusion of 1 mM triethylammonium acetate in the eluent was used as a volatile ion-pairing reagent, which markedly improved retention times.

Sample preparation for NMR spectroscopy

Samples were prepared for NMR experiments by adding water (or D_2O, 10–50 μL) directly to the sample in $CDCl_3$ in a 5-mm NMR tube (Wilmad), which floated on and saturated the $CDCl_3$. Exchangeable protons can be replaced by deuterium or back again with impunity by layering water or D_2O (about 0.3 mL) over the organic phase, allowing time to equilibrate, carefully removing it with an elongated pipette and repeating this twice to fully exchange. In 5-mm tubes, enough $CDCl_3$ was added so that the water was at least 1 cm above the receiver coil. Samples were not mixed, just layered with water; small water droplets stick on the sides of the NMR tube in the area of the coil if mixed thoroughly. The addition of water or D_2O is absolutely necessary to obtain reproducible chemical shifts in $CDCl_3$. In 3-mm tubes having a magnetic susceptibility matched to chloroform, with a glass insert to minimize sample volume to the region of the coil (Shigemi Co.), the sample was dissolved in 200 μL $CDCl_3$, the insert set in position, and water (20 μL) layered on top by adding it down the side of the insert. To prevent evaporation of the solvent, the sample can be effectively sealed using a heat-shrinkable plastic tubing at the top of the tube (product 278–1627B, Radio Shack) and a hot air blower.

NMR spectroscopy

NMR spectroscopy was carried out on a Varian Inova instrument equipped with *z*-axis gradients at a ^1H frequency of

© 2002 NRC Canada

500 MHz. For all samples, experiments were carried out at 27°C, with some samples also recorded at 35°C to compare linewidths. Either a Varian 5-mm or Nalorac 3-mm triple resonance probe was used. The spectrometer was configured with pulse shaping capability on both ^{1}H and ^{13}C transmitter channels and on the gradient channel. Shaped pulse waveforms were generated using the Varian software "Pbox" and verified in the program "Pulsetool," then checked experimentally. Gradient waveforms were generated from in-house programs. Data were either processed with VNMR (Varian) or Felix (MSI Inc.). A mild composite sinebell–Gaussian window function (75) was applied in all dimensions prior to Fourier transformation. Details of specific pulse sequences are indicated in the legend of Fig. 3 and in ref. 43.

A strategy for the one-pot synthesis of sialylated oligosaccharides

Zhiyuan Zhang, Kenichi Niikura, Xue-Fei Huang, and Chi-Huey Wong

Abstract: A new strategy has been developed for the synthesis of branched sialylated oligosaccharides using one-pot technology. Sialyl donors are in general too weak in reactivity to be used as the first glycosyl donors in the one-pot synthesis. When sialic acid is linked to a different sugar such as galactose, the reactivity is, however, significantly enhanced and can be tuned to enable the one-pot synthesis. A combination of NIS–TfOH–AgOTf was used for activation of the thioglycosides to improve the glycosylation yield when a hindered acceptor was used, as illustrated in the one-pot assembly of sialylated hexasaccharide.

Key words: one-pot synthesis, sialyl oligosaccharides, new activation.

Résumé : Faisant appel à une technologie monotope, on a développé une nouvelle stratégie pour réaliser la synthèse d'oligosaccharides sialylés ramifiés. La réactivité des donneurs sialyles est généralement trop faible pour les utiliser comme premiers donneurs de glycosyle dans une synthèse monotope. Lorsque l'acide sialique est lié à divers sucres, comme le galactose, la réactivité est toutefois considérablement augmentée et elle peut être ajustée pour utilisation dans une synthèse monotope. Lorsque des accepteurs stériquement empêchés ont été utilisés, on a fait appel à une combinaison de NIS–TfOH–AgOTf pour l'activation des thioglycosides afin d'augmenter le rendement de la glycosylation; cette technique est illustrée par la synthèse monotope d'un hexasaccharide sialylé.

Mots clés : synthèse monotope, saccharides sialylés, nouvelle activation.

[Traduit par la Rédaction]

Introduction

Sialylated oligosaccharides are attractive targets for synthesis as most cancer cells carry sialylated oligosaccharides as unique markers on their surface (1). However, synthesis of sialylated oligosaccharides remains a major problem (2), mainly due to the low yield and low stereoselectivity in the sialylation step. Strategically, the difficult sialylation should be conducted at the early stage to maximize the overall yield and stereoselectivity. Sialic acid is, however, often found at the nonreducing end of oligosaccharides, and most methods developed for oligosaccharide synthesis start from the reducing end to the nonreducing end. The strategy based on Danishefsky et al.'s (3) glycal assembly, via epoxide intermediates, starts from the nonreducing end, but it is not applicable to sialic acid, as undesirable β-selectivity occurs.

Alternatively, fragment coupling using sialyl oligosaccharides as glycosylation reagents may minimize the problems. Another approach is based on the one-pot strategy (4), where an oligosaccharide is assembled rapidly from the nonreducing end to the reducing end by sequential addition of building blocks, with the most reactive one being added first. However, sialic acid thioglycosides (even a per-*O*-benzylated thioglycoside) are much less reactive and less influenced by the protecting group than the other thioglycosides (5). We have found that the major effect on the anomeric reactivity of sialic acid is from the carboxyl, not from the side-chain protecting groups. The reactivity difference between per-*O*-benzylated and per-*O*-acetylated sialosides is less than 100, compared to ~1×10^5 for the corresponding thioglycosides of the other sugars (5). Reduction of the carboxyl group does increase the reactivity by >1×10^4, but the α-selectivity is completely diminished and gives mainly the undesirable β-glycoside product (5). To tackle this problem, we decided to use sialylated disaccharides as building blocks in the one-pot synthesis, as the reactivity of a disaccharide or trisaccharide glycosyl donor is mainly determined by the reducing end unit (4*d*). Here we report the representative one-pot synthesis of a protected sialyl Lewis X hexasaccharide (1) to illustrate this strategy.

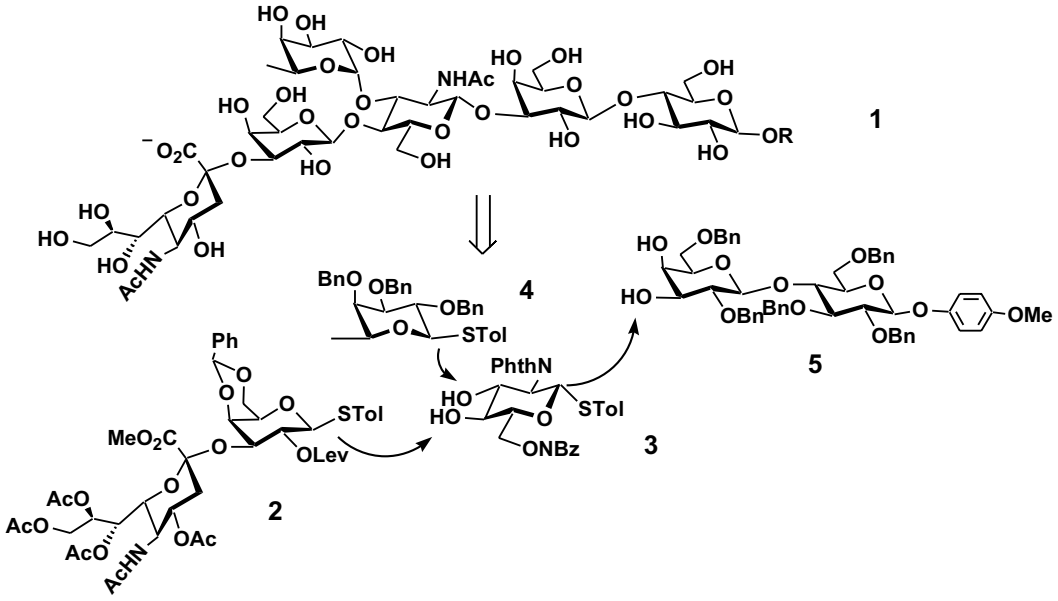
Experimental and results and discussion

As shown in Fig. 1, the target molecule could be assembled from the sialylated disaccharide **2**, the thiofucoside **4**, the 2-*N*-Phth glucoside **3**, and the lactoside **5**. This strategy is based on the following analysis: when a 2-*O*-acylated glycosyl donor couples with a 2-*N*-phthalimido protected 3,4-diol glucosyl acceptor (i.e., **2** + **3**), it is expected to give a 1,4-β linked product (5). This would allow the one-pot strategy to proceed through a fucosylation with **4** after the

 DOI: 10.1139/V02-131 © 2002 NRC Canada

Fig. 1. Retro-synthetic analysis for the one-pot assembly of protected sialyl Lewis X hexasaccharide.



first step, followed by coupling with the final acceptor lactoside **5**.

We expect that the 2,3-linked disaccharide **2** would have a similar reactivity as the methylphenyl 2,3-di-*O*-benzoyl-4,6-*O*-benzylidene-1-thio-β-D-galactopyranoside (RRV = 285), and would be at least 10 times more reactive than 6-*O*-nitrobenzoyl-2-*N*-phthalimido β-glucoside **3**. Compound **2** was synthesized from phosphite **6** (7) and thiogalactoside **7** followed by acylation. The desired α-product **8** was isolated in 21% yield, and the lactonized product **9** was the major side product (8% yield). Protection of the 2-OH group using levulinic acid gave the desired product **2** in 86% yield.

To reduce the reactivity of the 2-*N*-Phth glucoside, a nitrobenzoyl group was selected as the 6-*O* protecting group. Monobenzoylation of the 2-*N*-phthalimido glucoside **3** was first tried with *p*-NO_2BzCl–DMAP–pyridine in THF. This reaction mainly gave two products, the 3,6-di-*p*-nitrobenzoylated compound **10** (35% yield), and 6-*O*-NBz **3** (53% yield), which were difficult to purify. However, pure compound **3** was easily obtained in 83% yield when we treated compound **10** with $(Bu_2Sn)_2O$ followed by *p*-nitrobenzoyl chloride.

The last component, lactoside acceptor **5**, was prepared (in 74% overall yield) from the free lactoside **11** (Fig. 2) through three steps and a single purification. An improved procedure, using DMF as the cosolvent together with α,α-dimethoxypropane under H_2SO_4 treatment, gave a good yield of isopropylidene lactoside. The crude product was subjected to further benzylation and TFA treatment to give the diol **5** after final purification.

Before we started the assembly, we measured the reactivities of compound **2** and compound **3**, using the HPLC method developed in this group. Compound **2** (RRV = 1308) was found to be 23 times more reactive than compound **3** (RRV = 57). To make sure that the glycosylation and the regio- and stereoselectivities would work as predicted during the one-pot synthesis, we tried a one-pot synthesis (Fig. 3) of the protected Lewis X trisaccharide **14**, and the product was isolated in more than 85% yield.

Encouraged by this result, we then conducted the assembly of the four components **2**–**5** in a one-pot procedure. Our experience suggests that exclusively dry conditions are the key to a successful glycosylation step, and these conditions are even more important in the one-pot procedure as more reagents and substrates are added to the reaction flask. The relative amounts of building blocks used is also one of the important factors. Normally, the use of less equivalents of the acceptor at each step can have many advantages. First, it increases the selectivity; for example, if the concentration ratio of the donor and the acceptor in the beginning is 1.5, the ratio would roughly be ~2.0 in the middle of the reaction, and much higher near the end. Second, the excess amount of donor can still be activated, even though all of the acceptor is consumed and trapped by the released succinimide to form the glycosyl succinimide. When the last acceptor is an *O*-linked glycoside, using an excess of the acceptor will increase the yield. Through several attempts at the synthesis of the SLe X hexasaccharide, we found that the optimal ratio of building blocks (**2**:**3**:**4**:**5**) is 1.3:1:1.5:2.

We first tried the one-pot assembly using NIS–TfOH as the promoter. TLC analysis showed a good result in the first step (coupling **2** with **3**); however, almost no reaction was observed in the second step, probably due to the steric hindrance at 3-OH after the 4-OH position was glycosylated to the disaccharide **2**. In addition, most of the thiofucoside **4** was converted to its succinimide derivative.

To reduce the amount of the succinimide, we have developed a new procedure (Fig. 4) using NIS–TfOH–AgOTf. In this reaction the side product TolS-I is generated, as shown in Scheme 1. In the presence of AgOTf, it reacts with TolS-I to generate another more powerful promoter, TolS-OTf (8), which can further activate the donor. In this manner, 0.5 equiv of NIS, together with 0.5 equiv of AgOTf, activate 1 equiv of the donor. As an extended application of this reaction, we used 1.5 equiv of compound **2** and 1.5 equiv of NIS in the first step (Fig. 4). The resultant mixture ideally is composed of about 1 equiv of trisaccharide product, 0.5 equiv of succinimide derivative of compound **2**, and

1.5 equiv amount of ToS-I. Therefore, addition of AgOTf after adding thiofucoside **4** in the second step would generate an adequate amount of TolS-OTf (8) to activate the trisaccharide and to give the tetrasaccharide. In the last step we used NIS for the coupling, as the lactoside diol **5** (2.5 equiv) is much more reactive than succinimide, and less hindered. By using this one-pot procedure, we were able to isolate the final hexasaccharide **15** in 42% yield after flash chromatography.[2]

In summary, we have successfully developed a one-pot synthesis of sialyl oligosaccharide using a sialylated disaccharide and other building blocks in combination with regioselective glycosylation. We have also developed a new method using NIS–TfOH–AgOTf for activation of thioglycosides. Further application of the one-pot strategy in

Serological and conformational properties of *E. coli* K92 capsular polysaccharide and its *N*-propionylated derivative both illustrate that induced antibody does not recognize extended epitopes of polysialic acid: Implications for a comprehensive conjugate vaccine against groups B and C *N. meningitidis*

Robert A. Pon, Nam Huan Khieu, Qing-Ling Yang, Jean-Robert Brisson, and Harold J. Jennings

Abstract: The capsular polysaccharide of *E. coli* K92 (K92P) contains elements in common with the capsular polysaccharides of both groups B and C *N. meningitidis*, and may therefore form the basis of a bivalent vaccine. In an attempt to augment the cross-protective immune response to group B meningococci, the *N*-acetyl groups of the K92P were replaced by *N*-propionyl groups (NPrK92P) and conjugated to protein. This strategy had previously been applied with success to the poorly immunogenic capsular polysaccharide of group B meningococcus (GBMP), and the bactericidal epitope was found to be exclusively mimicked by extended helical segments of the NPrGBMP. The NPrK92P-conjugate, in relation to a K92P-conjugate, failed to enhance the response to GBMP but did generate a measurable response to NPrGBMP, but only at the expense of a greatly reduced GCMP response. Despite the presence of an immune response to NPrGBMP, the anti-NPrK92 serum was not bactericidal. Competitive inhibition studies with NPrGBMP oligosaccharides suggested the NPrK92 antibodies could not cross-react with the protective epitope on group B meningococci, as defined by extended helical segments of the NPrGBMP, but only recognized short non-bactericidal NPrGBMP epitopes. This hypothesis was supported from the conformational and molecular dynamics studies of the K92P, which demonstrated a lack of extended conformations that resemble the GBMP extended epitope. Indeed, the conformational properties of the K92P more closely resembled those of the GCMP, thereby explaining the observed moderate cross-protection of the K92P antiserum towards group C meningococci. Thus, on the basis of these results, it can be concluded that K92P, regardless of *N*-propionyl modification, will not serve as an effective single vaccine component against both groups B and C meningococci.

Résumé : Le polysaccharide capsulaire du *E. coli* K92 (K92P) comprend des éléments communs avec les polysaccharides capsulaires des *N. meningitidis* des groupes B et C et il pourrait donc être à la base d'un vaccin bivalent. Dans un essai d'augmenter la réponse immunitaire à protection croisée par rapport au méningocoque du groupe B, on a remplacé les groupes *N*-acétyles du K92P par des groupes *N*-propionyles (NPrK92P) et on les a conjugués à une protéine. On avait utilisé antérieurement cette stratégie avec succès avec le polysaccharide capsulaire peu immunogène du méningocoque du groupe B (GBMP) et on a trouvé que l'épitope bactéricide n'est répliqué que par des segments hélicoïdaux étendus du NPrGBMP. Par rapport à un conjugué à K92P, le conjugué au NPrK92P n'augmente pas la réponse au GBMP; il provoque toutefois une réponse mesurable au NPrGBMP, mais la réponse au GCMP est toutefois grandement réduite. Malgré la présence d'une réponse immunitaire au NPrGBMP, le sérum anti-NPrK92 n'est pas bactéricide. Des études d'inhibitions compétitives avec des oligosaccharides NPrGBMP suggèrent que les anticorps NPrK92 ne peuvent pas réagir de façon croisée avec l'épitope protecteur des méningocoques du groupe B, tels que définis par des segments hélicoïdaux étendus de NPrGBMP; ils ne reconnaissent que de courtes chaînes d'épitopes

NPrGBMP non-bactéricides. Cette hypothèse est confirmée par des études de dynamiques moléculaire et conformationnelle du K92P qui ont démontré l'absence de conformations étendues qui pourraient ressembler à l'épitope étendu du GBMP. Les propriétés conformationnelles du K92P ressemblent en fait beaucoup plus à celles du GCMP; ceci expliquerait la protection croisée modérée observée du sérum K92P vis-à-vis des méningocoques du groupe C. Sur la base de ces résultats, on peut donc conclure que le K92P, même avec une modification *N*-propionyle, ne pourra pas servir de composant unique d'un vaccin efficace contre les méningocoques des groupes B et C.

[Traduit par la Rédaction]

Introduction

The *E. coli* K92 polysaccharide (K92P) is composed of alternating α(2,8)- and α(2,9)-linked sialic acid units (1). These structural elements are also respective components of the group B and group C meningococcal polysaccharides (GBMP and GCMP, respectively) (2, 3). Because of the poor immunogenicity of the group B polysaccharide (4), a protein conjugate of the K92 polysaccharide was evaluated as a possible alternate vaccine against disease caused by both group B and group C meningococci (5). Substantial antibody levels to GCMP were generated in mice; however, the response to the GBMP remained poor, despite an observed increase in GBMP-antibody titre relative to the homologous antiserum from a comparable GBMP conjugate. Similar results were noted from studies conducted in non-human primates that compared different group B meningococcal vaccine constructs, although the effect was lower and resulted in no observable GBM bactericidal activity (6, 7).

In previous studies, we had shown that the immunogenicity of the GBMP could be greatly improved by a simple chemical modification, in which its *N*-acetyl groups were replaced by *N*-propionyl (NPr) groups prior to its conjugation to protein (8). In addition, this antibody was found to be bactericidal against all group B meningococci (9–11), and the epitope responsible for bactericidal activity was exclusively associated with extended helical segments of the NPrGBMP (12–15). This demonstrates the great potential of this type of synthetic vaccine for group B meningococcal prophylaxis, especially when one considers that there is still no fully efficacious vaccine available (16). Using the same strategy, we hoped to enhance bactericidal activity against group B meningococci induced by a conjugate of the NPrK92 polysaccharide, while at the same time maintaining an adequate immune response to the GCMP.

Numerous studies have characterized the unique requirement for >10 contiguous sialic acid residues for binding to GBMP specific antibody (17–19), as opposed to the classical binding size of three to four carbohydrate residues (20). We have employed NMR and molecular dynamic studies to characterize the intrinsic properties of the GBMP, which gives rise to this unique binding behaviour (14, 15, 21). It was proposed that the GBMP-specific antibody only recognized polysialic acids capable of forming extended helical epitopes, which are highly dependent on the spatial distribution of the negative charge and the reduced mobility between interchain residues (14, 15). Furthermore, X-ray crystallography and thermodynamic studies were entirely consistent with this hypothesis (13).

Using this approach, this study demonstrates that the conformational properties of the K92 polysaccharide or its *N*-propionylated derivative are more similar to GCMP as opposed to GBMP, which therefore precludes their use in a comprehensive vaccine towards both groups B and C meningococci.

Results

Antiserum to K92P cross reacts with GCMP but not to GBMP

Conjugate vaccines comprising the capsular polysaccharide of *E. coli* K92 (alternating α(2,8)- and α(2,9)-*N*-acetyl neuraminic acid (NeuAc) residues) were proposed to function as a comprehensive vaccine towards both group B and group C meningococcus (α(2-8) and α(2-9)NeuAc homopolymers, respectively) (Fig. 1) (5). To test this hypothesis, T-independent GBM, GCM, and K92 polysaccharides were converted to T-dependent antigens by covalently coupling them to tetanus toxoid (TT). We have also previously demonstrated that the poor immunogenicity of GBMP-conjugate vaccines can be enhanced by chemically modifying the *N*-acetyl functionalities to their propionylated homologs (8). This not only enhances its immunogenicity, but propionylated GBMP (NPrGBMP) was also found to mimic a unique bacterial epitope found on the surface of GBM, and NPrGBMP-specific antisera possessed both bactericidal and protective activity in mice (11, 12). In an attempt to enhance the potential functional component of K92 antisera to GBM, vaccine constructs were also generated with modified NPrK92 polysaccharide (Fig. 1). Direct-binding ELISA analysis on antisera to the various vaccine constructs revealed strong recognition of their homologous polysaccharide antigens, with the exception of the poor reactivity to GBMP by GBMP–TT antiserum, as previously observed (Fig. 2). Cross reactivity of the individual antisera was then assessed by ELISA using both native and modified GBM, GCM, and K92 polysaccharide – HSA conjugates (Fig. 2). K92 antiserum cross reacted modestly with GCMP–HSA (~fivefold less than native K92–HSA) but noticeably did not react to any great extent with GBMP–HSA. GCMP antiserum conversely cross-reacted strongly with K92–HSA, but again failed to recognize GBMP–HSA. These results suggest there is a shared epitope between K92P and GCMP that is not present within the GBMP.

Similar cross-reactivity studies were performed to assess the impact of *N*-propionylation of K92, employed in an attempt to enhance any potential GBM specific activity arising from a K92 conjugate vaccine (Fig. 2). Consistent with prior observations, NPrGBMP–TT resulted in a strong antibody

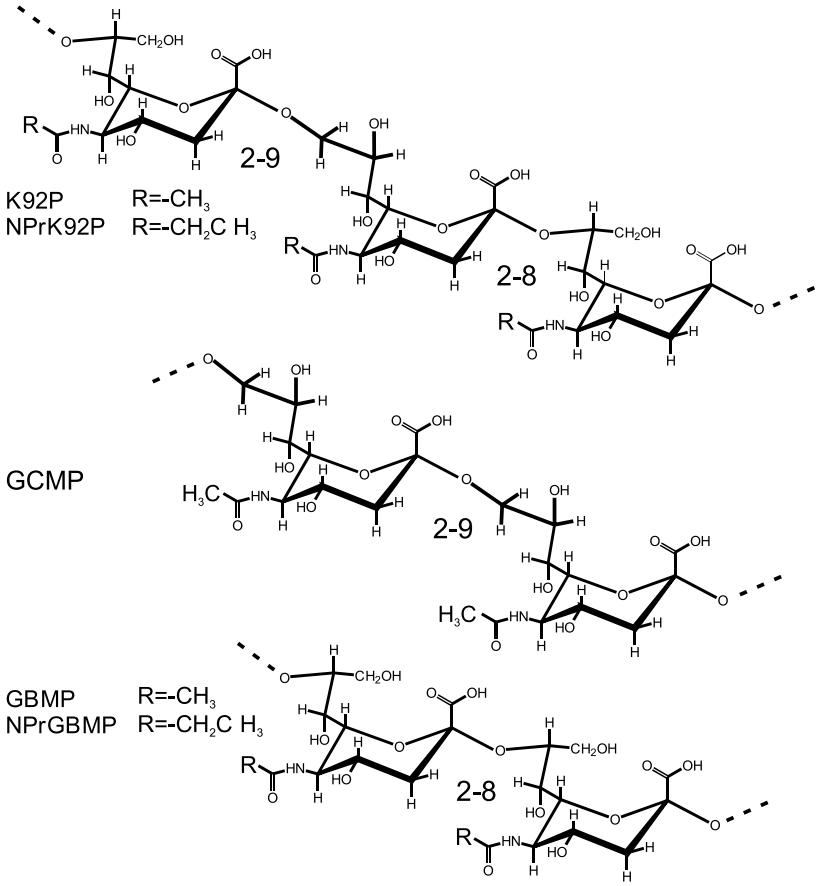

Fig. 2. Reactivity profiles of native and NPr-modified K92P, GBMP, and GCMP-TT conjugate vaccines determined by direct-binding ELISA. The 96-well plate was coated with HSA conjugates of each respective polysaccharide and the mean ELISA titer was determined to evaluate both the homologous and cross-reactivity profiles of the individual conjugate vaccine antisera. ELISA titers are represented by the total IgG response and were calculated from the OD × dilution^{-1} averaged over three points on the curve.

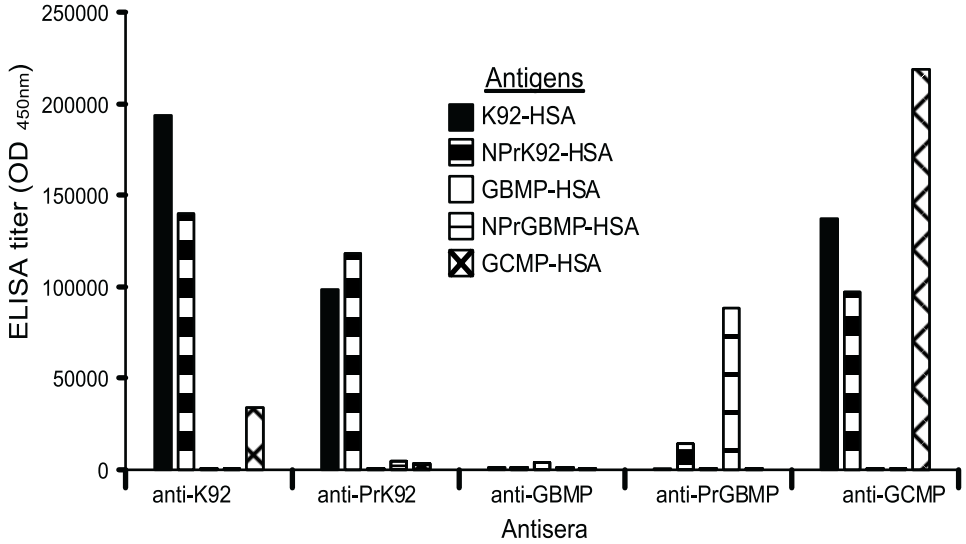

response to its homologous antigen compared with GBMP–TT sera to native GBMP (88 400 vs. 3 750 titre, respectively). Also similar to previous results, the NPrGBMP–TT antiserum was highly specific for NPrGBMP and showed only very low cross reactivity with native GBMP (<1% cross reactivity). The NPrGBMP–TT antiserum, however, was able to weakly recognize NPrK92P (14 567 vs. 88 400 titre for NPrK92P vs. NPrGBMP, respectively). In contrast, the NPrK92–TT antiserum only recognized, in addition to its homologous antigen, the native form of K92 and cross

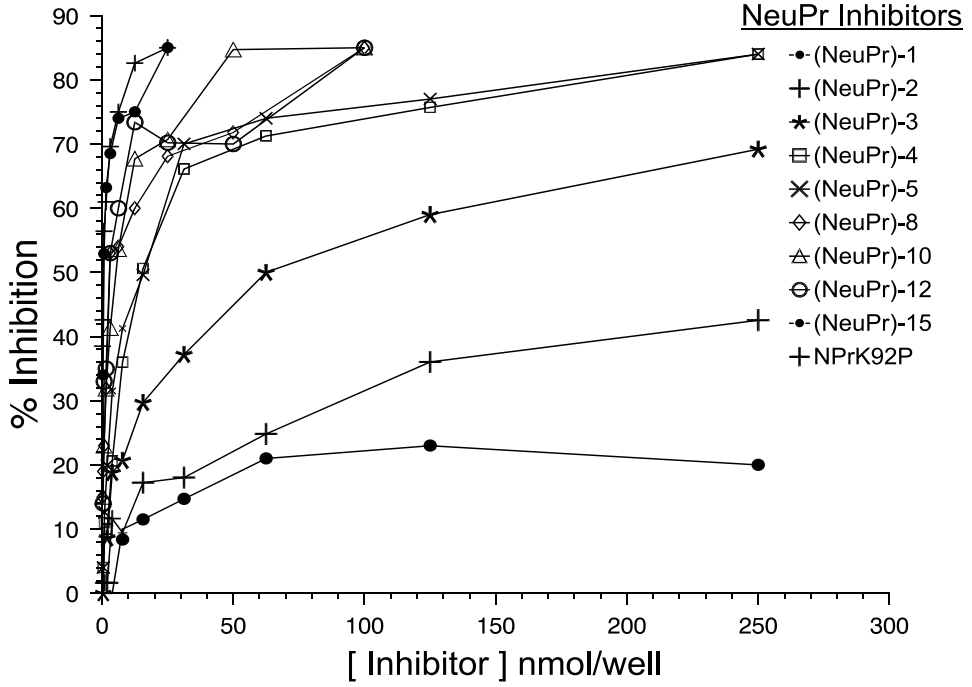
Fig. 3. Antibodies elicited by NPrK92P–TT are maximally inhibited by NeuPr oligosacchrides with degrees of polymerization >4. Binding of NPrK92P antiserum to NPrGBMP–HSA was competitively inhibited by NeuPr oligosaccharides of increasing size and assessed using ELISA.



reacted poorly with NPrGBMP–, GBMP–, and GCMP–HSA conjugates. This suggests that the propionyl group modification of K92P will not be an effective strategy for increased protection against GBM, since there is poor reactivity to the putative GBM epitope that is mimicked by NPrGBMP. Similarly, the poor cross reactivity observed towards GCMP suggests that the modification will also result in decreased activity towards GCM.

K92 antiserum can kill GCM but not GBM

To determine whether the K92– or NPrK92–TT conjugate vaccines generate effector activity towards GCM and (or) GBM, their bactericidal activities were evaluated (Table 1). It was evident that both individual mouse- and pooled-K92 antisera generated significant bactericidal activity against GCM ($Titre_{Bactericidal} > 900$), while only marginal GBM bactericidal activity (2 out of 10 individual mice) was observed ($Titre_{Bactericidal} \approx 60$). In contrast, individual NPrK92–TT antisera elicited GCM bactericidal activity in only 2 out of 10 mice ($Titre_{Bactericidal} > 900$); again no GBM bactericidal activity was observed. These results are entirely consistent with our ELISA findings where the K92 antiserum was cross reactive with only GCMP, and the NPrK92 antiserum was poorly cross reactive to all (GCMP, GBMP, and NPrGBMP, Fig. 2).

Antibodies to NPrK92 are inhibited by small oligosaccharide fragments of NPrGBMP

Inhibition binding studies using oligosaccharides with increasing degrees of polymerization have proven to be extremely useful in probing the epitope size requirements for antibody to polysaccharide antigens (17, 19). To probe the size requirements of K92-specific antibodies for the α(2,8) polysialic acid component, a series of (-8NeuPrα2-) oligosaccharides were used to competitively inhibit the binding of NPrK92 antiserum to NPrGBMP capsular polysaccharide (Fig. 3). From this analysis, it was evident that significant inhibition occurred with a (-8NeuPrα2-) tetrasaccharide fragment — this inhibition was only minimally enhanced with oligosaccharides of increasing size. This result contrasts the inhibition binding behaviour of NPrGBMP antiserum, where the majority of NPrGBMP-specific antibodies, which

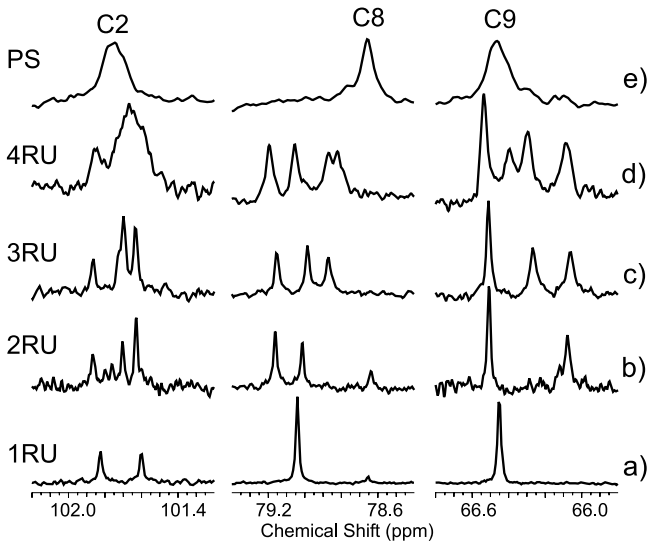
Fig. 4. ^{13}C NMR resonances of atoms involved in the glycosidic linkages for increasing repeat units (RU) of K92P oligosaccharides.



recognize an extended epitope of α(2,8) polysialic acid, were characterized by progressive inhibition with (-8NeuPrα2-) oligosaccharides up to n = 16 (12). Taken together these results suggest that the observed NPrGBMP cross reactivity generated from NPrK92–TT immunization was directed towards short epitopes of NPrGBMP and not towards extended epitopes, which were previously shown to be a prerequisite for GBM bactericidal activity and protection in a passive mouse model.

NMR and conformational analysis

NMR studies were performed on oligosaccharides derived from GBMP, GCMP, and K92P to probe their conformational properties. Proton vicinal coupling constant measurements, which are dependent on the H-C-C-H torsion angles, were used to estimate the flexibility of the exocyclic chains. Flexibility of (2,8)-linked NeuAc is primarily due to rotation around the glycosidic bond, while for the (2,9)-linked NeuAc, there is an additional degree of freedom about the C8–C9 bond. The GCMP $J_{H,H}$ coupling constants ($J_{6,7}$ = 1 Hz, $J_{7,8}$ = 10 Hz, $J_{8,9}$ = 2 Hz, and $J_{8,9'}$ = 6 Hz) indicated that the ω7 is near 60°, ω8 near 180°, and that the CH_2OH group is not restricted to one rotamer (22). For K92P, the determination of the $J_{H,H}$ coupling constants for both the trisaccharide and polysaccharide was complicated by the ^1H NMR spectral overlap. It was expected however that the (2,8)- and the (2,9)-linkages present in K92P would behave similarly to their linkage counterparts within GBMP and GCMP, respectively. Thus, all these polysaccharides exist in solution as random coils because of their high degree of flexibility about both their glycosidic and exocyclic bonds.

^{13}C NMR chemical shift differences surrounding the glycosidic bonds within oligo-repeat units of increasing size have been interpreted to reflect the conformational distribution of the various residues, with a coalescence of signals occurring when conformational equilibrium is established (21). No differences in chemical shifts were found for the C2 and C9 atoms surrounding the (2,9)-glycosidic bond in both a GCMP trisaccharide and the polysaccharide itself, indicating similar flexibility. Chemical shift differences for C8 and C9 atoms surrounding both the (2,8)- and (2,9)-linkages, were observed in K92 oligo-repeat units up to n = 4–5 (Fig. 4). Both of these observations are in contrast with the chemical shift behaviour for GBMP oligosaccharides of increasing size, where coalescence of the signals occurred only at high degrees of polymerization (n = 6). This indicated that both GCMP and K92 exhibited increased mobility around their internal linkages relative to GBMP, despite the fact that they all existed as random coils in solution.

The potential energy (PE) maps were calculated for the dimers of GBMP and GCMP (Figs. 5*a* and 5*d*). The PE surface for the dimer indicated that the conformational mobility of the sialic acids, with respect to (ϕ, φ), would be flexible since there is an extensive, relatively flat potential region. The aqueous MD results (Figs. 5*b* and 5*e*) also indicated considerable flexibility in the region of lowest energy of the PE map. The (2,8)-linkage was moderately rigid as compared with the (2,9)-linkage. In our case, the (2,8)-linkage showed more flexibility than in a previous study (23). For the (2,8)-linkage the ω7 and ω8 values were also consistent with the ω7 and ω8 rotamers being gauche (60°), as found by NMR studies (15). The extended conformation of the bound epitope for α(2,8)-linked polysialic acid with ϕ = 166°, φ = 137°, ω7 = 55°, and ω8 = 70° (13) is readily accessible in the PE surface (Fig. 4*a*), although at higher energy than the global minimum (15). Comparison of the PE and MD maps, suggests that although the presence in solution of such a conformer is not highly favored dynamically, it is still accessible to antibody binding. The aqueous MD simulation of the (2,9)-linked tetra sialic acid revealed an even more extensive dynamics region consistent with its PE map (Fig. 5*e*). The aqueous MD simulation for $(K92P)_4$ showed that the extensive mobility also apply to all the central (2,8)- and (2,9)-linkages.

For extended epitopes (GBMP), the spatial organization of the PS becomes important. As Perez and Vergelati (24) noted in their study of polysaccharide conformations, the spatial organization of the PS can de defined by consecutive fragments that can have well-defined helical parameters. For GBMP, various helical structures are probable (Fig. 5*g*). The postulated helical epitope for GBMP (13) has six residues per turn (n = 6) with ρ = 60° and λ = 0.8. Because GCMP has greater flexibility, a wider range of helical parameters are possible (Fig. 5*h*) — although mostly for short helices with n = 2 (ρ = 180°). Extended helices are not favored and similar conformations to that of the GBMP helix cannot be found. Similarly, extended helices for K92 are not favored. As previously shown for GBMP, its conformational properties are not affected by replacing the NAc group with an NPr group (14). Similarly, molecular modeling of the NPrGCMP and NPrK92P tetrasaccharide showed no effect on their conformation.

Discussion

In previous studies (5–7), which had the goal of using K92 as a bivalent vaccine against disease caused by groups B and C meningococci, it was ascertained that, while the conjugated form of K92P gave a strong cross-reactive immune response to GCMP, the response to GBMP was marginal

by comparison. It was also concluded from these studies that the K92P conjugate was superior to the GBMP conjugate in terms of inducing GBMP-specific antibodies (5). Our control studies generally confirm these results, with the exception that our GBMP conjugate was able to raise more GBMP-specific antibody relative to our K92P-conjugate antiserum, consistent with the results found in a study done on monkeys (6). The titre difference was marginal, however, and indeed the K92P-conjugate induced antiserum possessed low levels of GBM bactericidal activity; this despite having lower quantities of a specific antibody relative to the GBMP-conjugate antiserum. This failure of the K92P conjugate to raise significant levels of GBMP cross-reactive antibody therefore precludes its usefulness as a vaccine candidate to group B meningococcus, as evidenced by its poor bactericidal response to GBM. To preserve the concept of using K92 as a bivalent vaccine against groups B and C meningococci, it was imperative that the immune response to the group B component be enhanced. To achieve this, we converted the native K92 polysaccharide into its *N*-propionylated derivative followed by its conjugation to protein; a strategy proven successful in rendering the GBMP more immunogenic (8).

The results of the experiments were not encouraging on two fronts. Firstly, we observed that by chemically modifying K92P, its ability to generate cross-reactive antibody to the GCMP was considerably reduced in comparison to the native K92P conjugate and, furthermore, this antibody possessed reduced bactericidal activity against group C meningococci. It must therefore be concluded that *N*-propionylation of K92P resulted in a conjugate with diminished protective properties against group C meningococci when compared with K92–TT. This finding is consistent with our previous studies investigating the effect of *N*-propionylating GCMP, where virtually all the bactericidal activity resided within the smaller GCMP specific antibody fraction, while the larger fraction that was specific to NPrGCMP, was completely unable to kill GCM (unpublished results). Secondly, the most important factor that mitigates against the use of an NPrK92 conjugate as a bivalent vaccine against groups B and C meningococci, is its failure to sufficiently augment antibody levels, or the protective properties of these antibodies, to either GBMP or NPrGBMP.

We can explain the above observations in terms of the epitopic specificities of the NPrK92 antiserum. Our serological evidence suggests that NPrK92P cannot adopt the extended helical conformation of NPrGBMP (12–15), which is essential for the induction of bactericidal antibodies against group B meningococci (9–12). It is not likely that the effect of *N*-propionylation was responsible for our serological observations, since we have previously shown with the GBMP that *N*-acyl modifications marginally impact

© 2002 NRC Canada

its conformational properties (14). Furthermore, since the negative charge distribution and inter-residue mobilities within NPrK92P and K92P remained consistent, it was expected that conformationally, they would behave similarly. Our NMR and molecular dynamics studies support the notion that both the native K92P and NPrK92P should have similar serological behaviour, since in both cases extended helices are not favoured, and indeed similar conformations to that of the GBMP helix were not found. In other words, both the K92 and NPrK92 polysaccharides are unable to mimic the extended helical epitope found in the GBMP, which is characterized by 8–10 contiguous α(2,8)-linked sialic acids. Consequently, K92P or NPrK92P conjugates are unable to elicit an antibody capable of recognizing these epitopes on the surface of group B meningococci, which is critical to invoke a bactericidal response (12). Illustrating this concept, it was possible to generate a small amount of NPrGBMP cross-reactive antibody with the NPrK92P conjugate; however, there was no associated GBM bactericidal activity. Inhibition of antibody binding to NPrGBMP, clearly demonstrated that complete inhibition was achieved using relatively short (-8NeuPrα2-) oligosaccharides (n = 4 or 5), signifying the NPrK92 antibodies were capable of recognizing short epitopes of GBMP, most probably by only recognizing the conformational features present in the terminal residues. Furthermore, it has been well established that such epitopes are not bactericidal against group B meningococci (12).

It is interesting to note that K92P, and to a lesser extent NPrK92P, share common bactericidal epitopes with GCMP. Given the similar chemical shift behaviour of GCMP and K92P oligosaccharides, together with the low probability that these polysaccharides can adopt extended helical conformations, it is likely that the epitopes giving rise to GCMP cross-reactive antibody are short. This is consistent with our previous studies that show that GCMP-conjugate induced antibodies are generated to short conventional epitopes (17).

Experimental

General

E. coli Ec432 (O73:K92:H34) (K92), *N. meningitidis* strains 80–165 (B:2b:P1.Ham) (GBM), and 60EC11 (L3) (GCM) were obtained from the Population and Public Health Branch (Ottawa, Canada). *E. coli* K92 capsular polysaccharide (K92P) was prepared and purified essentially as described (25), using Davis supplemented minimal medium. GBMP-, NPrGBMP-, GCMP-, and NPrGCMP-tetanus toxoid conjugates were prepared as described (12).

K92P modification, oligosaccharide generation, and conjugate vaccine formation

N-Propionylation of K92P was carried out in a similar manner to that reported for NPrGBMP (12). Briefly, K92P (100 mg) was *N*-deacetylated using 2 M NaOH (10 mL) containing $NaBH_4$ (100 mg) for 6.5 h at 110°C. The *N*-deacetylated product was then treated with propionic anhydride (10 equiv) at a constant pH (9.5) using autotitration with 2 M NaOH. Following exhaustive dialysis and lyophilization, complete derivitization was confirmed by ^{1}H NMR spectroscopy.

High molecular weight K92P and NPrK92P were depolymerized by $NaIO_4$ treatment resulting in the oxidative cleavage of the susceptible C7–C8 vicinal diol of the α(2,9)-*N*-acetyl neuraminic acid (NeuAc) residues. Briefly, high molecular weight polysaccharide (100 mg; 0.16 mmol repeat unit) in phosphate buffer (0.2 M, pH 7.5) was treated in stages with a 0.5 M $NaIO_4$ solution (200 μL final) with monitoring by size-exclusion (SEC) HPLC (Superose-12; Amersham Pharmacia, Baie D'Urfe, Canada). The depolymerized polysaccharide was size fractionated on a BioGel A.5 column (1.6 × 100 cm; Bio-Rad, Hercules, Ca), collecting 10 kD fragments as previously described (12). K92, NPrK92, and GCM oligosaccharides were generated in a similar manner from their respective high molecular weight polysaccharides (100 mg; 0.16 mmol repeat unit) using more extensive $NaIO_4$ treatment (0.25 equiv) and SEC-HPLC monitoring (Superdex-75; Amersham Pharmacia). Pure oligosaccharides were isolated by anion exchange chromatography as described (17). For NMR analysis, oligosaccharide terminal aldehydes were first reduced with $NaBH_4$ (100 equiv)

NPrK92P and K92P protein conjugates were prepared by incubating the respective 10 kD oxidized fragment (15 mg) with either tetanus toxoid monomer (TTm; 5 mg; Statenserum Institut, Copenhagen, Denmark) or human serum albumin (HSA; 7.5 mg; Sigma, St. Louis, MI) and $NaBH_3CN$ (10 mg) in phosphate buffer (0.1 M; pH 8.1) for 5 days. K92-protein conjugates were purified from starting materials by SEC chromatography (BioGel A.5). Sugar-to-protein analysis (26) revealed a 33.3 and 36.1% (wt/wt) NeuAc incorporation within the K92– and NPrK92–TT conjugates, respectively.

Mouse immunizations

Groups of ten mice per vaccine (female CFI; 6–8 weeks; Charles River, St. Constant, Canada) were immunized intraperitonealy with NPrK92P–, K92P–, GBMP–, NPrGBMP–, and GCMP–TT conjugate vaccines (2 μg NeuAc/0.2 mL/mouse) emulsified in RIBIs complete adjuvant (RIBI ImmunoChem, Hamilton, MT). The mice were boosted with equivalent vaccine doses on day 21 and day 35, followed by exsanguination and harvesting of blood 10 days later.

Serological analysis by ELISA

Microtitre plates (96-well; Corning, Corning, NY) were all coated at 4°C for 1 h with HSA-polysaccharide conjugate (1 μg/well). Following plate washing with 0.5% Tween-20 in PBS (3 times) and blocking (1% BSA in PBS), serial dilutions of antisera in 3% BSA were performed. Incubation (rt, 1 h) was followed by washing (2 times) and the addition of a 1:2000 dilution in 3% BSA of a peroxidase labeled goat anti-mouse IgG (H + L) antibody (Cedarlane, Hornby, Ont.). The reaction was stopped after 15 min with 1 M H_3PO_4 (50 μL), and the plates were read at 450 nm using a BioTek multiscan ELISA reader (Fisher Scientific, Ottawa, ON).

Competitive-inhibition assays with (-8NeuPrα2-) oligosaccharides were performed by first incubating graded amounts of oligosaccharides at an optimal dilution of antiserum (OD_{450} = 1) in 3% BSA for 1 h at 4°C. Oligosaccharide–antibody mixtures were then transferred to a 96-well plate

© 2002 NRC Canada

pre-absorbed with the HSA-coating antigen of interest and treated as described above.

Bactericidal assays

GBM 80–165 and GCM 60EC11 were grown overnight on Chocolate agar plates (QueLab, Montreal, Que.) at 37°C/5% CO_2, followed by re-inoculation of a second plate and incubating for a further 5 h. Dilutions of antiserum in HBSS containing 1% casein hydrozylate were performed in a 96-well plate, to which were added 30 μL of a 1:20 000 dilution (2 500 CFU/well) of either a freshly isolated suspension of GBM or GCM (OD_{490} = 0.29). Freshly thawed baby-rabbit complement (20 μL, Cedarlane) was immediately added to each well, followed by incubation at 37°C with shaking for 1 h. The contents of each well were mixed before plating onto Chocolate agar (20 μL/plate) and CFUs were enumerated following overnight incubation. The % killing was calculated relative to HBSS controls according to the following equation: $\%kill = (CFU_{control} - CFU_{treated})/CFU_{control} \times 100$.

NMR spectroscopy and molecular modeling

Capsular polysaccharides and oligosaccharides were prepared at concentrations of 5–10 mg in 0.5 mL 99.9% D_2O, pH 7, Na^+ salt. Experiments were performed on a 600 MHz (^1H) NMR spectrometer. ^{13}C NMR chemical shifts are referenced to internal acetone (CH_3) set at 31.07 ppm.

Potential energy (PE) calculations for the $(GBMP)_2$ and $(GCMP)_2$ disaccharides was performed by energy minimization (BFGS method) of a set of geometries under the torsional angle restraints of Φ (*b*O6-*b*C2-*b*O2-*a*C8) and Ψ (*b*C2-*b*O2-*a*C8-*a*C7) for αNeuAc(2,8)αNeuAc (*b*-*a*), or Φ (*b*O6-*b*C2-*b*O2-*a*C9) and Ψ (*b*C2-*b*O2-*a*C9-*a*C8) for αNeuAc(2,9)αNeuAc (*b*-*a*) using 8° increments constrained by a harmonic force constant of 200 kcal rad^{-2} and a dielectric constant of 80. Torsional maps were generated using Discover-3 and Analysis modules of the INSIGHTII software package (Accelrys). Helical parameters were calculated as previously described (27).

Molecular dynamic (MD) simulations for the $(GBMP)_2$ and $(GCMP)_2$ disaccharides were performed with AMBER 5.0 software package on a SGI computer (Indigo 2 Solid Impact R10000 195 MHz). The GLYCAM_93 parameter set (27) and its structural database were used to generate the initial conformation for sialic acids and prepare them for MD simulation with the SANDER module. In addition, different starting values for the glycosidic torsional angles were applied in separate dynamics runs, while the initial values chosen for ω7 (O6-C6-C7-O7) and ω8 (O7-C7-C8-O8) were 55° and 70°, respectively. The Na^+ counter ion was initially placed 3 Å from the carboxylate oxygen atom. TIP-3P water molecules were used in MD with periodic boundary conditions, and the box sizes set to extend 12 Å beyond the sugar. Energy minimization (500 cycles using steepest descent method) was performed first to configure water and the Na^+ counter ion, followed by 50 ps MD with minimization for water only. All the atoms in the system were then subjected to 500-cycle steepest descent energy minimization before being heated to 300 K for 100 ps. A 3000 ps MD run was finally performed at a constant temperature of 300 K and with a dielectric constant of unity. The Verlet algorithm with a 2 fs time step was applied for the simulation where bond lengths involving hydrogen atoms were constrained via the SHAKE algorithm. The Maxwell distribution at 5 K was used to generate initial atomic velocities. MD simulation was similarly performed for $(K92P)_4$, $(-9NeuAc\alpha2,8NeuAc\alpha2-)_4$.

Anchimeric assistance in hexosaminidases

Brian L. Mark and Michael N.G. James

Abstract: Configuration retaining glycosidases catalyse the hydrolysis of glycosidic bonds via a double displacement mechanism, typically involving two key active site carboxyl groups (Glu or Asp). One of the enzymic carboxyl groups functions as a general acid–base catalyst, the other acts as a nucleophile. Alternatively, configuration-retaining hexosaminidases from the sequence-related glycosidase families 18, 20, and 56 lack a suitably positioned enzymic nucleophile; instead, they use the carbonyl oxygen atom of the neighbouring C2-acetamido group of the substrate. The carbonyl oxygen atom of the 2-acetamido group provides anchimeric assistance to the enzyme catalyzed reaction by acting as an intramolecular nucleophile, attacking the anomeric center and forming a cyclized oxazolinium ion intermediate that is stereochemically equivalent to the glycosyl–enzyme intermediate formed in the "normal" double displacement mechanism. Although there is little sequence similarity between families 18, 20, and 56 hexosaminidases, X-ray crystallographic studies demonstrate that they have evolved similar catalytic domains and active site architectures that are designed to distort the bound substrate so that the C2-acetamido group can become appropriately positioned to participate in catalysis. The substrate distortion allows for a substrate-assisted catalytic reaction that displays all the general characteristics of the classic double-displacement mechanism including the formation of a covalent intermediate.

Key words: glycoside hydrolase, hexosaminidase, glycosidase, substrate-assisted catalysis, anchimeric assistance.

Résumé : Les glycosidases qui maintiennent la configuration catalysent l'hydrolyse des liaisons glycosidiques par le biais d'un mécanisme de double déplacement qui implique d'une façon typique deux groupes carboxyles de sites actifs clés (Glu ou Asp). L'un des groupes carboxyles enzymatiques agit comme un catalyseur acide–base général alors que l'autre agit comme nucléophile. De façon alternative, les hexosaminidases qui maintiennent la configuration et qui proviennent des familles de glycosidases à séquences apparentées 18, 20 et 56 ne comportent pas de nucléophile enzymatique bien orienté; elles utilisent plutôt l'oxygène du carbonyle du groupe acétamido en C2 du substrat. L'atome d'oxygène du carbonyle du groupe acétamido en C2 fournit l'assistance anchimérique à la réaction catalysée par l'enzyme en agissant comme un nucléophile intramoléculaire qui attaque le centre anomère et qui forme un ion oxazolinium cyclique intermédiaire qui est l'équivalent stéréochimique de l'intermédiaire glycosyle-enzyme qui se forme dans le mécanisme de double déplacement "normal". Même si la similarité de séquence est faible entre les familles 18, 20 et 56 des hexosaminidases, des études de diffraction des rayons X montrent qu'elles ont développé des domaines catalytiques semblables et que les architectures des sites actifs sont façonnées de manière à déformer le substrat lié de façon à ce que le groupe acétamido en C2 puisse se positionner correctement pour participer à la catalyse. La distorsion du substrat permet de réaliser une réaction catalytique assistée par le substrat qui présente toutes les caractéristiques générales du mécanisme classique de double déplacement, y compris la formation d'un intermédiaire covalent.

Mots clés : hydrolase de glycoside, hexosaminidase, glycosidase, catalysée assistée par le substrat, assistance anchimérique.

[2]Dedicatory note by Michael James: Conformations of pyranose rings were a fascination for Ray Lemieux. Ray foresaw the need for X-ray crystallographic studies of carbohydrates and was one of the major movers to establish X-ray crystallography at the University of Alberta. I had the pleasure, as a post-doctoral fellow with David Hall, to collaborate with Ray on the structures of monosaccharides, some of which exhibited unusual pyranose ring conformations. These early structures of compounds synthesized by A. Richard Morgan when he was a Ph.D. student with Ray, led the way to the reverse anomeric effect. Our present review is centered on enzymes that distort pyranose rings into conformations that allow for anchimeric assistance by 2-deoxy-2-*N*-acetamido groups in hydrolytic reactions. Certainly, the structures that are discussed in our review would have been of great interest to Ray as enzymes that have evolved to carry out reactions on the carbohydrates that were so dear to Ray's heart. It was a great pleasure and inspiration to have been associated with Ray at the time I was formulating my own research program in enzyme structure and function.

Introduction

It has been well documented in physical organic chemistry that a chemical reaction can be accelerated by the intramolecular participation of a functional group on the reactant (1). The functional group acts as an intramolecular catalyst, providing what is referred to as anchimeric assistance to the catalytic mechanism of the reaction. Having a catalyst attached to the reactant such that it is not stereochemically nor structurally hindered from accessing the reactive centre, not only increases the effective concentration of the catalyst at the site of chemical reactivity, but also it provides an entropic advantage by reducing at least one aspect of the reaction mechanism from what would typically be a bimolecular to a unimolecular event (reviewed in ref. 2). Many biological substrates have functional groups possessing the required characteristics that could allow for their participation in enzyme catalysis via anchimeric assistance (substrate-assisted catalysis). Indeed, much evidence has been provided for the involvement of such functional groups in the mechanisms of natural and engineered enzymes including GTPases, type II restriction endonucleases, serine proteinases, and glycoside hydrolases (glycosidases) (3). Of particular interest to the authors of this review is the role of anchimeric assistance in glycosidases that catalyze the hydrolysis of β(1→4) linked glycosidic bonds between C2 *N*-acetylated hexosamine residues (*N*-acetylhexosamine) and other sugars. Neighbouring C2-acetamido group participation has been well documented in the acid-catalyzed hydrolysis of *N*-acetylglucosaminides in solution (4), and a number of glycosidases have evolved to incorporate C2-acetamido group participation into their catalytic mechanisms. Enzymes that hydrolyze *N*-acetylhexosamine-containing substrates are generally referred to as hexosaminidases and they have received much attention over the last 50 years. Recently, structural and biochemical research endeavors have provided new insights into the catalytic mechanisms of hexosaminidases and the role of anchimeric assistance.

The hexosaminidases

The term hexosaminidase is usually reserved for enzymes that catalyze the removal of *N*-acetylhexosamine residues from the non-reducing end of oligosaccharides and glycoconjugates; however, it may also be used in a generic sense to refer to all glycosidases that hydrolyze glycosidic bonds between an *N*-acetylhexosamine residue and an adjacent sugar. Thus, the term hexosaminidase also includes chitinases, chitobiases, hyaluronidases, and lysozymes (for an extensive review of the glycosidases, see ref. 5). Chitinases hydolyze chitin, the β(1→4) linked polymer of *N*-acetylglucosamine (NAG), either randomly within the polymer chain (*endo*-acting) or at the ends of the polymer (*exo*-acting). Chitobiases hydrolyze the glycosidic linkage within chitobiose (di-β(1→4)-NAG) and have also been shown to hydrolyze tri- and tetra-β(1→4)-NAG as well (6). Hyaluronidases are *endo-N*-acetylhexosaminidases that hydrolyze the β(1→4) glycosidic linkage between NAG and glucuronic acid (GlcA) within the glycosaminoglycan hyaluronic acid (HA) (7). Lysozymes hydrolyze the peptidoglycan cell wall of Gram-positive bacteria, which are composed of crosslinked oligosaccharides of alternating β(1→4) linked NAG and *N*-acetylmuramic acid (NAM) residues. Hen egg white (HEW) lysozyme, the exemplary member of the hexosaminidases and glycosidases in general, was the first enzyme to have its three-dimensional structure determined using X-ray crystallographic methods. This early crystallographic work on HEW lysozyme provided the first insights into enzyme catalysis at the molecular level (8, 9).

Glycosidases have been classified into families based on primary amino acid sequence similarities. There are currently more than 70 sequence-related families, of which at least 30 contain members that have had their three-dimensional structures determined (10–12). Although the individual sequence-related families may contain enzymes with distinct substrate specificites, structural studies have shown that within many of these families, the protein fold is highly conserved. Thus, once the three-dimensional structure has been determined for at least one of the proteins within a family, comparative molecular modeling techniques can be used to predict the molecular structure of other family members (for examples, see refs. 13 and 14). The URL http://afmb.cnrs-mrs.fr/~cazy/CAZY/index.html contains a frequently updated database of the sequence-related glycosidase families. Moreover, glycosidases exist in one of two possible mechanistic groups: those that catalyze bond hydrolysis with net retention of anomeric configuration and those that invert the anomeric configuration (15, 16). It has been found that this mechanistic distinction is conserved within each sequence-related family — all members of an individual family catalyze reactions with the same stereochemical outcome (17).

Biochemical and structural studies of the hexosaminidases from families 18, 20, and 56 demonstrate that these enzymes use an anchimeric-assistance mechanism involving neighboring C2-acetamido group participation. Family 18 consists of chitinases and *endo*-β-*N*-acetylhexosaminidases; whereas, family 20 contains chitobiases and β-hexosaminidases, including the human β-hexosaminidase isoforms A and B. Human β-hexosaminidase isoform A is a heterodimer of subunits α (encoded by *HEXA*) and β (encoded by *HEXB*), while isoform B is a homodimer of β subunits. Inborn errors in *HEXA* and *HEXB* result in Tay-Sachs and Sandhoff disease, respectively (18). These serious genetic diseases have made the human β-hexosaminidase isoforms, and family 20 enzymes in general, the focus of much biomedical research. Family 56 contains hyaluronidases and recently discovered mutations in *HYAL1*, a human gene encoding a serum hyaluronidase, have been shown to be linked to a disorder known as mucopolysaccharidosis IX (19). Although the hexosaminidases from families 18, 20, and 56 share very little overall sequence identity, they have similar $(\beta/\alpha)_8$ catalytic domains (Fig. 1), and a number of their catalytic residues are identical (20, 21). The glycosidases within these families carry out glycosidic bond hydrolysis with net retention of anomeric configuration (6, 21–25) and, interestingly, the active site residues that are identical among these three families, give rise to common structural features that are involved in optimizing the C2-acetamido group participation in a double-displacement mechanism described below.

General glycosidase mechanisms

For the vast majority of glycosidases, there are two key active site carboxyl groups (Glu or Asp) that are intimately involved in the catalytic mechanisms of both inverting and retaining glycosidases (26, 27). Inverting glycosidases use a single displacement mechanism for which the two carboxyl groups are typically spaced 10.5 Å apart, thereby allowing for a substrate molecule and a water molecule to bind between them (15, 16, 27). One of the carboxyl groups promotes general acid-catalyzed cleavage of the glycosidic bond, whereas the other acts as a general base, catalyzing the nucleophilic attack of a water at the anomeric centre in a single nucleophilic reaction that occurs via an oxocarbenium ion-like transition state (16, 26, 28, 29). The result of this reaction is a hemiacetal product with inverted anomeric stereochemistry (Fig. 2A).

Retaining glycosidases use a double displacement mechanism for which the two carboxyl groups are spaced 5.5 Å apart, on average, and allow only for a substrate molecule to fit between them (15, 16, 27). One carboxyl group promotes general acid-catalyzed cleavage of the glycosidic bond, whereas the other acts as a nucleophile, directly attacking the anomeric centre and forming a covalent glycosyl–enzyme intermediate. After departure of the leaving group, the intermediate, which has an inverted anomeric centre relative to the substrate, undergoes general base catalyzed nucleophilic attack by an incoming water molecule to yield a product with retained anomeric stereochemistry (Fig. 2B, upper pathway) (26). Both steps of the double displacement mechanism proceed through transition states with substantial oxocarbenium ion character (16, 28, 29).

Alternatively, the configuration-retaining hexosaminidases from families 18, 20, and 56 lack an apparent enzymic nucleophile needed to form the glycosyl–enzyme intermediate in the first step of the double-displacement mechanism. Instead, the C2-acetamido group of the substrate participates in the reaction and assumes the role of the missing nucleophile (Fig. 2B, lower pathway) (13, 20, 21, 26). A number of equivalent catalytic residues within the active sites of families 18, 20, and 56 glycosidases result in common structural features that appropriately distort the bound substrate so that the carbonyl oxygen atom of the C2-acetamido group can become positioned for nucleophilic attack at the anomeric centre. In keeping with the geometrical considerations of the general retaining mechanism, this substrate distortion creates an average distance of 5.4 Å between the C2-acetamido group oxygen atom of the substrate and the carboxyl oxygens of the enzymic general acid–base catalytic residue. In the first step of the mechanism, the enzymic carboxyl group promotes general acid-catalyzed cleavage of the glycosidic bond, while a concerted nucleophilic attack by the C2-acetamido group oxygen results in an enzyme-stabilized oxazolinium-ion intermediate (30, 31). After departure of the leaving group, the cyclized intermediate undergoes base-catalyzed nucleophilic attack by an incoming water molecule at the anomeric centre to yield a product with retained stereochemistry. As for the "normal" double displacement mechanism, both steps of the reaction are believed to pass through oxocarbenium ion-like transition states (30). Another example of a glycosidase lacking a suitably disposed nucleophile in its active site is soluble lytic transglycosylase (32), and suggests that anchimeric assistance may be used by glycosidases from other sequence-related families.

Fig. 1. Ribbon diagrams of representative three-dimensional glycosidase structures from the sequence-related families 18 (A), 20 (B), and 56 (C). Although there is little sequence identity amoung the three families, they all have similar $(\beta/\alpha)_8$ barrel catalytic domains, shown here with α-helices and loops in light blue and β-strands in purple. (A) Family 18 Chitinase B from *Serratia marcescens* (36). (B) Family 20 β-hexosaminidase from *Streptomyces plicatus* (30). (C) Family 56 hyaluronidase from bee venom (21). The catalytic domains of family 18 and 20 glycosidases contain a typical eight-stranded β-barrel; however, the β-barrel of the bee venom hyaluronidase is incomplete and only contains seven β-strands. The ribbon diagrams were drawn with MOLMOL (55) and rendered with PovRay™ (Hallam Oaks Pty. Ltd).

Fig. 2. Proposed catalytic mechanisms for inverting (A) and retaining glycosidases (B). Hydroxyl groups and C6 have been removed from the sugar ring for clarity and, ignoring the C2-acetamido group, the mechanisms shown in panels (A) and (B) (upper pathway) can be used to describe the catalytic mechanisms of inverting and retaining glycosidases in general. The mechanism shown in panel (B), lower pathway, involves anchimeric assistance from the C2-acetamido group, and the carboxylate illustrated beneath the cyclic intermediate is not positioned to act as a nucleophile. Instead, this carboxylate represents an enzymic residue, common amoung families 18, 20, and 56 glycosidases, and is responsible for stabilizing the positive charge that develops on the acetamido nitrogen, N2, upon cyclization (see Fig. 4B and related text). No attempt has been made to indicate the true position of this enzymic residue. Crystallographic evidence has demonstrated that the Michaelis complexes of β-retaining glycosidases, using either the upper or lower pathway in panel (B), contain a distorted substrate such that the glycosidic bond and leaving group (*R*) adopt a pseudo-axial position (13, 34, 35). Molecular modeling studies suggest that the Michaelis complex of inverting glycosidases may also contain a similarly distorted substrate (40, 41). Convincing structural evidence is lacking for the conformation of product bound in the –1 subsite. However, there is some evidence to suggest that the conformation of the pyranose ring of the product bound in the –1 subsite of β-retaining glycosidases is not a relaxed $^4C_1$ chair and is instead slightly distorted towards a higher energy half-chair-like structure (35, 38). A high-energy conformation for bound product may indeed prompt its expulsion from the active site. Figure drawn with CS CHEMDRAW STD. (CambridgeSoft Corp., Cambridge, Mass, U.S.A.).

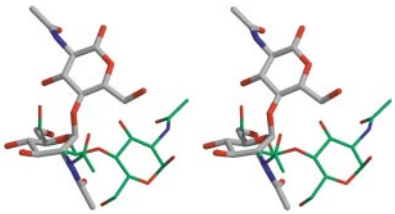
Substrate distortion

According to the currently accepted *–n* to *+n* nomenclature for glycosidase sugar-binding subsites (33) (where *n* is an integer and *–n* signifies the non-reducing end and *+n* the reducing end of the bound oligosaccharide), the scissile glycosidic bond of the substrate spans subsites –1 and +1. Crystallographically determined structures of complexes between intact substrates and retaining β-glycosidases demonstrate significant distortions in the pyranoside ring of the sugar bound in the –1 subsite prior to bond cleavage (Fig. 3) (13, 34–36). Distortion in the pyranoside ring bound in the –1 subsite was first proposed for HEW lysozyme in the late 1960's (37), and most recently supported by a high-resolution structure determination of the complex of HEW lysozyme with NAM–NAG–NAM bound as a product (38). Although the product complex between HEW lysozyme and NAM–NAG–NAM suggested a sofa conformation for the pyranose ring of the NAM residue bound in the –1 subsite, the true extent of substrate distortion was not revealed, however, until structures of retaining β-glycosidases were determined in complex with intact substrates spanning the active site, indicating that substrate interactions at the +1 subsite contribute significantly to pyranoside ring distortion in the –1 subsite (39).

The first three-dimensional structure of an intact substrate spanning the active site of a glycosidase was determined crystallographically — it was a complex between a family 20 chitobiase from *Serratia marcescens* and its natural substrate chitobiose (13). Although it is unclear why the chitobiose was not cleaved by the chitobiase crystals, the non-reducing and reducing NAG residues of the intact chitobiose molecule were located in the –1 and +1 subsites, respectively. The pyranoside ring of the sugar bound in subsite –1 was found to be distorted from the standard $^4C_1$ chair conformation into a skew-boat conformation such that the scissile bond and leaving group were held in a pseudo-axial orientation by the enzyme (Fig. 3). Representative hexosaminidases of both *endo*- and *exo*-acting enzymes from families 18 and 20, respectively, demonstrate this mode of substrate distortion in their respective Michaelis complexes (Figs. 4A and B) (13, 36). The three-dimensional structure of a Michaelis complex for a family 56 glycosidase has not been determined thus far; however, the structure of a family 56 hyaluronidase from bee venom has been solved in complex with a hyaluronic acid tetramer bound product (21). The substrate distortions seen in the Michaelis complexes for the family 18 and 20 glycosidases are nearly identical to those observed in the crystallographically determined Michaelis complexes of retaining cellulases from families 5 and 7 (34, 35). It has been postulated that similar substrate distortion also occurs in the enzyme-substrate complexes of inverting β-glycosidases (40, 41). Together, these findings suggest that a distorted pseudo-axial position for the glycosidic linkage and leaving group may indeed be a general mechanistic requirement for retaining and inverting β-glycosidases. Indeed, distortion of the pyranoside ring in the –1 site from a $^4C_1$ chair towards a boat conformation helps to satisfy the requirements of stereoelectronic theory. A boat conformation orients a lone pair of electrons on the ring oxygen (O5) antiperiplanar with respect to the scissile bond and leaving group. This

Fig. 3. Stereographic representation of a superposition of the small molecule crystal structure of unbound chitobiose (green carbon atoms) (56) and chitobiose bound to a family 20 *Serratia marcescens* chitobiase as a Michaelis complex (gray carbon atoms) (13). For both molecules, nitrogen atoms are shown in blue and oxygens in red. As previously demonstrated by Tews et al. (13), a superposition of these two structures shows that the non-reducing sugar of chitobiose, bound to the –1 subsite of the *S. marcescens* chitobiase, is distorted from a $^4C_1$ chair (as observed for the unbound chitobiose (green)), into a skew-boat conformation. The pyranoside ring distortion brings the leaving group and scissile bond into a pseudo-axial position and moves the anomeric carbon atom to a position slightly above the plane of the sugar ring. The skew-boat conformation allows the C2-acetamido group of the non-reducing sugar bound in the –1 subsite group to rotate approximately 156° about the C2–N2 bond so that the carbonyl oxygen atom O7 is positioned underneath the α-face of the sugar ring and into position for nucleophilic attack at the anomeric centre. All superpositions were carried out using the program O (57) and molecular diagrams were drawn with MOLSCRIPT (58) and rendered with the RASTER 3D (59).



conformational arrangement maximizes electron donation from O5 to the antibonding orbital at the electron deficient anomeric center and thus accommodates much of the positive charge that develops at the anomeric center during the transition states (42, 43). The pseudo-axial orientation of the leaving group also places the oxygen atom of the glycosidic bond in an appropriate position for lateral protonation by the enzymic general acid catalyst (39).

In addition to the pyranoside ring distortion, the glycosidases from families 18, 20, and 56 have evolved remarkable active site architectures that position the C2-acetamido group of the NAG reside bound in the –1 subsite so that the carbonyl oxygen of this functional group can provide anchimeric assistance to the catalytic reaction. Although families 18, 20, and 56 share little sequence homology, the –1 subsite of the enzymes belonging to these families contain a homologous hydrophobic pocket that orients the C2-acetamido group into an appropriate position for nucleophilic attack at the anomeric centre (Fig. 4A) (13, 20, 21, 36). For the enzymes within each family, there exist an Asp and Tyr located in analogous positions on either side of the pocket (Fig. 4B). The Asp residue is positioned so that it can form a short hydrogen-bonding interaction with nitrogen atom (N2) of the C2-acetamido group; whereas, the position of the Tyr residue allows for it to form a hydrogen bond with the carbonyl oxygen atom (O7) of the C2-acetamido group (13, 21, 30, 36). These hydrogen bonds not only help to steer and lock the C2-acetamido group into position for nucleophilic attack, they also enhance the polarization of the amide beyond its naturally occurring dipole moment,

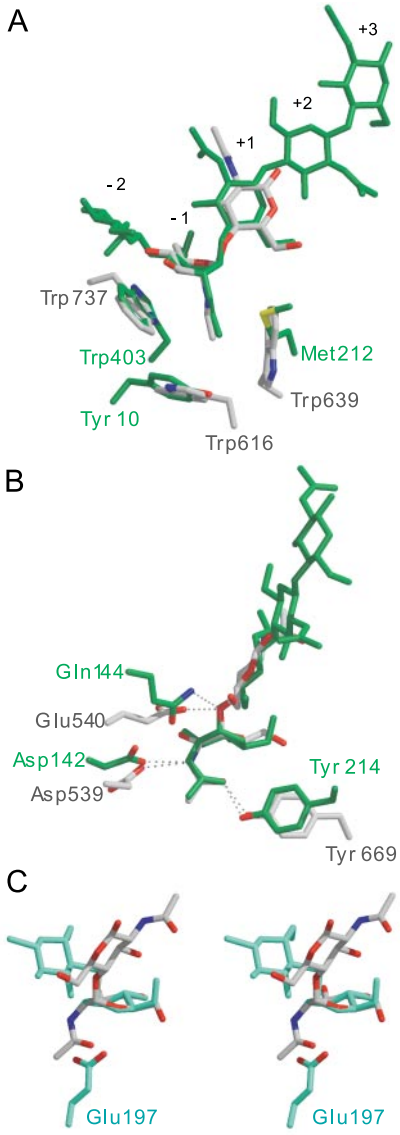

Fig. 4. Superpositions of crystallographic Michaelis complexes determined for representative family 18 and 20 glycosidases (A and B) (13, 36) and a family 7 β-retaining endoglucanase I from *Fusarium oxysporum* (C) (34). (A) Superposition of a family 20 chitobiase (gray carbon atoms) (13) and family 18 *endo*-chitinase (ChiB) (all atoms are green) from *S. marcescens* (36). The occupied sugar-binding subsites –2 to +3 have been labeled. The superposition demonstrates that *endo*- and *exo*-acting glycosidases from families 18 and 20, respectively, distort the pyranoside ring of the sugar bound in the –1 subsite from a $^4C_1$ chair into a skew boat prior to bond cleavage. This distortion results in a pseudo-axial orientation of the scissile glycosidic bond and leaving group. Both glycosidases have an analogus hydrophobic pocket as part of their –1 sugar binding subsites. This pocket helps to position the carbonyl oxygen of the C2-acetamido group underneath the α-face of the sugar and into an appropriate position for catalysis. A similar distorted position for the C2-acetamido group is observed for the NAG residue bound in the –1 subsite of the bee venom hyaluronidase product complex (21). (B) Rotated 90° relative to panel (A), this diagram of the superposition between the family 18 chitinase and family 20 chitobiase shows analogous hydrophilic residues that interact with the bound substrate. The general acid–base residue Glu540 from the family 20 chitobiase and the analogus family 18 chitinase residue Gln144 (mutated from a Glu in the wild-type enzyme), are equally situated to interact with the pseudo-axially positioned glycosidic oxygen atom of the substrate. The residues Asp539 and Tyr669 from the family 20 chitobiase and Asp142 and Tyr214 from the family 18 chitinase, form equivalent hydrogen-bonding interactions with the C2-acetamido nitrogen N2 and carbonyl oxygen O7, respectively. These hydrogen-bonding interactions not only appear to lock the C2-acetamido group into a catalytically favorable position, they may also polarize the amide and increase the nucleophilicity of O7. Recently, a crystallographic complex between a mutated form of the family 20 chitobiase (Asp539Ala) and chitobiose demonstrated that in the absence of the Asp539 carboxylate, the carbonyl oxygen of the C2-acetamido group does not become positioned underneath the α-face of the pyranoside ring as shown here, but instead occupies the space where the missing Asp caboxyl group is normally located (60). This complex supports the conjecture that Asp539 and the equivalent Asp in other family 18 and 20 glycosidases is important for positioning the C2-acetamido group into a catalytically competent position. (C) Superposition of the *F. oxysporum* endoglucanase I from family 7 (34) and the family 20 chitobiase from *S. marcescens* (13). The crystallographic Michaelis complex between endoglucanase I and a non-hydrolyzable substrate (shown in light green) demonstrated that substrate distortion occurs in an analogous manner to that observed for family 18 and 20 glycosidases, where the sugar bound to subsite –1 is distorted into a skew-boat and the scissile bond and leaving group are in a pseudo-axial position (34). Moreover, as previously demonstrated by Sulzenbacher et al. (34), the superposition of these two Michaelis complexes reveals that the carboxylate of the enzymic nucleophile, Glu197, of endoglucanase I superposes almost perfectly with the C2-acetamido group oxygen of the non-reducing sugar of chitobiose bound to the family 20 chitobiase. The remarkable spatial equivalence of the two functional groups within the active sites of these glycosidases clearly indicates that the C2-acetamido group oxygen is suitably positioned to act in place of an enzymic nucleophile in the catalytic mechanism of family 18 and 20 glycosidases.

thereby causing a further increase in charge density on the carbonyl oxygen and increasing its nucleophilicity. Kinetic studies with substrate analogues and inhibitors have provided biochemical support for the structural findings that implicate C2-acetamido group participation in the catalytic mechanism of the glycosidases from families 18, 20, and 56 (6, 7, 22, 31, 44, 45).

Interestingly, it can be been shown that the nucleophilic oxygen atom of Glu197 of the family 7 β-retaining endoglucanase I from *Fusarium oxysporum* (which uses the catalytic mechanism described in Fig. 2B, upper pathway) essentially overlaps the position of the C2-acetamido carbonyl oxygen of chitobiose bound to the family 20 chitobiase from *Serratia marcescens* when the two structures are superimposed (Fig. 4C) (34). Thus, anchimeric assistance by the neighboring C2-acetamido group of the substrate not only replaces the need for a second enzymic carboxylate, but also the stereochemistry of the nucleophilic attack is conserved between retaining β-glycosidases that use either an enzymic or substrate-based nucleophile.

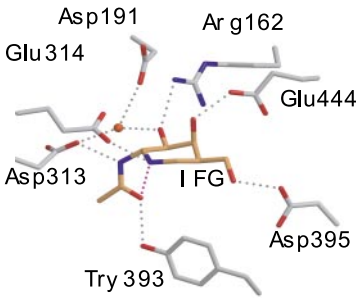
Fig. 5. Crystallographic complex of the 1-*N*-azasugar GalNAc-isofagomine (IFG, brown carbon atoms) bound in –1 sugar-binding subsite of a β-*N*-acetylhexosaminidase from *Streptomyces plicatus* (gray carbon atoms) (46). For both the enzyme and azasugar inhibitor, oxygen atoms are shown in red and nitrogen atoms in blue. The conformation of GalNAc-isofagomine is distorted from a $^4C_1$ chair toward a half-chair. The endocyclic nitrogen atom N1 is displaced 0.4 Å below the least-squares plane defined by atoms C2, C3, C5, and C9 (C9 replaces the endocyclic oxygen atom O5 of pyranose rings); whereas, atom C4 is displaced 0.7 Å above this plane. N1 is assumed to be protonated when bound to the enzyme; the axial proton forms a 2.7 Å intramolecular hydrogen bond with the C2-acetamido group oxygen O7 (dashed magenta line), whereas the equatorial proton forms a novel 2.8 Å hydrogen bond with the carboxyl group of the general acid–base residue Glu314. The intramolecular hydrogen bond between N1 and O7 of GalNAc-isofagomine is analogus to the strong electrostatic interaction demonstrated to occur between N1 of a xylobiose-derived 1-*N*-azasugar inhibitor and the enzymic nucleophile of Cex, a family 10 β-retaining glycosidase from *Cellulomonas fimi* (46, 47).



A family 20 β-hexosaminidase from *Streptomyces plicatus* was recently shown to be strongly inhibited by a C2 *N*-acetylated 1-*N*-azasugar, GalNAc-isofagomine (K_i = 2.7 μM) (Fig. 5) (46). 1-*N*-Azasugar inhibitors are thought to derive most of their binding energy from a strong electrostatic interaction between the protonated endocyclic nitrogen at the "anomeric" centre of the inhibitor and the negatively charged enzymic nucleophile of a retaining β-glycosidase (47). It was therefore surprising to find that a 1-*N*-azasugar could also act as a potent competitive inhibitor of a glycosidase lacking an enzymic nucleophile. The crystallographically determined complex between *S. plicatus* β-hexosaminidase and GalNAc-isofagomine provided an explanation for the effective binding of this inhibitor to the enzyme. The complex demonstrated that the binding mode of the inhibitor allowed for a novel 2.8 Å hydrogen-bonding interaction to occur between the endocyclic ring nitrogen of the inhibitor and the carboxyl group of the enzymic general acid–base catalytic residue Glu314. An equivalent hydrogen-bonding interaction is not observed in the recent crystallographically determined complex between a xylobiose-derived 1-*N*-azasugar inhibitor and Cex, a family 10 β-retaining glycosidase from *Cellulomonas fimi* (47). Cex instead contains an enzymic nucleophile to which the endocyclic ring nitrogen of the xylobiose-derived 1-*N*-azasugar was found to closely interact. The lack of such an electrostatic interaction between the *S. plicatus* β-hexosaminidase and GalNAc-isofagomine appears to allow for the inhibitor to bind so that the endocyclic ring nitrogen can instead form a compensatory hydrogen-bonding interaction with the general acid–base catalytic residue. This alternative hydrogen bond seems to explain the unexpected potency of GalNAc-isofagomine towards the β-hexosaminidase and may form the basis for a new series of pharmacological agents that inhibit family 20 glycosidases.

Intermediate structure

The oxazolinium ion intermediate formed by C2-acetamido group participation in the catalytic mechanism of families 18, 20, and 56 glycosidases is too hydrolytically unstable for use in crystallographic studies. A relatively stable analogue, NAG-thiazoline, was synthesized and shown to be a potent competitive inhibitor of jack bean β-hexosaminidase (K_i = 280 nM) (31). Furthermore, it was shown that a precursor substrate of NAG-thiazoline, 4-methylumbelliferyl-2-deoxy-2-thioacetamido-β-glucoside, could be converted into NAG-thiazoline by jack bean β-hexosaminidase, leading to time dependent loss of enzyme activity and thereby providing direct biochemical support for anchimeric assistance and the formation of a covalent, cyclized intermediate by the enzyme.

Recently, an X-ray crystal structure of NAG-thiazoline in complex with the family 20 β-hexosaminidase from *S. plicatus* was determined (Fig. 6) (30).[3] The structure of the complex indicates that after the reaction has progressed through the first transition state to the cyclized intermediate (Fig. 2B, lower pathway), the sugar ring (bound in the –1 subsite) relaxes from the skew-boat conformation, as observed in the Michaelis complex of the related chitobiase from *S. marcescens* (13), to what could best be described as a $^4C_1$ chair conformation (Fig. 7). Taken together, the crystal structures of the Michaelis complex from the family 20 chitobiase, and the intermediate analogue bound to the family 20 β-hexosaminidase, reveals that the anomeric carbon

[3] Crystallographic data for the protein structures discussed in this review are available from the Protein Data Bank (URL: http://www.rcsb.org/pdb/) under the following PDB identifiers: *S. marcescens* chitobiase in complex with chitobiose, 1QBB; Mutant *S. marcescens* chitobiase (D539A) in complex with chitobiose, 1C7S; *S. plicatus* β-hexosaminidase in complex with the intermediate analouge NAG-thiazoline, 1HP5; *S. plicatus* β-hexosaminidase in complex with GalNAc-isofagomine, 1JAK; Mutant *S. marcescens* ChiB (E144Q) in complex with penta-NAG, 1E6N; *S. marcescens* ChiB in complex with allosamidin, 1E6R; Mutant *S. marcescens* ChiA (E315Q) in complex with octa-NAG, 1EHN; Mutant *S. marcescens* ChiA (D313A) in complex with octa-NAG, 1EIB; Mutant *S. marcescens* ChiA (Y390F) in complex with hexa-NAG, 1FFR; *F. oxysporum* endoglucanse 1 in complex with thio-DP5 (methyl-*S*-β-D-glucopyranosyl-(1→4)-*S*-4-thio-β-D-glucopyranosyl-(1→4)-*S*-4-thio-β-D-glucopyranosyl-(1→4)-*S*-4-thio-β-D-glucopyranosyl-(1→4)-*S*-4-thio-α-D-glucopyranoside), 1OVW; NAG-(1→4)-2-deoxy-2-fluoro-β-D-glucopyranosyl·HEW lysozyme covalent intermediate complex, 1H6M; Hevamine in complex with allosamidin, 1LLO; Bee venom hyaluronidase in complex with hyaluronic acid tetramer, IFCV. Fig. 6. Crystallographic complex between the oxazolinium ion intermediate analogue NAG-thiazoline (NGT) and a family 20 β-*N*-acetylhexosaminidase from *Streptomyces plicatus* (30). The conformation of the pyranose ring of NAG-thiazoline approaches that of a relaxed $^4C_1$ chair and is held within the –1 subsite of the enzyme (gray carbon atoms) by an extensive hydrogen bonding network (dashed lines). Site directed mutagenesis studies confirm that the bidentate hydrogen-bonding interaction occurring between O3 and O4 of NAG-thiazoline and the conserved family 20 residue Arg162, appears to be particularly important for binding substrate and stabilizing transition states that occur along the reaction corrdinate (13, 14, 61). Glu314 acts as the general acid–base residue for this β-hexosaminidase and does not interact with the intermediate analogue. The thiazoline ring of the cyclic intermediate analogue forms the same hydrogen-bonding interactions as observed for the C2-acetamido group in the Michaelis complexes of related family 18 and 20 glycosidases (Fig. 4B). In particular, the short hydrogen bond formed between Asp313 and the C2-acetamido group nitrogen N2 is understood to balance the positive charge that develops on this nitrogen atom upon cyclization to form the oxazolinium ion intermediate (Fig. 2B, lower pathway). Asp313 is conserved among family 20 glycosidases and has an equivalent residue in family 18 glycosidases, indicating that the charge stabilization provided by this residue is a common mechanistic feature of both glycosidase families.

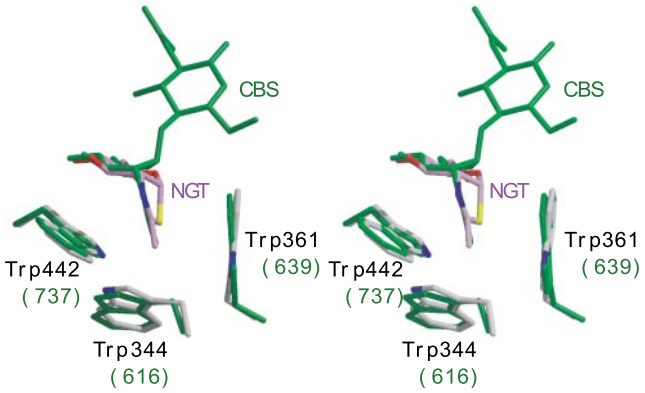
atom (C1) experiences the greatest nuclear motion along the reaction coordinate. Initially, atom C1 is above the plane of the sugar ring and then, as the covalent bond to the glycosidic oxygen breaks, the anomeric center (C1) moves approximately 0.9 Å to a position below the plane of the sugar ring, where it forms a new covalent bond with the C2-acetamido group oxygen atom, resulting in an oxazolinium ion intermediate (Fig. 2B, lower pathway). The nuclear motion proposed for the anchimeric assistance mechanism of family 20 glycosidases is in agreement with the recently proposed theory of electrophilic migration of the anomeric center along the reaction coordinate of HEW lysozyme and retaining β-glycosidases in general (48).

The pyranoside ring conformation of the cyclic intermediate analogue NAG-thiazoline bound to the *S. plicatus* β-hexosaminidase is strikingly similar to that observed for the recently determined glycosyl–enzyme intermediate structure of HEW lysozyme (Fig. 8) (48) and other retaining β-glycosidases that use an enzymic nucleophile (35, 49, 50). The "textbook" mechanism of HEW lysozyme originally proposed by Phillips (9), suggested a dissociative S_N1-type reaction mechanism involving a long-lived oxocarbenium ion intermediate that was stabilized by the enzyme through

Fig. 7. Stereographic representation of a superposition of the *S. plicatus* β-hexosaminidase–NAG-thiazoline intermediate complex (coloured as in Fig. 6) (30) and the *S. marcescens* chitobiase–chitobiose Michaelis complex (atoms and labels shown in green) (13). Both family 20 glycosidases contain three conserved Trp residues that help to position the C2-acetamido group and stabilize the oxazolinium ion intermediate as indicated by the NAG-thiazoline analogue. The superposition clearly demonstrates that upon cleavage of the scissile glycosidic bond and nucleophilic attack by the C2-acetamido oxygen, the pyranose ring of the sugar bound in the –1 subsite relaxes from a skew-boat conformation as observed for chitobiose (CBS) towards a relaxed $^4C_1$ chair as seen for NAG-thiazoline (NGT). This conformational change requires very little movement by any atoms other than the migration of the anomeric centre from above the β-face to below the α-face of the sugar ring (30).



electrostatic interactions, primarily with the carboxylate of Asp52. Vocadlo et al. (48) have recently trapped and solved the crystal structure of a glycosyl–enzyme intermediate form of HEW lysozyme (Fig. 8), demonstrating, however, that this enzyme proceeds via a covalent intermediate during catalysis and uses instead the S_N2-type double-displacement mechanism described in the upper pathway of Fig. 2B. This finding now places HEW lysozyme in the general class of retaining glycosidases and strengthens the general configuration-retaining mechanism that includes substrate distortion, electrophilic migration of the anomeric carbon atom during catalysis, and the formation of a covalent intermediate.

Previously, an Asp52Ala mutant of HEW lysozyme was found to retain appreciable activity against substrates that were believed to have no functional groups that could compensate for the missing Asp carboxylate (51). Thus, it was assumed that Asp52 was not essential to the catalytic mechanism of HEW lysozyme. The authors did not consider, however, that the residual activity could have been a result of C2-acetamido group participation. It is possible that the C2-acetamido group of the sugar bound in the –1 subsite during catalysis might have compensated for the missing carboxyl group on the mutant enzyme. It could occupy the position of the missing Asp52 carboxylate in a conformation similar to that observed for the Michaelis complexes of the family 18 and 20 glycosidases. This conformation may then result in the formation of an oxazoline intermediate as opposed to the glycosyl–enzyme intermediate observed by Vocadlo et al. (48).

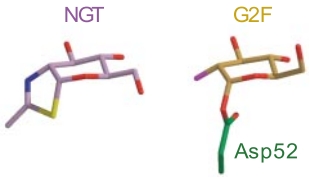
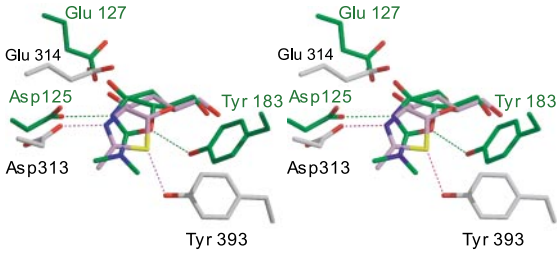
Fig. 8. Comparison of the enzyme bound conformation of NAG-thiazoline (NGT) (30) and the covalent NAG-(1→4)-2-deoxy-2-fluoro-β-D-glucopyranosy-HEW lysozyme intermediate structure (only the sugar bound in the –1 subsite is shown (G2F)) (48). The comparison clearly demonstrates that the sugar ring bound in the –1 subsite of both the *S. plicatus* β-hexosaminidase and HEW lysozyme intermediate complexes, adopts a conformation best described as a $^4C_1$ chair regardless of whether the nucleophile is provided by the substrate or by the enzyme.



There is convincing crystallographic evidence for the formation of an oxazolinium ion intermediate on the catalytic pathway of family 18 glycosidases. The potent family 18 chitinase inhibitor, allosamidin, is a natural pseudo-trisaccharide with an aminocyclitol derivative at its "non-reducing" end that mimics the stereochemical characteristics of the oxazolinium ion intermediate (52). The structure of this inhibitor has been determined in complex with the chitinase–lysozyme hevamine (22), and Chitinase B (ChiB) from *S. marcescens* (36). A superposition of the *S. plicatus* β-hexosaminidase–NAG-thiazoline and hevamine–allosamidin complexes demonstrates that the oxazoline-like structure of allosamidin not only occupies the same location as the thiazoline ring of NAG-thiazoline, but also it forms the same hydrogen-bonding interactions with equivalent Asp and Tyr residues (Fig. 9). A similar observation is found when the *S. marcescens* ChiB–allosamidin and NAG-thiazoline–β-hexosaminidase complexes are superimposed. Although the structure of a complex between a family 56 hyaluronidase and a cyclic intermedate analogue has not been determined, it has recently been demonstrated that a GlcA-β(1→3)-NAG oxazoline derivative can be used as an "activated" substrate monomer for the artificial synthesis of hyaluronic acid by either bovine or ovine testicular hyaluronidase (7).

Finally, a well-ordered water molecule can be observed approximately 3.3–3.4 Å from C1 of the allosamizoline ring when in complex with either hevamine or ChiB from *S. marcescens* (36). This water molecule is hydrogen-bonded to the respective general acid–base residue of each enzyme (ChiB Glu 144, hevamine Glu 127) and is in roughly the same position as the glycosidic oxygen atom prior to cleavage (36). If an oxazolinium ion intermediate were to be bound in the position of the allosamizoline ring in these complexes, this water molecule would be perfectly poised for base-catalyzed nucleophilic attack at the anomeric center of the intermediate, completing the catalytic cycle and producing a product with retained anomeric stereochemistry (36). Support for these findings in family 18 glycosidases is provided by the family 20 *S. plicatus* β-hexosaminidase in complex with NAG-thiazoline (30). In this complex, one of the hydroxyl groups of a glycerol molecule, bound in the +1 subsite, is hydrogen-bonded to the general acid–base residue Glu314 and is positioned 3.5 Å above the β-face of the intermediate analogue. This hydroxyl group occupies a position

Fig. 9. Superposition of the *S. plicatus* β-hexosaminidase–NAG-thiazoline complex (30) and family 18 hevamine–allosamidin complex (22). The oxazoline-like moiety of the naturally occurring chitinase inhibitor allosamidin and the thiazoline ring of NAG-thiazoline occupy the same relative position within the active site of each enzyme. The striking similarity of the active site architecture and hydrogen-bonding interactions responsible for binding the oxazoline-like moieties of allosamidin to hevamine and NAG-thiazoline to *S. plicatus* β-hexosamnindase, provides convincing evidence for the formation of a cyclic intermediate in the reaction pathways of both family 18 and 20 glycosidases.



analogous to that of the water molecule observed in the complexes between allosamidin and the family 18 glycosidases discussed above, and is indeed well situated to attack C1 of an oxazolinium ion intermediate.

In light of the recent structural and biochemical findings for family 18 and 20 glycosidases and for HEW lysozyme, an alternative mechanism recently proposed on the basis of structural studies of a family 18 Chitinase A (ChiA) from *Serratia marcescens* seems unlikely (53). A series of S. *marcescens* ChiA structures containing various active site mutations were solved in complex with octa- or hexa-*N*-acetylglucosamine. Based primarily on the electron density ascribed to a hexa-*N*-acetylglucosamine molecule bound in the active site of a ChiA mutant (Tyr390Phe, ChiA Tyr390 is equivalent to the Tyr residues shown in Figs. 4B, 5, 6, and 9), it was concluded that the C2-acetamido group of the sugar bound in the –1 subsite of the enzyme was inappropriately positioned to form an oxazolinium ion intermediate (53). Instead, it was suggested that the carbonyl oxygen atom of the acetamido group assisted in stabilizing a long-lived oxocarbenium ion intermediate through electrostatic interactions in an S_N1-type mechanism. However, there is now a substantial amount of evidence refuting a glycosidase mechanism involving a long-lived oxocarbenium ion intermediate (5, 48), and the electron density for the sugar bound in the –1 subsite of this complex is ambiguous. Thus, mechanistic conclusions based on the structure of this complex are suspect, and C2-acetamido group participation that results in the formation of a cyclized oxazolinium ion intermediate in the catalytic mechanism of *S. marcescens* ChiA should not be ruled out based on these findings alone.

Conclusions

There is a substantial amount of evidence demonstrating that anchimeric assistance is a common mechanistic feature of the glycosidases belonging to families 18, 20, and 56. Future structural and functional investigations may demonstrate anchimeric assistance to be an integral mechanistic component of glycosidases in other sequence-related families.

© 2002 NRC Canada

Substrate-assisted catalysis may have indeed occurred during the evolutionary history of many enzymes. It has been suggested for the serine proteinases at least, that the spontaneous formation of the classic triad of catalytic residues (Ser-His-Asp) would have been a highly unlikely evolutionary event. Alternatively, it was proposed that the serine proteinases once contained only a catalytic diad (Ser and Asp) and operated via an anchimeric assistance mechanism whereby the His residue of the catalytic triad was provided by the substrate (54). It was only later in evolutionary history that these proteinases incorporated within their active sites a suitably positioned His residue that could take over from the substrate, thereby dramatically broadening substrate specificity (54). We may be observing a similar evolutionary path for the glycosidases from families 18, 20, and 56; however, it is also possible that existing evolutionary pressures demand that these enzymes maintain an active site architecture and catalytic mechanism that is dependent and specific for the presence of the C2-acetamido group. Regardless of the evolutionary fate of the family 18, 20, and 56 glycosidases, these enzymes presently have an active site structure that carries out a catalytic mechanism displaying all the general characteristics of the double-displacement mechanism first proposed by Koshland (26). They provide unique support for the general mechanism of retaining β-glycosidases that includes substrate distortion, formation of a covalent intermediate, and electrophilic migration of C1 along the reaction coordinate.

Reciprocal donor acceptor selectivity (RDAS): A new concept for "matching" donors with acceptors

Bert Fraser-Reid, J. Cristobal Lopez, K.V. Radhakrishnan, Mateusz Mach, Urs Schlueter, Ana Gomez, and Clara Uriel

Abstract: Lemieux's extensive work on replacement reactions at the anomeric center helped to establish the fact that the O-2-protecting group of a donor exerts powerful control over stereoselectivity in glycoside coupling reactions. This manuscript shows that the O-2-protecting group of a donor also exerts powerful, indeed sometimes total, control over regioselectivity in glycosidation of diols. The latter acceptors also exhibit preferences over the donor, thereby providing evidence for the concept of reciprocal donor acceptor selectivity (RDAS). The latter concept is put to the test by simultaneously presenting an acceptor diol with equivalent amounts of two donors, in the hope of achieving double differential glycosidation leading to one-pot assembly of a trisaccharide. When the pair of donors did *not* conform to RDAS principles the reaction did not proceed beyond a dissacharide. However, when the pair was RDAS sanctioned, a *single* trisaccharide (out of four possibilities) was obtained.

Key words: regiocontrolled glycosidation, armed and disarmed donors, di- and trioxolenium ions, oxocarbenium ion.

Résumé : Les nombreux travaux de Lemieux sur les réactions de remplacement au niveau du centre anomérique on permis d'établir le fait que le groupe protecteur en position O-2 d'un donneur exerce un contrôle important sur le stéréosélectivité des réactions de couplage des glycosides. Les résultats présentés dans ce travail montrent que le groupe protecteur en position O-2 exerce aussi un contrôle important, et quelquefois total, sur la régiosélectivité de la glycosidation des diols. Ces accepteurs présentent aussi des préférences par rapport au donneur et ceci correspond à des indications en faveur du concept d'une sélectivité réciproque donneur accepteur (SRDA). On a évalué ce dernier concept en présentant un diol accepteur à des quantités équivalentes de deux donneurs, en espérant obtenir une glycosidation doublement différentielle qui conduirait à un assemblage monotope d'un trisaccharide. Dans les cas où la paire de donneurs n'est pas conforme au concept de SRDA, la réaction ne procède pas au-delà du disaccharide. Toutefois, lorsque la paire était conforme au concept de SRDA, on n'obtient qu'un seul trisaccharide (parmi les quatre possibilités).

Mots clés : glycosidation, donneurs armés et désarmés, ions di- et trioxolénium, ion oxocarbénium.

Introduction

By the time Lemieux began his studies on "Replacement reactions at the anomeric center" (1), Isbell's elegant rationalization for the stereoselectivity observed in reactions of "acetyl glycoside halides" had been recognized as a monumental mechanistic breakthrough (2) (Scheme 1*a*), which was to give rise to the concept of neighboring group participation in organic chemistry (3). Thus Isbell's work showed that an O-2 acyl protecting group would foster 1,2-*trans* glycoside synthesis (**1**→**3**) a process in which a dioxolenium ion (**2**) was subsequently (4) implicated (Scheme 1*a*). The corollary of this insight was that a nonparticipating group would enhance the chances of obtaining the corresponding 1,2-*cis* stereoisomer (5).

However, enhance did not mean ensure, as was already evident to Lemieux from repeated failures to conquer sucrose using fully benzylated donors, which had led instead to excellent syntheses of "β-sucrose" (6). In this context, Lemieux's historic breakthrough utilizing Briggl's anhydride as a donor (7) (Scheme 1*b*) was seemingly contra-intuitive since epoxide cleavage should (and usually did) proceed from the β-face. However, prior investigations had given evidence of O-6 involvement (Scheme 1*b*) when "large" nucleophilic acceptors were used (8). In addition to being another type of "neighboring group participation", Lemieux's synthesis demonstrated the importance of "matching" donor with acceptor, although the concept had not been explicitly stated as such (see below).

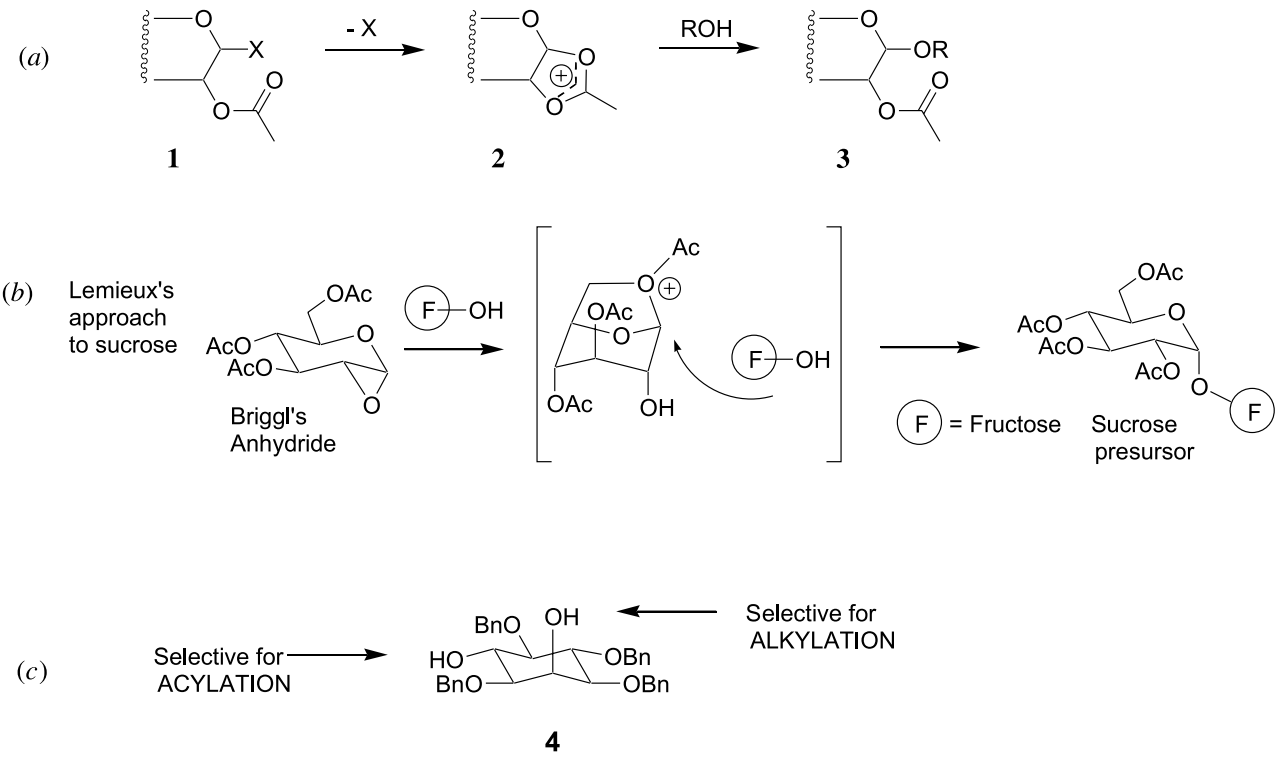
Scheme 1.



Following Isbell's lead, the O-2 protecting group has been justifiably established as an implement for anomeric stereocontrol — as is apparent from various textbooks dealing with carbohydrate synthesis (9). Nevertheless, recent reports (10) from our laboratory suggest that an O-2 protecting group can also provide a ready, low-tech implement for achieving regio control in glycosidation of polyhydroxylic acceptors.

These observations have profound importance for matching donor with acceptor, a concept, which has long been championed by Paulsen et al. (11). However, that matching modality is not to be confused with the subsequent, and now common usage of the term for "double stereodifferentiation" as introduced by Masamune et al. (12) in connection with the coupling of two enantiopure partners. In this regard, Masamune's usage is ably demonstrated by Spijker and VanBoeckel's example (13) showing that a given acceptor gave better yields with a D donor than its L enantiomer. On the other hand, Paulsen's matching concept has also demonstrated in VanBoeckel's collaboration with Petitou (14) on heparin analogs, in which prodigious preliminary experimentation served to reveal the best "match" for each linkage of the oligosaccharide array.

Results

Our interest in this question of regioselectivity emanated from the observation reported in 1998 (15) that the *myo*-inositol diol **4**, underwent acylation at C-6-OH exclusively, but alkylation primarily at C-2-OH, when a unimolar amount of the pertinent reagent was used (Scheme 1*c*). These differences in regioselectivity could not be rationalized by imputing "more or less" reactivity to either the OH or to the alkylation and (or) acylation reagent in question. For example, the (presumably) "more reactive" equatorial C-6-OH was rejected by the more reactive benzylating agent.

We were interested to see if the regioselectivity shown for **4** in Scheme 1*c* could be extended to glycosidation reactions. For this experiment, Lemieux's procedure (16) allowed ready preparation of orthoesters such as **5** (17) (Scheme 2). Acid-catalyzed rearrangement gave the disarmed 2-*O*-acyl donor (NPG_{AC}) **6**, which was transformed by two routine reactions into the armed (18) counterpart **7**. Compounds **8**–**10** were obtained similarly. Thus, a variety of *n*-pentenyl donors, armed and disarmed (18) to different extents, were available which could be made to react under similar conditions on a level playing field, so that valid comparisons could be drawn.

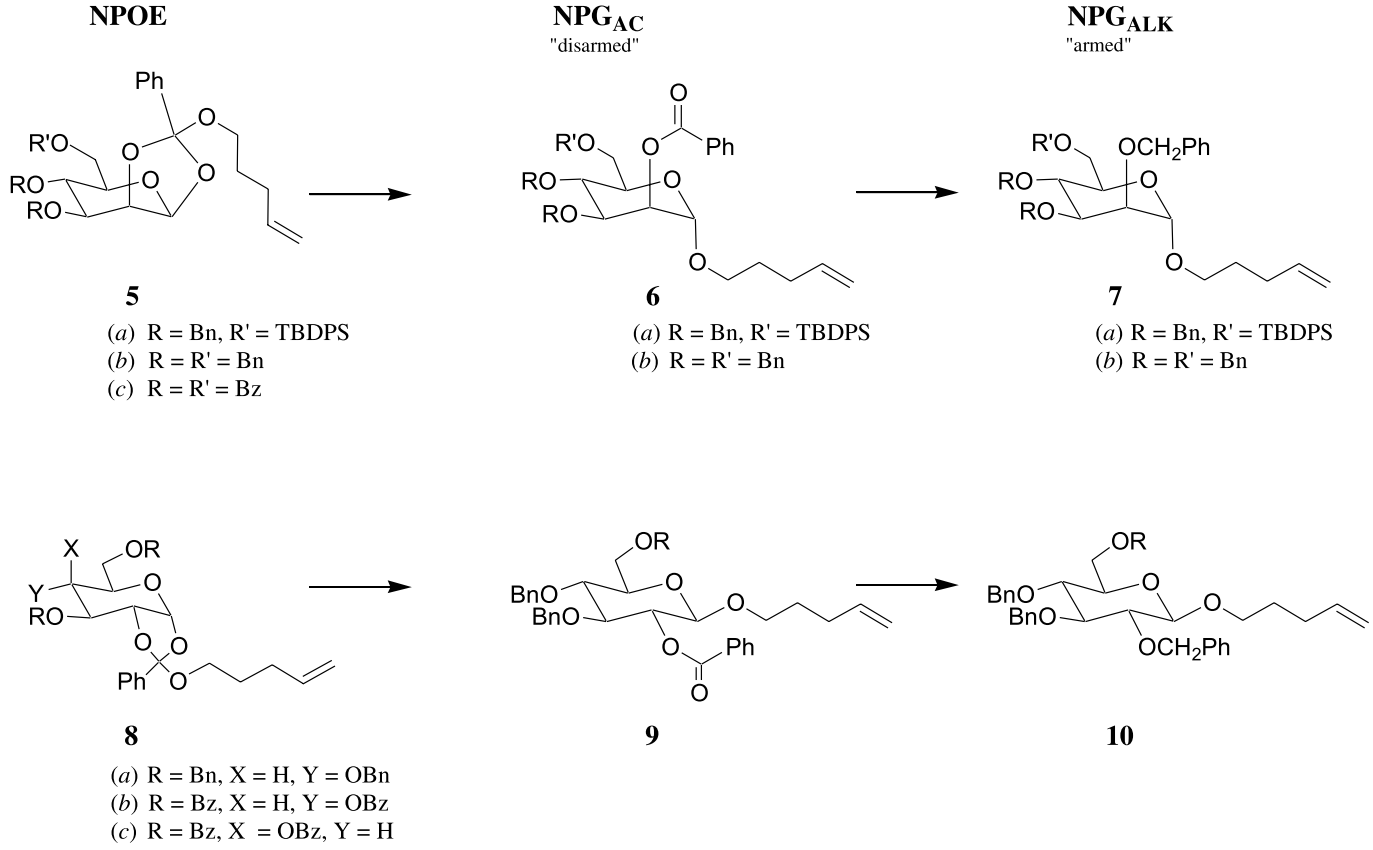
When diol **4** was treated with 1 equiv of the *manno* NPG_{AC} **6a**, the only compound obtained was the pseudo disaccharide **11a** (Scheme 3*a* and Table 1, entry *i*). The NPOE **5a** followed similar regioselectivity giving **11a** exclusively — indeed in the better yield of 73% (Table 1, entry *ii*). By contrast, the armed counterpart **7a**, gave a mixture of regioisomers **11b** and **12b** in a 1:3 ratio (Table 1, entry *iii*).

In all of these studies (above and below), assignment of the regiosomeric structures was readily accomplished by acylating the material in question, and determining the couplings of the newly downshifted proton (these are shown in the *Experimental* section). For example in **11a**, acetylation gave rise to a double doublet at 5.84 ppm (J = 2.8 and 2.4 Hz) readily assignable to the inositol's H-2. By contrast the benzoate of **12** gave rise to a double doublet at 5.76 ppm (J = 9.6 and 10 Hz) as required by the inositol's H-6.

The trends in Scheme 3*a* for inositol **4** prompted us to examine the comparable mannoside diol **13**. The results were

© 2002 NRC Canada

Scheme 2.



even more striking in that both the NPOE **5b** and the armed NPG$_{ALK}$ **7b**, reacted to give respectively, **14** only, and **15** mainly.

That these remarkable regioselectivities were not confined to *manno*-NPOEs was established by showing that the *gluco*- and *galacto*-NPOEs **8b** and **8c**, were also regioselective for the C-6-OH of **4** (Scheme 3*c*) giving disaccharides **16a** and **16b** in 76% and 73% yields, respectively.

The results in Scheme 3*a* and 3*b* (Table 1, entries *i–v*) challenged our assumptions about which hydroxyl group of compounds **4** and **13** would (should!) be the more reactive. Thus, if the accepted wisdom correlating reactivity and orientation were applied, the equatorial-OH of each should have been glycosylated more readily by the armed donor **7**, than by the disarmed counterpart **5**.

We therefore decided to examine the merits of a steric hindrance-based rationalization by employing altroside **17** (Scheme 4), the two hydroxyl groups of which present an unequivocal choice of steric environments. We found, as indicated in Scheme 4, that the armed donor **7b** showed little discrimination between the two sites of **17**, although the unencumbered C-2-OH should have been a clear favorite. Instead, the C-2-mannosylation product **19** was minor, whereas the C-3-regioisomer **18a** was major in a 1:2 ratio) (Table 1, entry *vi*).

On the other hand, the very hindered C-3-OH was selected exclusively by NPOEs **5b** and **5c**, to give **18b** and **18c**, respectively, reaching quantitative proportions (92%) with the NPOE **5c**. (Table 1, entries *vii* and *viii*).

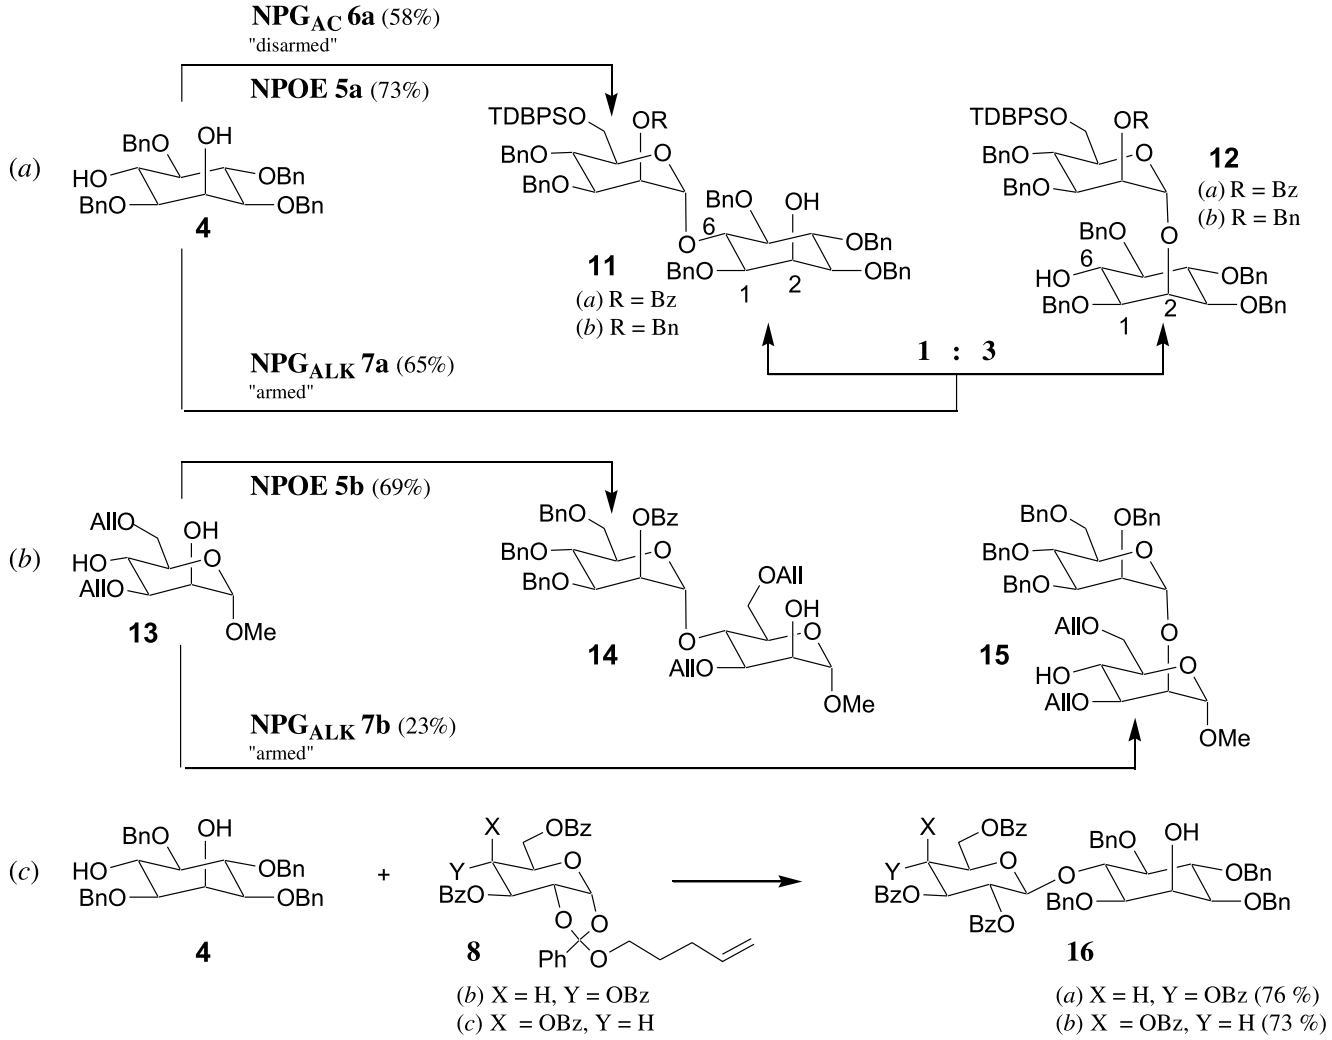
The anomeric glucosides **20** and **23** were logical choices since the relative reactivities of the hydroxyl groups have been frequently tested with respect to acylating and alkylating reagents (19). According to the results of some earlier glycosidation studies (20, 21), there would seem to be very little difference in reactivity between the C-2- and C-3-OH groups. To leverage these slight differences, the reactions were begun at –78°C and allowed to warm to room temperature gradually. Under these non-forcing conditions, the donors tended to decompose, and so substantial amounts of the acceptor diols were recovered. Nevertheless, the reactivities were clearly discernible as shown in Scheme 5. Thus, the α-diol **20**, reacted with the *manno*-NPOE to give **21a** and **22a** in a 7.4:1 ratio. Similarly, the *gluco*-NPG$_{AC}$ donor **9**, gave overwhelming preferences for the C-2-OH producing **21b** and **22b** in a 7.6:1 ratio. On the other hand, with the "armed donors" NPG **7b** and **10**, the regioselectivities were unremarkable, sending out mixed messages about their preferences. Thus, C-3-OH was favored in the former giving mainly **22c** (22) with armed **7b**, but C-2-OH was favored (slightly) with the armed donor, the latter **10** giving mainly **21d** (22) (Table 1, entries *xii* and *xiii*).

Comparison of the "same" reaction in entries *x* and *xi* of Table 1 is instructive. The yield at the higher temperature is nearly twice as high as at the lower temperature, but with a 50% sacrifice in regioselectively.

For the β-anomer **23**, the regioselectivities were less pronounced; however, NPOE **5b** and NPG$_{AC}$ **9** were consistent in their preference for C-2-OH (Table 1, entries *xiv* and *xv*),

© 2002 NRC Canada

Scheme 3.



whereas NPG$_{ALK}$ **7b** and **10**, again sent mixed messages in their preferences for C-2-OH and (or) C-3-OH (Table 1, entries *xvi* and *xvii*).

Discussion

The concept of reciprocal donor acceptor selectivity (RDAS)

The data above provide a new angle to the donor–acceptor matching principle adumbrated by Paulsen and co-workers (5, 11). The regioselectivities observed in Schemes 3–5 clearly cannot be accommodated by traditional explanations based on reactivity and (or) steric hindrance.

This conclusion is dramatically exemplified in the results of altroside **17** (Scheme 4 and Table 1, entries *vi–viii*) where the exclusive preference of the C-3-OH for NPOEs **5b** and **5c**, a remarkable 92% in the case of the latter, must be regarded as surprising. But even more surprising is the fact that the unencumbered C-2-OH of **17** underwent no detectable coupling with NPOE **5b** or **5c**.

Thus, the results in Scheme 4 implied that the donor as well as the acceptor were expressing strong independent selectivities. The formation of **18** and **19** therefore reveal the interplay of reciprocal donor acceptor selectivity (RDAS).

Although the concept of RDAS emanated from regioselective preferences observed in a series of diols (see Table 1), the concept also has profound implications for glycosidic coupling, *even where the acceptor has only one hydroxyl group*. Unfortunately, gathering pertinent literature examples is problematic because (*i*) reactions that fail, or proceed in unflattering yields, are rarely reported; (*ii*) forcing conditions may have been used to eke out the coveted success, instead of going-with-the-flow; (*iii*) yields may have been enhanced by changing reagents and (or) conditions, thereby vitiating the ability to draw comparisons.

Fortunately, reports from van Boom's laboratory provide a vivid example of RDAS (23, 24) in which failure and success related to a specific target, similar reactants and conditions having been maintained. Thus, in attempting to prepare the trisaccharide **27** (Scheme 6), the 2-*O*-benzoyl thioglycoside donor **26**, reacted with disaccharide **11**, to provide only a 10% yield of the desired target material (23). However, when the same donor (**26**) was exposed to disaccharide **12**, the target was produced in the excellent yield of 84% (24). The results clearly indicated that the disarmed donor

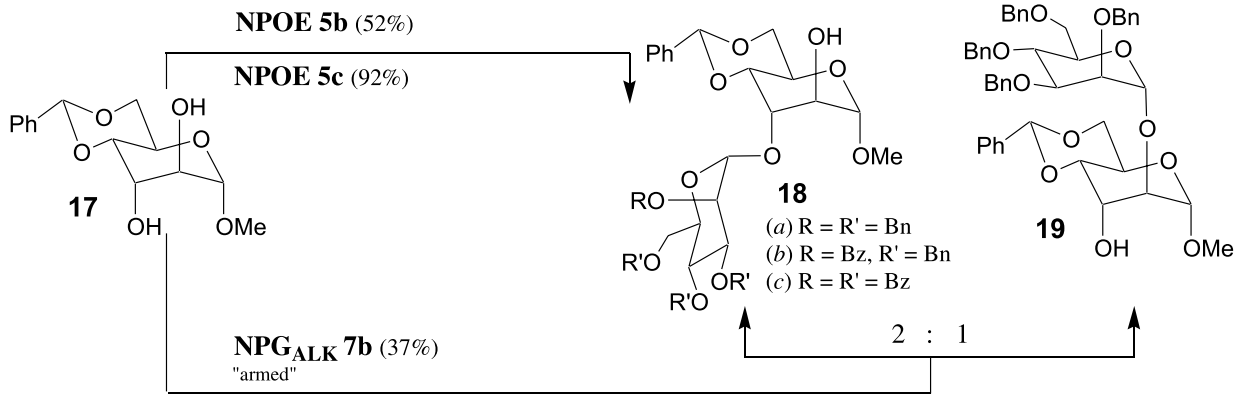
Scheme 4.



26, was "matched" with the C-6-OH of **12**, but not the C-2-OH of **11**.

The concept of RDAS suggests that one-pot, target-oriented, double glycosidations should be possible *when appropriate partners are employed*. A case in our laboratory involving non-reciprocal donors is seen in Scheme 7*a*. Thus, treatment of the diol acceptor **4**, with 2 equiv of donor **7a** stopped at disaccharide stage **12b**. Difficulty in proceeding to trisaccharide **28** was evident from the fact, that subsequent treatment of disaccharide **12b** with 3 equiv of the armed donor (**7a**) afforded only a 14% yield of **28a** (25).

Note that our poor result (25) coincides with van Boom's 10% yield in Scheme 6*a* confirming that these are couplings not RDAS sanctioned.

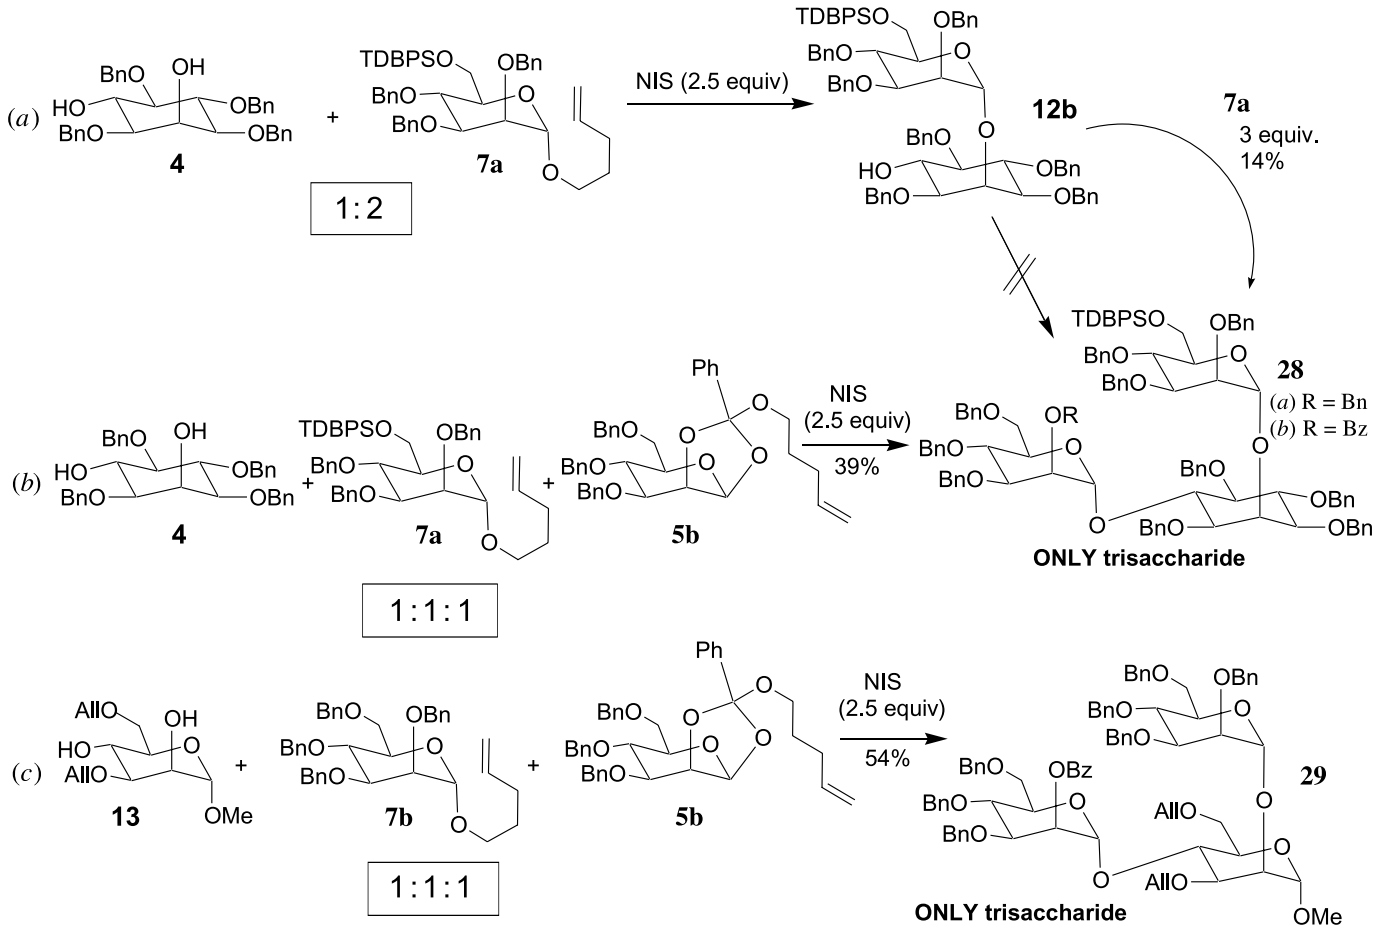
Scheme 7.



By contrast a 1:1:1 mixture of the diol **4** + NPOE **5b** + NPG_{ALK} **7a** in the presence of 2.5 equiv of the promoter gave the trisaccharide **28b** in unoptimized yield of 39% (Scheme 7*b*). Similarly diol **13** + donors **5b** and **7b** gave trisaccharide **29** in 54% yield. Clearly, in both cases, each of the donors had gone to its RDAS-sanctioned site.

Rationalization

A rationalization of the basis for RDAS obviously requires analysis of both the donor and acceptor. With respect to donors, an examination of Table 1 shows that the NPOE–NPG_{AC} group displays similar preferences qualitatively, and is generally more discriminating than NPG_{ALK}. Are these choices related to the donor's reactivity? This question prompted us to determine the relative reactivities of donors **5b**, **6b**, and **7b**. We have recently shown that oxidative hydrolysis provides a ready method for comparing relative reactivities of any two *n*-pentenyl glycosyl donors (26). Using this method, the ranking of the donors was found to be **5b** > **7b** > **6b**. These observations show that the regioselectivities are not dependent on the relative reactivities of the donors, since the most and least reactive donors, NPOE **5b** and NPG_{AC} **6b**, respectively, showed regioselectivity for the same hydroxyl (C-6-OH) of the diol **4**. *Thus, RDAS is not based on donor reactivity.*

As shown in Scheme 8, NPOE and NPG_{AC} are able to produce the same intermediate complex where the charge is distributed over two (dioxolenium) and three (trioxolenium) oxygens, **30** and **31**, respectively. The charge in this complex may be described as "diffuse" in contrast to that on the armed oxocarbenium ion **32** where the charge is more "compact". Experiments and theoretical studies are underway to determine whether the diffuse–compact dichotomy is valid, and the results will be described in due course.

Analysis of factors which have an impact on the diols' selectivities is more difficult. But as shown for Scheme 4 in the *Discussion* section, *RDAS is not based on steric hindrance* of the acceptor's OH.

The most thorough investigation of glycosidation of polyhydroxylic acceptors has been undertaken by Vasella in connection with his scholarly development of the chemistry of glycosylidene carbenes (**33**) as glycosyl donors (27) (Scheme 9). These donors are unique in that they proceed to the critical oxocarbenium ion intermediate (**34**) by bond formation to a proton, whereas "classical donors" (**35**) achieve the same objective by bond cleavage (sooner or later!), usually electrophile induced, of the anomeric leaving group. For **33**, the more acidic OH group should therefore be the preferred glycosidation site. In turn, hydrogen bonding within the diol **28** can be a determining influence on the acidity of the OH concerned.

The results obtained by us thus far, do not provide any insight into the implications of OH-acidity and (or) hydrogen bonding. The role of such factors await future study.

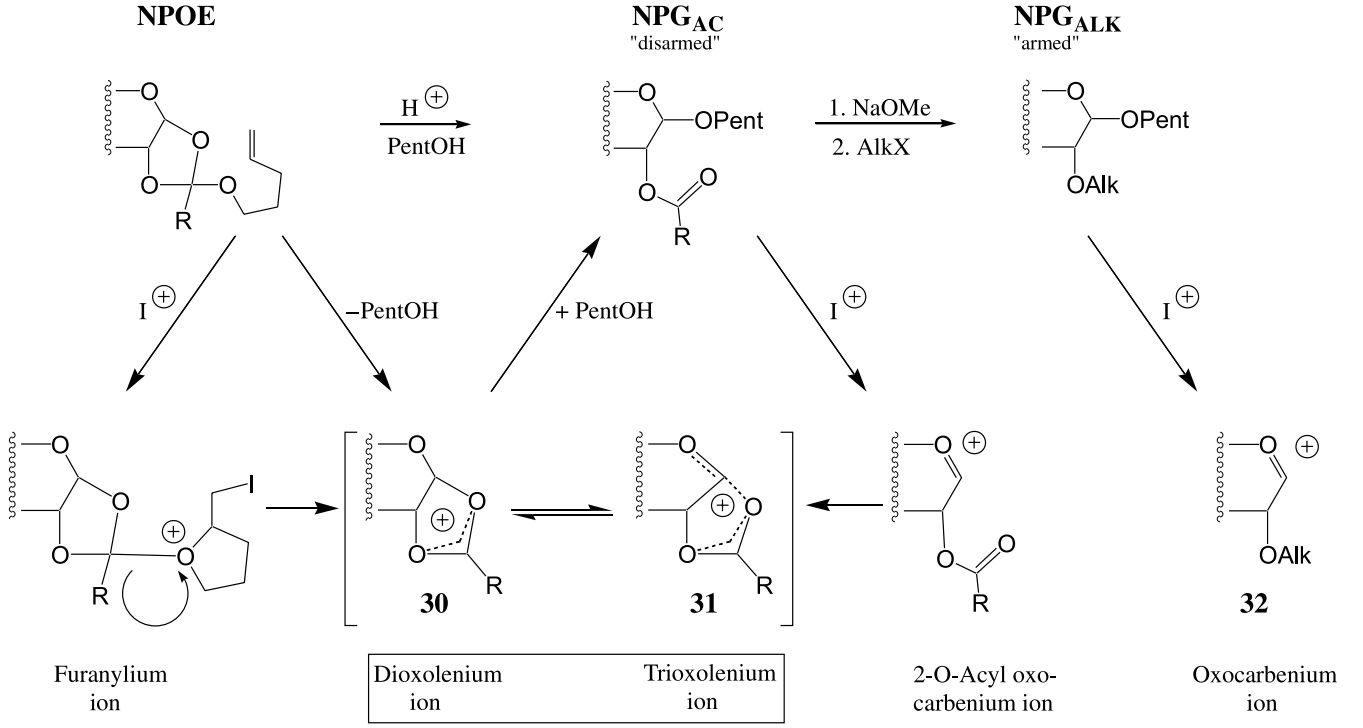
Scheme 8.



Experimental

General procedures

All NMR spectra were recorded on a GE 300 or a Varian 400 MHz NMR spectrometer and chemical shifts are reported relative to internal TMS. Chemical ionization (CI) mass spectroscopy was done on a Hewlett–Packard 5988A GC–MS using 1% ammonia in methane as the reagent gas, with a source temperature of 100°C, at 1 torr (1 torr = 133.322 Pa). High-resolution mass spectra (HR-MS) and fast atom bombardment (FAB) analyses were recorded with a JEOL JMS-SX 102A mass spectrometer operating at 10 K resolution, using a dithiothreitol–dithioerythritol or *m*-nitrobenzyl alcohol as the matrix with xenon as the fast atom. Elemental analyses were conducted at Atlantic microlab, Norcross, GA. All reactions were conducted under an argon atmosphere. Thin layer chromatography (TLC), was done on plates (Riedel-de Haen, coated with silicagel 60F 254) and were detected by UV or by spraying or dipping in ammonium molybdate solution and subsequent heating.

The regioisomers were separated by flash chromatography, evaporated to dryness, and weighed to obtain the ratios reported in Schemes 3–5 and Table 1. Flash column chromatography was performed on silica gel (spectrum SIL 58, 230 –400 mesh, grade 60) using mixtures of hexane and ethyl acetate as eluants. Dichloromethane and toluene were distilled from CaH_2. *N*-Iodosuccinimide was purchased from Aldrich and recrystallized from hot CH_2Cl_2.

Glycosidation conditions

(*a*) The diol (~0.092 mmol) and glycosyl donor (~0.119 mmol) were dissolved in a small quantity of toluene, azeotroped to dryness, and then dissolved in CH_2Cl_2 (2 mL) at 0°C under an argon atmosphere. *N*-Iodosuccinimide (0.1219 mmol) was added to the solution, and after stirring for 3 min, TDBMSOTf (0.027 mmol) was added. The reaction was quenched after 20 min with 10% aqueous sodium thiosulfate and saturated aqueous sodium bicarbonate, extracted with CH_2Cl_2, and worked up in the usual way. After work up the mixture was separated by flash chromatography to give the disaccharide products.

(*b*) To a solution of the diol (0.208 mmol) and the glycosyl donor (0.16 mmol) in anhyd CH_2Cl_2 (3 mL) were added molecular sieves 5 Å (100 mg) and NIS (73 mg, 0.32 mmol) at –30°C. After stirring for 5 min, $BF_3{\cdot}OEt_2$ (6 μL, 0.048 mmol) was added. The reaction was quenched after 15 min and processed as in part (*a*).

(*c*) To a solution of diol (0.208 mmol) and glycosyl donor (0.16 mmol) in anhyd CH_2Cl_2 (3 mL) were added molecular sieves 5 Å (97 mg) and NIS (73 mg, 0.32 mmol) at –30°C. After stirring for 5 min, $BF_3{\cdot}OEt_2$ (6 μL, 0.048 mmol) was added. The mixture was allowed to warm to 0°C. After 40 min the reaction was quenched and processed as in part (*a*).

(*d*) The diol (0.177 mmol, 50 mg) and the glycosyl donor (0.177 mmol) were dissolved in a small quantity of a dichloromethane–toluene mixture, azeotroped to dryness, and then dried under vacuum for ~30 min. The residue was taken up in dry dichloromethane (2 mL for α-acceptor, 10 mL for β-acceptor) and molecular sieves (4 Å) were added. The reaction mixture was kept under an argon atmosphere at –78°C (acetone – dry ice) and 68 mg (0.266 mmol, 1.5 equiv) of *N*-iodosuccinimide were added. After 3 min stirring, 10 μL (0.05 mmol, 0.3 equiv) of TBDMSOTf were added. After 15 min at –78°C the reaction mixture was allowed to warm up to room temperature. The reaction was quenched after 45 min with 10% aqueous sodium thiosulphate and saturated aqueous sodium bicarbonate solution,

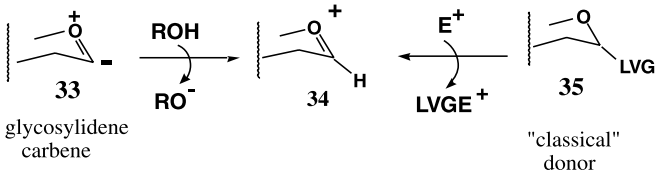
Scheme 9.



extracted with dichloromethane, dried with sodium sulfate, and purified by column chromatography using silica gel (hexanes – ethyl acetate, 4:1 → 1:1).

Identification of regioisomers

The ^{1}H NMR spectra of the chromatographically pure reaction product, before and after acylation, were examined for new signals in the 6.0–5.4 ppm region. The coupling contant(s) of the new proton gave unequivocal information about its proton's environment. In the ^{1}H NMR data listed below, the "new" signal upon acylation is shown in italics.

*1,3,4,5-Tetra-*O*-benzyl-6-*O*-(2-*O*-benzoyl-3,4-di-*O*-benzyl-6-*O*-[*tert*-butyldiphenylsilyl]-α-D-mannopyranosyl)-D-myo-inositol (11a)*

(*a*) The diol **4** and the NPG_{AC} donor **6a** were reacted under conditions (*a*). Standard work up and flash column chromatography (EtOAc–hexanes, 1:4) afforded **11a** (65 mg, 58%) as a colorless paste.

(*b*) The diol **4** and glycosyl donor **5a** were reacted under conditions (*a*) for 20 min. Standard work up, and flash column chromatography of the crude residue (EtOAc–hexanes, 1:4) afforded **11a** (80 mg, 73%) as a colorless paste. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.12–6.84 (m, 45H, Ar-H), 5.78 (dd, *J* = 1.6 Hz, 2 Hz, 1H), 5.60 (d, *J* = 1.6 Hz, 1H, H-1), 4.90–4.55 (m, 12H, $BnCH_2$), 4.22 (dd, *J* = 9.6, 10 Hz, 1H), 4.17–4.12 (m, 2H), 4.05 (dd, *J* = 3.2, 10 Hz, 1H), 3.98–3.91 (m, 2H), 3.58–3.48 (m, 2H), 3.37 (dd, *J* = 2.8, 3.2 Hz, 1H), 3.34 (dd, *J* = 3.2, 3.2 Hz, 1H), 3.27 (dd, *J* = 9.6, 9.2 Hz, 1H), 2.36 (br s, 1H, OH), 1.06 (s, 9H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 165.74 (C=O Ph), 139.09, 138.53, 138.25, 137.86, 137.16, 135.93, 135.64, 133.78, 133.31, 132.94, 130.00, 129.36, 128.57, 128.46, 128.39, 128.27, 128.22, 128.03, 127.96, 127.88, 127.55, 127.49, 127.09, 98.26 (C-1), 81.34, 81.06, 80.61, 79.50, 78.41, 75.81, 75.51, 74.93, 74.92, 74.08, 72.63, 72.10, 71.47, 69.31, 66.44, 62.39, 26.84, 19.31. Acetylation of **11a** gave a colorless paste. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.12–6.83 (m, 45H, Ar-H), 5.84 (dd, *J* = 2.8, 2.4 Hz, 1H), 5.80 (dd, *J* = 1.6, 2 Hz, 1H), 5.60 (d, *J* = 1.2 Hz, 1H, H-1) 4.01–4.47 (m, 12H, $BnCH_2$,s), 4.14 (dd, *J* = 9.6, 10 Hz, 1H), 4.07–3.96 (m, 3H), 3.83 (dd, *J* = 9.6, 9.6 Hz, 1H), 3.61–3.52 (m, 2H), 3.46 (dd, *J* = 3.2, 3.2 Hz, 1H), 3.44 (dd, *J* = 2.8, 3.2 Hz, 1H), 3.31 (dd, *J* = 9.6, 9.6 Hz, 1H), 2.10 (s, 3H), 1.05 (s, 9H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 170.39 ($OCOCH_3$), 165.97 (OCOPh), 139.08, 138.49, 138.17, 137.65, 137.52, 136.82, 135.94, 135.66, 133.65, 133.36, 132.95, 130.01, 129.41, 129.29, 128.86, 128.48, 128.42, 128.22, 128.12, 128.02, 127.83, 127.60, 127.57, 127.43, 127.22, 127.12, 97.99 (C-1), 81.68, 81.08, 78.72, 78.32, 78.12, 75.99, 75.76, 75.03, 74.66, 74.06, 72.17, 71.86, 71.42, 69.05, 65.93, 62.55, 26.83, 21.03, 19.27. FAB-MS *m*/*z*: 1265.56 $[M - 1]^+$. Anal. calcd. for $C_{79}H_{82}O_{13}Si$: C 74.86, H 6.52; found: C 74.66, H 6.59.

*1,3,4,5-Tetra-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-6-*O*-[tert-butyldiphenylsilyl]-α-D-mannopyranosyl)-D-myo-inositol (12b) and 1,3,4,5-tetra-*O*-benzyl-6-*O*-(2,3,4-tri-*O*-benzyl-6-*O*-[tert-butyldiphenylsilyl]-α-D-mannopyranosyl)-D-myo-inositol (11b)*

The diol **4** and glycosyl donor **7a** were reacted under the general glycosidation conditions. The crude residue obtained after work up on purification by flash column chromatography (EtOAc–hexanes, 1:4) afforded **12b** (49 mg, 49%) and **11b** (15 mg, 16%). Acetylation of **11b** gave a colorless paste: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.71–6.88 (m, Ar), 5.84 (dd, *J* = 2.8, 2.4 Hz, 1H), 5.49 (d, *J* = 1.2 Hz, 1H) 4.91–4.32 (m, 14H), 4.18 (dd, *J* = 10, 10 Hz, 1H), 4.06 (dd, *J* = 10 Hz, 9.6 Hz, 1H), 3.92–3.76 (m, 4H), 3.59–3.57 (m, 2H), 3.44 (dd, *J* = 10 Hz, 2.8 Hz, 1H), 3.37 (dd, *J* = 9.6, 2.4 Hz, 1H), 3.28 (dd, *J* = 9.6, 9.6 Hz, 1H), 2.12 (s, 3H), 0.99 (s, 9H). FAB-MS *m*/*z*: 1251.56 $[M - 1]^+$. Data for **12**: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.75–6.92 (m, 45H, Ar), 5.35 (d, *J* = 1.2 Hz, 1H, H-1), 4.95–4.41 (m, 14H, Bn), 4.37 (t, *J* = 2.4 Hz, 1H), 4.26 (dd, *J* = 10, 9.6 Hz, 1H), 3.98–3.85 (m, 3H), 3.79–3.71 (m, 3H), 3.57 (d, *J* = 11.2 Hz, 1H), 3.32–3.25 (m, 2H), 3.19–3.16 (dd, *J* = 9.6, 2 Hz, 1H), 2.39 (br s, 1H, OH), 1.02 (s, 9H, *t*-Bu). ^{13}C NMR δ: 138.99, 138.67, 138.57, 137.73, 137.43, 136.096, 135.64, 133.91, 133.61, 129.42, 129.36, 128.62, 128.47, 128.347, 128.29, 128.22, 128.18, 128.13, 128.06, 128.02, 127.96, 127.74, 127.56, 127.47, 127.36, 127.33, 127.17, 127.11, 127.06, 98.00 (C-1), 83.22, 80.85, 80.47, 79.38, 79.15, 75.78, 75.61, 75.21, 74.43, 72.90, 72.71, 72.16, 72.10, 70.08, 62.70, 26.80, 19.33. FAB-MS *m*/*z*: 1209.6 $[M - 1]^+$. Benzoylation under standard conditions afforded a colorless paste: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.17–6.95 (m, Ar), 5.76 (dd, *J* = 9.6, 10 Hz, 1H), 5.40 (br s, 1H), 4.99–4.41 (m, 15H), 4.27 (dd, *J* = 10, 10 Hz, 1H), 4.02–3.86 (m, 4H), 4.27 (dd, *J* = 11.2, 2.8 Hz, 1H), 3.60–3.51 (m, 2H), 3.42 (dd, *J* = 10, 2 Hz, 1H), 3.30 (dd, *J* = 10, 2.3 Hz, 1H), 1.03 (s, 9H). FAB-MS *m*/*z*: 1312.45 $[M - 1]^+$, 1354.40 $[M + K]^+$, 1447.42 $[M + Cs]^+$.

*Methyl-3,6-di-*O*-allyl-4-*O*-(2-*O*-benzoyl-3,4,6-tri-*O*-benzyl-α-D-mannopyranosyl)-α-D-mannopyranoside (14)*

The diol **13** and glycosyl donor **5b** were reacted under conditions (*a*). The crude residue on flash column chromatography (EtOAc–hexanes, 1:3) afforded **14** (69%) as a colorless paste. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.07–7.19 (m, 20H, Ar-H), 6.04–5.85 (m, 2H), 5.67 (dd, *J* = 2, 2.8 Hz, 1H), 5.42 (d, *J* = 1.6 Hz, 1H, H-1), 5.33–5.09 (m, 4H), 4.89–4.73 (m, 4H), 4.59–4.52 (m, 3H), 4.14–3.88 (m, 10H), 3.78–3.63 (m, 5H), 3.39 (s, 3H), 2.42 (s, 1H, OH). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 165.48, (OCOPh), 138.45, 138.04, 134.83, 134.02, 133.01, 129.92, 128.31, 128.27, 127.91, 127.56, 127.50, 118.33, 116.83, 99.98 (C-1), 99.51 (C-1′), 79.72, 78.15, 75.21, 74.15, 73.50, 73.13, 72.60, 72.44, 71.53, 70.46, 70.19, 69.33, 69.08, 67.54, 54.99. FAB-MS *m*/*z*: 809.3 $[M - 1]^+$, 811.3 $[M + 1]^+$. Acetylation of **14** afforded the acetate as a colorless paste: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.00–7.13 (m, 20H, Ar-H), 5.92–5.81 (m, 2H), 5.65 (dd, *J* = 2.4, 2.8 Hz, 1H), 5.38 (d, *J* = 2 Hz,

© 2002 NRC Canada

1H, H-1), 5.21 (d, *J* = 1.2 Hz, 1H) 5.19 (dd, *J* = 2, 3.2 Hz, 1H), 5.17 (d, *J* = 1.6 Hz, 1H), 5.08–5.05 (m, 2H), 4.82–4.64 (m, 4H), 4.52–4.47 (m, 3H), 4.06–3.62 (m, 14H), 3.32 (s, 3H), 2.02 (s, 3H).

Methyl-3,6-di-O-allyl-2-O-(2,3,4,6-tetra-O-benzyl-α-D-mannopyranosyl)-α-D-mannopyranoside (15)

The diol **13** and glycosyl donor **7b** were reacted under conditions (*a*) for 3 min. Standard work up followed by flash column chromatography (EtOAc–hexanes, 1:3) afforded **15** (23%) as a colorless paste. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.35–7.15 (m, 20H, Ar-H), 5.95–5.81 (m, 2H), 5.30–5.11 (m, 4H), 5.09 (br s, 1H, H-1), 4.88–4.46 (m, 12H), 4.10–3.35 (m, 21H), 3.24 (s, 3H). FAB-MS *m*/*z*: 795 $[M - 1]^+$. Benzoylation afforded the corresponding benzoate: ^{1}H NMR (300 MHz, $CDCl_3$) δ: 8.13–8.04 (d, 2H, Ar-H), 7.64–7.14 (m, 23H, Ar-H), 5.85–5.06 (m, 2H), 5.36 (dd, *J* = 9.6, 9.3 Hz, 1H), 5.19 (br s, 1H), 5.15–4.99 (m, 4H), 4.91–4.80 (m, 2H), 4.72–4.46 (m, 7H), 4.07–3.85 (m, 11H), 3.74 (br s, 2H), 3.55 (br s, 2H), 3.29 (s, 3H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 172.25 (OCOPH), 138.60, 138.59, 138.58, 134.72, 134.64, 134.00, 133.30, 130.41, 129.92, 129.48, 128.69, 128.61, 128.55, 128.21, 128.11, 127.93, 127.70, 127.63, 117.45, 117.03, 100.01 (C-1), 100.20 (C-1), 79.64, 75.14, 75.08, 74.73, 74.46, 73.46, 72.69, 72.62, 72.37, 72.08, 71.59, 70.45, 70.15, 69.76, 55.11.

Methyl-4,6-O-benzylidene-3-O-(2-O-benzoyl-3,4,6-tri-O-benzyl-α-D-mannopyranosyl)-α-D-altropyranoside (18b)

The altroside diol **17** and the NPOE glycosyl donor **5b**, were allowed to react under conditions (*b*) for 15 min. After work up the crude material was purified by flash chromatography (hexane– EtOAc, 3:2) to give the 3-*O*-mannosylated derivative of **18b** in 52% yield. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 8.09–7.06, (m, 25H), 5.60 (m, 1H), 5.55 (s, 1H), 5.14 (d, *J* = 1.8 Hz, 1H), 4.87 (d, *J* = 10.9 Hz, 1H), 4.81 (d, *J* = 11.2 Hz, 1H), 4.63 (d, *J* = 12.4 Hz, 1H), 4.61 (br s, 1H), 4.58 (d, *J* = 12.1 Hz, 1H), 4.49 (d, *J* = 10.9 Hz, 1H), 4.33 (m, 10H), 3.77 (m. 1H), 3.62 (dd, *J* = 11.0, 3.7 Hz, 1H), 3.43 (dd, *J* = 11.0, 1.6 Hz, 1H), 3.40 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 165.88 (OC(O)Ph), 138.81, 138.42, 137.98, 137.42, 133.10, 129.96, 129.88, 128.94, 128.37, 128.26, 128.21, 128.13, 127.85, 127.59, 127.46, 127.36, 127.32, 126.34, 102.33 (PhCH), 101.83 (C-1), 95.57 (C-1′), 77.88, 74.92, 74.72, 74.31, 72.92, 71.93, 71.63, 71.08, 69.42, 69.29, 68.61, 67.93, 58.67, 55.57. API-ES *m*/*z*: 837 $[M + NH_4]^+$.

Methyl-4,6-O-benzylidene-3-O and 2-O (2,3,4,6-tetra-O-benzyl-α-D-mannopyranosyl)-α-D-altropyranosides (18a and 19)

To a solution of diol **17** and glycosyl donor **7b** were reacted under conditions (*a*). After stirring for 5 min, $BF_3{\cdot}OEt_2$ (6 mL, 0.048 mmol) was added. The mixture was allowed to warm to 0°C. After 90 min the reaction was quenched and after work up the crude residue was purified by flash column chromatography (hexane–EtOAc, 7:3) to give the *O*-3 and *O*-2 mannosylated products **18a** and **19** in 2:1 ratio in 37% combined yield. Data for *O*-3 product **18a**: ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.56–7.01 (m, 25H), 5.54 (s, 1H), 5.00 (d, *J* = 1.8 Hz, 1H), 4.92–4.44 (m, 9H), 4.30–3.43 (m, 12H), 3.30 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 139.05, 138.88, 138.48, 137.62, 132.11, 128.80, 128.26, 128.11, 127.83, 127.68, 127.48, 127.25, 126.36, 125.99, 102.25 (PhCH), 101.79 (C-1), 95.00 (C-1′), 79.65, 77.42, 75.08, 74.78, 74.67, 72.76, 72.50, 71.22, 70.33, 69.96, 69.34, 69.15, 67.32, 58.76, 55.31. Selected ^{1}H NMR (300 MHz, $CDCl_3$) peaks δ: 5.48 (s, 1H, PhCH), 1.93 (s, 3H, $OC(O)CH_3$). Lit. (28) δ value: 5.49 (s, 1H), 1.94 (s, 3H).

*For **25d** (α-anomer)*

Selected ^{1}H NMR (300 MHz, $CDCl_3$) peaks δ: 5.57 (d, *J* = 3.6 Hz, 1H), 3.50 (s, 3H, OCH_3), 2.02 (s, 3H, $OC(O)CH_3$). Lit. (28) δ value: 5.58 (d, *J* = 3.4 Hz, 1H, H-1′), 3.51 (s, 3H), 2.03 (s, 3H).

*For **25d** (β-anomer)*

Selected ^{1}H NMR (300 MHz, $CDCl_3$) peaks δ: 3.49 (s, 3H, OCH_3), 3.21 (m, 1H), 1.92 (s, 3H, $OC(O)CH_3$). Lit. (28) δ value: 3.49 (s, 3H), 3.22 (ddd, *J* = 2.3, 4.9, 9.2 Hz, 1H, H-5′), 2.03 (s, 3H).

1,3,4,5-Tetra-O-benzyl-2-O-(2,3,4-tri-O-benzyl-6-O-[tert-butyldiphenylsilyl]-α-D-mannopyranosyl-6-O-(2-O-benzoyl-2,4,6-tri-O-benzyl-α-D-mannopyranosyl)-D-myo-inositol (28)

The diol **4** (50 mg, 0.092 mmol) and glycosyl donors **5b** (90 mg. 0.12 mmol) and **7a** (75 mg, 0.12 mmol) were taken up together in a small quantity of toluene and azeotroped to remove traces of water. The mixture was dissolved in CH_2Cl_2 (3 mL) at 0°C under an argon atmosphere. *N*-Iodosuccinimide (54 mg, 0.24 mmol) was added to the solution. After stirring for 3 min, TBDMSOTf (12 μL, 0.054 mmol) was added. The reaction was quenched after 1 h with 10% aqueous sodium thiosulphate and saturated sodium bicarbonate, and extracted with CH_2Cl_2. The organic layer was removed under reduced pressure. The crude residue on flash column chromatography (EtOAc–hexanes, 1:4) afforded the pseudo-trisaccharide **28** (62 mg, 0.036 mmol, 39%) as the only trisaccharide along with **11a** (40 mg, 0.037 mmol, 40%). Note: To confirm the regioselectivity, the pseudo-disaccharide **11a** was coupled with **7a** which afforded the same pseudo-trisaccharide **28**. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.10–6.94 (m, 65H, Ar-H), 5.83–5.81 (dd, *J* = 2.4, 2 Hz, 1H), 5.626–5.621 (d, *J* = 2 Hz, 1H, H-1), 5.35 (s, 1H, H-1), 4.97–4.36 (m, 20H), 4.29–3.99 (m, 7H), 3.93–3.90 (dd, *J* = 2.8, 9.6 Hz, 1H), 3.85–3.59 (m, 4H), 3.48–3.26 (m, 5H), 1.03 (s, 9H). FAB-MS *m*/*z*: 1745.76 $[M - 1]^+$. Anal. calcd. for $C_{111}H_{114}O_{17}Si$: C 76.26, H 6.57; found: C 76.00, H 6.71.

Methyl-3,6-di-O-allyl-1-O-methyl-2-O-(2,3,4,6-tetra-O-benzyl-α-D-mannopyranosyl)-4-O-(2-O-benzoyl-3,4,6-tri-O-benzyl-α-D-mannopyranosyl)-α-D-manno-pyranoside (29)

The diol **13** (27.4 mg, 0.1 mmol) and glycosyl donors **5b** (68.42 mg, 0.11 mmol) and **7b** (66.88 mg, 0.11 mmol) were taken up together in a small quantity of toluene and azeotroped to remove traces of water. The mixture was dissolved in CH_2Cl_2 (3 mL) at 0°C under an argon atmosphere. *N*-Iodosuccinimide (58.5 mg, 0.26 mmol) was added to the solution. After stirring for 3 min, TBDMSOTf (13.78 μL, 0.06 mmol) was added. The reaction mixture was quenched after 1 h with 10% aqueous sodium thiosulphate and saturated sodium bicarbonate, and extracted with CH_2Cl_2. The organic layer was removed under reduced pressure. The crude residue on flash column chromatography (EtOAc–hexanes, 1:4) afforded the trisaccharide **29** (45 mg, 0.034 mmol, 54%) as the major product, along with the disaccharide **14** (20 mg, 0.025 mmol, 39%). Unreacted acceptor **13** (10 mg, 0.03 mmol) was recovered. Note: Regioselectivity was confirmed by coupling disaccharide **14** with **7b** affording the same trisaccharide **29** in 36% isolated yield. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.09–8.06 (d, 2H, Ar-H), 7.58–7.06 (m, 38H, Ar-H), 5.94–5.84 (m, 2H), 5.70 (br s, 1H), 5.39 (br s, 1H), 5.26–4.99 (m, 5H), 4.95–4.46 (m, 15H), 4.12–3.61 (m, 21H), 3.24 (s, 3H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 165.31 (OCOPh), 138.59, 138.53, 138.45, 138.39, 138.27, 138.07, 135.01, 134.01, 134.32, 133.04, 130.03, 129.96, 129.92, 128.39, 128.30, 128.28, 128.24, 128.19, 128.04, 127.98, 127.96, 127.83, 127.81, 127.69, 127.59, 127.48, 117.68, 116.41, 99.81 (C-1), 99.68 (C-1), 97.80 (C-1), 79.82, 79.43, 78.32, 75.26, 74.91, 74.76, 74.16, 74.00, 73.49, 73.36, 73.24, 72.56, 72.32, 72.27, 72.15, 71.55, 70.84, 70.70, 69.74, 69.48, 69.03, 54.81. Anal. calcd. for $C_{80}H_{86}O_{17}$: C 72.82, H 6.57; found: C 72.90, H 6.66.

Stochastic conformational search on the Lewis X (Le^x) trisaccharide and three Le^x analogues

France-Isabelle Auzanneau, Elizabeth Sourial, Jonathan M. Schmidt, and Miklos Feher

Abstract: Biased stochastic conformational searches using the MMFF94 force field and the Born continuum solvation model were applied to the molecular modeling of the Lewis X (Le^x) trisaccharide (β-D-Gal-(1,4)-[α-L-Fuc-(1,3)]-β-D-GlcNAc-OH) and three Le^x analogues, in which each of the three sugar units was replaced by another sugar residue, i.e., *N*-acetyl-glucosamine by glucose, galactose by glucose, and fucose by rhamnose. The stochastic search accurately identified a lowest energy conformation of the Le^x determinant that corresponds to the reported conformations of Le^x deduced experimentally in the solid state by X-ray crystallography and in solution by NMR measurements. In this conformation stacking exists between the galactosyl and fucosyl residues. Five new local minima for the Le^x trisaccharide were found within 3 kcal mol^{-1} of the global minimum using the stochastic search and metric scaling. Modeling studies of the analogues showed that the stacking observed in the Le^x trisaccharide was maintained when either galactosyl or *N*-acetylglucosamine were replaced by glucosyl residues. In contrast, substitution of the fucose residue by rhamnose led to two conformers in which stacking of the galactose and rhamnose residues was no longer maintained. These results indicate that the substitution of the non-reducing end galactosyl or *N*-acetyl-glucosaminyl residues by a glucose unit in the dimeric Lewis X ($dimLe^x$) tumour associated antigen could help in the development of a vaccine that cross-reacts with $dimLe^x$ but no longer displays Le^x associated three-dimensional epitopes also presented by non-cancerous cells. In contrast, an analogue in which the fucosyl residue is replaced by rhamnose does not constitute a good vaccine candidate, since our results indicate that this substitution will induce an important conformational change that is likely to abolish cross-reactivity with the natural $dimLe^x$ tumor associated antigen.

Key words: molecular modeling, stochastic, conformational analysis, Lewis X, oligosaccharide.

Résumé : On a fait des recherches conformationnelles stochastiques biaisées en utilisant le champ de force MMFF94 et modèle de solvatation continue de Born. On a appliqué la modélisation moléculaire au trisaccharide Lewis X (Le^x) (β-D-Gal-(1,4)-[α-L-Fuc-(1,3)]-β-D-GlcNAc-OH) et à trois analogues Le^x dans lesquels chacune des trois unités de sucre a été remplacée par un autre résidu de sucre, par exemple la *N*-acétyl-glucosamine par du glucose, le galactose par du glucose et le fucose par du rhamnose. Les recherches stochastiques ont permis d'identifier correctement une conformation d'énergie minimale du déterminant Le^x qui correspond aux conformations rapportées expérimentalement pour Le^x en se basant sur la diffraction des rayons X à l'état solide et sur des mesures de RMN en solution. Dans cette conformation, il existe un empilement entre les résidus galactosyle et fucosyle. En se basant sur l'étude stochastique et sur une mise à l'échelle métrique, on a identifié cinq nouveaux minima locaux pour le trisaccharide Le^x; ils se trouvent en deçà de 3 kcal mol^{-1} du minimum global. Les études de modélisation des analogues ont montré que l'empilement observé dans le trisaccharide Le^x sont maintenues quand on remplace le galactosyle ou la *N*-acétylglucosamine par des résidus glucosyles. Toutefois, la substitution du résidu de fucose par du rhamnose conduit à deux conformères dans lesquels l'empilement des résidus galactose et rhamnose n'est plus maintenu. Ces résultats indiquent que la substitution par une unité glucose des résidus galactosyle et *N*-acétylglucosaminyle dans portion non réductrice de la molécule d'antigène Lewis X dimère ($dimLe^x$) associée à la tumeur, pourrait aider au développement d'un vaccin donnant lieu à une réaction croisée avec le $dimLe^x$ sans toutefois présenter les épitopes tridimensionnels associés au Le^x qui sont aussi présents dans les cellules non cancéreuses. Toutefois, un analogue dans lequel le résidu fucosyle a été remplacé par un rhamnose n'est pas un bon candidat à un vaccin puisque nos résultats indiquent que cette substitution induira un changement conformationnel important qui empêchera la réactivité croisée avec l'antigène $dimLe^x$ naturel associé à la tumeur.

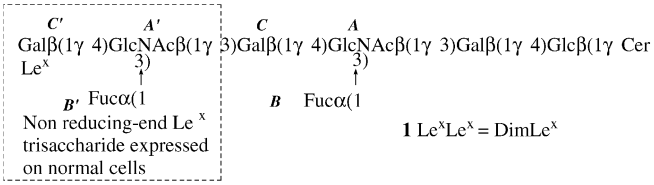
Fig. 1. The tumour associated carbohydrate antigen dimeric Lewis X (dimLe^x).



Introduction

Aberrant glycosylation in human cancer was first indirectly suggested in the mid-sixties when several papers reported the accumulation of fucose-containing glycolipids in adenocarcinomas (1, 2). Tumour associated carbohydrates antigens (TACAs) can be involved in specific immune responses, during which antibodies recognizing specific carbohydrate epitopes are produced. Extensive work has been performed on glycoconjugates displaying TACAs as potential vaccines against cancer and the approach was shown to be very promising (3–8). Monoclonal antibodies raised against the tumour associated hexasaccharide dimeric Le^x **1** (Fig. 1, dimLe^x) were shown to recognize internal epitopes of dimLe^x displayed by colorectal tumour tissues (9–13). If used as a vaccine, however, the dimLe^x hexasaccharide is also likely to trigger the production of antibodies binding to the non-reducing trisaccharide Le^x (Fig. 1) also largely expressed in normal tissues and cells (14). To avoid such autoimmune reactions, our research program is aimed at discovering analogues of the dimLe^x hexasaccharide that would retain the internal epitopes present on the surface of colorectal cancer cells but no longer possess the epitopes associated with the Le^x trisaccharide ***A′(B′)C′***. Thus, we are investigating the possibility of using analogues of hexasaccharide **1** in which one of the sugar units ***A′***, ***B′***, or ***C′*** defining the Le^x epitope is replaced by other sugar residue (Fig. 2), i.e., *N*-acetylglucosamine by glucose (**2**), galactose by glucose (**3**), and fucose by rhamnose (**4**). It is reasonable to expect that the conformational changes induced by any of these substitutions will affect the cross-reactivity between the analogues and the natural antigen. In fact, if the conformations of hexasaccharides **2**–**4** are drastically different from that of **1** it is likely that these analogues will not maintain the wanted cross-reactivity with dimLe^x. In contrast, if the conformations of hexasaccharides **2**–**4** are similar to that of **1** they could retain a tumor-associated cross-reactivity with the natural dimeric antigen while losing cross-reactivity with the Le^x determinant. Predicting such conformational changes will allow significant savings to our synthetic efforts. If the conformations of hexasaccharides **2**–**4** are similar to that of **1**, the conformation of the non-reducing trisaccharide ***A′***(***B′***)***C′*** in these analogues must also be similar to that of the Le^x residue ***A′***(***B′***)***C′*** in dimLe^x **1**. Conversely, it seems reasonable to expect that any drastic conformational change imposed to the terminal trisaccharide ***A′***(***B′***)***C′*** by these substitutions will induce a large conformational change in the corresponding hexasaccharide. Thus, the computationally less demanding conformational study of trisaccharide analogues **7**–**9** is sufficient to obtain a good insight into the conformational changes imposed by these substitutions to the hexasaccharides **2**–**4**. To assess if analogues **7**–**9** (Fig. 3) would maintain a Le^x-like conformation while presenting different electrostatic topographies to anti-Le^x antibodies, we applied biased stochastic conformational searches using the Molecular Operating Environment program suite (15). In this stochastic search method all bonds including ring and side-group bonds are allowed to rotate randomly and simultaneously to generate new molecular conformations that are energetically evaluated. Thus, this search method attempts to map the whole conformational space without any driving force, as is the case in some other conformational search methods, such as MMC calculations. The energies were calculated using the MMFF94 force field (16) and applying the Born continuum solvation model (17–19), which has been shown (20) to be efficient for the modeling of carbohydrates.

Fig. 2. Analogues of dimLe^x as potential targets for vaccine development.

3 R^1 = NHAc, R^2 = R^5 = OH, R^3 = R^4 = H
4 R^1 = NHAc, R^2 = R^5 = H, R^3 = R^4 = OH

To assess the validity of our results on the analogues, we first applied the stochastic search method to the molecular modeling of the Le^x determinant, for which a large amount of both computational and experimental data is available in the literature. In fact, the lowest energy conformation of the Le^x trisaccharide methyl glycoside (**6**) was first calculated in the pioneering work of Lemieux and co-workers (21) who developed the Hard Sphere ExoAnomeric (HSEA) modeling method (22). Since these early calculations, other molecular mechanics force field methods have been applied to the modeling of this trisaccharide (23–25). Moreover, in a thorough study, Csonka et al. (26) used ab initio calculations (HF/6–31G(d)) to validate the results obtained in the molecular modeling of trisaccharides **5** and **6** using the MM2*–SUMM conformational search method. In addition to being calculated by these various methods, the conformation of the Le^x trisaccharide was also experimentally determined both by NMR measurements (23, 25) for its solution state and X-ray crystallography (27) for its solid state. Thus, because the conformational manifold of the Le^x trisaccharide has been well established computationally and experimentally, it was used as a test case to evaluate the stochastic search method and force field used in our study before applying it to analogues **7**–**9**.

Computational methods

All calculations in this work were performed using the fully programmable Molecular Operating Environment program suite (15). Conformational searches were performed with the stochastic search method, as implemented in MOE (15). The procedure is similar to the RIPS method (28). In stochastic searches new molecular conformations are generated by random

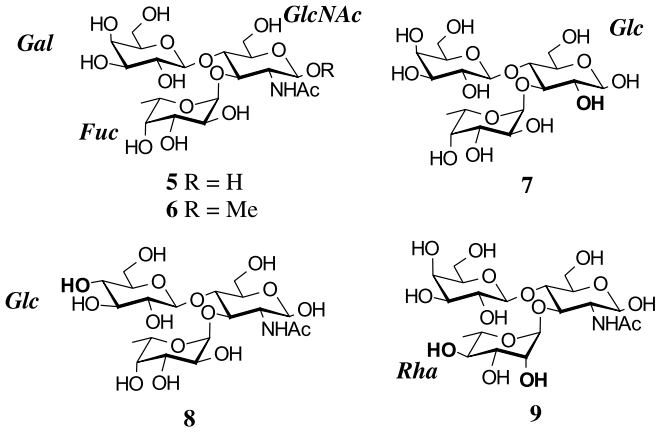
Fig. 3. Le^x (**5**), Le^x β-methyl glycoside (**6**), and analogues of Le^x (**7**–**9**) modeled.

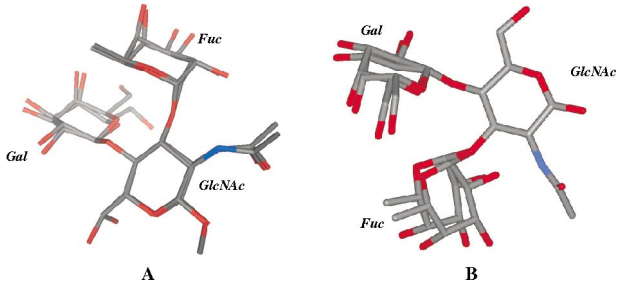


rotation of bonds (including ring bonds) instead of only Cartesian coordinate perturbation. In the calculations a bias of ~30° was selected, which means that dihedral angles were rotated by random angle with a sum-of-gaussians distribution with peaks at multiples of 30°. To make the search even more efficient, a simultaneous Cartesian perturbation of 0.4 Å was also applied. The structures were subsequently optimized using the Merck force field (MMFF94, ref. 16) and employing the Born continuum solvation model (17–19) as implemented in MOE. Each resulting conformation was checked to determine if it had already been generated by comparing all atom positions using a predefined root-mean-square (RMS) tolerance (0.1 Å in this work). The hydrogens were included in establishing the RMS tolerance because of the importance of hydrogen bonding among these carbohydrates: molecules with identical heavy atom positions but different hydrogen positions may substantially differ in energy. The procedure was terminated when the number of failures to find new conformations exceeded 10 000 in a row, a stringent criterion. Conformations with energies over 10 kcal mol^{-1} above the respective minima were rejected. In the process, 1034 conformations were obtained for the Le^x trisaccharide **5**, whereas the number of conformers for analogues **7**–**9** were 442, 268, and 472, respectively. During the entire process, the absolute configuration of each molecule was preserved.

To identify conformations with similar properties, conformer generation was followed by a clustering process. This conformer clustering was based on the metric scaling procedure (29), an efficient technique to project high dimensional conformational space to two dimensions. In metric scaling the distances between points representing different conformers are equal to the RMS distance between the corresponding conformers themselves, provided all eigenvalues in the process are positive. This was satisfied in all examples. The metric scaling technique allows the visual inspection of differences between clusters, which makes it simple to determine the optimum number of clusters. Only heavy atoms were involved in the metric scaling.

The minimum energy geometry of selected conformers of Le^x (**5**) were also calculated using the AM1 and PM3 semi-empirical calculations, without considering the effects of solvation. At termination of the optimizations, the average gradient was less than 0.0001 kcal $Å^{-1}$ mol^{-1}. Electrostatic potential surfaces were calculated from the Gasteiger charges of the surface atoms.

(B) Overlay of the local minimum found for **5** 8.3 kcal mol^{-1} above the global minimum (Table 2, entry 1) with the local minimum reported by Peters and co-workers (25) (Table 2, entry 2).



Results

A large number of crystal structures and semi-empirical calculations have revealed that pyranose rings adopt well-defined geometries and exist in their regular unstrained chair conformations: $^4C_1$ for D-GlcNAc, D-Glc, and D-Gal or $^1C_4$ for L-Fuc and L-Rha (30). Since the flexibility of these rings is limited, the global shape of oligosaccharides depends mainly on the rotation of the individual sugar residues around the glycosidic linkages. The relative orientations of the carbohydrate units in an oligosaccharide are usually expressed in terms of the torsional angles of the glycosidic linkages Φ and Ψ, which are defined here as Φ = O5-C1-O-C′*x* and Ψ = C1-O-C′*x*-C′(*x* + 1) for the (1 → *x*) linkages. The angles measured for the global minimum found by the stochastic search are given in Table 1 (entry 1). Table 1 (entries 2–6) also gives the Φ/Ψ torsional angles for the minimum energy conformations previously found by various conformational search methods (21, 23–25) and further supported by the ab initio calculations of Csonka et al. (entry 7, ref. 26). As can be seen from these results the global minimum found by the stochastic search is in complete agreement with those calculated by the various computational methods. Table 1, entries 8 and 9, as well as Fig. 4A show that the closely related conformations of the Le^x trisaccharide in the solid state found by X-ray crystallography (27) are in full agreement with the global minimum obtained by the stochastic search (entry 1). Finally, the solution conformations deduced experimentally by NMR measurements (NOEs and non-selective T_1) reported by Miller et al. (23) and more recently by Peters and co-workers (25) are given in Table 1, entries 10 and 5, respectively. Again, these conformations are in very good agreement with the global minimum found by the stochastic search (Table 1, entry 1). As described in Table 2 (entry 1) and illustrated in Fig. 4B, the stochastic search also found a local minimum 8.3 kcal mol^{-1} above the global minimum that corresponds to a local minimum found by Metropolis Monte Carlo simulations 7.3 kcal mol^{-1} (see Table 2, entry 2) above the global minimum.

Because it allows random rotation of all bonds, the stochastic search is a powerful method for locating additional conformational minima that were not necessarily found

using other search methods. In fact, the stochastic search on **5** lead to 1034 conformations in a 10 kcal mol^{-1} window above the global minimum. Nineteen conformations were found within 3 kcal mol^{-1} of the lowest energy conformation. Five of these conformations presented twisted or inverted chairs and were discarded. The torsional angles Φ and Ψ angles were defined in MOE for each glycosidic linkage and automatically measured for the remaining 12 conformers. Based on these angles the conformations were found to fall into six main clusters (**A**–**F**) listed in Table 3. The overlays of the conformers belonging to the same cluster (**A**, **C**, and **D**) are represented in Fig. 5. These overlays show that conformations that belong to the same cluster but have different energies differ essentially in the orientation of the CH_2OH or *N*-acetyl groups. These results can be related to the work of Csonka et al. (26). In their study the conformations found by MM2*–SUMM within 1 kcal mol^{-1} of the global minima for trisaccharides **5** and **6** were also evaluated at the ab initio (HF/6–31G(d)) level. These results based on a higher level of calculations also point towards an important energy contribution defined by the orientation of the side chains and hydroxyl groups to the total energy of conformations having the same Φ and Ψ angles. As can be seen in Fig. 6, metric scaling on heavy atoms (29) allowed the simple identification and distinction of the six clusters, **A**–**F**.

Based on the *N*-acetylglucosamine ring we rigidly aligned the local minima best representing each of the conformational families (**A**–**F**) found by the stochastic search. The results presented in Fig. 7 show that these conformers differ from each other mostly in the orientation of the galactose residue represented in blue and to a lesser extent in the orientation of the fucosyl residue represented in red. Thus, our results seem to be in contrast with previous studies in which it was concluded from molecular dynamics (23) and ab initio calculations (26) that the Le^x trisaccharide was fairly rigid around the glycosidic linkages. However, it was also shown by Csonka et al. (26) that there was no obvious correlation between the MM2* energies calculated for the reducing trisaccharide **5** and the methyl glycoside analogue **6**. Thus, to assess whether the conformations found by the stochastic search for reducing analogue **5** could be reasonably expected for glycoside **6** used in most other calculations, we performed semi-empirical geometry optimizations of selected conformations of hemiacetal **5** and methyl glycoside **6**. Calculations at the PM3 and AM1 levels suggest that conformer **B** is about 3–3.5 kcal mol^{-1} more energetic

than conformer **A** and that methyl glycoside conformer **B** remains about 2.5–3 kcal mol^{-1} more energetic than conformer **A** (see Table 4). These calculations confirmed that the new families of conformers identified by the stochastic search are indeed likely to be in the 5 kcal mol^{-1} window from the global minimum. Nevertheless, accounting for the relative energy of conformers remains an important issue in conformational analysis. In fact, Csonka et al. (26) showed that while the MM2* method provided small energy differences for the first 11 rotamers of trisaccharide **5** (1 kcal mol^{-1}), ab initio calculations (HF/6–31G(d)) on the same rotamers yielded more than 4.5 kcal mol^{-1} in energy difference. It is also known that there are great differences in relative energies of conformers when calculated with different force fields (20) and that the energies calculated for individual conformations are often highly inaccurate. Thus, the extent

with which these new conformational families are indeed populated in solution is uncertain. So far the NMR measurements reported for the Le^x determinant (23, 25) did not point towards a close contact (2.1–2.3 Å) between $H\text{-}1^G$ and $H\text{-}3^{GN}$, which should be observed for the conformations **B** and **C**. It is to be borne in mind that although a powerful method to support highly populated conformations, multiple conformations can, however, only be observed by NMR if the conformational change is fast. In fact, the local minimum found by Peters and co-workers (25) 7.3 kcal mol^{-1} above the global minimum that should have given a NOE signal corresponding to a 2 Å contact between $H\text{-}6^F$ and NAc^{GN} could not be experimentally observed. In contrast, a second local minimum found in the same study 8.3 kcal mol^{-1} above the global minimum was supported by NMR data (25).

Even though the additional conformational families that were described above have not, so far, been supported by experimental evidence, it is clear that the stochastic search method applied to the modeling of trisaccharide **5** reliably identified the lowest energy conformation generally found computationally and supported experimentally for the Le^x determinant. Thus, this search method was applied to the modeling of trisaccharides **7**–**9** to obtain an accurate description of the lowest energy conformations of these analogues. Stochastic conformational searches of analogues **7**–**9** (Fig. 3) led to fewer conformers than that obtained for the Le^x trisaccharide. In fact, in a 3 kcal mol^{-1} window from the global minima, three conformational families were found for analogue **7**, one for analogue **8**, and two for analogue **9**. When defined by the Φ, Ψ torsional angles, as reported in Table 5, the lowest energy conformations obtained for analogues **7** and **8** (entries 1 and 4, respectively) are similar to that obtained for the Le^x trisaccharide reported in Table 3, entry 1. Thus replacing the *N*-acetylglucosaminyl or galactosyl residues by glucose did not result in a large conformational change in the trisaccharide. In addition, the other two conformational families identified for analogue **7** (**C** and **E**, Table 5, entries 2 and 3) were also found in the Le^x conformational search. In contrast, substitution of the fucosyl by a rhamnosyl residue as in analogue **9** resulted in a dramatic change in the conformation of the trisaccharide. As reported in Table 5 (entries 5 and 6), two new conformational families (**H** and **I**) were identified. When comparing the global minimum obtained for **9** (**H**) with that calculated for Le^x (**A**), the rhamnosyl residue ($\Phi^2 = –102°$, $\Psi^2 = 150°$) assumes essentially the same orientation as the fucosyl residue ($\Phi^2 = –62°$, $\Psi^2 = 146°$), while the galactosyl residue occupies a drastically different orientation shown by the value of the Ψ torsional angle (Ψ^1 (**A**) = –107°, Ψ^1 (**H**) = 82°). In contrast, when comparing the local minimum **I** given in Table 5 (entry 6) with the Le^x global minimum **A**, we observe that the galactosyl residues assume the same orientation ($\Phi^1 = –76°$, $\Psi^1 = –106°$ vs. $\Phi^1 = –68°$, $\Psi^1 = –107°$), while the rhamnosyl residue in **I** assumes a different orientation from the fucosyl residue in **A** ($\Phi^2 = –161°$, $\Psi^2 = 96°$ vs. $\Phi^2 = –62°$, $\Psi^2 = –146°$). Interestingly, this conformation is very similar to the conformer found 8.3 kcal mol^{-1} above the global minimum in Le^x and described in Table 2 (entry 1). Thus, as shown in Fig. 8, the stacking that exists between the galactosyl and fucosyl residues in the Le^x trisaccharide is maintained when either galactosyl or *N*-acetylglucosamine are replaced by glucosyl residues but is abolished when the fucosyl residue is replaced by a rhamnosyl residue. Non-stacked rotamers were also identified by Csonka and Sosa (31) in their ab initio conformational study of Lewis X analogues **10** and **11** shown in Fig. 9. The global minima found for these two analogues had the usual stacked conformation between the galactose and fucose residues. Non-stacked rotamers of low energy were frequent, however, amongst the

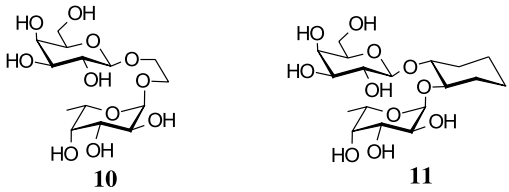
rotamers of the 1,2-ethandiol analogue **10**, while one such rotamer was found 2.3 kcal mol^{-1} above the global minimum for analogue **11**. Thus, the study by Csonka and Sosa (31) shows that while an increased flexibility around the ethanediol linker in analogue **10** allows access to non-stacked conformations, stacking between the galactosyl and fucosyl residues constitute a stabilizing force since the stacked conformation remains the lowest energy one. In our results, the absence of stacked conformations for analogue **9** likely results from the loss of this stabilizing force.

Conclusions

The stochastic conformational search was used successfully to model the Le^x trisaccharide since it accurately identified a lowest energy conformation of the Le^x determinant in agreement with previous computational studies (21–26). This global minimum fits the conformation of Le^x deduced experimentally in the solid state by X-ray crystallography (27) and in solution by NMR measurements (23, 25).

Through the random rotation of all bonds, which was typically repeated a few hundred thousand times for each molecule, the stochastic search is a highly efficient method for mapping all conformational minima. The twelve conformers found for Le^x within 3 kcal mol^{-1} of the global minimum were efficiently clustered using metric scaling (29) on heavy atoms permitting the visual identification of six major conformational families, five of which were previously unknown. Although these new conformational families are not yet supported by the experimental data collected so far for Le^x, they were shown to be energetically reasonable. It has been shown (19) that the active conformations of Le^x that bound to isolectin A from *Lotus tetragonolus* and to *Aleuria Aurantia* were radically different from the assumed rigid global minimum of Le^x. Interestingly, one of these conformations was not supported experimentally (25) in the unbound state. The identification of these new conformational families using the stochastic search could, therefore, constitute an important finding to help the discovery of new active conformations of the Le^x determinant.

Fig. 9. Lewis X analogues studied by Csonka and Sosa (31) using ab initio calculations with HF/6–31G(d).



Studies of oligosaccharides binding to biological receptors require a good knowledge of the conformations that oligosaccharide in question can adopt. In contrast, it is reasonable to expect that most antibodies generated during an immune response induced against an oligosaccharide (like any of analogues **1**–**4**) will target its most populated conformations in the unbound state. Thus, to save on unnecessary synthetic efforts, our research required that the stochastic search used here accurately model the lowest energy conformers of the Le^x determinant and its analogues. Since it gave a reliable description of the lowest energy conformation of the Le^x trisaccharide, which is supported experimentally, we can use the global minima found for analogues **7**–**9** by the stochastic search to gain insight on the conformational differences between these analogues and the Le^x determinant. Substituting the galactose or *N*-acetylglucosamine residues by glucose did not alter the overall conformation of the global minimum. In contrast, substitution of the fucose residue by rhamnose led to different global and local minima in which stacking of the galactose and rhamnose residues was no longer observed as is the case for the galactose and fucose residues in Le^x. It is interesting to note that one of the conformations obtained for analogue **9** is in fact very similar to the conformations assumed by Le^x in its bound form to isolectin A from *Lotus tetragonolus* and to *Aleuria Aurantia* agglutinin and shown in Table 2, entries 2 and 3 (25).

The electrostatic potential surfaces of Le^x and the three analogues studied here are displayed in Fig. 8. These results indicate that the subtle changes that result from the substitution of the galactose or *N*-acetylglucosamine residues by a glucose unit could be sufficient to abolish the cross-reactivity of hexasaccharides **2** and **3** with the Le^x determinants displayed on normal cells. These substitutions, however, do not induce a drastic conformational change that would also surely abolish cross-reactivity based on common internal epitopes between these analogues and the cancer associated dimLe^x antigen. In contrast, the large conformational change imposed by replacing the fucosyl residue by a rhamnosyl unit in trisaccharide **9** will likely be reflected in the conformation of hexasaccharide **4**. Thus, we can expect that analogue **4** will also loose major internal epitopes displayed by the tumour associated hexasaccharide dimLe^x and, therefore, will not be cross-reactive with this antigen. We conclude from this study that only hexasaccharide **2** and **3** constitute interesting candidates to develop dimLe^x-based anti-cancer vaccines.

Thermodynamic binding studies of cell surface carbohydrate epitopes to galectins-1, -3, and -7: Evidence for differential binding specificities

Nisar Ahmad, Hans-J. Gabius, Herbert Kaltner, Sabine André, Ichiro Kuwabara, Fu-Tong Liu, Stefan Oscarson, Thomas Norberg, and C. Fred Brewer

Abstract: Binding of a series of sialylated and non-sialylated cell surface carbohydrates to bovine heart galectin-1, recombinant murine galectin-3, and recombinant human galectin-7 was investigated by isothermal titration microcalorimetry (ITC) and hemagglutination inhibition measurements. Galectin-7 shows nearly equal affinities for lactose and Galβ(1–4)GlcNAc (LacNAc-II). Galectin-7, however, displays six- and 11-fold weaker affinity for LacNAc-II compared with galectins-1 and -3, respectively. The affinity of galectin-7 for LacNAc-II containing oligosaccharides is also weaker than the other two galectins. ITC measurements show that all three galectins bind to di- and trimeric oligomers of LacNAc-II, which are epitopes found in poly-*N*-acetyllactosamine chains of glycoprotein receptors, with affinity constants similar to that of LacNAc-II. The binding valencies of the di- and trimeric LacNAc-II oligomers were observed to be one from ITC measurements, indicating formation of 1:1 complexes with all three galectins. Thus, galectins-1, -3, and -7 all possess binding sites that primarily accommodate one LacNAc-II moiety per monomer of protein. Sialylated oligosaccharides show different specificities for the three galectins. While 2,3-sialyl LacNAc-II binds to all three galectins, 2,6-sialyl LacNAc-II fails to bind to any of the galectins; 2,6-sialylated diLacNAc binds well to galectin-3 and galectin-7, but only weakly to galectin-1. Similar results are obtained with 2,6-sialyl lacto-*N*-neo-tetraose, which has a reducing end lactose moiety. Thus, unlike galectin-1, which predominantly recognizes non-reducing terminal LacNAc-II residues in oligosaccharides, galectins-3 and -7 recognize both non-reducing terminal LacNAc-II residues as well as internal LacNAc-II and lactose residues in sialylated and non-sialylated oligosaccharides.

Key words: isothermal titration microcalorimetry, galectins, binding specificities, lectins, carbohydrates.

Résumé : Faisant appel à des titrages microcalorimétriques isothermes (TMI) et à des mesures d'inhibition de l'hémagglutination, on a étudié la fixation d'une série d'hydrates de carbones de surfaces cellulaires sialylées et non sialylées à la galectine-1 cardiaque bovine, à la galectine-3 de la murine recombinante et à la galectine-7 humaine recombinante. La galectine-7 présente des affinités pratiquement égales pour le lactose et la Galβ(1-4)GlcNAc (LacNAc-II). Toutefois, la galectine-7 présente des affinités pour le LacNAc-II qui sont respectivement six et onze fois plus faibles que celles des galectines-1 et -3. L'affinité de la galectine-7 pour les oligosaccharides contenant du LacNAc-II est aussi plus faible que celle des deux autres galectines. Des mesures de TMI montrent que les trois galectines se lient aux oligomères di- et trimères du LacNAc-II, des épitopes que l'on retrouve dans les chaînes de poly-*N*-acétyllactosamine des récepteurs glycoprotéiniques; les constantes d'affinité sont semblables à celles observées avec le LacNAc-II. Sur la base des TMI, on a déterminé les valences des liaisons des oligomères di- et trimères du LacNAc-II et elles indiquent qu'il y a formation de complexes 1:1 avec chacune des trois galectines. Les galectines-1, -3 et -7 possèdent toutes des sites de fixation qui accommodant en première approximation une portion de LacNAc-II par monomère de protéine. Les oligosaccharides sialylés présentent des spécificités différentes pour les trois galectines. Alors que la 2,3-sialyle LacNAc-II se fixe aux trois galectines, le 2,6-disialyle diLacNAc se fixe bien à la galectine-3 et à la galectine-7, elle ne se fixe que faiblement à la galectine-1. On a obtenu des résultats semblables avec le 2,6-sialyl lacto-*N*-néo-tétraose qui comporte un lactose avec une partie réductrice. Donc, contrairement à la galectine-1 qui reconnaît de façon prédominante les oligosaccharides portant des résidus LacNAc-II avec une extrémité non réductrice,

Introduction

Galectins are a family of Ca^{2+}-independent animal lectins defined by common consensus sequences and structures, with specificities for β-Gal and LacNAc-II (Fig. 1) residues in oligosaccharides (1–3). Since they are also expressed in nematodes and porifera, they are of ancient origin with conservation of their structure for more than a billion years (2, 4). Fourteen members of the family have currently been identified in mammals and designated galectins-1–14, and more are likely to be found since homologies have already been reported in the literature (4–6). Indeed, there may be a galectin superfamily with some members not possessing lectin-like properties, similar to the situation with C-type lectins (7, 8). For mammalian galectins-1–14, progress has been made in determining some of their biological activities which include roles in the regulation of inflammation, and modulators of cell adhesion, cell proliferation, and cell death (8, 9).

The structures of the mammalian galectins can be identified as prototypes (galectins-1, -2, -5, -7, -10, and probably -11, -13, and -14) that exist as monomers or homodimers consisting of one carbohydrate-recognition domain (CRD); a chimera type (galectin-3) that contains a non-lectin *N*-terminal short sequence segment followed by 8–129 amino acid long collagen-like repeats connected to the C-terminal of about 140 amino acids; and a tandem-repeat type (galectins-4, -6, -8, and -9) composed of two CRD domains in a single polypeptide chain connected by a linker peptide (1–3). The X-ray crystal structures of galectin-1 (10, 11), galectin-2 (12), galectin-7 (13), galectin-10 (14), and CRD domain of galectin-3 (15) have been reported (6). Studies of the carbohydrate binding specificities of the galectins have been largely restricted to galectin-1 (16, 17) and galectin-3 (17–19), with conflicting data reported for galectin-10, the Charcoat–Leyden crystal protein (14, 20). These studies generally show specificities of the galectins for LacNAc-II residues, with higher affinities reported for some naturally occurring oligosaccharides. Indeed, there is evidence that the galectins recognize polylactosamine chains with high affinity (cf. 21, 22), and that these chains are receptor sites on the surface of cells (cf. 23). However, thermodynamic data for mammalian galectins binding to LacNAc-II oligomers and sialyl LacNAc-II oligomers has not been reported.

Considerable insight has been gained on the biological properties of specific galectins. Galectin-1 has been implicated in various biological processes in multicellular organisms including inflammation, development, mRNA splicing, differentiation, and cell adhesion (1–3). Galectin-1 has also recently been demonstrated to play a role in the immune system by mediating apoptosis of activated T cells with CD7 as target (24). Galectin-3 has also been shown to exhibit roles in regulating inflammation, cell growth, and cell adhesion (3, 25). Galectin-3, unlike galectin-1, possesses anti-apoptotic

effects in various cells, and its expression has been shown to correlate with the metastatic potentials of certain cancers (26). Galectin-7 is reported to be marker for stratified epithelia (27). It has been shown that the galectin-7 gene is a transcriptional target of the tumor suppressor protein p53 and may play a role in the proapoptotic function of p53 (28). Concerning malignant cells, expression of galectin-7 is elevated in chemically induced rat mammary carcinomas (29), and its mRNA could be detected frequently in human breast and colon cancer cell lines (30). Galectin-7 thus appears to be another member of the galectin family with regulatory activity for cell survival. Diversification within the galectin family intimates that functional aspects will not simply be redundant. Besides the different CRD presentation in tandem-repeat prototype vs. chimera-type galectins, the carbohydrate binding properties might differ. Hence determining the fine carbohydrate binding specificities of these galectins is important in understanding their biological functions.

In the present report, we report hemagglutination inhibition data and thermodynamic data obtained by isothermal titration microcalorimetry (ITC) for binding of bovine heart galectin-1, recombinant murine galectin-3, and recombinant human galectin-7 to LacNAc-I and -II and related cell surface carbohydrate epitopes including di- and trimeric oligomers of LacNAc-II, and sialylated analogs of LacNAc-II and diLacNAc. The results demonstrate important differences in the binding specificities of the three galectins.

Experimental

Materials

Bovine heart was purchased from Pel-Freez Biologicals. Fetuin, cyanogen bromide, LacNAc-II, lactose, methyl β-lactoside, galactose, methyl β-galactopyranoside, dithiogalactopyranoside (ThiodiGal), lacto-*N*-tetraose, lacto-*N*-neotetraose, 2,3-sialyl LacNAc, 2,6-sialyl LacNAc, and 2,6-sialyl-lacto-*N*-neo-tetraose (Fig. 1) were obtained from Sigma Chemical Co. LacNAc-I and methyl β-LacNAc-I were obtained from Toronto Research Chemicals. Methyl β-LacNAc-II, DiLacNac, TriLacNAc, "trisaccharide," and 2,6-sialyl DiLacNAc (Fig. 1) were chemically and (or) enzymatically synthesized and will be reported elsewhere. All other reagents were of analytical grade.

Purification and expression of the proteins

Fetuin was desialylated and purified as previously described (31). Asialofetuin-Sepharose was prepared by following a published procedure (32). Bovine heart lectin (BHL) (galectin-1) was purified using the procedure for the isolation of calf spleen galectin-1 (31). SDS-PAGE of the affinity purified lectin was found to contain one additional band. Affinity purified lectin was fractionated into two clear peaks (I and II) by gel chromatography using a Sephadex G-50 column in the presence of 0.05 mM lactose. The 2nd peak corresponded to BHL and was found to be pure by SDS-PAGE. Fractions containing the 2nd peak were pooled, extensively dialyzed against PBS containing 10 mM β-mercaptoethanol, and then stored at 4°C.

Murine galectin-3 and human galectin-7 were purified after recombinant expression, using the plasmid prCBP35, kindly provided by J.L. Wang (East Lansing, MI) and *E. coli* JA221 cells (33) or pQE60-hGal-7 (establishment of a NcoI cleavage site required to switch from Ser^2 to Ala^2 in the protein sequence) and *E. coli* M15{pREP4} cells. Both proteins showed single bands by SDS-PAGE.

Monomeric lectin concentrations were determined spectrophotometrically at 280 nm using the specific extinction coefficients of the three proteins ($E^{1\%}_{1cm}$). $E^{1\%}_{1cm}$ values of 5.4, 6.1, and 5.5 were used for BHL, galectin-3, and galectin-7, respectively, as determined from ITC experiments. Molecular masses of the galectins were determined by MALDI and electrospray ionization mass spectrometry and were found to be 14 500 Da for galectin-1, 27 500 Da for galectin-3, and 14 600 Da for galectin-7. The carbohydrate concentration was measured by the phenol–sulfuric acid method (34, 35).

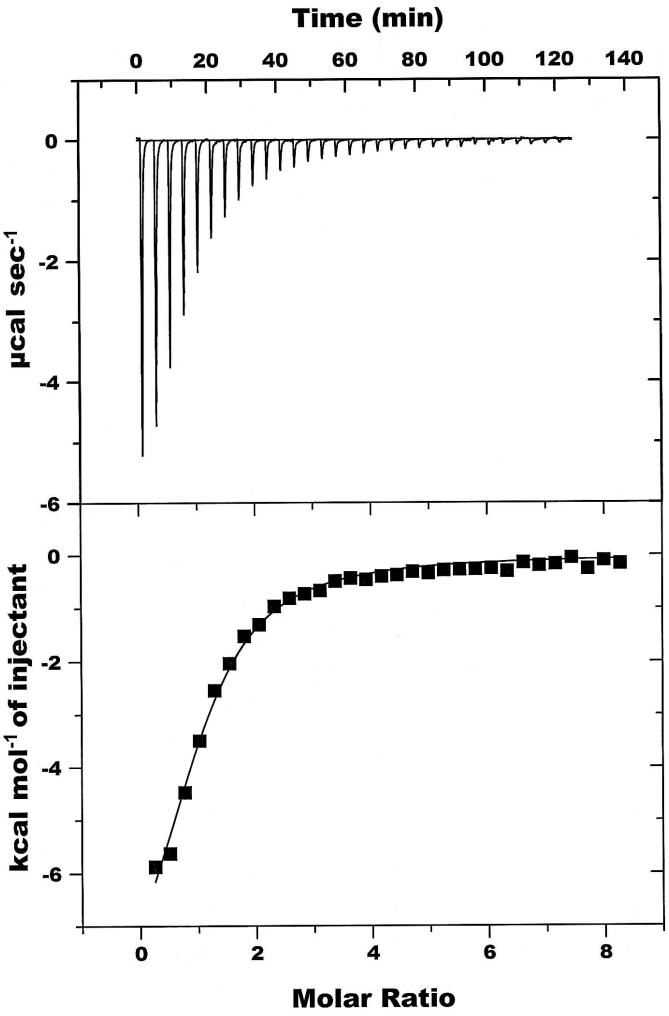
Hemagglutination inhibition assays

Hemagglutination assays were performed by serial dilution technique (36). Rabbit erythrocytes (3% (v/v)) were prepared in 20 mM sodium phosphate buffer containing 0.15 M NaCl, pH 7.2, whereas the sugar and protein solutions were prepared in 20 mM sodium phosphate buffer containing 0.15 M NaCl and 10 mM β-mercaptoethanol, pH 7.2. The final concentration of β-mercaptoethanol in the assay was 5 mM.

Isothermal titration microcalorimetry

Isothermal titration calorimetry (ITC) experiments were performed using an MCS Microcalorimeter from Microcal Inc. (Northampton, MA). A typical titration profile is shown in Fig. 2. Protein and carbohydrate samples were prepared in 20 mM sodium phosphate buffer containing 0.15 M NaCl and 10 mM β-mercaptoethanol, pH 7.2. The protein solution (2.5 mL) was taken in a syringe and loaded into the ITC sample cell (cell volume = 1.34 mL). Reducing agents in the buffer were found to increase the time for the baseline stabilization, which varied from 3–6 h. The effect of DTT on baseline stabilization was greater than β-mercaptoethanol. Degassing of protein solutions and using fresh buffers (maximum 12 h storage time) was found to decrease the time for baseline stabilization from 4 to 1 h. After the baseline had stabilized, 4-μL injections of the carbohydrate solution were added from the computer-controlled 100-μL rotating syringe (400 rpm) into the protein solution; exothermic heat changes accompanying the additions were recorded. The time period between the two consecutive injections was fixed at 4 min to allow the exothermic peak to return to the baseline. Control experiments were carried out by making identical injections into the cell-containing buffer with no protein. The experimental data were fitted using software ORIGIN TM Version 2.9 supplied by Microcal, with ΔH (enthalpy change in kcal mol^{-1}), K_a (association constant in M^{-1}), and n (number

Fig. 2. ITC profile of galectin-3 (69 μM) titrated with 2,6-sialyl DiLacNAc (6.0 mM) in pH 7.2 buffer at 300 K.



© 2002 NRC Canada

of binding sites per monomer) as adjustable parameters. The value of unitless constant c ($c = K_a M_t n$, where M_t is the initial protein concentration, K_a is the association constant in M^{-1}, and n is the number of binding sites per monomer of protein), is of great importance since it determines the shape of the binding isotherm (37). All the experiments were performed with c values of $1 < c < 200$. The instrument was calibrated using the calibration kit containing ribonuclease A (RNase A) and cytidine 2′-monophosphate supplied by the manufacturer. Thermodynamic parameters were calculated by using the standard equation, $\Delta G = \Delta H - T\Delta S = -RT \ln K_a$, where ΔG, ΔH, and ΔS are the changes in the free energy, enthalpy, and entropy of binding, respectively. T is the absolute temperature in kelvin, and R = 1.98 cal mol^{-1} K^{-1}. Different batches of recombinant murine galectin-3 were found to contain varying amounts of inactive molecules, with n values less than 1.0 (the lowest value of n was 0.6). These galectin-3 samples were purified by passage over an ASF-Sepharose affinity column until the n value was close to 1.0, using LacNAc-II as the titrating sugar in ITC measurements. Galectin-3 samples were tested with LacNAc-II before and after an ITC experiment with a new saccharide.

Results and discussion

Table 1 shows ITC thermodynamic data at two temperatures (287 and 300 K) for the binding of bovine heart galectin-1, murine recombinant galectin-3, and human recombinant galectin-7 to the carbohydrates in the present study. Table 2 shows hemagglutination inhibition data at room temperature for the three galectins. The most immediate conclusion from the data in both tables is that galectin-7 possesses weaker affinity for carbohydrates presenting LacNAc-II as the primary binding epitope, relative to the other two galectins. For example, ITC data in Table 1 show that the K_a value for galectin-7 binding LacNAc-II is nearly sixfold lower than the corresponding value for galectin-1, and nearly 11-fold weaker than that of galectin-3. Interestingly, the enthalpy of binding (ΔH) for galectin-7 to LacNAc-II (–11.8 kcal mol^{-1}) is greater than that of galectin-1 (–9.2 kcal mol^{-1}) and galectin-3 (–7.5 kcal mol^{-1}). Conversely, the entropy of binding ($-T\Delta S$) for galectin-7 to LacNAc-II is more unfavorable (7.4 kcal mol^{-1}) than that of galectin-1 (3.7 kcal mol^{-1}) and galectin-3 (1.6 kcal mol^{-1}). Because of the weaker affinity of galectin-7 for carbohydrates, most of the ITC binding data for galectin-7 was obtained at 287 K and compared with similar data for galectins-1 and -3 at the same temperature.

Thermodynamics of binding of disaccharides to galectins-1 and -3

The thermodynamics of binding of bovine heart galectin-1 and recombinant murine galectin-3 to simple disaccharides are shown in Table 1. The disaccharide LacNAc exists as two isomers in nature (LacNAc-I and -II), which differ in their linkage between Gal and GlcNAc. LacNAc-I possesses a β(1–3) linkage and LacNAc-II possesses a β(1–4) linkage. Previous studies of the binding of human galectin-1 (17) and rat galectin-3 (38) to an asialofetuin-Sepharose column showed similar inhibitory activities for LacNAc-I and LacNAc-II. ITC data at 300 K in Table 1 reveals that there is little difference in the K_a values of bovine heart galectin-1 for LacNAc-I (0.90×10^4 M^{-1}) vs. LacNAc-II (1.1×10^4 M^{-1}); the enthalpies of binding (ΔH) are –7.9 and –9.2 kcal mol^{-1}, respectively. Likewise, murine galectin-3 shows little difference in its K_a values for LacNAc-I (0.82×10^4 M^{-1}) vs. LacNAc-II (1.9×10^4 M^{-1}), with ΔH values of –6.4 and –7.5 kcal mol^{-1}, respectively. These results thus demonstrate similar affinities of both galectins for type I and II isomers of LacNAc. These results agree with those of Schwarz et al. (39) for bovine spleen galectin-1, and Surolia and co-workers (21) for recombinant human galectin-3.

Galectin-1 from a number of sources (40–42) has previously been shown to bind to β-thiodigalactopyranoside (ThiodiGal) with affinities comparable to LacNAc-II. Galectin-3 from human (17) and rat lung (38) has also been shown to bind to ThiodiGal. ITC data in Table 1 shows that bovine heart galectin-1 and recombinant murine galectin-3 bind to ThiodiGal at 300 K with nearly the same K_a values as LacNAc-II (factor of two difference for galectin-1). The enthalpies of binding ($-\Delta H$) of galectin-1 to the two disaccharides are similar, as are the $-\Delta H$ values for galectin-3 binding the two sugars. Thus, bovine spleen galectin-1 and recombinant murine galectin-3 share similar binding thermodynamics to ThiodiGal. These results are similar to those recently reported by Surolia and co-workers (21) for recombinant human galectin-3.

Binding of LacNAc-II oligomers to galectins-1 and -3

The thermodynamics of binding at 300 K of bovine heart galectin-1 and murine galectin-3 to dimeric (DiLacNAc) and trimeric (TriLacNAc) oligomers of LacNAc-II are shown in Table 1. Galectin-1 possesses K_a values of 0.74×10^4 and 2.2×10^4 M^{-1} for Di- and TriLacNAc, respectively, as compared with 1.1×10^4 M^{-1} for LacNAc-II. Hence, the K_a values for Di- and TriLacNAc are similar to that of LacNAc-II. The ΔH values for the three carbohydrates are also similar: –9.2 kcal mol^{-1} for LacNAc-II; –11.4 kcal mol^{-1} for DiLacNAc; and –10.1 kcal mol^{-1} for TriLacNAc. Furthermore, the n values for all three carbohydrates, the number of binding sites per monomer of protein, are all close to one, suggesting that all three oligosaccharides bind to the same site in the protein. The n values are also an indication of the valencies of the carbohydrates (43). Thus, all three oligosaccharides are monovalent, even though Di- and TriLacNAc have two and three LacNAc-II residues, respectively. Hemagglutination inhibition data with Di- and TriLacNAc also shows similar affinities of galectin-1 for all three carbohydrates (Table 2).

These results suggest that galectin-1 possesses a binding site that recognizes primarily one LacNAc residue, even when binding oligomers of LacNAc-II. ^{13}C NMR studies by Pierce and co-workers (44) of the binding of a C2S galectin-1 mutant from Chinese hamster ovary cells to specifically labeled oligomers of LacNAc-II also concluded that galectin-1 bound primarily to the non-reducing terminal LacNAc-II residues of the oligomers. The X-ray crystal structure of bovine spleen galectin-1 in complex with LacNAc-II also shows only one mole of the disaccharide bound to the protein (11).

Lacto-*N*-tetraose, which has the structure Galβ(1–3)GlcNAcβ-(1–3)Galβ(1-4)Glc, has previously been shown to bind well

to human galectin-1 (17). Lacto-*N*-tetraose possesses both a non-reducing terminal LacNAc-I moiety and a non-reducing terminal lactose moiety. Hemagglutination inhibition data demonstrate that bovine heart galectin-1 binds to lacto-*N*-tetraose as well as LacNAc-II (Table 2). ITC analysis shows a K_a value of 1.0×10^4 M^{-1} for galectin-1 binding to lacto-*N*-tetraose (Table 1), which is similar to that of LacNAc-II and DiLacNAc (Table 1). In addition, although there are two potential binding moieties in lacto-*N*-tetraose, the non-reducing terminal LacNAc-I moiety and the reducing internal lactose moiety, the n value for the tetrasaccharide is close to one. These results also support the conclusion that the CRD of bovine heart galectin-1 accommodates only one LacNAc or lactose residue in the above carbohydrates. Similar data were obtained for lacto-*N*-neo-tetraose by hemagglutination inhibition data (Table 2).

Table 1 shows the ITC thermodynamic data of galectin-3 binding to Di- and TriLacNAc. The K_a values for binding LacNAc-II, Di-, and TriLacNAc are 1.9×10^4, 3.5×10^4, and 6.3×10^4 M^{-1}, respectively; the ΔH values are –7.5,

[c]NI = not inhibitory.

–8.8, and –9.8 kcal mol^{-1}, respectively. Hence there is a factor of three increase in the affinity of galectin-3 from LacNAc-II to TriLacNAc, and a 2.3 kcal mol^{-1} increase in $-\Delta H$ values. Hemagglutination inhibition data also support the ITC data for the relative affinities of all three carbohydrates for galectin-3 (Table 2). The *n* values for galectin-3 binding to Di- and TriLacNAc are also close to one (Table 1), as for LacNAc-II, suggesting that all three oligosaccharides bind to the same site in the protein. The X-ray crystal structure of the CRD domain of human galectin-3 (C-terminal end of galectin-3) also shows one lactose molecule bound per monomer of the protein (15). The *n* values of one for Di- and TriLacNAc also indicate that these oligomers are monovalent in binding to galectin-3, even though they possess two and three LacNAc residues, respectively.

Table 1 shows that galectin-3 binds lacto-*N*-tetraose with a K_a value between that of LacNAc-II and DiLacNAc. Interestingly, the ΔH for lacto-*N*-tetraose binding to galectin-3 is much lower (–5.0 kcal mol^{-1}) relative to that of LacNAc-II (–7.5 kcal mol^{-1}) and Di- and TriLacNAc. The *n* value of one for galectin-3 binding lacto-*N*-tetraose indicates that the tetrasaccharide binds to one site in the protein, as observed for the other carbohydrates in Table 1. Similar data were obtained for lacto-*N*-neo-tetraose by hemagglutination inhibition data (Table 2).

Binding of sialylated LacNAc-II analogs

Galectin-1 from a number of sources is known to bind 2,3-sialyl lactose as well as lactose (17, 38, 45). Hemagglutination inhibition data in Table 2 shows that galectin-1 from bovine heart binds to 2,3-sialyl LacNAc as well as to LacNAc-II. Table 1 shows that the K_a value at 287 K for galectin-1 binding to 2,3-sialyl LacNAc (2.3×10^4 M^{-1}) is nearly the same as that for LacNAc-II (2.4×10^4 M^{-1}). Table 1 also shows that the $-\Delta H$ values for galectin-1 binding to the two oligosaccharides (–8.5 and –8.7 kcal mol^{-1}, respectively) are also similar. Galectin-1 from a number of sources is known not to bind to 2,6-sialyl lactose (17, 38). Hemagglutination inhibition data in Table 2 confirm that bovine heart galectin-1 does not bind to 2,6-sialyl LacNAc.

Galectin-3 from rat lung has been shown to bind threefold more weakly to 2,3-sialyl lactose than to lactose (38). Human galectin-3 exhibits nearly the same relative affinities for the two oligosaccharides in the inhibition assay (17). Table 2 presents hemagglutination inhibition data indicating that murine galectin-3 binds 2,3-sialyl LacNAc as well as LacNAc-II. Lack of precipitation of a neogylcoprotein with this sugar epitope (18) is thus not due to insufficient binding. ITC data in Table 1 indicate that the K_a value of 3.3×10^4 M^{-1} for 2,3-sialyl LacNAc at 287 K compared with LacNAc-II (3.7×10^4 M^{-1}) at that temperature for galectin-3. The ΔH values are –8.3 and –9.7 kcal mol^{-1}, respectively, for 2,3-sialyl LacNAc and LacNAc-II indicating that substitution of the non-reducing end Gal unit is tolerated.

Hemagglutination inhibition data in Table 2 shows that murine galectin-3 does not bind to 2,6-sialyl LacNAc, as has been previously demonstrated for this protein from human (17) and rat lung (38).

Since neither galectin-1 nor galectin-3 binds 2,6-sialyl LacNAc, 2,6-sialyl DiLacNAc was synthesized to determine if either galectin could bind to the internal (reducing end) LacNAc-II residue. While hemagglutination inhibition data in Table 2 show that galectin-1 binds 12-fold more weakly to 2,6-sialyl DiLacNAc than to LacNAc-II, galectin-3 binds 2,6-sialyl DiLacNAc as well as LacNAc-II. ITC data in Table 1 confirm these observations by showing that galectin-3 possesses nearly the same K_a value for 2,6-sialyl DiLacNAc (3.2×10^4 M^{-1}) as for LacNAc-II (1.9×10^4 M^{-1}). These results indicate binding of galectin-3 but not galectin-1 to the reducing LacNAc residue of 2,6-sialyl DiLacNAc.

© 2002 NRC Canada

Similar results for galectin-3 binding to 2,6-sialyl lacto-*N*-neo-tetraose were obtained. 2,6-Sialyl lacto-*N*-neo-tetraose differs from 2,6-sialyl DiLacNAc in having a type I LacNAc moiety at the non-reducing end of the molecule and a lactose moiety at the reducing end of the molecule. Hemagglutination inhibition data in Table 2 shows that galectin-3 binds 2,6-sialyl lacto-*N*-neo-tetraose nearly as well as LacNAc-II, and 16-fold better than galectin-1. ITC data obtained at 287 K shows that the K_a value for 2,6-sialyl lacto-*N*-neo-tetraose of galectin-3 is twofold less than for LacNAc-II. These results demonstrate that galectin-3 recognizes the internal lactose moiety in 2,6-sialyl lacto-*N*-neo-tetraose.

The trisaccharide GlcNAcβ(1–3)Galβ(1–4)Glc, which is present in 2,6-sialyl lacto-*N*-neo-tetraose and lacto-*N*-tetraose, was synthesized to further test the ability of galectin-3, but not galectin-1, to bind to "internal" lactose residues in oligosaccharides. Table 2 shows hemagglutination inhibition data that indicates that galectin-1 does not bind to the trisaccharide. Table 2, however, demonstrates that galectin-3 binds to the trisaccharide nearly as well as to lactose. ITC results at 287 K in Table 1 show that galectin-3 possesses a K_a value ~fourfold less than LacNAc-II, and only ~twofold less than 2,6-sialyl-lacto-*N*-neo-tetraose, which has a reducing end lactose moiety. The ΔH value for galectin-3 binding to the trisaccharide is –7.7 vs. –6.4 kcal mol^{-1} for 2,6-sialyl-lacto-*N*-neo-tetraose. These findings support the conclusion that galectin-3, but not galectin-1, can bind well to internal LacNAc or lactose residues in the above oligosaccharides.

The X-ray crystal structure of the CRD domain of human galectin-3 (15) shows differences in the amino acids near the binding site of the lectin with respect to galectin-1. Specifically, Ser29 in galectin-1 is replaced by Arg144 in galectin-3, and Leu31 in galectin-1 is replaced by Ala146 in galectin-3, and further modeling with the CRD of hamster galectin-3 implicated Arg 139, Glu 230, and Ser 232 as relevant for a putative extended binding site (46). These differences may account for the differences in specificities between galectin-3 and galectin-1.

Galectin-7 binding to carbohydrates

As previously mentioned, the ITC data at 300 K in Table 1 shows that galectin-7 possesses a K_a of 0.17×10^4 M^{-1} for LacNAc-II, which is nearly sixfold lower than that for galectin-1 (1.1×10^4 M^{-1}) and nearly 11-fold weaker than that of galectin-3 (1.9×10^4 M^{-1}). The ΔH value for galectin-7 binding LacNAc-II (–11.8 kcal mol^{-1}) is greater than that of galectin-1 (–9.2 kcal mol^{-1}) and galectin-3 (–7.5 kcal mol^{-1}). Conversely, $T\Delta S$ of galectin-3 binding LacNAc-II is more unfavorable (–7.4 kcal mol^{-1}) than that of galectin-1 (–3.7 kcal mol^{-1}) and galectin-3 (–1.6 kcal mol^{-1}). Hence, galectin-7 has a lower K_a for LacNAc-II than galectin-1 and galectin-3 because of its unfavorable binding entropy.

Galectin-1 from human (17), rat lung (38), bovine spleen (47), and the homologue of avain liver (42) all show four- to fivefold increases in affinity for LacNAc-II relative to lactose. Similarly, galectin-3 from rat and human lung (17, 38) both bind LacNAc-II with higher affinity than lactose. Bovine heart galectin-1 in the present study also binds LacNAc-II with ~fourfold higher affinity than lactose (Table 1), as does murine galectin-3 (Table 2). ITC data in Table 1 shows that galectin-7 at 300 K binds lactose with nearly the same K_a ($0.22 \times 10\,4$ M^{-1}) as LacNAc-II (0.17×10^4 M^{-1}). The same relative results are obtained at 287 K (Table 1). Table 1 shows that at 287 K bovine heart galectin-1 has a K_a for lactose of 0.61×10^4 M^{-1}, which is similar to the K_a of galectin-7 (0.49×10^4 M^{-1}) for lactose. Thus, galectin-7 binds lactose with nearly the same affinity as galectin-1. Based on the crystallographic data (11, 14) the extent of polar interaction of the *N*-acetyl part of the GlcNAc moiety in human galectin-7 is reduced to one with Arg53, whereas in bovine heart galectin this group makes contact with Arg48, Arg73, and Glu71. These results indicate a difference in specificity for lactose and LacNAc between galectin-7 and galectins-1 and -3. Similar data were obtained by hemagglutination inhibition measurements (Table 3).

ITC data in Table 1 at 287 K show that there is little difference in the specificity of galectin-7 binding to ThiodiGal as compared with lactose and LacNAc-II, and that their $-\Delta H$ values are similar for all three disaccharides. These results are similar to those for galectin-1 and galectin-3 in Table 1.

Table 1 shows the thermodynamics of binding Di- and TriLacNAc to galectin-7 at 287 K. There are little differences in the K_a values of LacNAc-II (0.64×10^4 M^{-1}), Di- (0.74×10^4 M^{-1}), and TriLacNAc (0.65×10^4 M^{-1}). The same is true for the ΔH values for all three carbohydrates. Hemagglutination inhibition data also support these findings (Table 3). The value of n for all three carbohydrates is also close to one, indicating that they are likely to bind to the same site in galectin-7, and that all three oligosaccharides are univalent. These results indicate that galectin-7 recognizes one predominant LacNAc-II moiety in binding to LacNAc-II oligomers, as observed for galectins-1 and -3. The X-ray crystal structure of human galectin-7 also shows one molecule of LacNAc-II in the B monomer of the protein (14), in agreement with these findings, while access to the A monomer is blocked in soaking experiments by crystal packing contacts.

Hemagglutination inhibition data in Table 3 demonstrates that galectin-7 binds to 2,3-sialyl LacNAc but not to 2,6-sialyl LacNAc. These findings are similar to those for galectins-1 and -3. The hemagglutination inhibition data also shows that galectin-7 binds to 2,6-sialyl DiLacNAc nearly as well as LacNAc-II. These results indicate that galectin-7 can recognize the internal (reducing end) LacNAc-II moiety of 2,6-sialyl DiLacNAc, as can galectin-3. Data in Table 3 also reveals that galectin-7 binds to 2,6-sialyl lacto-*N*-neotetraose slightly better than LacNAc-II. Binding of galectin-7 to lacto-*N*-tetraose and lacto-neo-*N*-tetraose are also similar to that of LacNAc-II (Table 3). Galectin-7 can also recognize the trisaccharide moiety, GlcNAcβ(1–3)Galβ(1–4)Glc~OH, which is present in lacto-*N*-tetraose and lacto-neo-*N*-tetraose. These results indicate that galectin-7, like galectin-3 but not galectin-1, can recognize internal LacNAc or lactose residues in the above carbohydrates. The X-ray crystal structure of human galectin-7 shows conservation of the carbohydrate binding residues of galectin-1, however there are significant changes in the binding pocket due to shortening of a loop structure in the region (14). These differences may relate to the observed differences in specificity of galectin-7 relative to galectins-1 and -3.

© 2002 NRC Canada

Table 3 also provides relative binding data for various mono- and oligosaccharides to galectin-7. The results indicate that galectin-7 is specific for lactose and LacNAc determinants.

Summary

The results of ITC and hemagglutination inhibition measurements demonstrate that galectin-7 possesses six- to 11-fold weaker affinities for carbohydrates with LacNAc as part of binding epitopes than galectins-1 and -3, respectively. Galectin-7 binds lactose and LacNAc-II with nearly the same affinity as is lactose for galectins-1 and -3. Galectin-7 thus differs in its fine carbohydrate binding specificity from galectins-1 and -3 in this regard. The present findings also show that galectin-1 is limited to binding primarily the non-reducing terminal LacNAc residues of oligosaccharides, while galectins-3 and -7 bind to non-reducing terminal LacNAc residues as well as internal LacNAc (and lactose) residues of oligosaccharides. These differences in the specificities of the three galectins may be related to their different biological activities and will be helpful to design head-groups of glycoclusters with improved target galectin selectivity (48, 49).

Synthesis of a polyphosphorylated GPI-anchor core structure

Martina Lahmann, Per J. Garegg, Peter Konradsson, and Stefan Oscarson

Abstract: Using a linear assembly approach a highly differentially protected derivative of the common GPI-anchor core structure (α-D-Man-(1→6)-α-D-Man-(1→2)-α-D-Man-(1→4)-α-D-GlcNH$_2$-(1→6)-D-*myo*-inositol) has been synthesized. All mannose donors were prepared from a common thioglycoside precursor (**1**), and coupled to GlcN$_3$-*myo*-inositol acceptor **5** in a linear five-step glycosylation–deprotection sequence in 49% overall yield, to give the key intermediate **10**, with orthogonal temporary protecting groups at the 6″, 2″, 6′, and 2 positions of the trimannoside motif and at the 1 and 2 positions of the inositol part. Consecutive removal of the temporary protecting groups in the trimannoside moiety followed by phosphorylation, gave a tetraphosphate derivative in 60% overall yield. Removal of a camphor acetal afforded a 1,2-inositol diol, which was converted to a 1,2-cyclic phosphate using commercial methyl dichlorophosphate (→**17**, 95%). One-step deprotection using sodium in liquid ammonia afforded the target polyphosphorylated core structure **18** (60%), which will be tested for metabolic insulin action.

Key words: glycophosphatidylinositols, linear synthesis, glycosylations, inositolphosphoglycans, IPG.

Résumé : Faisant appel à une approche d'assemblage linéaire, on a réalisé la synthèse d'un dérivé, portant des groupes protecteurs fortement diversifiés, de la structure ancrée fondamentale du GPI, le α-D-Man-(1→6)-α-D-Man-(1→2)-α-D-Man-(1→4)-GlcNH$_2$-(1→6)-D-*myo*-inositol. Tous les groupes mannoses donneurs ont été préparés à partir d'un thioglycoside précurseur commun, **1**, et ils ont été couplés à un GlcN$_3$-*myo*-inositol accepteur, **5**, dans une séquence en cinq étapes de glycosylation-déprotection, avec un rendement global de 49%, pour conduire à l'intermédiaire clé **10** portant des groupes protecteurs orthogonaux temporaires dans les positions 6″, 2″, 6′ et 2 du motif trimannoside et dans les positions 1 et 2 de la portion inositol. Les éliminations consécutives des groupes protecteurs temporaires de la portion mannoside, suivies d'une phosphorylation, on conduit au dérivé tétraphosphate, avec un rendement global de 60%, à partir duquel on a enlevé un acétal du camphre pour obtenir un diol 1,2-inositol qui a été transformé en un phosphate 1,2-cyclique à l'aide de dichlorophosphate de méthyle commercial (→**17**, 95%). Une déprotection en une étape à l'aide de sodium dans l'ammoniac liquide fournit le structure fondamentale phosphorylée recherchée, **18**, avec un rendement de 60% qui a été évaluée pour son action d'insuline métabolique.

Mots clés : glycophosphatidylinositols, synthèse linéaire, glycosylations, inositolphosphoglycanes, IPG.

[Traduit par la Rédaction]

Introduction

Ever since the discovery of a new way to anchor proteins to cell membranes through glycosylphosphatidylinositol structures (GPI-anchors, see refs. 1–3), these anchor structures have been of a main research interest, both analytically, synthetically, and biologically. Isolation and analysis have shown that these structures are present in almost all species, and that their structure is not only partly conserved but also species specific (2, 3). All GPI-anchors found and characterized so far contain a common pseudo-pentasaccharide backbone, α-D-Man-(1→6)-α-D-Man-(1→2)-α-D-Man-(1→4)-α-D-GlcNH$_2$-(1→6)-D-*myo*-inositol, but the substitution pattern varies between species (Fig. 1). Apart from functioning as protein anchors, a number of functions have been suggested for the GPI-structures (2, 3), such as they have been implicated as second messengers to insulin (4–6) and polyphosphorylated derivatives have been shown to give an insulin-type effect and have been considered as drug candidates towards diabetes (7).

The novelty and complexity of these structures in combination with the interest to investigate more in detail their biological functions have resulted in a number of syntheses of parts of the backbone, the complete backbone, and also the backbone with various substituents (8–10). The latter syntheses have generally been directed towards a species specific target molecule not allowing too much variation in the substitution pattern. Recently, Ley and co-workers (10) presented a synthesis of the backbone with orthogonal temporary protecting groups at relevant positions allowing the continued synthesis of a variant of species specific GPI-anchor structures. Another feature of their synthesis is that the orthogonal and one-pot glycosylations are used in the

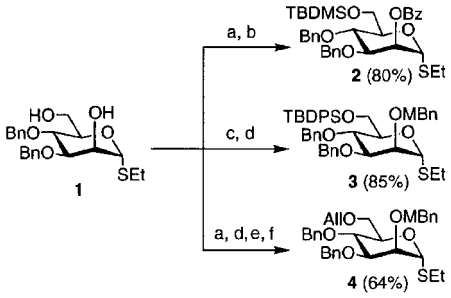
build-up of the target structures, utilizing the different reactivity of both the uniquely protected donors and the variety of donors. Although conceptually elegant, such an approach requires considerable fine-tuning of the reactivity to be successful. We herein describe a synthesis, using a linear synthetic approach, of a similar highly and differentially protected backbone structure that, will allow for the syntheses of most types of species-specific structures from the same intermediate. Furthermore, the temporary protecting groups were sequentially removed and the resulting hydroxyl derivatives were phosphorylated and deprotected to give a polyphosphorylated structure, which will be investigated for insulin activity.

Results and discussions

The linear approach can have considerable advantages, especially since the target structure is a rather small molecule containing no repeating units (at least no larger than a monosaccharide). Only monosaccharide donors have to be prepared and all mannose donors can be prepared from a common precursor. The protecting-group strategy can be planned to be optimal (selective and complete) in terms of protection and deprotection, since almost no considerations have to be taken to the reactivity or stereochemical influence of the protecting-group pattern in the various mannose donors. In the coupling reactions, self condensation and transglycosylation reactions, often found side reactions in orthogonal glycosylations, are not possible, which results in excellent glycosylation yields.

As donors we chose thioglycosides (11, 12). All the three different mannose donors could be obtained in a few high-yielding steps from the same precursor: ethyl 3,4-di-*O*-benzyl-1-thio-α-D-mannopyranoside (13) (**1**) (Scheme 1). Regioselective silylation at the primary position followed by benzoylation or *p*-methoxybenzylation gave donors **2** (80%) and **3** (85%), respectively. Subsequent desilylation and allylation afforded mannose donor **4** (64% overall yield). With these donors in hand the pseudo-pentasaccharide could then be assembled through three efficient glycosylations all promoted by DMTST in diethyl ether to ensure α-selectivity (Scheme 2). Acceptor **5** (14) and donor **2** were coupled to give pseudo-trisaccharide **6** in 98% yield. Removal of the TBDMS-protecting group afforded acceptor **7** (85%), which was condensed with donor **3** to yield the tetrasaccharide **8** in quantitative yield. Removal of the *p*-methoxybenzyl group

Scheme 1. Reagents and conditions: (*a*) TBDMSCl, pyridine; (*b*) BzCl, pyridine; (*c*) TBDPSCl, pyridine; (*d*) MBnCl, NaH, 0°C; (*e*) TBAF, THF; (*f*) AllBr, NaH, DMF, 0°C.



by DDQ treatment (→ **9**, 72%) and subsequent glycosylation with thioglycoside **4** gave the target intermediate **10** in 84% yield and a 49% overall yield over the five steps. The α-configuration of all glycosidic linkages was proven by the $^1J_{C,H}$ coupling constants of the anomeric carbons, which all were above 168 Hz.

In compound **10** all the functionalities are now in place to allow continued syntheses of many different GPI anchor structures. To prove the orthogonality of the temporary protecting groups, the groups were removed one by one in sequence to produce a tetraol (Scheme 3). The allyl group was removed under neutral conditions using an iridium catalyst followed by hydrolysis of the obtained vinyl ether with NIS–H_2O (15) (→ **11**, 98%). Removal of the *p*-methoxybenzyl protecting group was accomplished by DDQ treatment to give diol **12** (84%). The benzoate was removed using Zemplén conditions (→ **13**, 85%) and finally the silyl group was cleaved by TBAF treatment to give the tetraol **14** (86%) in an overall deprotection yield of 60%.

As mentioned, GPI structures have been suggested as insulin second messengers (4, 5). A key structure is believed to be a 1,2-cyclic phosphate on the insulin moiety obtained through enzymatic cleavage of the native glycerol fragment (6). Additional phosphorylation has been shown to enhance the biological activity (7). Accordingly, the tetraol was phosphorylated using the amidite approach (16) to give benzyl protected 6‴,2‴,6″,2′-tetraphosphate derivative **15** in quantitative yield, which was subsequently processed to give the corresponding 1,2-cyclic phosphate **17** (Scheme 4). Acidic hydrolysis of the campher acetal (→ **16**, 46%) followed by treatment with commercial methyl dichlorophosphate afforded **17** in 95% yield after work-up. Catalytic hydrogenolysis to remove benzyl protecting group is often troublesome with phosphate-containing compounds; however, as found earlier (17, 18), Birch-type reaction conditions smoothly removed all benzyl groups without any indication (NMR, MALDI-TOF MS) of phosphate migration or hydrolysis or opening of the cyclic phosphate. Concomitantly, the azido function was reduced, in a one-pot reaction, to yield target structure **18** in 60% yield.

Conclusion

In summary, a most effective linear synthesis of a highly differentially protected backbone structure of GPI anchors has been performed. The temporary protecting groups can be removed in an orthogonal fashion to allow synthesis of

various substituted anchor structures. The partly deprotected structures can be polyphosphorylated and deprotected using Birch-type reaction conditions in high yields, to give synthetic phosphoinositolglycans.

Experimental

All organic solvents were distilled before use, except Et_2O, which was stored over Na. Organic solutions were dried over $MgSO_4$ before concentration, which was performed under reduced pressure at <40°C (bath temperature). NMR spectra were recorded at 270 (JEOL), 300, 400, or 600 MHz (Varian) (^{1}H), or at 67.5, 75, or 100 MHz (^{13}C), unless otherwise stated, in $CDCl_3$. For ^{1}H NMR spectra, TMS was used as internal standard (δ = 0). ^{13}C NMR spectra were referred to the chloroform signal (δ = 77.17). ^{31}P NMR spectra were standardized by using an external H_3PO_4 sample (δ = 0). TLC was performed on silica gel 60 F_{254} (Merck) plates with detection by UV-light and (or) charring with 8% sulfuric acid. Column chromatography was performed on silica gel (Matrix Silica Si 60A, 35–70m, Amicon). MALDI-TOF spectra were recorded on a Bruker Biflex III using PEG 1500 as calibration reference.

Ethyl 2-*O*-benzoyl-3,4-di-*O*-benzyl-6-*O*-*tert*-butyldimethylsilyl-1-thio-α-D-mannopyranoside (2)

TBDMSCl (325 mg, 2.16 mmol) and a catalytic amount of DMAP were added to a solution of ethyl 3,4-di-*O*-benzyl-1-thio-α-D-mannopyranoside (13) (**1**, 550 mg, 1.36 mmol) in pyridine (2 mL). The reaction mixture was stirred at room temperature for about 3 h when benzoyl chloride (1 mL) was added and stirring was continued for an additional 45 min. For work up, the mixture was diluted with toluene, washed with water and brine, dried ($MgSO_4$), and concentrated. To remove the main part of pyridine, co-evaporation with toluene was performed twice before applying the residue to flash chromatography (light petroleum (bp 40–65°C) – Et_2O, 5:1) to give **2** (680 mg, 1.09 mmol, 80%). $[\alpha]_D$ +39 (*c* 1.0, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 0.06 (s, 6H, Me_2Si), 0.92 (s, 9H, *t-Bu*Si), 1.30 (m, 3H, *Me*CH_2S), 2.65 (m, 2H, SCH_2), 3.80–4.10 (m, 5H), 4.54, 4.65, 4.76, 4.92 (4 × d, 4 × 1H, PhCH_2), 5.38 (s, 1H, H-1), 5.68 (br s, 1H, H-2) 7.18–8.12 (m, 13H), 8.12 (m, 2H). ^{13}C NMR ($CDCl_3$) δ: – 4.9 (Me_2Si), 15.1 (*Me*CH_2S), 18.5 (*t-Bu*Si), 25.6 (SCH_2), 26.1 (*t-Bu*Si), 62.4, 71.2, 71.8, 73.2, 74.6, 75.3, 78.9 (C2–C6, CH_2Ph), 82.5 (C1), 127.8–138.8 (aromatic C), 165.9 (Ph*C*O). Anal. calcd. for $C_{35}H_{46}O_6SSi$: C 67.49, H 7.44; found: C 67.38, H 7.56.

Ethyl 3,4-di-*O*-benzyl-6-*O*-*tert*-butyldiphenylsilyl-2-*O*-*p*-methoxybenzyl-1-thio-α-D-mannopyranoside (3)

TBDPSCl (1.3 mL, 4.9 mmol) and a catalytic amount of DMAP were added to a solution of **1** (1.35 g, 3.34 mmol) in pyridine (10 mL). The reaction mixture was stirred at room temperature for about 24 h, then diluted with toluene and washed with brine and water, dried ($MgSO_4$), and filtered. The filtrate was concentrated and the pyridine co-evaporated with toluene. The crude product was purified by flash-chromatography (toluene–EtOAc, 3:1) to give ethyl 3,4-di-*O*-benzyl-6-*O*-*tert*-butyldiphenylsilyl-1-thio-α-D-manno-

pyranoside (1.98 g, 3.08 mmol, 92%). $[\alpha]_D$ +70 (*c* 1.0, CH_2Cl_2). ^{13}C NMR ($CDCl_3$) δ: 14.8 (*Me*CH_2S), 19.4 (*t-Bu*Si), 24.6 (S*CH*$_2$), 26.7, 26.9 (*t-Bu*Si), 63.2 (C6), 70.1, 72.3, 72.9, 74.7, 75.3, 80.7, (C2–C5, *CH*$_2$Ph), 82.8 (C1), 127.7–136.0 (aromatic C). A solution of this derivative (1.47 g, 2.29 mmol) in dry DMF (20 mL) was cooled to 0°C. NaH (190 mg, ~60% dispersed in oil) was added and the mixture was stirred for 30 min. Freshly prepared *p*-methoxybenzyl bromide (1.0 mL), dissolved in DMF (10 mL), was added dropwise. After 3 h the reaction was quenched by addition of MeOH (1 mL), diluted with toluene, washed with water and brine, dried ($MgSO_4$), and concentrated. Purification by flash chromatography (toluene–EtOAc, 18:1) gave **3** (1.60 g, 2.10 mmol, 92%). $[\alpha]_D$ +41 (*c* 1.0, $CHCl_3$). ^1H NMR ($CDCl_3$) δ: 1.06 (s, 9H, *t-Bu*Si), 1.22 (m, 3H, *Me*CH_2S), 2.56 (m, 2H, S*CH*$_2$), 3.68–4.10 (m, 8H), 4.46–4.76 (m, 5H, Ar*CH*$_2$), 4.92 (d, 1H, Ar*CH*$_2$), 5.38 (s, 1H, H-1), 5.68 (br s, 1H, H-2), 6.74–7.80 (m, 24H). ^{13}C NMR ($CDCl_3$) δ: 15.0 (*Me*CH_2S), 19.4 (*t-Bu*Si), 25.1 (S*CH*$_2$), 26.9 (*t-Bu*Si), 55.4 (*Me*OBn), 63.4 (C6), 71.8, 72.3, 73.5, 75.1, 75.3, 76.5, 80.6, 81.4 (C1–C5, *CH*$_2$Ph, MBn), 113.9 (MBn), 127.7–138.7 (aromatic C), 159.2 (MBn). Anal. calcd. for $C_{46}H_{54}O_6SSi$: C 72.40, H 7.13; found: C 72.27, H 7.28.

Ethyl 6-*O*-allyl-3,4-di-*O*-benzyl-2-*O*-*p*-methoxybenzyl-1-thio-α-D-mannopyranoside (4)

TBDMSCl (920 mg, 6.1 mmol) and a catalytic amount of DMAP were added to a solution of **1** (1.6 g, 4.0 mmol) in pyridine (10 mL). The reaction mixture was stirred at room temperature for about 3 h and then diluted with toluene, washed with water and dried over $MgSO_4$. After filtration, the mixture was concentrated and co-evaporated from toluene. Subsequent purification by flash-chromatography (toluene–EtOAc, 9:1) of the crude product afforded ethyl 3,4-di-*O*-benzyl-6-*O*-*tert*-butyldimethylsilyl-1-thio-α-D-mannopyranoside (1.7 g, 3.3 mmol, 83%) as a colourless syrup. A solution of this derivative (1.00 g, 1.93 mmol) in dry DMF (20 mL) was cooled to 0°C. NaH (120 mg, ~60% dispersed in oil) was added and the mixture was stirred for 30 min. Freshly prepared *p*-methoxybenzyl bromide (750 μL) dissolved in DMF (10 mL) was added dropwise. After 30 min the reaction was quenched by addition of MeOH (1 mL), diluted with toluene and washed with water and brine. Drying ($MgSO_4$), filtration, and evaporation gave a residue, which was purified by flash chromatography (toluene → toluene–EtOAc, 18:1) to yield ethyl 3,4-di-*O*-benzyl-2-O-*p*-methoxybenzyl-6-*O*-*tert*-butyldimethylsilyl-1-thio-α-D-mannopyranoside (1.16 g, 1.82 mmol, 94%). $[\alpha]_D$ +25 (*c* 1.0, CH_2Cl_2). ^{13}C NMR ($CDCl_3$) δ: 15.0 (*Me*CH_2S), 18.5 (*t-Bu*Si), 25.0 (S*CH*$_2$), 26.1 (*t-Bu*Si), 55.4 (*Me*OBn), 62.9 (C6), 71.6, 72.2, 73.6, 75.3, 76.1, 77.4, 80.5, 81.4 (C1–C5, *CH*$_2$Ph, MBn), 113.9 (MBn), 127.7–130.4, 138.7, 138.9 (aromatic C), 159.3 (MBn). This compound (1.10 g, 1.72 mmol) dissolved in a TBAF–THF solution (3.6 mL, 1 M) was stirred at room temperature overnight. After concentration, the residue was applied to flash chromatography (toluene → toluene–EtOAc, 12:1 → toluene–EtOAc, 3:1) to obtain ethyl 3,4-di-*O*-benzyl-2-*O*-*p*-methoxybenzyl-1-thio-α-D-mannopyranoside (780 mg, 1.49 mmol, 87%). ^{13}C NMR ($CDCl_3$) δ: 15.0 (*Me*CH_2S), 25.5 (S*CH*$_2$), 55.4 (*Me*OBn), 62.5 (C6), 72.1, 72.2, 72.5, 75.2, 76.2, 80.5, 82.4 (C1–C5, *CH*$_2$Ph, MBn), 114.0 (MBn), 127.8–129.7, 138.4, 138.4 (aromatic C), 159.2 (MBn). This compound (780 mg, 1.49 mmol) was dissolved in dry DMF (5 mL) and cooled to 0°C. NaH (120 mg, ~60% dispersed in oil) and allyl bromide (300 μL, 3.55 mmol) were added and the reaction mixture was allowed to reach room temperature. After 2 h the reaction was quenched by addition of MeOH (1 mL). The mixture was diluted with toluene, washed with water, dried ($MgSO_4$), and concentrated. Purification by flash chromatography (toluene–EtOAc, 12:1) gave **4** (792 mg, 1.40 mmol, 94%). $[\alpha]_D$ +57 (*c* 1.0, CH_2Cl_2). ^1H NMR ($CDCl_3$) δ: 1.24 (m, 3H, *Me*CH_2S), 2.58 (m, 2H, S*CH*$_2$), 3.60–3.84 (m, 7H), 3.90–4.18 (m, 4H), 4.48–4.74 (m, 6H), 4.92 (d, 1H, Ar*CH*$_2$), 5.14 (m, 1H), 5.26 (m, 1H), 5.36 (s, 1H, H-1), 5.94 (m, 1H), 6.80–6.84 (m, 2H), 7.16–7.40 (m, 12H). ^{13}C NMR ($CDCl_3$) δ: 15.2 (*Me*CH_2S), 25.5 (S*CH*$_2$), 55.4 (*Me*OBn), 69.4 (C6), 71.6, 71.9, 72.0, 72.5, 75.2, 75.3, 75.8, 80.4, 81.9 (C1–C5, *CH*$_2$Ph, MBn, allyl), 113.8 (MBn), 116.8 (allyl), 127.86–130.2 (aromatic C), 134.9 (allyl), 138.4, 138.7 (aromatic C), 159.2 (MBn). DDQ (17 mg, 75 μmol) was added to a solution of **8** (90 mg, 47 μmol) in water saturated CH_2Cl_2 (5% H_2O, 5 mL) and stirred overnight at room temperature. The mixture was diluted with CH_2Cl_2 (15 mL), washed with water and $Na_2S_2O_3$ (10% aq), dried ($MgSO_4$), and concentrated. The crude product was purified by flash chromatography (toluene–EtOAc, 6:1) to give 60 mg (34 μmol, 72%) of (6-*O*-allyl-3,4-di-*O*-benzyl-α-D-mannopyranosyl)-(1→6)-(2-*O*-benzoyl-3,4-di-*O*-benzyl-α-D-mannopyranosyl)-(1→4)-(2-azido-3,6-di-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-(1→6)-3,4,5-tri-*O*-benzyl-1,2-*O*-(L-1,7,7-trimethyl[2.2.1]bicycloheptt-6-yliden)-D-*myo*-inositol (**9**). $[\alpha]_D$ +51 (*c* 1.0, CH_2Cl_2). ^{13}C NMR ($CDCl_3$) δ: 10.0, 20.6, 20.9, 27.2, 30.0, 45.0, 45.3, 48.2, 51.8 (Cph), 63.4–80.8 ($C^{ino}1$–$C^{ino}6$, C2–C6, C2′–C6′, C2″–C6″, CH_2Bn, allyl), 95.6 (C1), 98.4 (C1″), 99.1 (C1′), 116.9 (allyl), 118.2 (Cph-acetal), 125.3–138.7 (aromatic C, allyl), 165.3 (Ph*C*O). A solution of **9** (300 mg, 168 μmol) and **3** (130 mg, 170 μmol) in dry Et_2O (80 mL) was stirred with powdered molecular sieves (4 Å) under argon for 1 h. Then DMTST (150 mg, 0.58 mmol) was added. The reaction, monitored by TLC (light petroleum (bp 40–60°C) – Et_2O, 1:1), was quenched after 45 min by addition of Et_3N (500 μL) and stirred for another 20 min. The mixture was diluted with Et_2O (20 mL), filtered through Celite, and concentrated. The residue was subjected to silica gel column chromatography (toluene–EtOAc, 12:1) to obtain 350 mg (141 μmol, 84%) of **10**. $[\alpha]_D$ +21 (*c* 1.0, CH_2Cl_2). ^{1}H NMR ($CDCl_3$) δ: 0.78–1.96 (m, 25H, *t-Bu*Si, Cph), 3.30–5.20 (m, 61H), 5.28 (d, *J* = 2 Hz, 1H), 5.50 (s, *J* = 2 Hz, 1H), 5.58 (d, *J* = 4 Hz, 1H), 5.63 (m, 1H), 5.71 (m, 1H), 6.78 (d, 2H), 7.00–8.00 (m, 72H). ^{13}C NMR ($CDCl_3$) δ: 10.0 (Cph), 19.6 (*t-Bu*Si), 20.6, 20.9, 21.7 (Cph), 27.2 (*t-Bu*Si, Cph), 30.0, 45.0, 45.3, 48.2, 51.8 (Cph), 55.3 (*MeO*Bn), 63.4–80.8 ($C^{ino}1$–$C^{ino}6$, C2–C6, C2′–C6′, C2″–C6″, C2‴-C6‴, CH_2Bn, MBn, allyl), 95.5 (C1), 98.7 (C1″), 98.8 (C1‴), 99.2 (C1′), 113.6 (MBn), 116.3 (allyl), 118.2 (Cph-acetal), 125.4–139.0 (aromatic C, allyl), 158.9 (MBn), 165.3 (Ph*C*O). Anal. calcd. for $C_{151}H_{165}N_3O_{27}Si$: C 73.07, H 6.70; found: C 72.93, H 6.75.

(3,4-Di-*O*-benzyl-6-*O*-*tert*-butyldiphenylsilyl-α-D-mannopyranosyl)-(1→2)-(3,4-di-*O*-benzyl-α-D-mannopyranosyl)-(1→6)-(2-*O*-benzoyl-3,4-di-*O*-benzyl-α-D-mannopyranosyl)-(1→4)-(2-azido-3,6-di-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-(1→6)-3,4,5-tri-*O*-benzyl-1,2-*O*-(L-1,7,7-trimethyl[2.2.1]bicyclohept-6-yliden)-D-*myo*-inositol (12)

Compound **10** (700 mg, 282 μmol) was dissolved in freshly distilled THF (10 mL) and stirred 10 min with a catalytic amount of Pd/C. The filtered solution was degassed and set under argon. After addition of 1,5-cyclooctadienebis(methyldiphenylphosphine)iridium(I)·PF_6 (27 mg, 32 μmol), the solution was saturated with hydrogen until the intensive red colour of the mixture had disappeared (approx. after 20 min). The solution was stirred for 1 h under argon at

© 2002 NRC Canada

room temperature, then NIS (420 mg, 1.87 mmol) and H_2O (1.75 mL) were added. After 2.5 h the reaction mixture was diluted with EtOAc, washed consecutively with 10% aqueous $Na_2S_2O_3$, $NaHCO_3$, dried ($MgSO_4$), and concentrated. The crude product was purified by flash chromatography (toluene–EtOAc, 12:1) to give (3,4-di-*O*-benzyl-6-*O*-*tert*-butyldiphenylsilyl-2-*O*-*p*-methoxybenzyl-α-D-mannopyranosyl)-(1→2)-(3,4-di-*O*-benzyl-α-D-mannopyranosyl)-(1→6)-(2-*O*-benzoyl-3,4-di-*O*-benzyl-α-D-mannopyranosyl)-(1→4)-(2-azido-3,6-di-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-(1→6)-3,4,5-tri-*O*-benzyl-1,2-*O*-(L-1,7,7-trimethyl[2.2.1]bicycloheptyliden)-D-*myo*-inositol (**11**, 674 mg, 276 μmol, 98%). $[\alpha]_D$ +30 (*c* 1.0, CH_2Cl_2). ^{13}C NMR ($CDCl_3$) δ: 10.0 (Cph), 19.6 (*t-Bu*Si), 20.6, 20.9 (Cph), 27.2 (*t-Bu*Si), 30.0, 45.0, 45.3, 48.2, 51.8 (Cph), 55.4 (*MeO*Bn), 61.9–80.8 ($C^{ino}1$–$C^{ino}6$, C2–C6, C2′–C6′, C2″–C6″, C2‴–C6‴ CH_2Bn, MBn), 95.5 (C1), 98.7 (C1″), 98.8 (C1‴), 99.1 (C1′), 113.6 (MBn), 118.2 (Cph-acetal), 125.4–138.7 (aromatic C), 158.9 (MBn), 165.3 (Ph*C*O). DDQ (80 mg, 350 μmol) dissolved in CH_2Cl_2 (2 mL) was added to an ice cooled solution of **11** (650 mg, 266 μmol) in water saturated CH_2Cl_2 (5% H_2O, 25 mL) and stirred for 4 h, an additional 30 mg of DDQ in portions of 10 mg were added until the conversion was complete. The mixture was diluted with CH_2Cl_2 (100 mL); washed with water, $Na_2S_2O_3$ (10% aq), and $NaHCO_3$; dried ($MgSO_4$); and concentrated. The crude product was purified by flash chromatography (toluene–EtOAc, 12:1) to give **12** (520 mg, 224 μmol, 84%). $[\alpha]_D$ +28 (*c* 1.0, CH_2Cl_2). ^1H NMR ($CDCl_3$) δ: 0.80–1.96 (m, 25H, *t-Bu*Si, Cph), 3.30–4.90 (m, 52H), 5.19 (s, 1H), 5.52 (s, 1H), 5.59 (d, *J* = 3 Hz, 1H), 5.63 (m, 1H), 7.00–8.00 (m, 70H). ^{13}C NMR ($CDCl_3$) δ: 10.0 (Cph), 19.5 (*t-Bu*Si), 20.6, 20.9 (Cph), 27.1 (*t-Bu*Si), 30.1, 45.0, 45.3, 48.2, 51.8 (Cph), 61.9–80.8 ($C^{ino}1$–$C^{ino}6$, C2–C6, C2′–C6′, C2″–C6″, C2‴–C6‴, CH_2Bn), 95.5 (C1), 98.7 (C1″), 99.1 (C1′), 100.9 (C1‴), 118.2 (Cph-acetal), 125.4–138.7 (aromatic C), 165.3 (Ph*C*O).

(3,4-Di-*O*-benzyl-α-D-mannopyranosyl)-(1→2)-(3,4-di-*O*-benzyl-α-D-mannopyranosyl)-(1→6)-(3,4-di-*O*-benzyl-α-D-mannopyranosyl)-(1→4)-(2-azido-3,6-di-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-(1→6)-3,4,5-tri-*O*-benzyl-1,2-*O*-(L-1,7,7-trimethyl[2.2.1]bicyclohept-6-yliden)-D-*myo*-inositol (14)

Compound **12** (490 mg, 211 μmol) was deacetylated under Zemplén conditions. To speed up the reaction, the mixture was warmed to 45°C. After 3 days the reaction mixture was neutralized with H^+ ion exchange resin, filtered, and concentrated. The residue was purified by flash-chromatography (toluene–EtOAc, 6:1→3:1) to obtain (3,4-di-*O*-benzyl-6-*O*-*tert*-butyldiphenylsilyl-α-D-mannopyranosyl)-(1→2)-(3,4-di-*O*-benzyl-α-D-mannopyranosyl)-(1→6)-(3,4-di-*O*-benzyl-α-D-mannopyranosyl)-(1→4)-(2-azido-3,6-di-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-(1→6)-3,4,5-tri-*O*-benzyl-1,2-*O*-(L-1,7,7-trimethyl[2.2.1]bicyclohept-6-yliden)–D-*myo*-inositol (**13**, 400 mg, 180 μmol, 85%). $[\alpha]_D$ +40 (*c* 1.0, CH_2Cl_2). ^{13}C NMR ($CDCl_3$) δ: 10.0 (Cph), 19.6 (*t-Bu*Si), 20.6, 20.9 (Cph), 27.1 (*t-Bu*Si), 30.1, 45.0, 45.3, 48.2, 51.8 (Cph), 62.0–80.6 ($C^{ino}1$–$C^{ino}6$, C2–C6, C2′–C6′, C2″–C6″, C2‴–C6‴, CH_2Bn), 95.4 ($J_{C1,H1}$ = 173 Hz, C1), 99.1 ($J_{C1,H1}$ = 168 Hz, C1′), 100.2, 101.4 ($J_{C1,H1}$ = 176, 169 Hz, C1″, C1‴), 118.2 (Cph-acetal), 127.2–138.5 (aromatic C). Compound **13** (350 mg, 157 μmol) was dissolved in THF (10 mL) and TBAF (200 μL, 1 M in THF) was added. The mixture was stirred at room temperature overnight, then concentrated, and purified by flash chromatography (toluene–EtOAc, 3:1→2:1) to give 267 mg (135 μmol, 86%) of **14**. $[\alpha]_D$ +50 (*c* 1.0, CH_2Cl_2). ^1H NMR ($CDCl_3$) δ: 0.80–2.04 (m, 16H, Cph), 3.34–4.90 (m, 52H), 5.03 (s, 1H), 5.06 (s, 1H), 5.28 (s, 1H), 5.58 (d, *J* = 2 Hz, 1H), 7.00–7.40 (m, 55H). ^{13}C NMR ($CDCl_3$) δ: 10.1, 20.7, 20.9, 27.3, 30.1, 45.0, 45.4, 48.2, 51.8 (Cph), 62.0–81.0 ($C^{ino}1$–$C^{ino}6$, C2–C6, C2′–C6′, C2″–C6″, C2‴–C6‴, CH_2Bn), 95.5 (C1), 99.5 (C1′), 100.8, 101.2 (C1″, C1‴), 118.2 (Cph-acetal), 127.5–128.6 and 137.5–138.6 (aromatic C). Anal. calcd. for $C_{117}H_{131}N_3O_{25}$: C 71.00, H 6.67; found: C 70.85, H 6.65.

(2,6-Di-[ammoniumphosphate]-α-D-mannopyranosyl)-(1→2)-(6-[ammoniumphosphate]-α-D-mannopyranosyl)-(1→6)-(2-[ammoniumphosphate]-α-D-mannopyranosyl)-(1→4)-(2-amino-2-deoxy-α-D-glucopyranosyl)-(1→6)-D-*myo*-inositol 1,2-cyclic phosphate ammonium salt (18)

1*H*-Tetrazole (115 mg, 1.64 mmol) was added to a solution of **14** (230 mg, 116 μmol) and dibenzyl diisopropylphosphoramidite (225 μL, 700 μmol) in CH_2Cl_2 (3.5 mL). After 20 min the reaction mixture was cooled to 0°C and 70% *m*-chloroperbenzoic acid (230 mg) was added. The mixture was stirred an additional 15 min and then diluted with CH_2Cl_2 and washed with $Na_2S_2O_3$ (10% aq), $NaHCO_3$ and, water. After drying ($MgSO_4$), filtration, and concentration, the crude product was subjected to flash chromatography (toluene → toluene–EtOAc, 20 → 25%) to yield (3,4-di-*O*-benzyl-2,6-bis-*O*-dibenzyloxyphosphoryl-α-D-mannopyranosyl)-(1→2)-(3,4-di-*O*-benzyl-6-*O*-dibenzyloxyphosphoryl-α-D-mannopyranosyl)-(1→6)-(3,4-di-*O*-benzyl-2-*O*-dibenzyloxyphosphoryl-α-D-mannopyranosyl)-(1→4)-(2-azido-3,6-di-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-(1→6)-3,4,5-tri-*O*-benzyl-1,2-*O*-(L-1,7,7-trimethyl[2.2.1]bicyclohept-6-yliden)-D-*myo*-inositol (**15**, 364 mg, 116 μmol, quant.). $[\alpha]_D$ +23 (*c* 1.0, CH_2Cl_2). ^{13}C NMR ($CDCl_3$) δ: 10.2, 20.8, 21.0, 27.4, 30.2, 45.2, 45.5, 48.3, 51.9 (Cph), 63.3–80.8 ($C^{ino}1$–$C^{ino}6$, C2–C6, C2′–C6′, C2″–C6″, C2‴–C6‴, CH_2Bn), 95.5 (C1), 98.9 (C1′), 99.4, 99.9 (C1″, C1‴), 118.3 (Cph-acetal), 127.2–138.6 (aromatic C). ^{31}P NMR ($CDCl_3$) δ: 4 signals between –0.5 and +0.5. TFA (1 mL) was added at 0°C to a solution of **15** (300 mg, 100 μmol) in CH_2Cl_2 (10 mL). The mixture was stirred for 18 h (room temperature), quenched by the addition of Et_3N (1 mL), and concentrated. The residue was purified by flash chromatography (toluene–EtOAc, 2:1) to give (3,4-di-*O*-benzyl-2,6-bis-*O*-dibenzyloxyphosphoryl-α-D-mannopyranosyl)-(1→2)-(3,4-di-*O*-benzyl-6-*O*-dibenzyloxyphosphoryl-α-D-mannopyranosyl)-(1→6)-(3,4-di-*O*-benzyl-2-*O*-dibenzyloxyphosphoryl-α-D-mannopyranosyl)-(1→4)-(2-azido-3,6-di-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-(1→6)-3,4,5-tri-*O*-benzyl-D-*myo*-inositol (**16**, 132 mg, 46 μmol, 46%). $[\alpha]_D$ +32 (*c* 1.0, CH_2Cl_2). ^{13}C NMR ($CDCl_3$) δ: 53.6, 64.2, 66.3–81.7 ($C^{ino}1$–$C^{ino}6$, C2–C6, C2′–C6′, C2″–C6″, C2‴–C6‴, CH_2Bn), 98.2, 98.7 (C1, C1″), 98.9, 99.0, 99.7, 99.7 (C1′, C1‴), 127.2–128.7, 135.6–137.8, 137.9–138.5 (aromatic C). ^{31}P NMR ($CDCl_3$) δ: 4 signals between –0.5 and +0.5. Methyl dichlorophosphate (50 μL, 50 mmol) was dissolved in dry pyridine (1 mL) at 15°C (water bath). The mixture was stirred for 20 min, after which a solution of **16**

© 2002 NRC Canada

(48 mg, 16.6 μmol) in dry pyridine (500 μL) was added. After 2 h the starting material was consumed (TLC: $CHCl_3$–MeOH, 9:1) and the reaction was quenched by addition of $NaHCO_3$. The mixture was transferred into a 100-mL round bottom flask (using approx. 10 mL pyridine) and concentrated. The residue was dissolved and partitioned between $CHCl_3$ (60 mL) and water (10 mL). HCl (1 M, aq.) was added until the solution was pH 1 (4 mL). The aqueous phase was extracted with $CHCl_3$, and the combined organic phases were dried ($MgSO_4$) and concentrated. After co-evaporation two times from EtOH, the crude product (3,4-di-*O*-benzyl-2,6-bis-*O*-dibenzyloxyphosphoryl-α-D-mannopyranosyl)-(1→2)-(3,4-di-*O*-benzyl-6-*O*-dibenzyloxy-phosphoryl-α-D-mannopyranosyl)-(1→6)-(3,4-di-*O*-benzyl-2-*O*-dibenzyloxyphosphoryl-α-D-mannopyranosyl)-(1→4)-(2-azido-3,6-di-*O*-benzyl-2-deoxy-α-D-glucopyranosyl)-(1→6)-3,4,5-tri-*O*-benzyl-D-*myo*-inositol 1,2-cyclic phosphate (**17**, 48 mg, 95%) was obtained, which was immediately used for the next reaction step. Raw material **17** dissolved in dry THF (2 mL) was dropped into liquid ammonia (20 mL). A catalytic amount of sodium was added to the white emulsion, which turned rapidly into a deep blue solution. After 2 min, NH_4Cl (s) was carefully added until the solution turned white again. The liquid ammonia was allowed to evaporate. The dry residue was dissolved in water (20 mL), and washed once with Et_2O (10 mL). After concentration, the crude product was purified by size exclusion chromatography (G15, eluent water containing 1% n-BuOH) to give, after freeze-drying, **18** (12 mg, 10 μmol, 60%). ^{1}H NMR (D_2O) δ: 3.38–4.60 (m, 31H), 5.14 (s, 1H), 5.25 (s, 1H), 5.49 (1H). ^{13}C NMR (D_2O) δ: 55.1, 60.9, 64.8, 64.9, 67.2, 67.3, 70.3–73.3, 74.8, 75.0, 76.6, 77.8, 79.5, 80.2, 82.2 ($C^{ino}1$–$C^{ino}6$, C2–C6, C2′–C6′, C2″–C6″, C2‴–C6‴), 96.8 (C1), 99.4 (C1″), 100.5, 101.5 (C1′, C1‴). ^{31}P NMR (D_2O) δ: 0.3, 0.9 ($PO(OH)_2$), 15.8 (cyclic phosphate). MALDI-TOF MS: 1209.2 $[M + H]^+$, 1227.2 $[M + H + NH_4]^+$, 1231.2 $[M + Na]^+$.

Oligosaccharide recognition by antibodies: Synthesis and evaluation of talose oligosaccharide analogues

T.L. Lowary, E. Eichler, and D.R. Bundle

Abstract: A series of monosaccharide **(4**–**6)**, disaccharide **(3**, **7**–**12),** and trisaccharide (**13**–**15)** analogs of the native ligand **2,** which fills the binding site of monoclonal antibody Se 155.4, have been synthesized and their bioactivity measured by solid- and solution-phase assays. The syntheses of disaccharide analogs sought to replace galactose by various alkyl groups at the O-2 position of mannose. The activity of one of these O-2 alkyl analogs was 75% of that observed for the trisaccharide and points to only weak net bonding between the solvent exposed galactose residue and the antibody binding site. The synthesis of talose analogs **13** and **14**, where the mannose or galactose residues of **2** were replaced by talose produced ligands with activities from one-third to one-half of that seen for the native ligand **2**. These activity changes did not exhibit discernable correlations with the ability of talose to disrupt water of solvation.

Key words: abequose, 3,6-dideoxy-D-*xylo*-hexose, talose disaccharide and trisaccharide, antibody oligosaccharide interactions, molecular recognition of carbohydrates, water in antibody complexes, *Salmonella* LPS, monoclonal antibody Se 155.4, bacterial *O*-antigen.

Résumé : On a réalisé la synthèse d'une série de monosaccharides (**4**–**6**), de disaccharides (**3, 7**–**12**) et de trisaccharides (**13**–**15**), des analogues du ligand naturel **2** qui remplit le site de liaison de l'anticorps monoclonal Se 155.4 et on a mesuré leur bioactivité par des essais en phase solide ainsi qu'en solution. Dans les synthèses des analogues de la série des disaccharides, on a tenté de remplacer le galactose par divers groupes alkyles en position O-2 du mannose. L'activité de l'un de ces analogues O-2 alkylés est égale à 75% de celle observée pour le trisaccharide et elle suggère qu'il n'existe qu'une faible liaison nette entre le résidu de galactose exposé au solvant et le site de liaison de l'anticorps. Les synthèses des analogues **13** et **14** dans lesquels les résidus de mannose ou de galactose du composé **2** ont été remplacés par du talose conduisent à des ligands dont les activités varient entre un tiers et une demie de celle observée avec le ligand **2** naturel. Ces changements d'activité ne donnent pas lieu à des corrélations qui pourraient avoir une corrélation avec l'habilité du talose à désorganiser l'eau de solvatation.

Mots clés : abéquose, 3,6-didésoxy-D-*xylo*-hexose, disaccharide et trisaccharide du talose, interactions anticorps-oligosaccharide, reconnaissance moléculaire des hydrates de carbone, eau dans des complexes d'anticorps, *Salmonella* LPS, anticorps monoclonal Se 155.4, *O*-antigène bactérien.

Introduction

The binding of carbohydrates by proteins is a biologically significant event, known to play a critical role in a diverse number of physiological processes such as viral (1, 2) and bacterial (3–5) infection and inflammation arising from cell adhesion (6–9). Consequently, in recent years interest in developing oligosaccharide-based therapeutics that inhibit carbohydrate–protein recognition has increased (3, 10, 11). However, to realize the potential of carbohydrate-based drugs, the milli- to micromolar K_ds characteristic of sugar–protein interactions must be improved (enhanced). This in turn requires a deeper appreciation of the origins of the free energy of binding. A significant body of three-dimensional structural data has been accumulated for oligosaccharide–protein complexes (12, 13). Despite supporting studies by NMR and thermodynamic measurements, the relative importance of competing processes that contribute to ΔG remains a subject of controversy (14, 15). Recent work suggests that solvation effects may make a far greater contribution to ΔG then was previously realized (16, 17). Possibly linked to the role of water is the observation by Lemieux that modification of functional groups located at or near the periphery of oligosaccharide–protein complexes can result in large swings in the enthalpy and entropy of binding, while the free energy changes by only small values. This observation led to

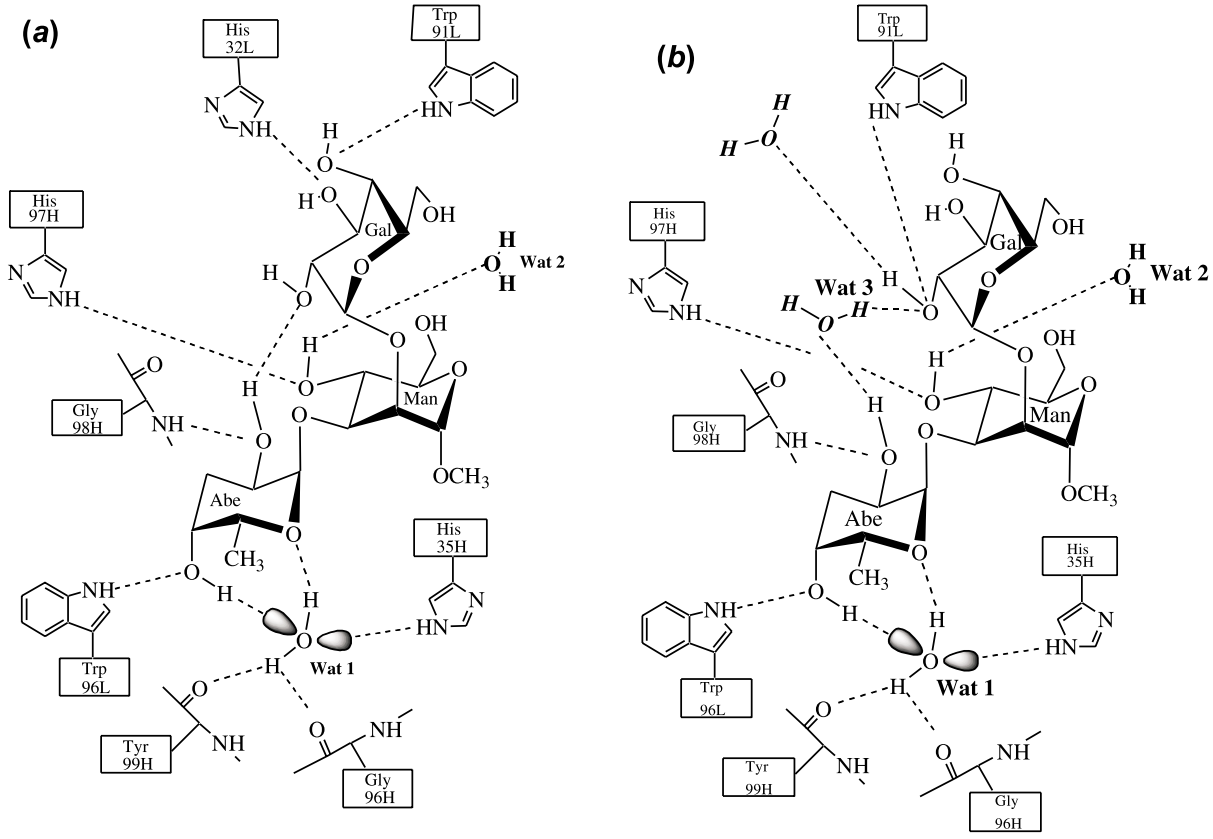
Fig. 1. (*a*) Bound conformation I (20) with a direct Abe O-2 to Man O-2 H-bond; (*b*) bound conformation II (21) with a water mediated Abe O-2 to Man O-2 H-bond. Note also the different H-bonding between the antibody and the galactose residue.



the proposal (18) (so far not realized) that significant gains in free energy might be achieved by concentrating on modification of groups in these positions. Here we focus on the synthesis of a carbohydrate epitope that should significantly disrupt structure of solvent, at least about the unbound carbohydrate ligand.

For this purpose we chose as a model system the monoclonal antibody Se 155.4 which recognizes a bacterial lipopolysaccharide antigen via the Gal[Abe]Man trisaccharide epitope (**2**). It is part of the tetrasaccharide α-D-Gal*p*-(1→2)[α-D-[Abe*p*-(1→3)]-α-D-Man*p*-(1→4)-α-L-Rha*p* (**1**) that comprises the repeating unit of the *O*-polysaccharide component of LPS (19). The structural (20, 21) and energetic (22–24) aspects of antigen binding to Se 155.4 have been well characterized, and an efficient *Escherichia coli* expression system has permitted extensive binding site mutagenesis (25) and antibody engineering studies (26, 27).

Functional group replacements of hydroxyl groups of the mannose (Man) and galactose (Gal) residues are reported here together with modification of the abequose (Abe) residue. The structural changes of the epitope are designed to probe the relative importance of hydrogen groups that are accessible to solvent water. The abequose C-2 hydroxyl group accepts a hydrogen bond from Gly 98 and donates a hydrogen bond to the Gal C-2 hydroxyl either directly (Fig. 1*a*) or via a water molecule (Fig. 1*b*). At the monosaccharide level, this was probed by methylation (**5**) or inversion of configuration (**6**) (Fig. 2). The relative importance of hydrogen bonds to the Man O-4 and Gal O-2 centres in trisaccharide **2** were investigated by synthesis of oligosaccharides in which a mannose or galactose residue is replaced by the corresponding talopyranoside: disaccharides **11** and **12** and trisaccharides **13** and **14** (Fig. 2). An additional rationale for investigating the activity of talopyranose containing structures derives from the observation that talose, more than other hexoses, disrupts the structure of water of solvation (28–31). Recently, the importance of solvent effects on protein binding of amphiphilic ligands has received attention (15, 32) and has been shown to make a large contribution to ΔG via enthalpic and entropic terms (16). Further information about the importance of the galactosyl residue in **2** was provided by the replacement of this moiety with small alkyl chains in compounds **7**–**10** (Fig. 2).

The results also raise questions about the strength of hydrogen bonds between protein and solvent exposed ligand-OH groups, the existence of which is based on the proximity and geometry of heavy atoms observed in high resolution crystal structures (20, 21). Two such hydrogen bonds involve the Gal O-3 and Gal O-4 atoms. Replacement of these hydroxyl groups by -OMe and -Cl, as in compound **15**, should abolish the hydrogen bond donor capability of the functionalities (33).

Results and discussion

Synthesis of methyl 2-*O*-methyl-3,6-dideoxy-α-D-*xylo*-hexopyranoside (5)

Treatment of methyl 3,6-dideoxy-α-D-*xylo*-hexopyranoside (**4**) (34) with barium oxide and a limiting amount of methyl iodide provided, in 45% yield, the 2-*O*-methyl derivative **5**.

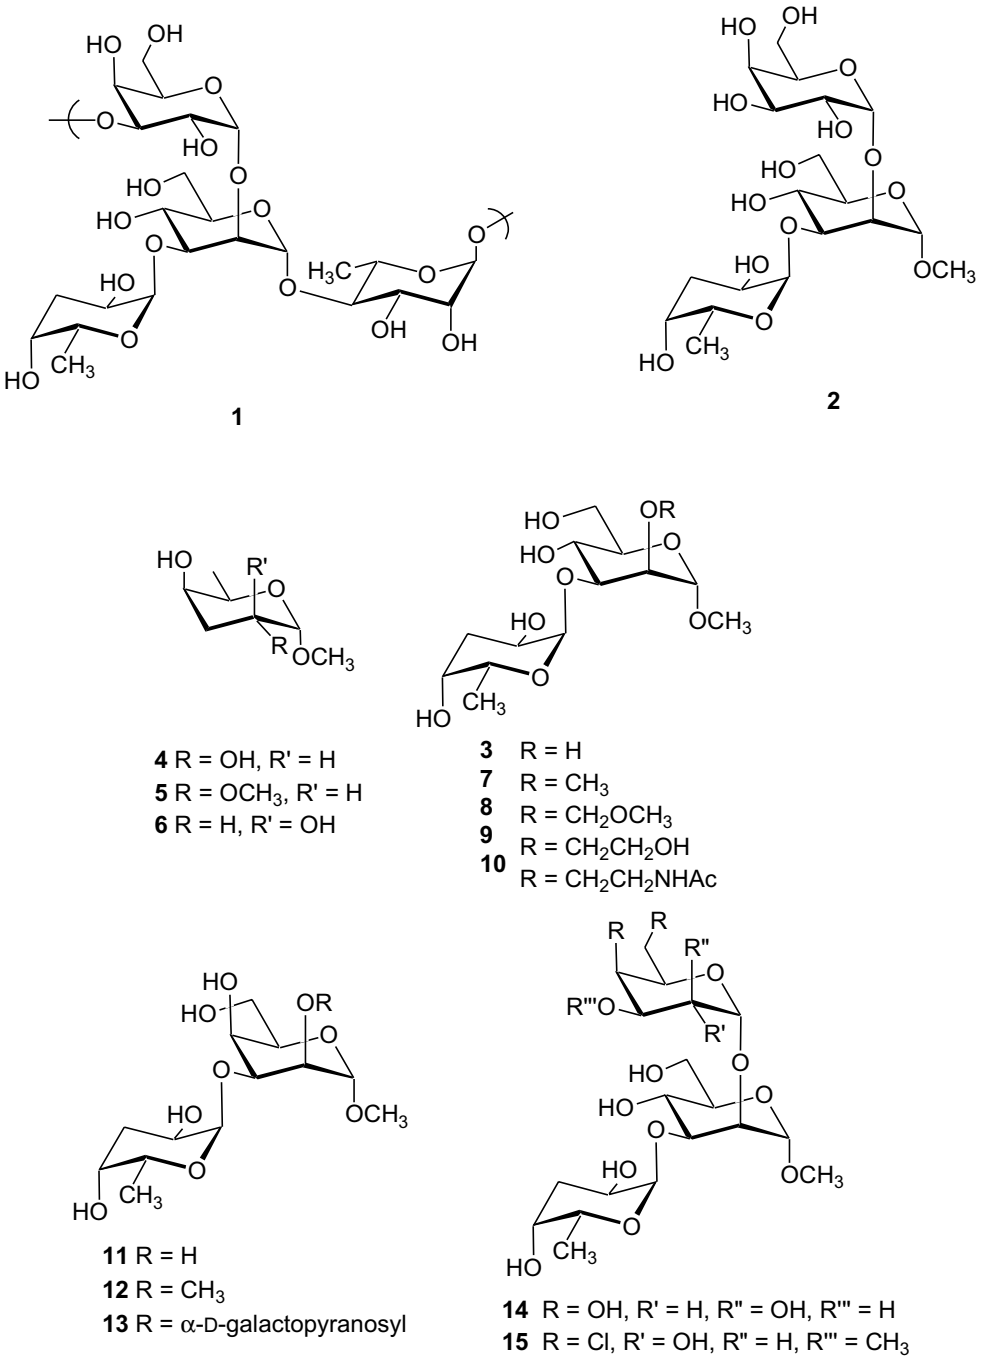
Fig. 2. Tetrasaccharide repeating unit of the *Salmonella* LPS (**1**) and the native trisaccharide epitope (**2**). Synthetic targets **3**–**15**.



The regiochemistry of methylation was established by comparing the ^{1}H NMR chemical shifts of product **5** with those of starting material **4** (Scheme 1).

Synthesis of methyl 3,6-dideoxy-α-D-*lyxo*-hexopyranoside (6)

Treatment of methyl 3,6-dideoxy-D-*arabino*-hexopyranoside (**16**) (35) with *tert*-butyldiphenylsilyl chloride in pyridine with catalysis by DMAP resulted in the formation of the silyl ether **17** in 80% yield. Silylation of this alcohol proved to be extremely sluggish, possibly owing to steric hindrance resulting from the size of the silyl protecting group. Consequently, attempts were made to prepare the less bulky *tert*-butyldimethylsilyl ether. However, protection with this group was equally slow and this approach was therefore abandoned. It was hoped that a large protecting group on O-2 would facilitate the stereoselectivity of a later reduction (see below) and for this reason the use of smaller protecting groups was not investigated.

Subsequent treatment of **17** with sodium methoxide to remove the benzoate ester provided alcohol **18** in 94% yield (Scheme 1). The stereochemistry at C-4 was then inverted, first by oxidation with pyridinium chlorochromate and then by reduction with sodium borohydride, to provide, in 76% yield over the two steps, the 3,6-dideoxy-D-*lyxo*-hexopyranoside derivative **19**. The reduction was not, however,

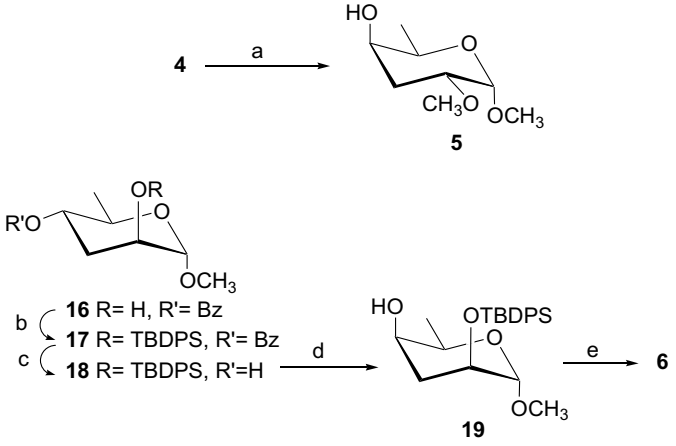
Scheme 1. (*a*) CH_3I, BaO, $Ba(OH)_2$, DMF; (*b*) TBDPSCI, pyridine, DMAP; (*c*) $NaOCH_3$, CH_3OH; (*d*) PCC, CH_2Cl_2, then $NaBH_4$, CH_3OH; (*e*) TBAF, THF.



completely stereoselective and thus a small amount (16%) of methyl-3,6-dideoxy-D-*arabino*-hexopyranoside (**18**) was also obtained. Removal of the silyl ether in **19** with tetrabutylammonium fluoride provided the desired product **6** in 95% yield. Interestingly, compound **6** is a volatile liquid; attempts to dry the compound while heating under vacuum resulted in complete evaporation overnight.

Synthesis of 2-*O*-alkylated disaccharides (Scheme 2) (7–10)

Methylation of the previously reported (36) disaccharide **20** provided methyl ether **21** in 87% yield. Hydrogenation of the benzyl protecting groups provided the deprotected disaccharide **7** (66%).

The 2-methoxymethyl derivative **8** could be prepared after prolonged reaction of disaccharide alcohol **20** with chloromethyl methyl ether. The MOM-protected disaccharide **22** was obtained in 80% yield and then converted to the target compound **8** by hydrogenation (88% yield).

Protection of **20** as a 2-*O*-allyl ether was achieved by reaction with allyl bromide to give **23** (92%). Ozonolysis of the allyl double bond and reductive work-up with sodium borohydride gave, in 70% yield, the 2′-hydroxyethyl ether disaccharide **24**. A portion of this alcohol was then deprotected (H_2, Pd/C) to give disaccharide **9** (74%). The remainder of alcohol **24** was converted to the phthlamido derivative **25** under Mitsunobu conditions (37) in 91% yield. Removal of the phthalimide group with hydrazine acetate and acetylation of the resulting amino group gave the protected *N*-acetyl disaccharide **26**. After deprotection, the disaccharide **10** was obtained in 62% yield from **25**.

Synthesis of talopyranosyl-containing disaccharides (Scheme 3) (11, 12)

Preparation of the two disaccharides containing talopyranosyl residues began with the known mannoside **27** (38), which was subjected to an oxidation–reduction protocol to provide the talopyranoside alcohol **28** in 85% yield. The benzoate ester was removed by transesterification (92%) and the resulting diol protected as benzyl ethers (97%) to give **30**. Hydrolysis of the isopropylidene acetal from **30** gave methyl 4,6-di-*O*-benzyl-talopyranoside (**31**) in 91% yield. Transient protection of the diol as an orthobenzoate was achieved by reaction of **31** with trimethylorthobenzoate and was followed immediately by treatment with acid to afford the 2-*O*-benzoate **32** (81%). Glycosylation of **32** with the abequose thioglycoside **33** (39) provided the fully protected disaccharide **34** in 83% yield. Treatment of **34** with sodium methoxide gave the disaccharide alcohol **35** in 96% yield. A portion of this alcohol was hydrogenated to provide disaccharide **11** (84%). Methylation of the remainder of **35**

Scheme 2. (*a*) CH_3I, NaH, DMF; (*b*) MOMCl, Hunig's base, acetone; (*c*) AllBr, NaH, DMF; (*d*) O_3, CH_2Cl_2–CH_3OH, then $NaBH_4$; (*e*) $(Ph_3)_3P$, DEAD, phthalimide, THF; (*f*) H_2NNH_2–HOAc, CH_3OH, then Ac_2O, pyridine; (*g*) H_2, 10% Pd/C, HOAc.

gave the 2-*O*-methyl disaccharide **36** (90%), which was deprotected by hydrogenation to disaccharide **12** in 78% yield.

Synthesis of talopyranosyl-containing trisaccharides (13, 14)

Alcohol **35** was glycosylated with the galactose thioglycoside **37** (40) to provide the trisaccharide **38** in modest (35%) yield. The desired product, **13**, was obtained in 86% yield upon hydrogenation (Scheme 4).

The synthesis of trisaccharide **14** required first the preparation of a suitable talopyranosyl donor that could be coupled to disaccharide alcohol **20**. To this end, the acetal protected methyl talopyranoside **29** was converted to methyl α-D-talopyranoside (**39**) by acid hydrolysis (Scheme 5). Acetylation then gave **40** in 76% yield (from **29**). Acetolysis provided the peracetate **41** (41) (95%), which in turn was

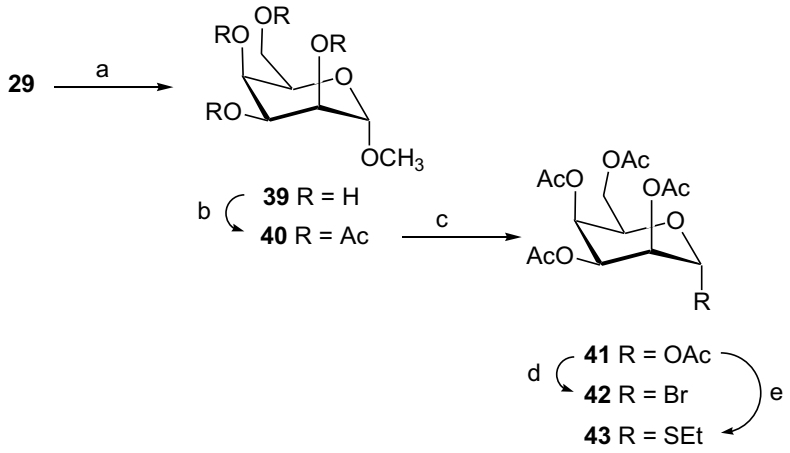
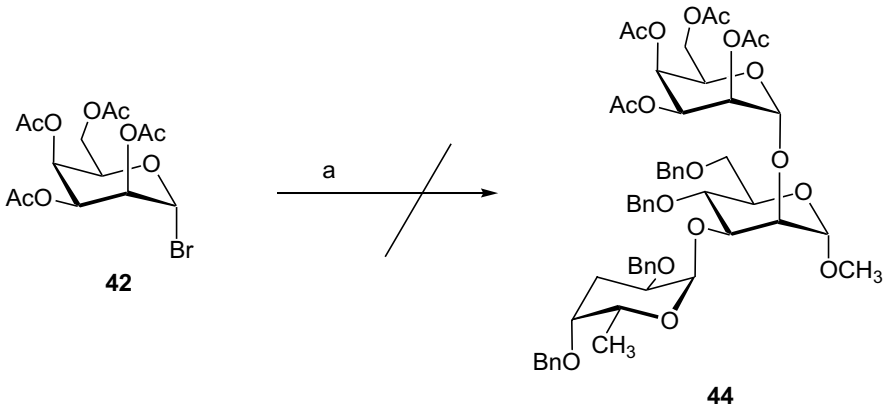
Scheme 5. (*a*) 95% TFA–H_2O; (*b*) Ac_2O, pyridine; (*c*) Ac_2O, H_2SO_4; (*d*) 48% HBr–HOAc, Ac_2O; (*e*) EtSH, $BF_3{\cdot}OEt_2$, CH_2Cl_2.



Scheme 6. (*a*) **20**, AgOTf, collidine, CH_2Cl_2.



converted to the unstable talosyl-bromide **42** in quantitative yield. Unfortunately, when the disaccharide acceptor **20** was treated with an excess of bromide **42**, no trisaccharide product **44** could be isolated (Scheme 6). Decomposition of the bromide upon addition of the promoter (AgOTf) was virtually instantaneous. In hopes of circumventing this problem, attempts were made to prepare the more stable thioglycoside donor **43** from the peracetate using ethanethiol and boron trifluoride etherate. These attempts failed as well; despite prolonged reaction times and elevated temperatures, only small amounts (<10%) of **43** could be obtained. Therefore, another route to a more stable talopyranose donor was investigated.

Acetonation of galactoside **45** (42) with dimethoxypropane provided, in 66% yield, **46** (Scheme 7). Regioselective protection of this acetonide as a 6-*O*-silyl ether (**47**) could be achieved in 85% yield. Oxidation of the C-2 hydroxyl group under Swern conditions and subsequent reduction with sodium borohydride gave, in 85% yield, an anomeric mixture of thioglycosides **48** with the talo-configuration. Presumably the basic conditions of the oxidation resulted in the anomerization of the product ketone. Removal of the isopropylidene and silyl protecting groups was achieved by acid hydrolysis to give ethyl 1-thio-talopyranoside (**49**) which was immediately acetylated to give thioglycoside **43** in 89% yield. Either anomer of **43** could be used in the ensuing glycosylation reaction. When the acceptor **20** was treated with the glycosyl donor **43**, trisaccharide **44** was obtained in 47% yield. Final deprotection of **44** by transesterification and hydrogenation afforded the desired trisaccharide **14** (87%) (Scheme 7).

Synthesis of the dichlorogalactosyl containing trisaccharide (15) (Scheme 8)

Synthesis of the galactose thioglycoside donor **55** required for the preparation of trisaccharide **15**, began with the treatment of 3-*O*-methyl glucose (**50**) (43) with sulfuryl chloride. The dichlorinated galactosyl chloride **51** was obtained as a mixture of anomers (1:1.7 (α:β), total yield 65%). Conversion to the methyl glycoside and concurrent removal of the chlorosulfate group gave **52** as an anomeric mixture of methyl glycosides (1.7:1 (α:β), total yield 67%). Proceeding only with the α-anomer, the hydroxyl group in glycoside **52** was protected as a benzyl ether (71%) and then **53** was subjected to acetolysis affording **54** in an 80% yield. Reaction of acetate **54** with ethanethiol gave the desired thioglycoside **55** (42%). Finally, glycosylation of disaccharide alcohol **20** with **55** provided the trisaccharide **56** (73%). The target trisaccharide **15** was obtained in 66% yield upon hydrogenation.

Talopyranosides in the $^4C_1$ conformation experience a strong destabilizing interaction between axial hydroxyl groups at C-2 and C-4. However, adoption of the $^1C_4$ chair is not likely, since an even stronger destabilizing interaction

then arises between axial substituents at C-3 and C-6. Distortion of the $^4C_1$ chair to skew conformations could occur and it is likely that such conformations could be readily sampled. Coupling constants (^3J) for the $^4C_1$ chair are expected

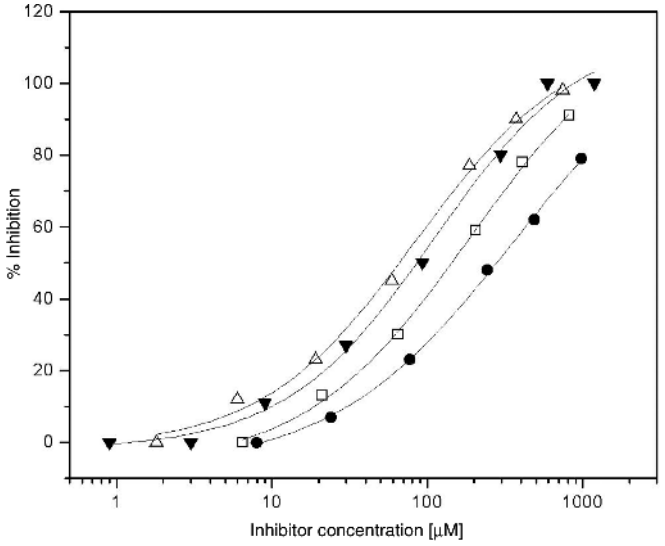
Fig. 3. Solid-phase inhibition assays for selected compounds. Trisaccharide **15** (△), trisaccharide **13** (□), disaccharide **7** (▼), disaccharide **10** (●).



to be small since there are no vicinal diaxial hydrogens. Flattening of the ring or skewing would lead to high ^3J values as neighbouring protons change from ~60° toward 0°. Observed values, especially for $J_{2,3}$ and $J_{3,4}$ show no clear trend toward such larger coupling constants. In several instances these coupling constants are lower than the expected 3–5 Hz for equatorial–axial hydrogens. A complete analysis of this conformational issue is beyond the scope of this paper, but there is no strong evidence to suggest that the α-talopyranosides reported here adopted conformations that deviate significantly from the $^4C_1$ chair.

The activity of the synthetic mono- (**4**–**6**), di- (**3**,**7**–**12**) and trisaccharides (**13**–**15**) as inhibitors of antibody binding were initially evaluated in a previously described solid-phase binding assay (24, 44). In brief, affinity purified Se 155.4 antibody is absorbed onto microtitre plates and the binding of biotinylated *O*-polysaccharide antigen to the solid-phase antibody is measured in the presence and absence of inhibitors. The data for representative oligosaccharides are shown (Fig. 3). The association constants were determined by titration microcalorimetry (Table 1) for all compounds except **6** and **15**[2]. Data for compounds **3**–**5** and **8** are taken from ref. 24 and were determined at an earlier date and on different equipment. Disaccharide **7** (^{13}C labeled in the 2-*O*-methyl group) has been used to derive kinetic data for ligand antibody interactions and to observe ligand–protein NOEs (45).

A detailed analysis of the full calorimetry data will be reported together with molecular modeling[2]. However, several points emerge from the data (Table 1). The relatively high activities of 2-*O*-alkylated disaccharides **7** and **9** are consistent with earlier interpretations that in solution any hydrogen bonds between the galactose residue and the antibody site are very weak and of little net benefit. For disaccharide analogs substitution of mannose by talose results in a five- to 10-fold loss of binding energy, which correlates with the important hydrogen bond from a histidine residue to Man O-4 (Fig. 1). When talose is substituted for mannose and galactose in trisaccharides **13** and **14** a two- to threefold loss of binding occurs. As will be reported elsewhere, modeling of the antibody complex with each of these trisaccharides shows that the hydrogen bonding patterns of Fig. 1 can be maintained with only small movements about the glycosidic linkages. It is also apparent that initial hopes that the talose analogs would provide readily discernable trends to correlate with solvent reorganization about the ligand antibody complex have not been realized.

Table 1. Association constants and relative inhibitory power of the mono-, di-, and trisaccharides **3**–**15**.

Compound	$K_a \times 10^5$ (M^{-1})[a]	Relative inhibitory power[b]

Experimental

Optical rotations were measured with a PerkinElmer 241 polarimeter at 22 ± 2°C. Analytical TLC was performed on Silica Gel 60-F_{254} (E. Merck, Darmstadt) with detection by quenching of fluorescence and (or) by charring with sulfuric acid. Iatrobeads refers to a beaded silica gel 6RS-8060 manufactured by Iatron Laboratories (Tokyo). All commercial reagents were used as supplied and chromatography solvents were distilled prior to use. Column chromatography was performed on Silica Gel 60 (40–60 μM, E. Merck, Darmstadt). Millex-GV (0.22 μM) filter units were from Millipore (Mississauga, ON). ^1H NMR were recorded at 360 MHz (Bruker AM-360) or at 500 MHz (Varian Unity 500) with either internal $CHCl_3$ (δ: 7.24, $CDCl_3$) or internal acetone (δ: 2.225, D_2O). ^{13}C NMR were recorded either at 75.5 MHz (Bruker AM-300) or 125.7 MHz (Varian Unity 500) with internal $CHCl_3$ (δ: 77.00, $CDCl_3$) or internal acetone (δ: 37.01, D_2O). ^1H NMR data are reported as though they were first order. Proton and carbon resonances for **7** and **9**–**15** were assigned using ^1H-^1H and ^1H-^{13}C correlation 4 carried out at room temperature. Organic solutions were

[2]M. Warwas and D.R. Bundle. Unpublished results.

dried prior to concentration under vacuum at <40°C (bath). Microanalyses were carried out by the analytical services at this department and all samples, except **6**, submitted for elemental analyses were dried overnight under vacuum with phosphorus pentoxide at 56°C (refluxing acetone). Compound **6** was dried at room temperature. High resolution mass spectra (HR-MS) of **6** were recorded on a Kratos MS-50 instrument using electron-impact ionization. For other compounds, FAB-HR-MS were recorded on samples suspended in Cleland's matrix using a Kratos MS-50B instrument with xenon as the bombarding gas. Inhibition assays were performed in 96 well microtiter plates as previously described (24), and inhibition curves were drawn using the software package Origin 5.0 (OriginLab, Northampton, MA). Titration microcalorimetry was performed as previously described (22, 24).

Methyl 2-*O*-methyl-3,6-dideoxy-α-D-*xylo*-hexopyranoside (5)

To a stirred suspension of **4** (33) (350 mg, 2.16 mmol), barium oxide (1.32 g, 8.64 mmol), and barium hydroxide octahydrate (350 mg, 1.08 mmol) in DMF (10 mL) was added methyl iodide (151 μL, 2.38 mmol). The reaction was stirred for 4 h, diluted with CH_2Cl_2, and filtered through Celite. The filtrate was concentrated under reduced pressure, diluted with CH_2Cl_2, and washed successively with saturated solutions of $KHCO_3$ and NaCl. After drying ($MgSO_4$) and evaporation of the solvent, the product was chromatographed (hexane–EtOAc, 1:1) to provide **5** (170 mg, 45%) as an oil. $[\alpha]_D$ +118.7 (*c* 1.7, $CHCl_3$). R_f = 0.40 (hexane–EtOAc, 1:3). The regiochemistry of methylation was established by ^{1}H decoupling experiments. ^{1}H NMR ($CDCl_3$) δ: 4.69 (d, $J_{1,2}$ = 3.0 Hz, 1H, H-1), 3.83 (q, $J_{5,6}$ = 6.5 Hz, 1H, H-5), 3.67 (br. s, 1H, H-4), 3.57 (ddd, $J_{2,3eq}$ = 5.0 Hz, $J_{2,3ax}$ = 12.0 Hz, 1H, H-2), 3.35 (s, 3H, OCH_3), 3.29 (s, 3H, OCH_3), 2.01 (ddd, $J_{3ax,3eq}$ = 13.0 Hz, $J_{2,3eq}$ = 5.0 Hz, $J_{3eq,4}$ = 3.0 Hz, H-3eq), 1.86 (ddd, $J_{3ax,4}$ = 3.0 Hz, 1H, H-3ax), 1.11 (d, $J_{5,6}$ = 6.5 Hz, 3H, H-6). Anal. calcd. for $C_8H_{16}O_4$ (176.21): C 54.53, H 9.15; found: C 54.10, H 9.29.

Methyl 4-*O*-benzoyl-2-*O*-*tert*-butyldiphenylsilyl-3,6-dideoxy-α-D-*arabino*-hexopyranoside (17)

Alcohol **16** (34) (1.0 g, 3.76 mmol) was dissolved in pyridine (25 mL) and then DMAP (500 mg) was added followed by *tert*-butyldiphenylsilyl chloride (2.0 mL, 7.9 mmol). The reaction was heated to 60°C and stirred for 6 days and then the solution cooled and partitioned between water and CH_2Cl_2. The organic layer was then washed in succession with 0.5 N HCl, water, and a saturated solution of NaCl, and then dried (Na_2SO_4). After evaporation, chromatography (pentane–ethyl acetate, 9:1) gave the product **17** (1.50 g, 80%) as an oil. $[\alpha]_D$ +83.2 (*c* 0.9, $CHCl_3$). R_f = 0.53 (pentane–ethyl acetate, 9:1). ^{1}H NMR ($CDCl_3$) δ: 7.30-8.05 (m, 15H, Ph), 5.32 (ddd, $J_{3ax,4}$ = 13.0 Hz, $J_{3eq,4}$ = 4.5 Hz, $J_{4,5}$ = 10.0 Hz, 1H, H-4), 4.39 (br. s, 1H, H-1), 3.90–3.98 (m, 2H, H-2, H-5), 3.28 (s, 3H, OCH_3), 2.20 (dt, $J_{3ax,3eq}$ = 12.5 Hz, $J_{2,3eq}$ = 4.5 Hz, H-3eq), 1.86 (ddd, $J_{3ax,4}$ = 13.0 Hz, $J_{2,3ax}$ = 3.0 Hz, 1H, H-3ax), 1.33 (d, $J_{5,6}$ = 6.5 Hz, 3H, H-6), 1.17 (s, 9H, C(CH_3)$_3$). ^{13}C NMR ($CDCl_3$) δ: 165.57 (C=O), 100.20 (C-1), 54.74 (OCH_3), 32.45 (C-3), 26.98 (C(CH_3)$_3$), 19.26 (*C*(CH$_3$)$_3$), 18.07 (C-6). Anal. calcd. for $C_{30}H_{36}O_5Si$ (504.70): C 71.39, H 7.19; found: C 71.59, H 7.31.

Methyl 2-*O*-*tert*-butyldiphenylsilyl-3,6-dideoxy-α-D-*arabino*-hexopyranoside (18)

Benzoate **17** (950 mg, 1.88 mmol) was dissolved in CH_3OH (50 mL) and a small piece of sodium was added. After stirring for 36 h, the reaction was quenched by adding acetic acid until the pH was neutral. The solvent was evaporated and then the residue chromatographed (pentane–ethyl acetate, 6:1) to give the product **18** (710 mg, 94%) as an oil. $[\alpha]_D$ +19.1 (*c* 0.8, $CHCl_3$). R_f = 0.20 (pentane–ethyl acetate, 6:1). ^{1}H NMR ($CDCl_3$) δ: 7.20–7.70 (m, 10H, Ph), 4.30 (br. s, 1H, H-1), 3.88–3.92 (m, 1H, H-2), 3.73–3.84 (m, 1H, H-4), 3.49–3.58 (m, 1H, H-5), 3.21 (s, 3H, OCH_3), 1.93 (ddt, $J_{2,3eq}$ = 3.5 Hz, $J_{1,3eq}$ = 1.0 Hz, H-3eq), 1.64 (ddd, $J_{3ax,3eq}$ = 13.0 Hz, $J_{3ax,4}$ = 11.5 Hz, $J_{2,3ax}$ = 2.5 Hz, 1H, H-3ax), 1.39 (d, $J_{4,4\text{-OH}}$ = 6.0 Hz, 1H,), 1.34 (d, $J_{5,6}$ = 6.5 Hz, 3H, H-6), 1.10 (s, 9H, C(CH_3)$_3$). ^{13}C NMR ($CDCl_3$) δ: 99.96 (C-1), 54.55 (OCH_3), 35.70 (C-3), 26.98 (C(CH_3)$_3$), 19.25 (*C*(CH$_3$)$_3$), 17.93 (C-6). Anal. calcd. for $C_{23}H_{32}O_4Si$ (400.59): C 68.96, H 8.05; found: C 68.60, H 7.85.

Methyl 3,6-dideoxy-2-*O*-*tert*-butyldiphenylsilyl-α-D-*lyxo*-hexopyranoside (19)

Compound **18** (674 mg, 1.61 mmol) was dissolved in CH_2Cl_2 (30 mL) and stirred with crushed 4 Å molecular sieves (500 mg) for 15 min. Pyridinium chlorochromate (1.74 g, 8.05 mmol) was added and the reaction stirred for 4 h at which point there was a complete conversion to the ketone (R_f = 0.89, pentane–ethyl acetate, 4:1). The reaction was filtered through Celite and washed with water and a saturated solution of NaCl and then dried (Na_2SO_4). After evaporation of the organic layer, the resulting residue was dried for 1 h under vacuum. The black solid was then dissolved in CH_3OH (50 mL) and $NaBH_4$ (100 mg, 2.66 mmol) added. After stirring for 10 min, the reaction was quenched by adding acetic acid until the pH was neutral. The solvent was evaporated and then the residue chromatographed (pentane–ethyl acetate, 9:1) to give the product **19** (488 mg, 76%) and some starting material **18** (108 mg, 16%) as oils. $[\alpha]_D$ –4.0 (*c* 0.9, $CHCl_3$). R_f = 0.67 (pentane–ethyl acetate, 9:1). ^{1}H NMR ($CDCl_3$) δ: 7.25–7.75 (m, 10H, Ph), 4.30 (br. s, 1H, H-1), 3.84 (dq, $J_{4,5}$ = 1.0 Hz, $J_{5,6}$ = 6.5 Hz, 1H, H-5), 3.74–3.80 (m, 2H, H-2, 4-OH), 3.45–3.52 (m, 1H, H-4), 3.16 (s, 3H, OCH_3), 2.07 (ddd, $J_{3ax,3eq}$ = 14.5 Hz, $J_{2,3ax}$ = 4.5 Hz, $J_{3ax,4}$ = 1.5 Hz, 1H, H-3ax), 1.89 (dt, $J_{2,3eq}$ = 3.0 Hz, H-3eq), 1.30 (d, $J_{5,6}$ = 6.5 Hz, 3H, H-6), 1.12 (s, 9H, C(CH_3)$_3$). ^{13}C NMR ($CDCl_3$) δ: 100.35 (C-1), 54.76 (OCH_3), 31.71 (C-3), 26.93 (C(CH_3)$_3$), 19.01 (*C*(CH$_3$)$_3$), 17.09 (C-6). Anal. calcd. for $C_{23}H_{32}O_4Si$ (400.59): C 68.96, H 8.05; found: C 68.91, H 8.27.

Methyl 3,6-dideoxy-α-D-*lyxo*-hexopyranoside (6)

Silyl ether **19** (450 mg, 1.12 mmol) was dissolved in THF (7.5 mL) and then tetrabutyl ammonium flouride (2.5 mL of a 1 M solution in THF, 2.24 mmol) was added. The reaction was stirred for 30 min and then evaporated. Chromatography of the residue (pentane–ethyl acetate, 1:1) gave the product **6** (172 mg, 95%) as an oil. $[\alpha]_D$ +46.4 (*c* 0.9, H_2O). R_f = 0.34

Methyl 3-*O*-(2,4-di-*O*-benzyl-3,6-dideoxy-α-D-*xylo*-hexopyranosyl)-2-*O*-methyl-4,6-di-*O*-benzyl-α-D-mannopyranoside (21)

Sodium hydride (20 mg, 0.42 mmol, 50% dispersion in oil) was washed twice with petroleum ether under an N_2 atmosphere. The solvent was decanted and the solid suspended in DMF (4 mL). Methyl 3-*O*-(2,4-di-*O*-benzyl-3,6-dideoxy-α-D-*xylo*-hexopyranosyl)-4,6-di-*O*-benzyl-α-D-mannopyranoside (35) (**20**, 102 mg, 0.15 mmol) was then added as a solid and the reaction mixture was cooled to 0°C, and methyl iodide (20 μL, 0.3 mmol) added. After 1 h the reaction was quenched by the addition of methanol and the solvent evaporated. The resulting residue was then taken up in CH_2Cl_2 and washed succesively with water, 1 N HCl, water, $NaHCO_3$, and a saturated solution of NaCl. After drying ($MgSO_4$) and evaporation of the solvent the product was purified by chromatography (hexane–EtOAc, 3:1) to give **21** (91 mg, 87%) as an amorphous solid. $[\alpha]_D$ +64.7 (*c* 0.7, $CHCl_3$). R_f = 0.45, (hexane–EtOAc, 3:1). ^{1}H NMR ($CDCl_3$) δ: 7.10–7.30 (m, 20H, Ph), 5.13 (s, 1H, H-1′), 5.14 (d, ^2J = 12.0 Hz, 1H, PhCH_2), 4.86 (br. s, 1H, H-1), 4.62, 4.57, 4.54, 4.49, 4.45, 4.41, 4.38 (7d, ^2J = 12.0 Hz, 7H, PhCH_2), 4.18 (dd, $J_{5',6'}$ = 6.5 Hz, 1H, H-5′), 4.11 (dd, $J_{2,3}$ = 3.0 Hz, $J_{3,4}$ = 9.5 Hz, 1H, H-3), 3.32–3.90 (m, 2H, H-2′, H-4), 3.77–3.80 (m, 1H, H-5), 3.69–3.75 (m, 2H, H-6a, H-6b), 3.64 (br. s, 1H, H-2), 3.49 (s, 3H, OCH_3), 3.48 (br. s, 1H, H-4′), 3.41 (s, 3H, OCH_3), 1.99–2.14 (m, 2H, H-3′eq, H-3′ax), 1.22 (d, $J_{5'6'}$ = 6.6 Hz, 3H, H-6′). ^{13}C NMR ($CDCl_3$) δ: 99.26 (C-1′), 97.36 (C-1). Methyl 3-*O*-(2,4-di-*O*-benzyl-3,6-dideoxy-α-D-*xylo*-hexopyranosyl-2-*O*-methoxymethyl-4,6-di-*O*-benzyl-α-D-mannopyranoside (22)

To a stirred solution of alcohol **20** (35) (68 mg, 0.1 mmol) in acetone (4 mL) was added ethyldiisopropylamine (40 μL, 0.21 mmol) and chloromethyl methyl ether (20 μL, 0.22 mmol). The reaction was stirred at room temperature for 1 h and then heated at 60°C for 48 h during which time ethyldiisopropylamine (40 μL, 0.21 mmol) and chloromethyl methyl ether (20 μL, 0.22 mmol) were added twice. The reaction was cooled, the solvent evaporated, and the crude material taken up in CH_2Cl_2, and washed succesively with water, 1 N HCl, water, $NaHCO_3$, and a saturated solution of NaCl. The organic layer was dried ($MgSO_4$) and the solvent evaporated to provide a residue that was chromatographed (hexane–EtOAc, 3:1) to give the product **22** (57.3 mg, 80%) as an oil. $[\alpha]_D$ +87.1 (*c* 0.9, $CHCl_3$). R_f = 0.35 (hexane–EtOAc, 3:1). ^{1}H NMR ($CDCl_3$) δ: 7.10–7.30 (m, 20H, Ph), 5.23 (d, $J_{1',2'}$ = 3.0 Hz, 1H, H-1′), 5.12 (d, ^2J = 12.0 Hz, 1H, PhCH_2), 4.89 (d, ^2J = 7.0 Hz, 1H, OCH_2O), 4.87 (br. s, 1H, H-1), 4.78 (d, ^2J = 7.0 Hz, 1H, OCH_2O), 4.65, 4.56, 4.54, 4.49, 4.47, 4.37, 4.36 (d, ^2J = 12.0 Hz, 7H, PhCH_2), 4.25 (dd, $J_{2,3}$ = 3.0 Hz, $J_{3,4}$ = 9.5 Hz, 1H, H-3), 4.08 (q, $J_{5',6'}$ = 6.5 Hz, 1H), 3.96 (t, $J_{3,4}$, $J_{4,5}$ = 9.5 Hz, 1H, H-4), 3.93 (br. s, 1H, H-2), 3.86 (ddd, $J_{2',3'eq}$ = 5.0 Hz, $J_{2',3'ax}$ = 12.0 Hz, 1H, H-2′), 3.81–3.72 (m, 3H, H-5, H-6a, H-6b), 3.40–3.45 (m, 7H, H-4′, 2 × OCH_3), 1.91–2.11 (m, 2H, H-3′eq, H-3′ax), 1.20 (d, $J_{5',6'}$ = 6.5 Hz, 3H, H-6′). ^{13}C NMR ($CDCl_3$) δ: 99.86 (OCH_2O), 98.83 (C-1′), 97.25 (C-1). Anal. calcd. for $C_{43}H_{52}O_{10}$ (728.88): C 70.86, H 7.19; found: C 70.88, H 7.26.

Methyl 3-*O*-(3,6-dideoxy-α-D-*xylo*-hexopyranosyl-2-*O*-methoxymethyl-α-D-mannopyranoside (8)

Glycoside **22** (39 mg, 0.05 mmol) was dissolved in ethanol (4 mL), and then 10% Pd/C (40 mg) was added and the reaction stirred under an atmosphere of H_2 for 24 h. At this point the reaction was still not complete and therefore additional 10% Pd/C (40 mg) and acetic acid (0.5 mL) were added. After 3 h the reaction was finished and the solution was filtered through Celite and the filtrate evaporated, coevaporating twice with toluene. Chromatography (water) on Biogel P-2 gave **8** (17.5 mg, 88%) as an amorphous white solid after lyophilization. $[\alpha]_D$ +27.7 (*c* 0.6, H_2O). ^{1}H NMR (D_2O) δ: 5.12 (d, $J_{1',2'}$ = 3.5 Hz, 1H, H-1′), 4.91 (br. s, 1H, H-1), 4.80–4.86 (m, 2H, 2 × OCH_2O), 4.06–4.00 (m, 2H, H-2′, H-5′), 3.95–3.99 (m, 2H, H-2, H-3), 3.88–3.93 (m, 2H, H-6a, H-4′), 3.84 (t, $J_{3,4} \approx J_{4,5}$ = 10.0 Hz, H-4), 3.77 (dd, $J_{6a,6b}$ = 12.5 Hz, $J_{5,6b}$ = 6.0 Hz, 1H, H-5), 3.64–3.69 (m, 1H, H-4), 3.43 (s, 3H, OCH_3), 3.45 (s, 3H, OCH_3), 1.97–2.02 (m, 2H, H-3′eq, H-3′ax), 1.18 (d, $J_{5',6'}$ = 6.5 Hz, 3H, H-6′). ^{13}C NMR (D_2O) δ: 101.00 (C-1′), 99.83 (C-1), 97.28

Methyl 2-*O*-(2′-hydroxyethyl)-3-*O*-(3,6-dideoxy-α-D-*xylo*-hexopyranosyl)-α-D-mannopyranoside (9)

Alcohol **24** (100 mg, 0.13 mmol) was dissolved in acetic acid (5 mL) and 10% Pd/C (50 mg) added and the reaction stirred overnight under a flow of H_2. The catalyst was filtered, the solvent evaporated and the product was purified by chromatography on Iatrobeads (CH_2Cl_2–CH_3OH, 4:1). The product obtained was then redissolved in water, filtered through a 0.22 μM filter and lyophilized to give **9** (35 mg, 74%), as an amorphous white solid. $[\alpha]_D$ +73.4 (*c* 0.6, H_2O). R_f = 0.21 (CH_2Cl_2–CH_3OH, 4:1). ^{1}H NMR (D_2O) δ: 5.105 (d, $J_{1',2'}$ = 3.5 Hz, 1H, H-1′), 4.941 (d, $J_{1,2}$ = 1.5 Hz, 1H, H-1), 4.070 (q, $J_{5',6'}$ = 6.5 Hz, 1H, H-5′), 4.106 (ddd, $J_{1',2'}$ = 3.5 Hz, $J_{2',3'eq}$ = 7.0 Hz, $J_{2',3'ax}$ = 11.0 Hz, 1H, H-2′), 3.926 (dd, $J_{2,3}$ = 3.0 Hz, $J_{3,4}$ = 9.5 Hz, 1H, H-3), 3.87–3.91 (m, 2H, H-6a, H-4′), 3.860 (t, $J_{4,5}$ = 9.5 Hz, 1H, H-4), 3.70–3.83 (m, 6H, H-2, H-6b, 2 × CH_2CH_2OH, 2 × CH_2CH_2OH), 3.656 (ddd, $J_{4,5}$ = 9.5 Hz, $J_{5,6a}$ = 2.5 Hz, $J_{5,6b}$ = 6.0 Hz, 1H, H-5), 3.432 (s, 3H, OCH_3), 1.98–2.05 (m, 2H, H-3′ax, H-3′eq), 1.182 (d, $J_{5',6'}$ = 6.5 Hz, 3H, H-6′). ^{13}C NMR (D_2O) δ: 101.238 (C-1′, $^1J_{C,H}$ = 170.4 Hz), 98.906 (C-1, $^1J_{C,H}$ = 170.0 Hz), 79.425 (C-2), 78.799 (C-3), 73.485 (OCH_2CH_2OH), 73.064 (C-5), 69.126 (C-4′), 67.759 (C-5′), 67.258 (C-4), 64.301 (C-2′), 61.591 (OCH_2CH_2OH), 61.529 (C-6), 55.666 (OCH_3), 33.764 (C-3′), 16.306 (C-6′). HR-FABMS calcd. for $C_{15}H_{28}O_{10}$ $[M + Na]^+$: 391.1580; found: 391.1595.

Methyl 4,6-di-*O*-benzyl-3-*O*-(2,4-di-*O*-benzyl-3,6-dideoxy-α-D-*xylo*-hexopyranosyl)-2-*O*-(2′-phthlamidoethyl)-α-D-mannopyranoside (25)

Compound **24** (300 mg, 0.41 mmol) was dissolved in THF (5 mL) and triphenylphosphine (215 mg, 0.82 mmol) and phthalimide (91 mg, 0.62 mmol) were added followed by diethylazodicarboxylate (141 μL, 0.82 mmol). The reaction was stirred overnight and evaporated. Chromatography (toluene–EtOAc, 9:1) provided **25** (320 mg, 91%) as an oil. $[\alpha]_D$ +57.6 (*c* 1.4, $CHCl_3$). R_f = 0.38 (toluene–EtOAc, 9:1). ^{1}H NMR ($CDCl_3$) δ: 7.00–7.80 (m, 24H, Ph), 5.09 (d, $J_{1',2'}$ = 3.5 Hz, 1H, H-1′), 4.99 (d, ^2J = 11.5 Hz, 1H, PhCH_2), 4.75 (d, $J_{1,2}$ = 1.5 Hz, 1H, H-1), 4.28–4.53 (m, 7H, 7 × PhCH_2), 4.06 (dd, $J_{2,3}$ = 2.5 Hz, $J_{3,4}$ = 8.5 Hz, 1H, H-3), 3.88–4.02 (m, 9H, H-2, H-4, H-5, H-6a, H-6b, H-2′, H-5′, 2 × OCH_2CH_2NPhth), 3.63 (dd, ^2J = 10.5 Hz, J_{vic} = 1.5 Hz, 1H, CH_2NPhth), 3.33 (s, 3H, OCH_3), 3.20 (br. s, 1H, H-4′), 1.94 (dt, $J_{3'eq,3'ax}$ = 13.0 Hz, $J_{2',3'eq}$, $J_{3'eq,4'}$ = 3.5 Hz, 1H, H-3′eq), 1.67 (dt, $J_{2',3'ax}$ = 13.0 Hz, $J_{3'ax,4'}$ = 2.5 Hz, 1H, H-3′ax), 1.15 (d, $J_{5',6'}$ = 6.5 Hz, 1H, H-6′). ^{13}C NMR ($CDCl_3$) δ: 167.85 (C=O), 99.06 (C-1′), 97.71 (C-1), 69.48 (OCH_2CH_2NPhth), 66.50 (C-6), 54.67 (OCH_3), 37.79 (OCH_2CH_2NPhth), 27.29 (C-3′), 16.46 (C-6′). Methyl 2-*O*-(2′-acetamidoethyl)-4,6-di-*O*-benzyl-3-*O*-(2,4-di-*O*-benzyl-3,6-dideoxy-α-D-*xylo*-hexopyranosyl)-α-D-mannopyranoside (26)

Phthalimide **25** (300 mg, 0.34 mmol) was dissolved in methanol (15 mL) and hydrazine acetate (805 mg,

© 2002 NRC Canada

10.2 mmol) was added. The reaction was heated at reflux for 3 h and then more hydrazine acetate (805 mg, 10.2 mmol) was added. After refluxing for another 20 h the solution was cooled and the solvent evaporated. Pyridine (20 mL) was added followed by acetic anhydride (10 mL), and the reaction stirred overnight. The mixture was then diluted with EtOAc and washed with 0.5 N HCl, water, and brine. Evaporation of the solvent followed by chromatography (pentane–EtOAc, 3:1) provided **26** which was characterized only by ^{1}H NMR and then immediately carried through to the next reaction. ^{1}H NMR ($CDCl_3$) δ: 7.10–7.40 (m, 20H, Ph), 6.55 (br. s, 1H, N*H*), 5.24 (d, $J_{1',2'}$ = 3.5 Hz, 1H, H-1′), 5.07 (d, ^2J = 11.5 Hz, 1H, PhCH_2), 4.74 (d, $J_{1,2}$ = 1.5 Hz, 1H, H-1), 4.34–4.64 (m, 7H, 7 × PhCH_2), 4.19 (dd, $J_{2,3}$ = 3.0 Hz, $J_{3,4}$ = 9.5 Hz, 1H, H-3), 4.01–4.09 (m, 2H, H-4, H-5′) 3.85 (dt, $J_{2',3'eq}$ = 3.5 Hz, $J_{2',3'ax}$ = 13.0 Hz, 1H, H-2′), 3.58–3.79 (m, 8H, H-2, H-5, ^2JH-6a, H-6b, 2 × OCH_2CH_2NHAc, 2 × OCH$_2$CH_2NHAc), 3.46 (br. s, 1H, H-4′), 3.37 (s, 3H, OCH_3), 2.12 (dt, $J_{3'eq,3'ax}$ = 13.0 Hz, $J_{3'eq,4'}$ = 3.5 Hz, 1H, H-3′eq), 1.83–1.93 (m, 4H, NHCOCH_3, H-3′ax), 1.19 (d, $J_{5',6'}$ = 6.5 Hz, 1H, H6′).

Methyl 2-*O*-(2′-acetamidoethyl)-3-*O*-(3,6-dideoxy-α-D-*xylo*-hexopyranosyl)-α-D-mannopyranoside (10)

The protected *N*-acetyl disaccharide **26** (from above) was dissolved in acetic acid (5 mL) and 10% Pd/C (200 mg) added and the reaction stirred overnight under a flow of H_2. The catalyst was then filtered away and the solvent evaporated. Purified by chromatography on Iatrobeads (CH_2Cl_2–CH_3OH, 4:1) gave a product that was then redissolved in water, filtered through a 0.22 μM filter and lyophilized to give **10** (85 mg, 62% from **25**), as an amorphous white solid. $[\alpha]_D$ +76.4 (*c* 0.6, H_2O). R_f = 0.29 (CH_2Cl_2–CH_3OH, 4:1). ^{1}H NMR (D_2O) δ: 5.094 (d, $J_{1',2'}$ = 4.0 Hz, 1H, H-1′), 4.899 (d, $J_{1,2}$ = 1.5 Hz, 1H, H-1), 4.021 (ddd, $J_{2',3'eq}$ = 6.0 Hz, $J_{2',3'ax}$ = 11.5 Hz, 1H, H-2′), 4.006 (q, $J_{5',6'}$ = 7.0 Hz, 1H, H-5′), 3.912 (dd, $J_{2,3}$ = 3.5 Hz, $J_{3,4}$ = 10.0 Hz, 1H, H-3), 3.86–3.91 (m, 2H, H-6a, H-4′), 3.835 (t, $J_{4,5}$ = 10.0 Hz, 1H, H-4), 3.74–3.80 (m, 3H, H-2, H-6b, CH_2CH$_2$NHAc), 3.67–3.72 (m, 1H, CH_2CH$_2$NHAc), 3.648 (ddd, $J_{5,6a}$ = 2.5 Hz, $J_{5,6b}$ = 6.5 Hz, 1H, H-5), 3.426 (s, 3H, OCH_3), 3.33–3.42 (m, 2H, 2 × CH$_2$CH_2NHAc), 1.94–2.01 (m, 5H, H-3′ax, H-3′eq, NHCOCH_3), 1.174 (d, $J_{5',6'}$ = 7.0 Hz, 3H, H-6′). ^{13}C NMR (D_2O) δ: 174.986 (C=O), 101.297 (C-1′, $^1J_{C,H}$ = 169.9 Hz), 98.892 (C-1, $^1J_{C,H}$ = 170.7 Hz), 79.090 (C-3), 78.005 (C-2), 73.566 (C-5), 69.995 (O*C*H$_2$CH$_2$NHAc), 69.116 (C-4′), 67.841 (C-5′), 67.334 (C-4), 64.294 (C-2′), 61.669 (C-6), 55.712 (O*C*H$_3$), 40.305 (OCH$_2$*C*H$_2$NHAc), 33.853 (C-3′), 22.756 (NHCO*C*H$_3$), 16.346 (C-6′). Methyl 6-*O*-benzoyl-2,3-*O*-isopropylidene-α-D-talopyranoside (28)

The known mannoside **27** (37) (3.0 g, 8.88 mmol) was dissolved in CH_2Cl_2 (70 mL) and stirred with crushed 4 Å molecular sieves (10 g) for 15 min. Pyridinium chlorochromate (9.6 g, 44.37 mmol) was added and the reaction stirred for 4 h at which point there was a complete conversion to the ketone (R_f = 0.51, hexane–EtOAc, 2:1). The reaction was filtered through Celite and then washed with water and a saturated solution of NaCl. After drying (Na_2SO_4) and evaporation of the organic layer, the resulting residue was dried for 1 h under vacuum. The black solid was dissolved in CH_3OH (50 mL) and $NaBH_4$ (336 mg, 8.88 mmol) added. After stirring for 10 min, the reaction was quenched by adding acetic acid until the pH was neutral. The solvent was evaporated and then the residue chromatographed (hexane–EtOAc, 1:1) to give the product **28** (2.54 g, 85%) as a crystalline solid; mp 111 to 112°C. $[\alpha]_D$ +39.1 (*c* 1.0, $CHCl_3$). R_f = 0.40 (hexane–EtOAc, 2:1). ^{1}H NMR ($CDCl_3$) δ: 7.30–8.10 (m, 5H, Ph), 5.01 (s, 1H, H-1), 4.53–4.67 (m, 2H, H-6a, H-6b), 4.24 (t, $J_{5,6a}$, $J_{5,6b}$ = 5.0 Hz, H-5), 4.03–4.10 (m, 2H, H-2, H-3), 3.84 (t, $J_{3,4}$, $J_{4,4\text{-OH}}$ = 6.0 Hz, H-4), 3.42 (s, 3H, OCH_3), 2.41 (d, 1H, 4-OH), 1.59, 1.39 (s, 3H, C(CH_3)$_2$). ^{13}C NMR ($CDCl_3$) δ: 166.36 (C=O), 109.62 (O_2C(CH$_3$)$_2$), 98.50 (C-1), 66.43 (C-6), 55.19 (O*C*H$_3$), 25.90, 25.17 (O_2C(*C*H$_3$)$_2$). Anal. calcd. for $C_{17}H_{22}O_7$ (338.36): C 60.35, H 6.55; found: C 60.35, H 6.65.

Methyl 2,3-*O*-isopropylidene-α-D-talopyranoside (29)

Benzoate **28** (10.0 g, 29.58 mmol) was dissolved in CH_3OH (125 mL) and $NaOCH_3$ (200 mg) was added. After stirring overnight, the solution was neutralized with Amberlite IR-120 (H+) resin, filtered and evaporated. Chromatography (hexane–EtOAc, 1:1) gave **29** (6.37 g, 92%) as a white foam. $[\alpha]_D$ +42.2 (*c* 1.5, $CHCl_3$). R_f = 0.18 (hexane–EtOAc, 1:1). ^{1}H NMR ($CDCl_3$) δ: 4.99 (s, $J_{1,2}$ = 1.0 Hz, 1H, H-1), 4.26 (dd, $J_{3,4}$ = 6.5 Hz, 1H, H-3), 4.07 (dd, $J_{2,3}$ = 5.0 Hz, 1H, H-2), 4.00 (ddd, $J_{5,6a}$ = 4.0 Hz, $J_{6a,6b}$ = 12.5 Hz, $J_{6a,6\text{-OH}}$ = 7.5 Hz, 1H, H-6a), 3.78–3.88 (m, 3H, H-4, H-5, H-6b), 3.44 (s, 3H, OCH_3), 2.50 (d, $J_{4,4\text{-OH}}$ = 5.5 Hz, 1H, 4-OH), 2.26–2.32 (m, 1H, 6-OH), 1.57, 1.39 (s, 3H, C(CH_3)$_2$). ^{13}C NMR ($CDCl_3$) δ: 109.63 (O_2C(CH$_3$)$_2$), 98.72 (C-1), 62.82 (C-6), 55.36 (O*C*H$_3$), 25.90, 25.08 (O_2C(*C*H$_3$)$_2$). Anal. calcd. for $C_{10}H_{18}O_6$ (234.25): C 51.27, H 7.74; found: C 51.21, H 7.69.

Methyl 4,6-di-*O*-benzyl-2,3-*O*-isopropylidene-α-D-talopyranoside (30)

Diol **29** (850 mg, 3.62 mmol) was dissolved in DMF (50 mL) and cooled to 0°C. Sodium hydride (400 mg, 80% dispersion in oil, 13.3 mmol) was added and the mixture stirred for 15 min. To this solution was added benzyl bromide (1.5 mL, 12.6 mmol) and the reaction stirred overnight while being allowed to warm to room temperature. The reaction was then quenched with CH_3OH and the solution partitioned between water with CH_2Cl_2. The organic layer was washed with water and a saturated solution of NaCl, and then dried (Na_2SO_4), and evaporated. Chromatography (pentane–EtOAc, 6:1) gave **30** (1.45 g, 97%) as an oil. $[\alpha]_D$ +1.1 (*c* 0.9, $CHCl_3$). R_f = 0.42 (pentane–EtOAc, 6:1). ^{1}H NMR ($CDCl_3$) δ: 7.25–7.35 (m, 10H, Ph), 4.88 (s, $J_{1,2}$ = 2.0 Hz, 1H, H-1), 4.85, 4.52, 4.49, 4.43 (4d, ^2J = 11.5 Hz, 8H, PhCH_2), 4.36 (dd, $J_{3,4}$ = 7.0 Hz, 1H, H-3), 4.06 (dd, $J_{2,3}$ = 4.5 Hz, 1H, H-2), 3.96 (ddd, $J_{4,5}$ = 3.0 Hz, $J_{5,6a}$ = 4.0 Hz, $J_{5,6b}$ = 5.5 Hz, 1H, H-5), 3.81 (dd, $J_{4,5}$ = 3.0 Hz, 1H, H-4), 3.71 (dd, $J_{5,6a}$ = 7.0 Hz, $J_{6a,6b}$ = 10.0 Hz, 1H, H-6a), 3.55 (dd, $J_{5,6b}$ = 5.5 Hz, 1H, H-6b), 3.42 (s, 3H, OCH_3), 1.52, 1.36 (s, 3H, C(CH_3)$_2$). ^{13}C NMR ($CDCl_3$) δ: 110.06 (O_2C(CH$_3$)$_2$), 98.93 (C-1), 74.41, 73.40 (PhCH_2), 69.75 (C-6), 55.56 (O*C*H$_3$), 26.18, 25.37 (O_2C(*C*H$_3$)$_2$). Anal.

Methyl 2-*O*-benzoyl-4,6-di-*O*-benzyl-α-D-talopyranoside (32)

Compound **31** (500 mg, 1.34 mmol) was dissolved in CH_2Cl_2 (10 mL) and triethylorthoformate (2.3 mL, 13.4 mmol) was added followed by *p*-TsOH (20 mg). The reaction was complete after stirring for 5 h as indicated by the appearance of a new TLC spot (R_f = 0.55, pentane–EtOAc, 3:1). The acid was neutralized with triethylamine and the solvent evaporated. The residue was redissolved immediately in 80% acetic acid (25 mL), stirred for 30 min, and evaporated. Chromatography (pentane–EtOAc, 3:1) of the resulting oil provided the product **32** (520 mg, 81%) as an oil. ^{1}H NMR ($CDCl_3$) δ: 7.10–7.90 (m, 15H, Ph), 5.12 (ddd, $J_{2,3}$ = 4.5 Hz, $J_{2,4}$ = 0.5 Hz, 1H, H-2), 4.87 (d, $J_{1,2}$ = 1.0 Hz, 1H, H-1), 4.76, 4.66, 4.63, 4.48 (4d, ^2J = 11.5 Hz, 4H, PhCH_2), 4.08–4.16 (m, 2H, H-3, H-5), 3.91–3.96 (m, 2H, H-4, H-6a), 3.75 (dd, $J_{5,6a}$ = 6.0 Hz, $J_{6a,6b}$ = 9.5 Hz, 1H, H-6a), 3.41 (s, 3H, OCH_3), 2.72 (d, $J_{3,3\text{-OH}}$ = 10.0 Hz, 1H, 3-OH).

Methyl 2-*O*-benzoyl-4,6-di-*O*-benzyl-3-*O*-(2,4-di-*O*-benzyl-3,6-dideoxy-α-D-*xylo*-hexopyranosyl)-α-D-talopyranoside (34)

Alcohol **32** (500 mg, 1.04 mmol) and donor **33** (38) (506 mg, 1.36 mmol) were dried with crushed 4 Å molecular sieves over P_2O_5 under vacuum overnight. The solids were suspended in CH_2Cl_2 (40 mL) and cooled to –40°C. *N*-Iodosuccinimide (310 mg, 1.36 mmol) and silver triflate (30 mg, 0.12 mmol) were then added. After 15 min, the reaction turned dark red and the reaction was allowed to proceed for another 15 min at which point it was quenched with triethylamine. After diluting with CH_2Cl_2 the solution was washed in succession with a saturated solution of sodium thiosulfate, water, a saturated solution of NaCl, and then dried (Na_2SO_4). Evaporation of the solvents and chromatography (pentane–EtOAc, 6:1) gave the product **34** (680 mg, 83%) as an oil. $[\alpha]_D$ +16.2 (*c* 0.9, $CHCl_3$). R_f = 0.38 (pentane–EtOAc, 6:1). ^{1}H NMR ($CDCl_3$) δ: 7.05–8.00 (m, 25H, Ph), 5.35 (m, 1H, H-2), 5.18 (d, ^2J = 12.0 Hz, 1H, PhCH_2), 4.89 (d, $J_{1,2}$ = 1.0 Hz, 1H, H-1), 4.50–4.64 (m, 6H, PhCH_2), 4.41 (d, ^2J = 12.0 Hz, 1H, PhCH_2), 4.16 (t, $J_{2,3} \approx J_{3,4}$ = 3.5 Hz, 1H, H-3), 4.09 (dt, $J_{4,5}$ = 1.0 Hz, $J_{5,6b}$ = 6.0 Hz, 1H, H-5), 3.90–3.98 (m, 2H, H-4, H-2′), 3.86 (dd, $J_{5,6a}$ = 6.0 Hz, $J_{6a,6b}$ = 9.5 Hz, 1H, H-6a), 3.78 (dd, $J_{5,6b}$ = 6.0 Hz, 1H, H-6b), 3.42 (s, 3H, OCH_3), 3.35 (br. s, 1H, H-4′), 2.11 (dt, $J_{2,3e'} \approx J_{3e',4}$ = 3.5 Hz, $J_{3'eq,3'ax}$ = 13.0 Hz, 1H, H-3′eq), 1.82 (dt, $J_{3'ax,4}$ = 13.0 Hz, $J_{2',3'ax}$ = 2.5 Hz, 1H, H-3′ax), 1.08 (d, $J_{5'6'}$ = 6.5 Hz, 3H, H-6′). ^{13}C NMR ($CDCl_3$) δ: 166.31 (C=O), 98.96 (C-1), 97.70 (C-1′), 74.38, 73.33, 71.07, 70.79 (PhCH_2), 69.24 (C-6), 54.86 (OCH_3), 27.42 (C-3′), 16.03 (C-6′). 1,2,3,4,6-Penta-*O*-acetyl-α-D-talopyranose (41)

Methyl glycoside **40** (5.5 g, 15.2 mmol) was dissolved in acetic anhydride (120 mL) and the solution cooled to 0°C. H_2SO_4 (400 μL) was added dropwise from a microsyringe and the reaction allowed to continue for 2 h at 0°C. The reaction was quenched by adding CH_2Cl_2 and then a solution of $NaHCO_3$ and stirring for 20 min. The reaction was diluted with more CH_2Cl_2 and then washed with $NaHCO_3$, water, and a saturated solution of NaCl. After drying (Na_2SO_4) and evaporation of the solvent, the product **41** (5.6 g, 95%) was obtained as a white crystalline solid; mp 103–105°C (lit. (40) value mp +104 to 105°C). $[\alpha]_D$ +68.8 (*c* 1.3, $CHCl_3$) (lit. (40) value $[\alpha]_D$ +68° (*c* 0.6)). R_f = 0.28 (hexane–EtOAc, 2:1). ^{1}H NMR ($CDCl_3$) δ: 6.12 (d, $J_{1,2}$ = 2.0 Hz, 1H, H-1), 5.34 (br. d, $J_{3,4}$ = 3.5 Hz, 1H, H-4), 5.29 (t, $J_{2,3}$ = 3.5 Hz, 1H, H-3), 5.08 (ddd, $J_{2,4}$ = 1.0 Hz, 1H, H-2), 4.30 (dt, $J_{4,5}$ = 1.5, 7.0 Hz, 1H, H-5), 4.18 (dd, $J_{6a,6b}$ = 11.0 Hz, $J_{5,6a}$ = 7.0 Hz, 1H, H-6a), 4.12 (dd, $J_{5,6b}$ = 7.0 Hz, 1H, H-6b), 2.13 (s, 6H, 2 × OCOCH_3), 2.12, 2.02, 1.99 (s, 3H, OCOCH_3). ^{13}C NMR ($CDCl_3$) δ: 170.37, 170.07, 169.64, 169.65, 168.02 (*C*=O) 91.14 (C-1), 61.41 (C-6), 20.82, 20.72, 20.60, 20.52 (OCO*C*H_3). Anal. calcd. for $C_{16}H_{22}O_{11}$ (390.35): C 49.23, H 5.68; found: C 49.26, H 5.63.

2,3,4,6-Tetra-*O*-acetyl-α-D-talopyranosyl bromide (42)

The peracetate **41** (500 mg, 1.28 mmol) was stirred with 45% HBr in acetic acid (10 mL) and acetic anhydride (1 mL) for 2 h. The solution was then evaporated to provide, in quantitative yield as determined by ^{1}H NMR, **42** as a yellow oil. Attempts to purify the product by flash chromatography resulted in complete decomposition of the bromide. ^{1}H NMR ($CDCl_3$) δ: 6.41 (s, 1H, H-1), 5.70 (t, $J_{2,3}$ = 3.5 Hz, 1H, H-3), 5.53 (br. d, $J_{3,4}$ = 3.5 Hz, 1H, H-4), 5.42 (d, $J_{2,3}$ = 3.5 Hz, 1H, H-2), 4.49 (br. t, $J_{5,6a}$, $J_{5,6b}$ = 6.0 Hz, 1H, H-5), 4.26 (dd, $J_{6a,6b}$ = 10.5 Hz, 1H, H-6a), 4.20 (dd, $J_{5,6b}$ = 6.5 Hz, 1H, H-6b), 2.03, 2.00, 1.90, 1.85 (s, 3H, OCOCH_3).

Ethyl 3,4-*O*-isopropylidene-1-thio-β-D-galactopyranoside (46)

The deprotected thioglycoside **45** (41) (285 mg, 1.28 mol) was suspended in dry CH_3CN (5 mL) and dimethoxypropane (785 μL, 6.40 mmol) was added followed by *p*-TsOH (15 mg). After 10 min the solid was dissolved and the reaction was allowed to proceed for 2 h. Water (1 mL) was added and the reaction stirred for 30 min before being neutralized with triethylamine and evaporated. Chromatography (EtOAc) gave the product **46** (222 mg, 66%) as a white crystalline solid; mp 88–91°C. $[\alpha]_D$ +13.9 (*c* 0.9, $CHCl_3$). R_f = 0.55 (EtOAc). ^{1}H NMR ($CDCl_3$) δ: 4.21 (dd, $J_{4,5}$ = 2.0 Hz, 1H, H-4), 4.27 (d, $J_{1,2}$ = 10.0 Hz, 1H, H-1), 4.09 (dd, $J_{3,4}$ = 5.5 Hz, 1H, H-3), 3.76–4.01 (m, 3H, H-6a, H-6b, H-5), 3.56 (ddd, $J_{2,3}$ = 7.0 Hz, $J_{2,2\text{-OH}}$ = 2.0 Hz, 1H, H-2), 2.70–2.80 (m, 2H, SCH_2CH$_3$), 2.45 (d, 1H, 2-OH), 2.10 (dd, $J_{6a,6\text{-OH}}$ = 4.0 Hz, $J_{6b,6\text{-OH}}$ = 9.5 Hz, 1H), 1.51, 1.35 (s, 3H, (CH_3)$_2$CO$_2$), 1.32 (t, ^3J = 6.5 Hz, 1H, SCH$_2$CH_3). ^{13}C NMR ($CDCl_3$) δ: 110.18 ((CH$_3$)$_2$*C*O$_2$), 85.23 (C-1), 62.25 (C-6), 28.03, 26.21 ((*C*H$_3$)$_2$CO$_2$), 24.30 (S*C*H$_2$CH$_3$), 15.18 (SCH$_2$*C*H$_3$). Anal. calcd. for $C_{11}H_{20}O_5S$ (264.34): C 49.98, H 7.63, S 12.13; found: C 50.16, H 7.96, S 12.04.

Ethyl 3,4-*O*-isopropylidene-6-*O*-*tert*-butyldimethylsilyl-1-thio-β-D-galactopyranoside (47)

Diol **46** (600 mg, 2.26 mole) was dissolved in dry pyridine (30 mL) and then *tert*-butyldimethylsilyl chloride (408 mg, 2.71 mmol) was added followed by DMAP (15 mg). The reaction was stirred overnight and then diluted with CH_2Cl_2 and washed successively with 0.5 N HCl, water, and a saturated solution of NaCl. After drying (Na_2SO_4), the organic layer was evaporated. Chromatogaphy (hexane–EtOAc, 2:1) gave the product **47** (700 mg, 85%) as an oil. $[\alpha]_D$ –5.1 (*c* 0.9, $CHCl_3$). R_f = 0.68 (hexane–EtOAc, 2:1). ^{1}H NMR ($CDCl_3$) δ: 4.25 (dd, $J_{3,4}$ = 5.5 Hz, $J_{4,5}$ = 2.5 Hz, 1H, H-4), 4.24 (d, $J_{1,2}$ = 10.0 Hz, 1H, H-1), 4.04 (dd, $J_{2,3}$ = 7.0 Hz, 1H, H-3), 3.78–3.89 (m, 3H, H-6a, H-6b, H-5), 3.55 (ddd, $J_{2,2\text{-OH}}$ = 2.0 Hz, 1H, H-2) 2.65–2.80 (m, 2H, SCH_2CH$_3$), 2.37 (d, $J_{2,2\text{-OH}}$ = 2.0 Hz, 1H, 2-OH), 1.53, 1.35 (s, 3H, (CH_3)$_2$CO$_2$), 1.32 (t, ^3J = 6.5 Hz, 1H, SCH$_2$CH_3), 0.90 (s, 9H, SiC(CH_3)$_3$), 0.08 (s, 6H, Si(CH_3)$_2$). ^{13}C NMR ($CDCl_3$) δ: 109.97 ((CH$_3$)$_2$*C*O$_2$), 85.58 (C-1), 62.10 (C-6), 28.28, 26.29 ((*C*H$_3$)$_2$CO$_2$), 25.82 (SiC(*C*H$_3$)$_3$), 24.46 (S*C*H$_2$CH$_3$), 18.26 (Si*C*(CH$_3$)$_3$), 15.39 (SCH$_2$*C*H$_3$), –5.34, –5.50 (Si(*C*H$_3$)$_2$). Anal. calcd. for $C_{17}H_{34}O_5SSi$ (378.60): C 53.93, H 9.05, S 8.47; found: C 54.06, H 8.95, S 8.52.

Ethyl 3,4-*O*-isopropylidene-6-*O*-*tert*-butyldimethylsilyl-1-thio-β-D-talopyranoside (48)

Oxalyl chloride (220 μL, 1.98 mmol) was dissolved in CH_2Cl_2 (10 mL) and cooled to –78°C. To this solution was added dropwise DMSO (310 μL, 4.36 mmol) in CH_2Cl_2 (10 mL). When the solution had stirred for 30 min, **47** (500 mg, 1.32 mmol) dissolved in CH_2Cl_2 (10 mL) was added dropwise over 10 min. After stirring for another 20 min and warming to –60°C, triethylamine (1.2 mL, 8.85 mmol) was added and the reaction brought to room temperature. After 40 min, water was added and the layers separated. The organic layer was washed with water, a saturated solution of NaCl, and then dried (Na_2SO_4). Evaporation of the solvent provided a residue that was immediately

© 2002 NRC Canada

dissolved in methanol (50 mL) and then $NaBH_4$ (100 mg, 2.64 mmol) was added. After stirring for 20 min, the reaction was quenched with acetic acid and the solvent evaporated. TLC indicated a mixture of two easily separable products (R_f = 0.66 and 0.61 (hexane–EtOAc, 2:1)), which were later shown to be an anomeric mixture of talopyranosides. The residue was coevaporated with CH_3OH (3 × 50 mL) and the residue chromatographed (hexane–EtOAc, 3:1). The two products **48** were isolated as oils, the β-glycoside (343 mg, 69% yield) and the α-glycoside (81 mg, 16% yield). Only the β-glycoside was fully characterized. $[\alpha]_D$ –34.6 (*c* 0.7, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 4.52 (d, $J_{1,2}$ = 1.5 Hz, 1H, H-1), 4.16–4.22 (m, 2H, H-3, H-4), 3.76–3.94 (m, 4H, H-5, H-6a, H-6b, H-2), 2.65–2.76 (m, 2H, SCH_2CH_3), 2.42 (d, $J_{2,2\text{-OH}}$ = 8.5 Hz, 1H, 2-OH), 1.58, 1.36 (s, 3H, $(CH_3)_2CO_2$), 1.30 (t, ^3J = 6.5 Hz, 1H, SCH_2CH_3), 0.84 (s, 9H, $SiC(CH_3)_3$), 0.08 (s, 6H, $Si(CH_3)_2$). ^{13}C NMR ($CDCl_3$) δ: 109.80 ($(CH_3)_2CO_2$), 84.42 (C-1), 62.13 (C-6), 25.81 ($SiC(CH_3)_3$), 25.74 ($(CH_3)_2CO_2$), 25.71 (SCH_2CH_3), 25.49 ($(CH_3)_2CO_2$), 18.25 ($SiC(CH_3)_3$), 15.24 (SCH_2CH_3), –5.36, –5.50 ($Si(CH_3)_2$). Ethyl 2,3,4,6-tetra-*O*-acetyl-1-thio-β-D-talopyranoside (43)

Acetal **48** (279 mg, 0.74 mmol) was dissolved in 80% acetic acid (35 mL) and the solution heated for 1 h at 80°C. The solution was cooled, the solvent evaporated and the residue immediately dissolved in pyridine (20 mL). Following the addition of acetic anhydride (5 mL) and DMAP, the reaction was stirred overnight before being quenched by cooling to 0°C and adding CH_3OH. The mixture was then diluted with CH_2Cl_2 and washed with 0.5 N HCl, water, and a saturated solution of NaCl. After drying (Na_2SO_4) and evaporation, chromatography (hexane–EtOAc, 2:1) gave the product **43** (258 mg, 89%) as an oil. $[\alpha]_D$ –53.8 (*c* 1.0, $CHCl_3$). R_f = 0.33 (hexane–EtOAc, 2:1). ^{1}H NMR ($CDCl_3$) δ: 5.37 (dd, $J_{3,4}$ = 3.5 Hz, $J_{4,5}$ = 1.5 Hz, 1H, H-4), 5.27 (dd, $J_{2,3}$ = 3.5 Hz, 1H, H-2), 5.08 (t, 1H, H-3), 4.76 (d, $J_{1,2}$ = 1.0 Hz, 1H, H-1), 4.21 (dd, $J_{5,6a}$ = 7.0 Hz, $J_{6a,6b}$ = 11.5 Hz, 1H, H-6a), 4.15 (dd, $J_{5,6b}$ = 7.0 Hz, 1H, H-6b), 3.92 (dt, $J_{4,5}$ = 1.5 Hz, 1H, H-5), 2.73 (q, ^3J = 6.5 Hz, 2H, SCH_2CH_3), 2.13, 2.09, 2.01, 1.94 (s, 3H, $OCOCH_3$), 1.28 (t, 1H, ^3J = 6.5 Hz, SCH_2CH_3). ^{13}C NMR ($CDCl_3$) δ: 170.37, 170.15, 170.03, 169.52 (C=O), 83.24 (C-1), 61.81 (C-6), 25.75 (SCH_2CH_3), 20.61, 20.53, 20.47, 20.35 ($OCOCH_3$), 14.96 (SCH_2CH_3). Anal. calcd. for $C_{10}H_{18}O_5S$ (392.42): C 48.97, H 6.16, S 8.17; found: C 49.18, H 6.09, S 8.22.

Methyl 2-*O*-(2,3,4,6-tetra-*O*-acetyl-α-D-talopyranosyl)-3-*O*-(2,4-di-*O*-benzyl-3,6-dideoxy-α-D-*xylo*-hexopyranosyl)-4,6-di-*O*-benzyl-α-D-mannopyranoside (44)

Talose donor **43** (114 mg, 0.292 mmol) and disaccharide **20** (35) (50 mg, 0.73 mmol) were dried with crushed 4 Å molecular sieves (300 mg) under vacuum with P_2O_5. The solids were suspended in CH_2Cl_2 (5 mL) and the solution cooled to 0°C. Upon stirring for 30 min, *N*-iodosuccinimide (65 mg, 0.292 mmol) and silver triflate (7.5 mg, 0.029 mmol) were added. The reaction was quenched with triethylamine after 1 h and the reaction mixture diluted with CH_2Cl_2, filtered, and then the organic layer washed with a saturated solution of sodium thiosulfate, water and a saturated solution of NaCl. After drying (Na_2SO_4) and evaporation of the solvent, the product was purified by chromatography (hexane–EtOAc, 1:1) to give **44** (35 mg, 47%) as an oil. $[\alpha]_D$ +69.1 (*c* 1.1, $CHCl_3$). R_f = 0.54 (hexane–EtOAc, 1:1). ^{1}H NMR ($CDCl_3$) δ: 7.10–7.50 (m, 20H, Ph), 5.27 (t, $J_{2'',3''}$, $J_{3'',4''}$ = 3.5 Hz, 1H, H-3″), 5.24 (br. s, 1H, H-2″), 5.17 (br. s, 1H, H-4″), 5.11 (br. s, 1H, H-1′), 5.06 (d, J_{gem} = 11.5 Hz, 1H, $PhCH_2$), 5.05 (s, 1H, H-1″), 4.93 (d, $J_{1,2}$ = 2.0 Hz, 1H, H-1), 4.34–4.60 (m, 7H, 7 × $PhCH_2$, H-5′), 4.20 (dd, $J_{5'',6a''}$ = 6.0 Hz, $J_{6a'',6b''}$ = 11.5 Hz, 1H, H-6a″), 4.15 (dd, $J_{2,3}$ = 2.5 Hz, $J_{3,4}$ = 9.5 Hz, 1H, H-3), 4.04 (dd, $J_{5'',6b''}$ = 7.0 Hz, 1H, H-6b″), 3.93–4.00 (m, 2H, H-4, H-2), 3.88 (dd, $J_{5'',6a''}$ = 6.0 Hz, 1H, H-5″), 3.81 (dt, $J_{2',3'eq}$ = 3.5 Hz, $J_{2',3'ax}$ = 12.5 Hz, 1H, H-2′), 3.70–3.76 (m, 1H, H-5), 3.60–3.69 (m, 2H, H-6a, H-6b), 3.54 (br. s, 1H, H-4′), 3.37 (s, 3H, OCH_3), 1.90–2.15 (m, 14H, 12 × $OCOCH_3$, H-3′ax, H-3′eq), 1.12 (d, $J_{5',6'}$ = 6.5 Hz, 1H, H-6′). ^{13}C NMR ($CDCl_3$) δ: 170.48, 170.10, 169.78, 169.32 (C=O), 100.35 (C-1), 99.78 (C-1″), 99.00 (C-1′), 74.69 ($PhCH_2$), 73.20 ($PhCH_2$), 71.43, 70.81 ($PhCH_2$), 69.21 (C-6), 62.58 (C-6″), 54.96 (OCH_3), 27.56 (C-3′), 20.89, 20.74, 20.69 ($OCOCH_3$), 16.47 (C-6′). Methyl 2-*O*-(α-D-talopyranosyl)-3-*O*-(3,6-dideoxy-α-D-*xylo*-hexopyranosyl)-α-D-mannopyranoside (14)

Trisaccharide **44** (51 mg, 0.05 mmol) was dissolved in CH_3OH (5 mL) and then $NaOCH_3$ (15 mg) was added. The reaction was stirred overnight and neutralized with Amberlite IR-120 (H+) resin. The solution was filtered, the filtrate evaporated and the residue immediately redissolved in acetic acid (10 mL). 10% Pd/C (30 mg) was added, and the reaction was stirred under a flow of H_2 overnight. The catalyst was filtered off and the solvent evaporated to yield a yellow residue. The colored impurities were removed by redissolution in water and filtration through a C-18 reverse-phase cartridge. The filtrate was evaporated and then passed through a Biogel P-2 column using water as the eluant. Concentration of the product by evaporation, filtration through a 0.22 μM filter and lyophilization gave the product **14** (21.2 mg, 87%) as an amorphous white solid. $[\alpha]_D$ +99.0 (*c* 0.7, H_2O). ^{1}H NMR (D_2O) δ: 5.205 (s, 1H, H-1″), 5.097 (d, $J_{1',2'}$ = 3.5 Hz, 1H, H-1′), 5.028 (d, $J_{1,2}$ = 2.0 Hz, 1H, H-1), 4.101 (dd, $J_{2,3}$ = 3.0 Hz, 1H, H-2), 4.01–4.07 (m, 3H, H-2′, H-5′, H-5″), 3.983 (dd, $J_{3,4}$ = 10.0 Hz, 1H, H-3), 3.91–3.97 (m, 3H, H-2″, H-3″, H-4″), 3.88–3.97 (m, 2H, H-6a, H-4′), 3.871 (t, $J_{4,5}$ = 10.0 Hz, 1H, H-4), 3.820 (dd, $J_{5,6'a}$ = 8.0 Hz, $J_{6''a,6''b}$ = 12.0 Hz, 1H, H-6″a), 3.74–3.79 (m, 2H, H-6b, H-6″b), 3.653 (ddd, $J_{5,6a}$ = 2.0 Hz, $J_{5,6b}$ = 6.0 Hz, 1H, H-5), 3.438 (s, 3H, OCH_3), 1.90–2.04 (m, 2H, H-3′ax, H-3′eq), 1.194 (d, $J_{5',6'}$ = 6.5 Hz, 3H, H-6′). ^{13}C NMR (D_2O) δ: 103.273 (C-1″, $^1J_{C,H}$ = 172.2 Hz), 101.15 (C-1′, $^1J_{C,H}$ = 170.8 Hz), 100.916 (C-1, $^1J_{C,H}$ = 174.5 Hz), 79.868 (C-3), 78.453 (C-2), 73.539 (C-5), 72.950 (C-5″), 71.085 (C-4″), 70.481 (C-2″), 69.037 (C-4′), 68.021 (C-5′), 67.404 (C-4), 65.976 (C-3″), 64.245 (C-2′), 62.426 (C-6″), 61.629 (C-6), 55.681 (OCH_3), 33.776 (C-3′), 16.324 (C-6′). Anal. calcd. for $C_7H_{10}Cl_4O_5S$ (352.03): C 23.88, H 2.86, S 9.11; found: C 24.41, H 2.91, S 9.45.

Methyl 4,6-dichloro-4,6-dideoxy-3-*O*-methyl-α/β-D-galactopyranoside (52)

Glycosyl chloride **51** (150 mg, 0.43 mmol) was dissolved in CH_3OH (5 mL), a few crystals of I_2 were added, and the reaction stirred for 48 h. Water (200 μL) was added and the reaction stirred for an additional 4 h. The solvent was then evaporated, coevaporating twice with toluene. The residue was then dissolved in 1 M $NaOCH_3$ (300 μL) and stirred overnight at which point the reaction pH had become slightly acidic. The solvent was evaporated and chromatographed (1:1 hexane–EtOAc) to give **52** as two separable anomers. Both the α-anomer (44 mg, 42%) and β-anomer (26 mg, 25%) were obtained as amorphous solids. α-Anomer: $[\alpha]_D$ +192.8 (*c* 0.7, $CHCl_3$). R_f = 0.25 (hexane–EtOAc, 1:1). ^{1}H NMR ($CDCl_3$) δ: 4.83 (d, $J_{1,2}$ = 3.5 Hz, 1H, H-1), 4.56 (d, $J_{3,4}$ = 2.5 Hz, 1H, H-4), 4.09 (br. t, $J_{5,6a}$, $J_{5,6b}$ = 6.5 Hz, 1H, H-5), 3.97 (dd, $J_{2,3}$ = 9.5 Hz, 1H, H-2), 3.66–3.68 (m, 2H, H-6a, H-6b), 3.60 (dd, 1H, H-3), 3.47 (s, 3H, OCH_3), 3.36 (s, 3H, OCH_3). ^{13}C NMR ($CDCl_3$) δ: 99.41 (C-1). Anal. calcd. for $C_8H_{14}O_4Cl_2$ (247.10): C 39.89, H 5.71; found: C 39.32, H 5.75. β-Anomer: $[\alpha]_D$ +32.8 (*c* 0.4, $CHCl_3$). R_f = 0.20, (hexane–EtOAc, 1:1). ^{1}H NMR ($CDCl_3$) δ: 4.56 (d, $J_{3,4}$ = 3.5 Hz, 1H, H-4), 4.24 (d, $J_{1,2}$ = 7.5 Hz, 1H, H-1), 3.69–3.80 (m, 4H, H-5, H-2, H-6a, H-6b), 3.55 (s, 3H, OCH_3), 3.48 (s, 3H, OCH_3), 3.39 (dd, $J_{2,3}$ = 9.5 Hz, 1H, H-3). ^{13}C NMR ($CDCl_3$) δ: 104.25 (C-1). Anal. calcd. for $C_8H_{14}O_4Cl_2$ (247.10): C 39.89, H 5.71; found: C 39.12, H 5.85.

Methyl 2-*O*-benzyl-4,6-dichloro-4,6-dideoxy-3-*O*-methyl-α-D-galactopyranoside (53)

To a stirred suspension of **52** (49 mg, 0.2 mmol) and powdered NaOH (12 mg, 0.3 mmol) in DMF (3 mL) was added benzyl bromide (31 μL, 0.26 mmol). The reaction was instantaneous and was immediately quenched with CH_3OH. The reaction was diluted with toluene and washed with water and then a saturated solution of NaCl. After drying ($MgSO_4$) and solvent evaporation, the product was titrated with hexane to give **53** (48 mg, 71%) as an amorphous white solid. $[\alpha]_D$ +83.3 (*c* 0.7, $CHCl_3$). R_f = 0.60 (hexane–EtOAc, 3:1). ^{1}H NMR ($CDCl_3$) δ: 7.14–7.25 (m, 5H, Ph), 4.74, 4.50 (d, ^2J = 12.0 Hz, 1H, PhCH_2), 4.48 (d, $J_{1,2}$ = 4.0 Hz, 1H, H-1), 4.46 (br. s, 1H, H-4), 3.98 (br. t, $J_{5,6a}$, $J_{5,6b}$ = 6.5 Hz, 1H, H-5), 3.69 (m, 2H, H-2, H-3), 3.52 (m, 2H, H-6a, H-6b), 3.41 (s, 3H, OCH_3), 3.28 (s, 3H, OCH_3). ^{13}C NMR ($CDCl_3$) δ: 98.9 (C-1). Anal. calcd. for $C_{15}H_{20}Cl_2O_4$ (337.23): C 53.43, H 5.98; found: C 53.58, H 5.87.

1-*O*-Acetyl-2-*O*-benzyl-4,6-dichloro-4,6-dideoxy-α/β-D-galactopyranose (54)

Methyl glycoside **53** (250 mg, 0.75 mmol) was dissolved in acetic anhydride:HOAc:H_2SO_4 (50:20:0.5, 10 mL) and stirred at 0°C for 1 h and then at room temperature for 30 min. The reaction was quenched by pouring the solution into an ice cold $KHCO_3$ solution and then the product was extracted with CH_2Cl_2. The organic layer was washed with water and a saturated solution of NaCl and then dried ($MgSO_4$) and evaporated. Chromatography (hexane–EtOAc, 6:1) of the residue afforded **53** as two separable anomers. Both the α-anomer (185 mg, 68%) and the β-anomer (34 mg, 12%) were obtained as solids. α-Anomer: $[\alpha]_D$ +156.3 (*c* 0.5, $CHCl_3$). R_f = 0.35 (hexane–EtOAc, 4:1). ^{1}H NMR ($CDCl_3$) δ: 7.25–7.35 (m, 5H, Ph), 6.22 (d, $J_{1,2}$ = 4.0 Hz, 1H, H-1), 4.69 (d, ^2J = 11.5 Hz, 1H, PhCH_2), 4.66 (d, $J_{3,4}$ = 3.5 Hz, 1H, H-4), 4.60 (d, ^2J = 11.5 Hz, 1H, PhCH_2), 4.14 (ddd, $J_{5,6a}$ = 8.5 Hz, $J_{5,6b}$ = 5.5 Hz, $J_{4,5}$ = 0.5 Hz, 1H, H-5), 3.90 (dd, $J_{2,3}$ = 10.0 Hz, 1H, H-2), 3.76 (dd, 1H, H-3), 3.64 (dd, $J_{6a,6b}$ = 11.0 Hz, 1H, H-6a), 3.55 (dd, 1H, H-6b), 3.50 (s, 3H, OCH_3), 2.15 (s, 3H, OCOCH_3). ^{13}C NMR ($CDCl_3$) δ: 90.22 (C-1). Anal. calcd. for $C_{16}H_{20}Cl_2O_5$ (365.24): C 52.62, H 5.52; found: C 52.86, H 5.60. β-Anomer: $[\alpha]_D$ +25.5 (*c* 0.5, $CHCl_3$). R_f = 0.5 (hexane–EtOAc, 4:1). ^{1}H NMR ($CDCl_3$) δ: 7.26–7.33 (m, 5H, Ph), 5.56 (d, $J_{1,2}$ = 8.0 Hz, 1H, H-1), 4.83, 4.66 (d, ^2J = 11.5 Hz, 1H, PhCH_2), 4.60 (d, $J_{3,4}$ = 3.5 Hz, 1H, H-4), 3.87 (ddd, $J_{4,5}$ = 0.5 Hz, $J_{5,6a}$ = 8.0 Hz, $J_{5,6b}$ = 5.5 Hz, 1H, H-5), 3.71–3.76 (m, 2H, H-2, H-6a), 3.66 (d, $J_{6a,6b}$ = 11.0 Hz, 1H, H-6b), 3.50–3.64 (m, 4H, H-3, OCH_3), 2.01 (s, 3H, OCOCH_3). ^{13}C NMR ($CDCl_3$) δ: 93.87 (C-1). Anal. calcd. for $C_{16}H_{20}Cl_2O_5$ (365.24): C 52.62, H 5.52; found: C 52.89, H 5.50.

Ethyl 2-*O*-benzyl-4,6-dichloro-4,6-dideoxy-3-*O*-methyl-1-thio-α-D-galactopyranoside (55)

Compound **54** (40 mg, 0.11 mmol) was dissolved in CH_2Cl_2 (3 mL) and crushed 4 Å molecular sieves (40 mg) were added. Ethanethiol (50 μL, 0.65 mmol) and boron trifluoride etherate (50 μL, 0.4 mmol) were added and the

© 2002 NRC Canada

reaction stirred for 6 h. At this point additional ethanethiol (50 μL, 0.65 mmol) and boron trifluoride etherate (50 μL, 0.4 mmol) were added and the reaction was stirred overnight. The reaction was quenched by the addition of triethylamine (110 μL, 0.8 mmol), and the mixture filtered through Celite and evaporated. Chromatography (hexane–EtOAc, 6:1) of the residue gave **55** (4 mg, 10% and 13 mg, 32%) as an α/β mixture, both as solids. α-Anomer: $[\alpha]_D$ +205.7 (*c* 0.5, $CHCl_3$). R_f = 0.55 (hexane–EtOAc, 6:1). ^{1}H NMR ($CDCl_3$) δ: 7.24–7.37 (m, 5H, Ph), 5.28 (d, $J_{1,2}$ = 5.5 Hz, 1H, H-1), 4.71, 4.66 (d, ^2J = 12.0 Hz, 1H, PhC*H*$_2$), 4.57 (d, $J_{3,4}$ = 2.5 Hz, 1H, H-4), 4.54 (d, $J_{5,6}$ = 6.5 Hz, 1H, H-5), 4.06 (dd, $J_{2,3}$ = 9.5 Hz, 1H, H-2), 3.68–3.59 (m, 3H, H-3, H-6a, H-6b), 3.48 (s, 3H, OC*H*$_3$), 2.50–2.62 (m, 2H, SC*H*$_2$CH$_3$), 1.26 (d, 3H, ^3J = 7.5 Hz, SCH$_2$C*H*$_3$). ^{13}C NMR ($CDCl_3$) δ: 83.56 (C-1). Anal. calcd. for $C_{16}H_{22}Cl_2O_3S$ (367.32): C 52.32, H 6.04, S 8.73; found: C 52.12, H 6.22, S 8.56.

Methyl 2-*O*-(2-*O*-benzyl-4,6-dichloro-4,6-dideoxy-3-*O*-methyl-α-D-galactopyranosyl)-3-*O*-(2,4-di-*O*-benzyl-3,6-dideoxy-α-D-*xylo*-hexopyranosyl)-4,6-di-*O*-benzyl-α-D-mannopyranoside (56)

Thioglycoside donor **55** (22 mg, 0.06 mmol) and alcohol **20** (35) (38 mg, 0.06 mmol) were dissolved in CH_2Cl_2 (10 mL) and the flask purged with N_2. Crushed 4 Å molecular sieves (300 mg) were added and the mixture stirred for 2 h. *N*-Iodosuccinimide (31 mg, 13.8 mmol) was added followed by the dropwise addition of a previously prepared 0.13 M solution of TfOH in CH_2Cl_2. After adding 100 μL of this solution, the reaction was complete. Triethylamine (100 μL) was added and the suspension diluted with CH_2Cl_2 and filtered through Celite. The filtrate was washed successively with a saturated solution of $NaHCO_3$, 10% sodium thiosulfate, water, and a saturated solution of NaCl. After drying ($MgSO_4$) and evaporation of the solvent, the residue was chromatographed (hexane–EtOAc, 9:1) to provide **56** (39 mg, 73%) as a thick syrup. $[\alpha]_D$ +107.3 (*c* 0.9, $CHCl_3$). R_f = 0.40 (hexane–EtOAc, 9:1). ^{1}H NMR ($CDCl_3$) δ: 5.45 (d, $J_{1'',2''}$ = 2.0 Hz, 1H, H-1″), 5.21 (d, $J_{1',2'}$ = 3.0 Hz, 1H, H-1′), 5.02, 4.92 (d, ^2J = 11.5 Hz, 1H, PhC*H*$_2$), 4.89 (br. s, $J_{1,2}$ = 1.5 Hz, 1H, H-1), 4.78, 4.64, 4.50 (d, ^2J = 11.5 Hz, 3H, PhC*H*$_2$), 4.49 (br. s, 1H, H-4″), 4.20–4.29 (m, 7H, H-5″, H-3, 5 × PhC*H*$_2$), 4.11–4.17 (m, 1H, H-4), 4.04 (br. s, 1H, H-2), 4.03–4.08 (m, 1H, H-5′), 3.90 (m, 2H, H-2″, H-3″), 3.78 (m, 3H, H-2′, H-5, H-6a), 3.60–4.70 (m, 3H, H-6b, H-6″a, H-6″b), 3.44 (s, 3H, OC*H*$_3$), 3.40 (s, 3H, OC*H*$_3$), 3.05 (s, 1H, H-4′), 1.95–1.96 (dt, $J_{2',3'eq}$, $J_{3'eq,4'}$ = 3.5 Hz, $J_{3'eq,3'ax}$ = 13.0 Hz, 1H, H-3′eq), 1.73 (ddd, $J_{3'ax,4'}$ = 12.5 Hz, $J_{2',3'ax}$ = 2.0 Hz, 1H, H-3′ax), 1.15 (d, $J_{5',6'}$ = 6.5 Hz, 3H, H-6′). ^{13}C NMR ($CDCl_3$) δ: 99.38 (C-1), 98.95 (C-1′), 97.67 (C-1″). Anal. calcd. for $C_{55}H_{64}Cl_2O_{12}$ (990.02): C 66.73, H 6.52; found: C 66.91, H 6.70.

Methyl 2-*O*-(4,6-dichloro-4,6-dideoxy-3-*O*-methyl-α-D-galactopyranosyl)-3-*O*-(3,6-dideoxy-α-D-*xylo*-hexopyranosyl)-α-D-mannopyranoside (15)

Trisaccharide **56** (39 mg, 0.04 mmol) was dissolved in acetic acid (10 mL) and 10% Pd/C (40 mg) added. The reaction was stirred under an atmosphere of H_2 for 4 h and then was filtered through Celite and the filtrate evaporated. Chromatography (water) on Bio-Gel P-2 gave, after lyophilization, **15** (14 mg, 66%) as a foam. $[\alpha]_D$ +146.6 (*c* 0.5, H_2O). ^{1}H NMR (D_2O) δ: 5.332 (d, $J_{1'',2''}$ = 3.5 Hz, 1H, H-1″), 5.112 (d, $J_{1',2'}$ = 3.5 Hz, 1H, H-1′), 5.052 (d, $J_{1,2}$ = 2.0 Hz, 1H, H-1), 4.855 (dd, $J_{3'',4''}$ = 3.0 Hz, $J_{4'',5''}$ = 1.0 Hz, 1H, H-4″), 4.415 (ddd, $J_{5'',6''a}$ = 5.0 Hz, $J_{5'',6''b}$ = 6.5 Hz, 1H, H-5″), 4.106 (t, $J_{2,3}$ = 2.0 Hz, 1H, H-2), 4.072 (dq, $J_{4',5'}$ = 1.0 Hz, 1H, H-5′), 3.99–4.06 (m, 2H, H-2′, H-3), 3.979 (t, $J_{3,4} \approx J_{4,5}$ = 9.5 Hz, 1H, H-4), 3.948 (dd, 3.5, $J_{2'',3''}$ = 10.0 Hz, 1H, H-2″), 3.86–3.92 (m, 3H, H-6a, H-4′, H-3″), 3.76–3.85 (m, 3H, H-6b, H-6″a, H-6″b), 3.674 (ddd, $J_{5,6a}$ = 2.0 Hz, $J_{5,6b}$ = 5.5 Hz, 1H, H-5), 3.473 (s, 3H, OC*H*$_3$), 3.434 (s, 3H, OC*H*$_3$), 1.90–2.02 (m, 2H, H-3′eq, H-3′ax), 1.183 (d, $J_{5',6'}$ = 6.5 Hz, 3H, H-6′). ^{13}C NMR (D_2O) δ: 101.110 (C-1′, $^1J_{C,H}$ = 171.2 Hz), 100.799 (C-1″, $^1J_{C,H}$ = 173.3 Hz), 100.356 (C-1, $^1J_{C,H}$ = 173.2 Hz), 77.206 (C-3), 77.920 (C-2), 77.767 (C-3″), 73.796 (C-5), 70.952 (C-5″), 69.108 (C-4′), 68.156 (C-2″), 67.738 (C-5′), 67.460 (C-4), 64.160 (C-2′), 61.423 (C-6), 59.945 (C-4″), 57.174 (OCH_3), 55.712 (OCH_3), 44.489 (C-6″), 33.733 (C-3′), 16.251 (C-6′). Anal. calcd. for $C_{20}H_{34}Cl_2O_{12}$ (539.39): C 44.54, H 6.35; found: C 44.49, H, 6.55.

Acknowledgements

This work was supported by the Natural Sciences and Engineering Research Council of Canada (NSERC). T. L. L. was the recipient of a post-doctoral fellowship from the Alberta Heritage Foundation for Medical Research. The authors thank Dr. Albin Otter for carrying out the high-field NMR spectral analysis of the final compounds and Joanna Sadowska for invaluable technical assistance.

Synthesis of three *Salmonella* epitopes for biosensor studies of carbohydrate–antibody interactions

Henry N. Yu, Chang-Chun Ling, and David R. Bundle

Abstract: Disaccharides **1**–**3** corresponding to the antigenic determinants of *Salmonella* serotypes A, B, and D_1 were synthesized in a form suited for use in biosensors. The disaccharide determinants each contain a unique 3,6-dideoxyhexose, namely abequose (3,6-dideoxy-D-*xylo*-hexose), paratose (3,6-dideoxy-D-*ribo*hexose), and tyvelose (3,6-dideoxy-D-*arabino*-hexose), are α-linked to the 3-position of D-mannopyranose. The disaccharides were further derivatized with a linear aglycon that has a terminal amino group, and can be readily coupled to pertinent chains carrying a terminal thiol for the construction of self-assembled monolayers (SAMs). Efficient routes that employed a single 3,6-dideoxygenation step were developed for the synthesis of paratoside **15** and tyveloside **22**.

Key words: *Salmonella O*-antigens, lipopolysaccharide, abequose, paratose, tyvelose, 3,6-dideoxyhexose, deoxygenation, glycoside tethers, immobilization via pentenyl glycosides.

Résumé : On a synthétisé des formes appropriées à un usage comme biosenseurs des disaccharides **1**–**3**, qui correspondent aux déterminants antigéniques de la *Salmonella* de sérotypes A, B et D_1. Les déterminants disaccharides comportent chacun un 3,6-didésoxyhexose unique, soit l'abéquose (3,6-didésoxy-D-*xylo*-hexose), le paratose (3,6-didésoxy-D-*ribo*-hexose) et le tyvelose (3,6-didésoxy-D-*arabino*-hexose), ainsi qu'une liaison α à la position 3 du D-mannopyranose. On en a ensuite préparé des dérivés à l'aide d'une aglycone linéaire portant un groupe amino terminal; ces dérivés peuvent facilement être couplés à des chaînes appropriées portant une fonction thiol terminale pour la construction de monocouches autoassemblées (MAA). On a développé des voies efficaces de synthèse du paratoside **15** et du tyveloside **22** qui font appel à une réaction permettant d'effectuer une 3,6-didéoxygénation en une seule étape.

Mots clés : *O*-antigènes de la *Salmonella*, lipopolysaccharide, abéquose, paratose, tyvelose, 3,6-didésoyxhexose, désoxygénation, téthères glycosidiques, immobilisation via des glycosides de pentényle.

[Traduit par la Rédaction]

Introduction

Structural and thermodynamic studies of carbohydrate–protein interactions have played a fundamental role in the development of an understanding of the features of a variety of carbohydrate-based biological recognition systems (1). Although a few examples of carefully designed carbohydrate clusters, such as the decameric *Escherichia coli* toxin inhibitor, Starfish (2), have demonstrated extraordinary association constants, carbohydrates generally exhibit association constants for proteins in the millimolar to micromolar range. Since carbohydrates are normally devoid of convenient spectroscopic reporter groups, convenient methods for the accurate and rapid measurement of these relatively weak interactions (affinity) are limited. Traditionally, solid-phase enzyme immunoassays (EIA) have been employed to give an indirect estimate of the association constant (K_a) (3). Titration microcalorimetry provides a very accurate measure of K_a as well as a complete thermodynamic description, enthalpy (ΔH), and entropy (ΔS) for reactions in solution. However, the drawback of this method is the requirement for large amounts of protein sample, typically 10–25 mg of relatively pure protein per measurement (3, 17). Surface plasmon resonance (SPR) has emerged as an alternative since it was first reported in the early 1990s (4, 18). This extremely sensitive technique is able to provide a value of K_a from on and off rates (5). Whitesides and co-workers were the first to use alkanethiolates to form self-assembled monolayers (SAMs) on gold surfaces for SPR analysis (6). This technique represents several advantages over other coating methods: (*i*) monolayers prepared from alkanethiols terminated in oligo(ethylene glycol) groups are inert to the nonspecific adsorption of protein (7, 8); (*ii*) linkers with defined length can be easily tailored chemically before attachment to the gold surface; and (*iii*) ligands are presented in a homogenous environment where their density can be easily

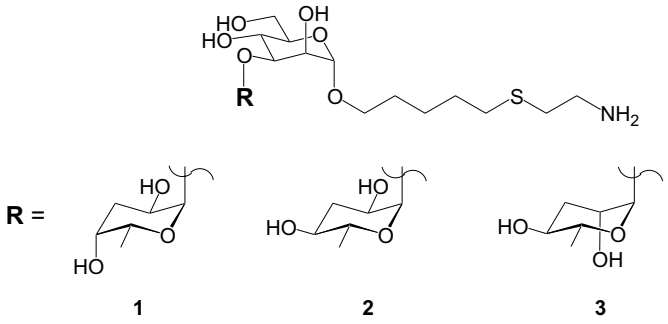
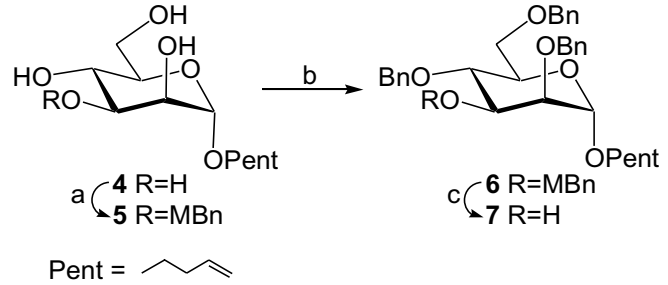
Fig. 1. Three disaccharide antigenic determinants of *Salmonella* serogroups B (**1**), A (**2**), and D_1 (**3**) derivatized for conjugation to biosensors.



Scheme 1. (*a*) (*i*) Bu_2SnO, toluene, reflux; (*ii*) *p*-MBnCl, Bu_2NBr, toluene, 60°C; (*b*) BnBr, NaH, DMF; (*c*) CAN, $CH_3CN–H_2O$.



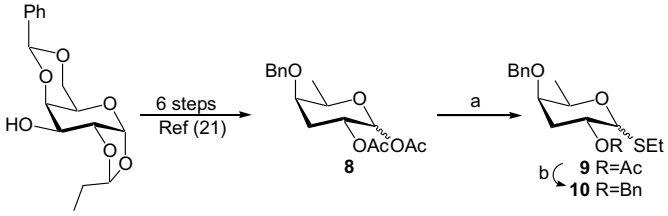
controlled. Experiments varying the linker length and carbohydrate density have been reported recently to probe the multivalency effect (9–11).

We report here the synthesis of three functionalized disaccharides (**1**–**3**), which are readily available for coupling to a pertinent chain carrying a terminal thiol. The functionalized disaccharide glycosides can then be conjugated to a gold surface to form SAMs for SPR or other biosensor analysis (12) (Fig. 1). These disaccharides are located in the *O*-antigen segment of the lipopolysaccharide component of the *Salmonella* cell wall (13). The 3,6-dideoxyhexoses function as the principal structural elements, antigenic determinants, or epitopes recognized by antibodies. Following cases of *Salmonella* food poisoning patient sera contains antibodies specific for the LPS *O*-antigen of the infecting bacterium. In the case of infection by *Salmonella* of serotypes A, B, and D_1, the antibodies bind and recognize disaccharides with terminal paratose, abequose, and tyvelose residues (14). The structural (15) and thermodynamic aspects (16, 17) of the abequose trisaccharide binding to monoclonal antibody Se155-4 have been well characterized by our group. SPR or other biosensor analysis using SAMs would provide a highly sensitive method to secure sensitive, rapid, and accurate measurement of association constants to complement our recent SPR analysis of antibody binding sites using a BSA-*O*-polysaccharide conjugates as the stationary phase (18).

Results and discussion

The 4-pentenyl group was introduced by Fraser-Reid's group (19) as a versatile and temporary protecting group for the anomeric position of sugars. It can be activated to conduct glycosylation under the promotion of *N*-iodosuccinimide. Fraser-Reid et al. (19, 20) have also developed an armed–disarmed strategy to synthesize oligosaccharides using this group. The group has appeal due to its linear structure and its terminal double bond that can be further derivatized to extend the linear chain, while remaining consistent with orthogonal protection strategies for the introduction of other functional groups during elaboration of oligosaccharides. In the context of the target disaccharides **1**–**3**, glycosyl acceptor **7** was identified as convenient synthon. As shown in Scheme 1, compound **7** was synthesized from 4-pentenyl α-D-mannopyranoside **4** (19). The 3-position was selectively protected as the *p*-methoxybenzyl ether under di-*n*-butyltin oxide activation (→**5**, 60%). The remaining hydroxyl groups were benzylated (→**6**, 76%). After removal of the *p*-methoxybenzyl group with ceric ammonium nitrate, the desired acceptor **7** was obtained in good yield (72%).

Scheme 2. (*a*) EtSH, $BF_3·Et_2O$, CH_2Cl_2; (*b*) (*i*) NaOMe, MeOH; (*ii*) BnBr, NaH, DMF.



We next turned our attention to methods for the rapid and convenient synthesis of the abequose, paratose, and tyvelose donors **10**, **16**, and **23**, respectively. As all the three 3,6-dideoxyhexose units adopt the α-configuration, we employed a nonparticipating benzyl ether group to protect the 2-position. Our recent published synthetic route to abequose allowed us to prepare the rare hexose in large quantity (Scheme 2) (21). The desired thioabequoside **10** was prepared from diacetate **8** (21). The anomeric *O*-acetate was first transformed to the thioethyl glycoside using a conventional method to afford the thioglycoside **9** as an anomeric mixture (α/β (1:3), 95%). The 2-*O*-acetyl group was then replaced with a benzyl group by first transesterifying the acetate, followed by benzylation of the intermediate alcohol to give **10** (22) in 92% overall yield for these two transformations.

The paratose methyl glycoside **12** was prepared from a known dibromide **11** (Scheme 3) (23). In the literature the dibromo-dideoxy hexose was reduced by catalytic hydrogenation in 85% yield. Barton–McCombie radical deoxygenation conditions (24) converted **11** into diol **12** in near quantitative yield (98%). After acetylation (→**13**) (25), this glycoside was subjected to acetolysis to yield the tri-*O*-acetate **14**, in 94% yield. Glycosidation with ethanethiol afforded thioglycoside **15** (75%, α/β (1:3)). The benzylated thioglycoside was finally prepared by a conventional two-step transformation sequence (→**16**, 78%).

We have published a method to synthesize a tyvelose donor from methyl α-glucopyranoside via an eight-step reaction sequence (26). A more concise synthesis of this dideoxyhexose was desired and we chose to exploit selectively benzoylated mannose derivatives to achieve this objective in four steps. It is known that when mannopyranosides are treated with excess trimethyl orthobenzoate in the presence

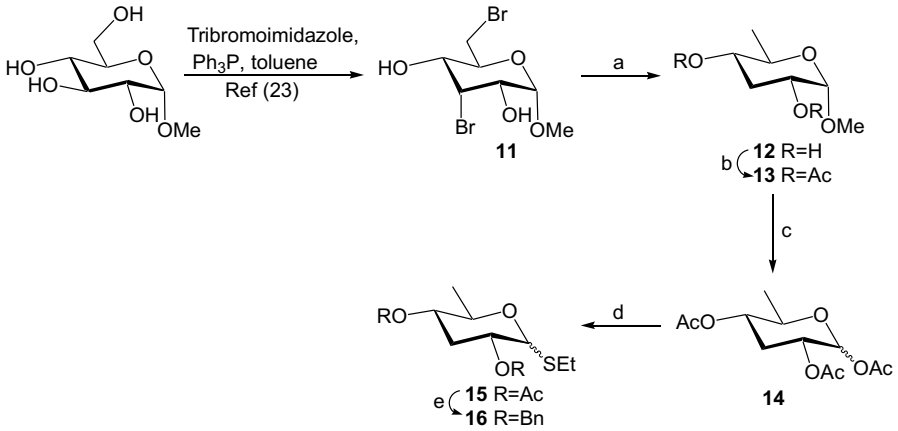
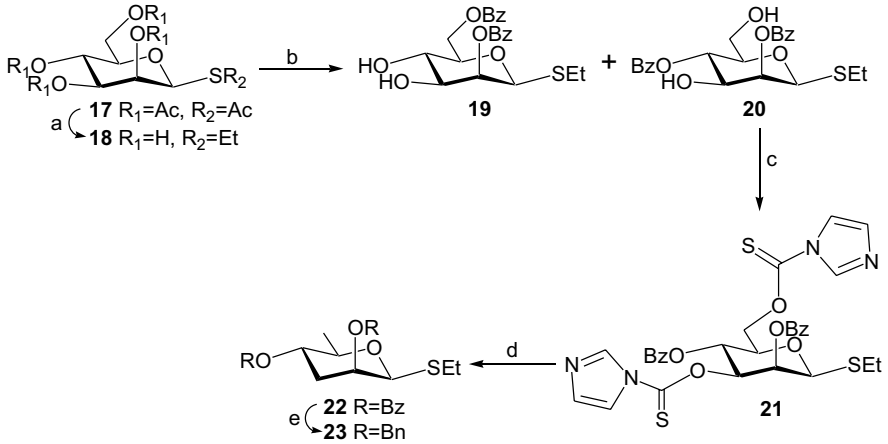
Scheme 3. (*a*) Bu_3SnH, AlBN, toluene, reflux; (*b*) Ac_2O, pyridine; (*c*) Ac_2O, H_2SO_4 (cat.); (*d*) EtSH, $BF_3{\cdot}Et_2O$, CH_2Cl_2; (*e*) (*i*) NaOMe, MeOH; (*ii*) BnBr, NaH, DMF.



Scheme 4. (*a*) NaOMe, MeOH; then Etl; (*b*) (*i*) $PhC(OMe)_3$, CSA, $CHCl_3$; (*ii*) 90% AcOH – H_2O; (*c*) 1,1′-thiocarbonyldiimidazole, toluene, reflux; (*d*) Bu_3SnH, AlBN, toluene, reflux; (*e*) (*i*) NaOMe, MeOH; (*ii*) NaH, BnBr, DMF.

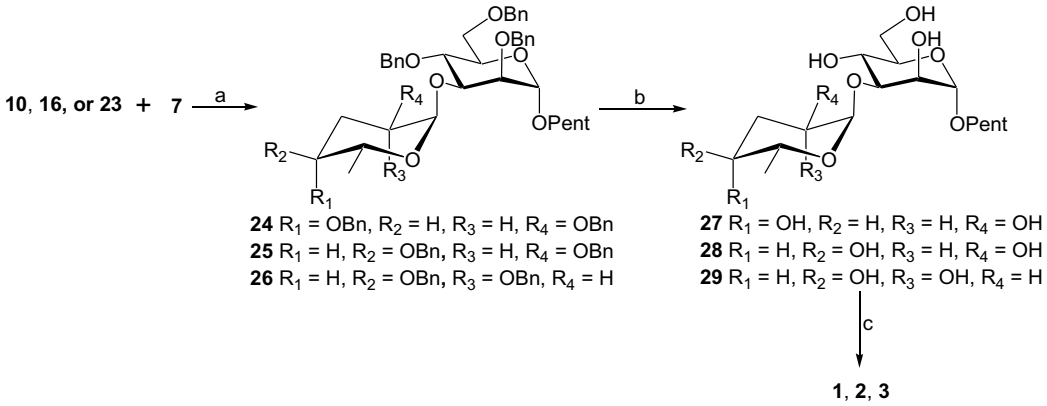


of acid followed by hydrolysis, two dibenzoylated compounds are obtained as the major products; one is the 2,4-di-*O*-benzoate, and the other is the corresponding 2,6-isomer (27, 28). Ethyl 1-thio-β-D-mannopyranoside **18** was prepared in 96% yield from 2,3,4,6-tetra-*O*-acetyl-1-*S*-acetyl-1-thio-β-D-mannopyranose (**17**) following our published methodology (28) (Scheme 4). Treatment of the β-thiomannoside **18** with excess trimethyl orthobenzoate in the presence of camphorsulphonic acid followed by opening of the intermediate orthoesters with 90% acetic acid – water afforded the undesired 2,6-dibenzoylated product **19** (43%) and the desired 2,4-dibenzoylated product **20** (44% yield). After activating the OH-3 and OH-6 groups in **20** using imidazolylthiocarbonyl groups (→**21**, 76%), the tyveloside **22** was obtained in 45% yield using Barton radical deoxygenation conditions with tri-*n*-butyltin hydride as reducing agent in boiling toluene. Attempts to increase the yield by varying reaction conditions failed. To rule out the possibility that the thioethyl group might be complicating the radical reaction, the *O*-methyl glycoside analogue of compound **22**, methyl 2,4-di-*O*-benzoyl-3,6-di-*O*-(imidazolylthiocarbonyl)-α-D-mannopyranoside, was synthesized and subjected to the same deoxygenation condition (data not reported) and a similar yield was obtained. A comparable yield was reported in the literature when the authors attempted to deoxygenate a 3,6-anhydro-galactopyranosyl derivative bearing two phenoxythiocarbonyl groups at the 2,4-positions (29). Normally, having a participating group at the O-2 position, donor **22** should be suitable for the preparation of α-tyveloside. However, in our acceptor, we have a 4-pentenyl group at the anomeric centre; preliminary studies demonstrated that when MeOTf was used to activate **22** for the glycosylation of **7**, orthoester was formed; when NIS–TfOH was used, the 4-pentenyl group was decomposed by the reagent. We thus decided to prepare the corresponding benzylated donor **23**, thereby allowing us to use MeOTf as activating reagent (30) and avoid the formation of orthoester. The benzoyl groups of **22** were replaced by benzyl groups as before to afford the tyvelose donor **23** in excellent yield (95%).

With all three 3,6-dideoxyhexose donors (**10**, **16**, and **23**) and the mannopyranosyl acceptor **7** in hand, glycosylations were carried out (Scheme 5). Coupling of **10** with **7** under activation by methyl triflate and 2,6-di-*tert*-butyl-4-methylpyridine in Et_2O afforded disaccharide **24** (82%), with excellent anomeric selectivity (α/β, 40:1). Compound **16** was glycosidated by **7** in a similar fashion to give **25** in good yield, but poor stereoselectivity (80%, α/β (3:2)).

© 2002 NRC Canada

Scheme 5. (*a*) MeOTf, DTBMP, Et_2O, 0°C; (*b*) Na, NH_3 (liquid), MeOH, –78°C; (*c*) $HSCH_2CH_2NH_3^+Cl^-$, MeOH, UV light (254 nm).



Disaccharide **26** was obtained in the same fashion (70%) with excellent stereoselectivity; no β-isomer was detected. Debenzylation for all three disaccharides was smoothly carried out by Birch reduction with preservation of the terminal double bond of the 4-pentenyl group provided that the reaction temperature was kept at –78°C. Reverse-phase HPLC allowed complete separation of the anomeric isomers (→**27** (100%), →**28** (47%α + 33%β), →**29** (84%)). The anomeric configuration of the protected and deprotected disaccharide products were confirmed by measurement of the one-bond heteronuclear coupling constant $^1J_{C1,H1}$ (31), since the $^3J_{1,2}$ homonuclear coupling constants would not distinguish the α- and β-tyvelose anomers.

The elongation and functionalization of the aglycon was achieved through photoaddition of cysteamine hydrochloride (32) to the terminal double bond to afford the desired target disaccharides **1** (90%), **2** (71%), and **3** (94%).

In summary, three immunodominant disaccharide epitopes present in the *O*-antigens of *Salmonella* LPS were synthesized as their 4-pentenyl glycosides and were functionalized for incorporation into SAMs. SPR studies with these compounds are in progress and will be reported in due course.

Experimental

Optical rotations were measured with a PerkinElmer 241 polarimeter at 22 ± 2°C. Analytical TLC was performed on Silica Gel 60-F_{254} (E. Merck, Darmstadt) with detection by quenching of fluorescence and (or) by charring with sulfuric acid. All commercial reagents were used as supplied and chromatography solvents were distilled prior to use. Column chromatography was performed on Silica Gel 60 (40–60 μM, E. Merck, Darmstadt). ^{1}H NMR spectra were recorded on 300 MHz (Varian), 400 MHz (Varian), 500 MHz (Varian), or 600 MHz (Varian) spectrometers. The first-order proton chemical shifts (δ_H) were referenced to either residual $CHCl_3$ (δ_H 7.24, $CDCl_3$) or internal acetone (δ_H 2.225, D_2O). HMQC-NMR spectra were recorded on Varian Unity 300, 400, 500, or 600 MHz NMR spectrometers. The ^{13}C chemical shifts (δ_C) were referenced to internal $CDCl_3$ (δ_C 77.00, $CDCl_3$). Organic solutions were dried prior to concentration under vacuum at <40°C (bath). Reverse-phase chromatography was performed on a Waters 600 HPLC system, using a Beckman semipreparative C-18 column (10 × 250 mm, 5 μ), and the products were detected with a Waters 2487 UV detector or a Waters 2410 refractive index monitor. Microanalyses and electrospray mass spectra were performed by the analytical services of this department.

4-Pentenyl 3-*O*-*p*-methoxybenzyl-α-D-mannopyranoside (5)

To a solution of 4-pentenyl α-D-mannopyranoside **4** (19) (6.86 g, 27.6 mmol) in anhydrous toluene (120 mL), was added di-*n*-butyltin oxide (7.56 g, 29.8 mmol); the mixture was refluxed with azeotropic removal of water for 6 h using a Dean–Stark tube. The reaction was cooled to 60°C, tetra-*n*-butylammonium bromide (9.79 g, 30.1 mmol) and 4-methoxybenzyl chloride (4.13 mL, 30.4 mmol) were added, and the reaction was stirred for 16 h at the same temperature. The mixture was concentrated and the residue was purified by column chromatography on silica gel (MeOH–EtOAc, 19:1 v/v), to give compound **5** (6.1 g, yield 60%). $[\alpha]_D^{22}$ +18.5 (*c* 2.6, $CHCl_3$). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.28–6.84 (m, 4H, MBn), 5.76 (ddt, *J* = 6.5, 10.2, 16.9 Hz, 1H, C*H*=CH_2), 4.96 (m, 2H, CH=CH_2), 4.77 (d, *J* = 1.1 Hz, 1H, H-1), 4.54 (d, *J* = 11.2 Hz, 1H, MBn), 4.49 (d, 1H, MBn), 4.00–3.30 (m, 8H, H-2 + H-3 + H-4 + H-5 + H-6 + OCH_2CH_2), 2.05 (m, 2H, CH_2CH=CH_2), 1.61 (m, 2H, OCH_2=CH_2). HR-ES-MS calcd. for $C_{19}H_{28}O_7Na^+$: 391.173273; found: 391.172706.

4-Pentenyl 2,4,6-tri-*O*-benzyl-3-*O*-*p*-methoxybenzyl-α-D-mannopyranoside (6)

To an ice-cooled solution of compound **5** (6.0 g, 16.3 mmol) in DMF (100 mL) under argon, was added sodium hydride (95%, 2.47 g, 97.8 mmol), and the mixture was stirred for 0.5 h. Benzyl bromide (8.7 mL, 72.9 mmol) was added dropwise and the reaction was continued for 6 h at room temperature. The reaction was cooled to 0°C and quenched with MeOH (10 mL). The mixture was concentrated and the resulting residue was partitioned between EtOAc (500 mL) and 5% aq NaCl solution (2 × 300 mL). The organic phase was dried over anhyd Na_2SO_4 and concentrated. Compound **6** (7.9 g, yield 76%) was obtained by column chromatography on silica gel (hexane–EtOAc, 19:1 v/v). $[\alpha]_D^{22}$ +33.2 (*c* 3.8, $CDCl_3$). ^{1}H NMR ($CDCl_3$, 600 MHz) δ: 7.36–6.83 (m, 19H, 3 × Bn + MBn), 5.76 (tdd, *J* = 6.6, 10.1, 16.9 Hz, 1H, C*H*=CH_2), 4.95 (m, 2H, CH=CH_2), 4.85 (d, *J* = 10.8 Hz, 1H, Bn), 4.81 (d, *J* = 1.9 Hz, 1H, H-1), 4.74 (d, *J* = 12.5 Hz, 1H, Bn), 4.69 (d, 1H, Bn), 4.63 (d, *J* = 12.1 Hz, 1H, Bn),

As both α and β anomers are equally reactive in glycosylation reactions, **9**α and **9**β were not separated.

Ethyl 2,4-di-*O*-benzyl-3,6-dideoxy-1-thio-α,β-D-*xylo*-hexopyranoside (10)

To a solution of compound **9**α,β (α/β (1:3), 200 mg, 0.62 mmol) in dry MeOH (20 mL) was added a catalytic amount of MeONa. The mixture was stirred overnight at room temperature. After neutralization with DOWEX 50W (H^+) resin, the organic solution was concentrated, and the resulting residue was dissolved in anhyd DMF (10 mL) at 0°C; NaH (60% in mineral oil, 244 mg, 6.1 mmol) was then added. After 5 min, benzyl bromide (0.37 mL, 3.1 mmol) was added dropwise, and the reaction was continued for 2 h at room temperature. The reaction was quenched with MeOH (1 mL) and the mixture was diluted with EtOAc (100 mL), washed with 5% brine (2 × 50 mL), dried over Na_2SO_4, and concentrated. The pure **10** (α/β (1:3), 211 mg, yield 92%) was obtained after chromatography on silica gel (toluene–EtOAc, 19:1 v/v). Physical data were identical to the literature (22).

Methyl 3,6-dideoxy-α-D-*ribo*-hexopyranoside (12)

To a refluxing solution of 3,6-dibromosugar **11** (23) (2.55 g, 8.0 mmol) in dry toluene (150 mL) was added dropwise a solution of tri-*n*-butyltin hydride (6.5 mL, 24.2 mmol) and azobis(cyclohexylcarbonitrile) (0.2 g, 818 μmol) in dry toluene (50 mL) under argon. After 1 h, the mixture was concentrated. The residue was purified by column chromatography on silica gel (toluene–EtOAc, 1:9 v/v) to give compound **12** (1.27 g, 98%). Physical data were identical to the literature (23).

1,2,4-Tri-*O*-acetyl-3,6-dideoxy-α,β-D-*ribo*-hexopyranose (14)

To a mixture of compound **13** () (1.20 g, 4.88 mmol) in acetic anhydride (35 mL) was added a solution of conc. H_2SO_4 (95%, 90 μL). After 1 h, the reaction was quenched with sat. $NaHCO_3$ solution (50 mL) and extracted with dichloromethane (300 mL). The organic layer was washed with H_2O (200 mL) and dried over Na_2SO_4. The solvent was evaporated and the residue was purified by silica gel (hexane–EtOAc, 4:1 v/v), to give compound **14** (α/β (4:1), 1.14 mg, yield 85%). ^{1}H NMR ($CDCl_3$, 300 MHz) for α-anomer δ: 6.15 (d, *J* = 3.4 Hz, 1H, H-1), 4.97 (ddd, *J* = 5.0, 12.5 Hz, 1H, H-2), 4.60 (ddd, *J* = 4.8, 9.8, 11.4 Hz, 1H, H-4), 3.84 (dq, *J* = 6.1 Hz, 1H, H-5), 2.28 (d′t′, *J* = 12.2 Hz, H-3a), 2.14 (s, 3H, OAc), 2.05 (s, 3H, OAc), 1.95 (s, 3H, OAc), 1.88 (d′t′, 1H, H-3b), 1.15 (d, 3H, H-6); β-anomer δ: 5.65 (d, *J* = 8.2 Hz, 1H, H-1), 4.97 (ddd, *J* = 5.2, 11.4 Hz, 1H, H-2), 4.60 (ddd, *J* = 4.8, 9., 11.0 Hz, 1H,

Ethyl *2,6*-di-*O*-benzoyl-1-thio-β-D-mannopyranoside (19) and ethyl 2,4-di-*O*-benzoyl-1-thio-β-D-mannopyranoside (20)

A suspension of compound **18** (1.2 g, 1.02 mmol), trimethyl orthobenzoate (3.8 mL, 5.3 mmol), and a catalytic amount of camphor sulfonic acid in $CHCl_3$ (250 mL) was evaporated down to 10 mL; this solution became almost clear. TLC showed that there was still unreacted starting material. $CHCl_3$ (150 mL) was added to the solution again, and the solution was again evaporated to a 10 mL volume. This process was repeated until TLC indicated the complete conversion of starting material. Triethylamine (3 mL) was added, and the mixture of intermediate orthoesters was concentrated to a syrup. The syrup was treated with 90% acetic acid – H_2O (50 mL) for 30 min at 20°C, and the solution was concentrated. After column chromatography on silica gel (EtOAc–toluene, 20 → 50%) compound **20** (1.02 g, 44%) and compound **19** (0.99 g, 43%) were obtained. Data for **20**: $[\alpha]_D^{22}$ –93.6 (*c* 2.8, $CHCl_3$). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 8.13–7.43 (m, 10H, Bz), 5.76 (d, *J* = 3.7 Hz, 1H, H-2), 5.39 ("t", *J* = 9.7 Hz, 1H, H-4), 4.92 (s, 1H, H-1), 4.19 (dd, *J* = 9.8 Hz, 1H, H-3), 3.85 (dd, *J* = 2.3, 12.2 Hz, 1H, H-6a), 3.78 (dd, *J* = 5.3, 12.2 Hz, 1H, H-6b), 3.73 (ddd, 1H, H-5), 2.76 (q, *J* = 7.5 Hz, 2H, CH_2), 1.29 (t, 3H, CH_3). Ethyl 2,4-di-*O*-benzoyl–3,6-dideoxy-1-thio-β-D-*arabino*-hexopyranoside (22)

To a refluxing solution of compound **21** (700 mg, 1.07 mmol) in dry toluene (8.0 mL) was added dropwise a solution of tri-*n*-butyltin hydride (0.8 mL, 3.0 mmol) and azobis(cyclohexylcarbonitrile) (90 mg, 368 μmol) in dry toluene (5.0 mL) under argon. After 6 h, the mixture was concentrated. Chromatography of the resulting residue on silica gel (toluene–EtOAc, 19:1 v/v) gave compound **22** (195 mg, 45%). Physical data were similar to those in the literature (33).

Ethyl 2,4-di-*O*-benzyl–3,6-dideoxy-1-thio-β-D-*arabino*-hexopyranoside (23)

To a solution of compound **21** (195 mg, 0.49 mmol) in dry MeOH (5 mL) was added a catalytic amount of MeONa. The mixture was stirred overnight at room temperature. After neutralization with DOWEX 50W (H^+) resin, the reaction was concentrated. The residue was dissolved in anhyd DMF (9 mL) at 0°C under argon and NaH (60% in mineral oil, 180 mg, 4.5 mmol) was then added. After 5 min, benzyl bromide (0.53 mL, 4.5 mmol) was added dropwise, and the reaction was continued for 2 h at room temperature. MeOH (1 mL) was added to quench the reaction, and the mixture was diluted with EtOAc (100 mL), washed with 5% brine (2 × 50 mL), dried over Na_2SO_4 and concentrated. Pure **23** (172 mg, yield 95%) was obtained by chromatography on silica gel (toluene–EtOAc, 9:1 v/v). $[\alpha]_D^{22}$ –10.0 (*c* 1.3, $CHCl_3$). ^{1}H NMR ($CDCl_3$, 600 MHz) δ: 7.35–7.25 (m, 10H, Bn), 4.58 (s, 1H, H-1), 4.56 (overlapped, 2H, Bn), 4.49 (d, *J* = 11.5 Hz, 1H, Bn), 4.44 (d, 1H, Bn), 3.71 (m, 1H, H-2), 3.45 (ddd, *J* = 4.4, 9.2, 11.2 Hz, 1H, H-4), 3.37 (qd, *J* = 6.1 Hz, 1H, H-5), 2.67 (q, *J* = 7.3 Hz, 2H, CH_2), 2.38 (d′t′, *J* = 3.7 Hz, 13.6 Hz, 1H, H-3a), 1.39 (ddd, *J* = 2.8 Hz, 1H, H-3b), 13.3 (d, 3H, H-6), 1.26 (t, *J* = 7.5 Hz, 1H, CH_3). HR-ES-MS calcd. for $C_{22}H_{28}O_3Na^+$: 395.165687; found: 395.165827. Anal. calcd. for $C_{22}H_{28}O_3S$: C 70.93, H 7.58; found: C 70.78, H 7.45.

4-Pentenyl 2,4-di-*O*-benzyl-3,6-dideoxy-α-D-*xylo*-hexopyranosyl-(1→3)-2,4,6-tri-*O*-benzyl-α-D-mannopyranoside (24α) and 4-pentenyl 2,4-di-*O*-benzyl-3,6-dideoxy-β-D-*xylo*-hexopyranosyl-(1→3)-2,4,6-tri-*O*-benzyl-α-D-mannopyranoside (24β)

To a mixture of **10** (1.18 g, 3.17 mmol), **7** (1.13 g, 2.17 mmol), 2,6-di-*tert*-butyl-4-methylpyridine (0.87 g, 4.24 mmol), and 4 Å molecular sieves in anhyd Et_2O (20 mL) at 0°C under argon, methyl trifluoromethanesulfonate (737 μL, 6.51 mmol) was added dropwise. The mixture was stirred at room temperature for 6 h and then quenched with Et_3N (3 mL). The molecular sieves were removed by filtration and the solvent was evaporated. The resulting residue was purified by column chromatography on silica gel (hexane–EtOAc, 24:1 v/v), to give the α-anomer **24**α (1.45 g, yield 80%) and β-anomer **24**β (34 mg, yield 2%). Data for **24**α: $[\alpha]_D^{22}$ +38.8 (*c* 4.0, $CHCl_3$). ^{1}H NMR ($CDCl_3$, 600 MHz) δ: 7.34–7.12 (m, 25H, 5 × Bn), 5.78 (tdd, *J* = 6.6, 10.1, 16.9 Hz, 1H, C*H*=CH_2), 5.14 (d, *J* = 3.3 Hz, 1H, H-1′), 5.07 (d, *J* = 11.4 Hz, 1H, Bn), 4.95 (m, 2H, CH=CH_2), 4.89 (d, *J* = 1.8 Hz, 1H, H-1), 4.73 (d, *J* = 12.1 Hz, 1H, Bn), 4.60 (d, *J* = 12.1 Hz, 2H, Bn), 4.49 (d, 1H, Bn), 4.48 (d, *J* = 12.1 Hz, 1H, Bn), 4.44 (d, 1H, Bn), 4.43 (d, *J* = 12.5 Hz, 1H, Bn), 4.35 (d, 1H, Bn), 4.30 (d, 1H, Bn), 4.15 (dd, *J* = 9.3 Hz, 1H, H-3), 3.97 (“t”, *J* = 9.5 Hz, 1H, H-4), 3.84 (m, 1H, H-5′), 3.80–3.76 (m, 2H, H-2′ + H-5), 3.75 (dd, *J* = 3.1 Hz, 1H, H-2), 3.71 (m, 2H, H-6), 3.67 (m, 1H, OC*Ha*HbCH_2), 3.38 (td, *J* = 6.4, 9.5 Hz, 1H, OCHa*Hb*CH_2), 3.26 (br s, 1H, H-4′), 2.10–2.03 (m, 3H, CH_2CH=CH_2 + H-3′a), 1.88 (d′t′, *J* = 2.6, 12.8 Hz, 1H, H-3′b), 1.65 (tt, *J* = 7.0, 7.0 Hz, 2H, OCH_2CH_2), 1.04 (d, *J* = 6.6 Hz, 3H, H-6′). ^{13}C NMR ($CDCl_3$, 600 MHz, from HMQC) δ: 138.0 (*C*H=CH_2), 128.2–126.9 (5 × Bn), 114.6 (CH=*C*H_2), 98.8 (C-1, $J_{C1,H1}$ = 169.3 Hz), 97.0 (C-1′, $J_{C1',H1'}$ = 169.3 Hz), 78.4 (C-3), 77.9 (C-2), 75.5 (C-4′), 74.8 (C-4), 74.3 (Bn), 73.2 (2 × Bn), 71.9 (C-5), 71.6 (Bn), 70.9–70.7 (2 × Bn), 70.7 (C-2′), 69.3 (C-6), 66.9 (O*C*H_2), 66.3 (C-5′), 30.2 (*C*H_2CH=CH_2), 28.5 (OCH_2*C*H_2), 27.1 (C-3′), 16.4 (C-6′). 4-Pentenyl 3,6-dideoxy-α-D-*xylo*-hexopyranosyl-(1→3)-α-D-mannopyranoside (27)

Redistilled liquid ammonia (50 mL) was collected in a flask with the help of a dry ice – acetone condenser, sodium (83 mg) was added, a dark blue solution was obtained and the mixture was cooled to –78°C. A solution of compound **24**α (200 mg, 0.24 mmol) and anhyd MeOH (52 μL, 1.29 mmol) in anhyd THF (20 mL) was added dropwise to a blue mixture during the course of 1 h. After another 1.5 h, the reaction was then quenched with MeOH (2 mL), the ammonia was evaporated to dryness. The residue was dissolved in MeOH and the mixture was neutralized to pH 7 by addition of 25% AcOH in H_2O. After concentration, the residue was purified by reverse-phase chromatography using a gradient of MeOH–H_2O (0 → 50%) as eluent to afford **27** (91 mg, 100%). $[\alpha]_D^{22}$ +70.0 (*c* 1.2, H_2O). ^{1}H NMR (D_2O, 600 MHz) δ: 5.92 (tdd, *J* = 6.6, 10.3, 17.0 Hz, 1H, C*H*=CH$_2$), 5.10 (d, *J* = 3.7 Hz, 1H, H-1′), 5.10 (overlapped, 1H, CH=C*Ha*Hb), 5.03 (m, 1H, CH=CHa*Hb*), 4.85 (d, *J* = 1.7 Hz, 1H, H-1), 4.12 (dq, *J* = 1.3, 6.6 Hz, 1H, H-5′), 4.05 (dd, *J* = 1.8 Hz, 3.1 Hz, 1H, H-2), 4.01 (d′t′, *J* = 4.0, 12.5 Hz, 1H, H-2′), 3.90–3.87 (m, 3H, H-3 + H-6a + H-4′), 3.84 ("t", *J* = 9.7 Hz, 1H, H-4), 3.77 (m, 2H, OC*Ha*HbCH$_2$ + H-6b), 3.70 (ddd, *J* = 2.2, 5.7, 9.5 Hz, 1H, H-5), 3.56 (d′t′, *J* = 6.1, 12.1 Hz, 1H, OCHa*Hb*CH$_2$), 2.16 (m, 2H, C*H*$_2$CH=CH$_2$), 2.06 (d′t′, *J* = 2.9, 13.0 Hz, 1H, H-3′a), 1.98 (d′t′, *J* = 4.6 Hz, 1H, H-3′b) 1.74 (m, 2H, OCH$_2$C*H*$_2$), 1.16 (d, 3H, H-6′). ^{13}C NMR (D_2O, 600 MHz, from HMQC) δ: 138.7 (*C*H=CH$_2$), 116.7 (CH=*C*H$_2$), 101.2 (C-1′, $J_{C1',H1'}$ = 169.8 Hz), 100.3 (C-1, $J_{C1,H1}$ = 171.9 Hz), 79.2 (C-3), 74.0 (C-5), 71.2 (C-2), 69.0 (C-4′), 68.1 (OCH$_2$), 65.5 (C-5′), 66.3 (C-4), 65.0 (C-2′), 61.9 (C-6), 33.4 (C-3′), 30.2 (*C*H$_2$CH=CH$_2$), 28.6 (OCH$_2$*C*H$_2$), 16.0 (C-6′). 4-Pentenyl 3,6-dideoxy-α-D-arabino-hexopyranosyl-(1→3)-α-D-mannopyranoside (29)

Compound **26** (60 mg, 72 μmol) was converted to **29** (23 mg, 84%) in the same manner as **24**α. $[\alpha]_D^{22}$ –47.2 (*c* 1.8, H_2O). ^{1}H NMR (D_2O, 600 MHz) δ: 5.94 (tdd, J = 6.6, 10.3, 16.9 Hz, 1H, C*H*=CH_2), 5.11 (m, 1H, CH=C*Ha*Hb), 5.04 (m, 1H, CH=CHa*Hb*), 4.90 (s, 1H, H-1′), 4.85 (s, 1H, H-1), 4.08 (m, 1H, H-2′), 4.05 (m, 1H, H-2), 3.89 (m, 2H, H-3 + H-6a), 3.82 (qd, J = 6.2, 9.5 Hz, 1H, H-5′), 3.78 (“t”, J = 9.5 Hz, 1H, H-4), 3.77 (m, 2H, H-6b + OC*Ha*HbCH_2), 3.70 (ddd, J = 2.2, 5.9, 9.3 Hz, 1H, H-5), 3.63 (ddd, J = 4.6, 11.2 Hz, 1H, H-4′), 3.57 (dt, J = 6.0, 9.9 Hz, 1H, OCHa*Hb*CH_2), 2.18 (m, 2H, C*H*$_2$CH=CH_2), 2.06 (d′t′, J = 4.0, 13.6 Hz, 1H, H-3′a), 1.90 (ddd, J = 2.9 Hz, 1H, H-3′b), 1.75 (m, 2H, OCH_2C*H*$_2$), 1.28 (d, 3H, H-6′). ^{13}C NMR (600 MHz, D_2O, from HMQC) δ: 138.2 (*C*H=CH_2), 115.7 (CH=*C*H$_2$), 102.1 (C-1′, $J_{C1',H1'}$ = 170.7 Hz), 100.5 (C-1, $J_{C1,H1}$ = 170.7 Hz), 78.5 (C-3), 73.7 (C-5), 70.9 (C-5′), 70.8 (C-2), 68.2 (O*C*H$_2$ + C-2′), 67.6 (C-4′), 66.9 (C-4), 61.6 (C-6), 34.1 (C-3′), 30.4 (*C*H$_2$CH=CH_2), 28.5 (OCH_2*C*H$_2$), 17.4 (C-6′). HR-ES-MS calcd. for $C_{17}H_{30}O_9Na^+$: 401.178753; found: 401.178261.

5-(2-Aminoethylthio)pentyl 3,6-dideoxy-α-D-*xylo*-hexopyranosyl-(1→3)-α-D-mannopyranoside, hydrochloride salt (1)

Compound **27** (10 mg, 26.4 μmol) and 2-aminoethanethiol hydrochloride (15 mg, 0.13 mmol) were dissolved in anhyd degassed MeOH (1 mL). The solution was stirred under argon for 48 h with irradiation by UV light of 254 nm wavelength. The solvent was evaporated and the resulting residue was purified by reverse-phase HPLC to give **1** (11.7 mg, 90%). $[\alpha]_D^{22}$ –127.2 (*c* 1.8, H_2O). ^{1}H NMR (D_2O, 600 MHz) δ: 5.10 (d, J = 3.7 Hz, 1H, H-1′), 4.85 (d, J = 1.7 Hz, 1H, H-1), 4.12 (dq, J = 1.3, 6.6 Hz, 1H, H-5′), 4.05 (dd, J = 3.1 Hz, 1H, H-2), 4.01 (ddd, J = 4.8, 12.5 Hz, 1H, H-2′), 3.90–3.87 (m, 2H, H-4′ + H-3), 3.83 (“t”, J = 9.7 Hz, 1H, H-4), 3.79–3.73 (m, 3H, OC*Ha*HbCH_2 + H-6), 3.69 (ddd, J = 2.2, 5.9 Hz, 1H, H-5), 3.56 (td, J = 5.9, 9.9 Hz, 1H, OCHa*Hb*CH_2), 2.84 (t, J = 6.4 Hz, 2H, SCH_2), 2.69 (t, J = 6.7 Hz, 2H, $CH_2NH_3^+Cl^-$), 2.60 (t, J = 7.3 Hz, 2H, CH_2S), 2.06 (d′t′, J = 2.9, 13.2 Hz, 1H, H-3′a), 1.98 (d′t′, J = 4.2 Hz, 1H, H-3′b), 1.68–1.61 (m, 4H, OCH_2CH_2 + CH_2CH_2S), 1.48 (m, 2H, $OCH_2CH_2CH_2$), 1.16 (d, 3H, H-6′). ^{13}C NMR (CD_3OD, 600 MHz, from HMQC) δ: 102.2 (C-1′, $J_{C1',H1'}$ = 167.3 Hz), 101.2 (C-1, $J_{C1,H1}$ = 164.6 Hz), 81.1 (C-3), 74.5 (C-5), 72.0 (C-2), 69.8 (C-4′), 68.5 (O*C*H$_2$), 67.6 (C-5′), 66.7 (C-4), 65.0 (C-2′), 62.7 (C-6), 41.2 (S*C*H$_2$), 36.0 (C-3′), 34.8 (SCH_2*C*H$_2$), 32.0 (*C*H$_2$S), 30.1 (OCH_2*C*H$_2$ + *C*H$_2$CH$_2$S), 26.2 (OCH_2CH_2*C*H$_2$), 16.7 (C-6′). HR-ES-MS calcd. for $C_{19}H_{38}NO_9SNa^+$: 456.226729; found: 456.227016.

5-(2-Aminoethanethio)pentyl 3,6-dideoxy-α-D-*ribo*-hexopyranosyl-(1→3)-α-D-manno-pyranoside (hydrochloride salt) (2)

As described for **1**, **28**α (13 mg, 34.4 μmol) was converted to **2** (12 mg, 71%). $[\alpha]_D^{22}$ –171.8 (*c* 1.1, H_2O). ^{1}H NMR (D_2O, 600 MHz) δ: 5.05 (d, J = 3.7 Hz, 1H, H-1′), 4.88 (d, J = 1.8 Hz, 1H, H-1), 4.05 (dd, J = 3.1 Hz, 1H, H-2), 3.88 (m, 2H, H-3 + H-6a), 3.83 (“t”, J = 9.5 Hz, 1H, H-4), 3.81 (ddd, J = 4.8, 12.3 Hz, 1H, H-2′), 3.78–3.71 (m, 3H, H-6b + OC*Ha*HbCH_2 + H-5′), 3.67 (ddd, J = 2.2, 6.0 Hz, 1H, H-5), 3.56 (td, J = 6.1, 9.9 Hz, 1H, OCHa*Hb*CH_2), 3.37 (ddd, J = 4.6, 9.5, 11.4 Hz, 1H, H-4′), 3.21 (t, J = 6.8 Hz, 2H, SCH_2), 2.84 (t, J = 6.8 Hz, 2H, C*H*$_2$NH$_3^+$Cl$^-$), 2.62 (t, J = 7.3 Hz, 2H, CH_2S), 2.13 (d′t′, J = 11.5 Hz, 1H, H-3′a), 1.78 (d′t′, 1H, H-3′b), 1.64 (m, 4H, OCH_2CH_2 + CH_2CH_2S), 1.48 (m, 2H, $OCH_2CH_2CH_2$), 1.22 (d, J = 6.2 Hz, 3H, H-6′). ^{13}C NMR (D_2O, 600 MHz, from HMQC) δ: 100.2 (C-1′, $J_{C1',H1'}$ = 168.0 Hz), 100.1 (C-1, $J_{C1,H1}$ = 168.4 Hz), 79.2 (C-3), 73.6 (C-5), 70.9 (C-2), 70.4 (C-4′), 69.8 (C-5′), 68.3 (O*C*H$_2$), 67.8 (C-2′), 66.7 (C-4), 61.6 (C-6), 39.0 (S*C*H$_2$), 35.0 (C-3′), 30.3 (*C*H$_2$S), 28.8 *C*H$_2$NH$_3^+$Cl$^-$), 28.7 (OCH_2*C*H$_2$ + *C*H$_2$CH$_2$S), 25.2 (OCH_2CH_2*C*H$_2$), 17.1 (C-6′). HR-ES-MS calcd. for $C_{19}H_{38}NO_9S^+$: 456.226729; found: 456.226642.

5-(2-Aminoethylthio)pentyl 3,6-dideoxy-α-D-*arabino*-hexopyranosyl-(1→3)-α-D-manno-pyranoside, acetic acid salt (3)

As described for **1**, **29** (20 mg, 53 μmol) was converted to **3** and isolated as the acetate salt form after purification by reverse-phase HPLC using a gradient of MeOH–H_2O (containing 0.3% acetic acid), (25.5 mg, 94%). $[\alpha]_D^{22}$ +54 (*c* 2.1, H_2O). ^{1}H NMR (D_2O, 600 MHz) δ: 4.88 (s, 1H, H-1′), 4.84 (d, J = 1.7 Hz, 1H, H-1), 4.06 (dd, J = 3.1, 4.7 Hz, 1H, H-2′), 4.03 (dd, J = 3.2 Hz, 1H, H-2), 3.88 (dd, J = 2.3, 12.3 Hz, 1H, H-6a), 3.87 (dd, J = 9.6 Hz, 1H, H-3), 3.78 (m, 3H, H-5′ + H-6b + OC*Ha*HbCH_2), 3.75 (“t”, J = 9.6 Hz, 1H, H-4), 3.67 (ddd, J = 6.0 Hz, 1H, H-5), 3.61 (ddd, J = 4.5, 9.3, 11.4 Hz, 1H, H-4′), 3.56 (td, J = 6.1, 9.9 Hz, 1H, OCHa*Hb*CH_2), 3.21 (t, J = 6.7 Hz, 2H, SCH_2), 2.85 (t, J = 6.6 Hz, 2H, C*H*$_2$NH$_3^+$OAc$^-$), 2.62 (t, J = 7.3 Hz, 2H, CH_2S), 2.04 (d′t′, J = 13.6 Hz, 1H, H-3′a), 1.94 (s, 3H, OAc), 1.87 (ddd, J = 14.0 Hz, 1H, H-3′b), 1.64 (m, 4H, OCH_2CH_2 +

Synthesis of disaccharide congeners of the *Trichinella spiralis* glycan and binding site mapping of two monoclonal antibodies

Ping Zhang, Judith Appleton, Chang-Chun Ling, and David R. Bundle

Abstract: The tetrasaccharide epitope, β-D-Tyv*p*(1→3)β-D-GalNAc*p*(1→4)[α-L-Fuc*p*(1→3)]β-D-GlcNAc*p* (**1**) is the major constituent of the *N*-glycan expressed on the cell surface of the parasite *Trichinella spiralis*. Two monoclonal antibodies (Mabs 9D4 and 18H1) that protect rats against infection by *T. spiralis* bind the terminal disaccharide epitope β-D-Tyv*p*(1→3)β-D-GalNAc*p* conjugated to BSA. The syntheses of disaccharide congeners containing mono-deoxy, mono-methyl, as well as modifications to replace the acetamido group are reported. These target disaccharides were assayed for binding to the protective MAbs. For each antibody different clusters of three hydroxyl groups, that include C-2 and C-4 of tyvelose and for 18H1, the GalNAc acetamido group, provide the key polar interactions with the antibody binding sites. Mapping of the sites by functional group replacement revealed a similar pattern of recognition for the dideoxyhexose by the two MAbs while each recognizes distinct surfaces of the GalNAc residue. Consequently although both antibodies bury the 4-OH of tyvelose, the principal contact surface occurs on opposite sides of the 3,6-dideoxyhexose.

Key words: β-tyveloside, 3,6-dideoxy-D-*arabino*-hexose, *Trichinella* carbohydrate antigen, antibody mapping, *Trichinella spiralis*, *N*-glycans, molecular recognition of carbohydrates, antigen topology, functional group replacement.

Résumé : Le tétrasaccharide épitope, β-D-Tyv*p*(1→3)β-D-GalNAc*p*(1→4)[α-L-Fuc*p*(1→3)]β-D-GlcNAc*p* (**1**) est un constituant majeur du *N*-glucane extrait de la surface de la cellule du parasite *Trichinella spiralis*. Deux anticorps monoclonaux (Mabs 9D4 et 18H1) qui protègent les rats contre les infections par le *T. spiralis* se lient au disaccharide terminal épitope β-D-Tyv*p*(1→3)β-D-GalNAc*p* conjugué au BSA. On rapporte les synthèses de congénères du disaccharide comportant des modifications de type monodésoxy- ou monométhyle ainsi que le remplacement du groupe acétamido. On a évalué les capacités de ces disaccharides à se lier aux MAbs protecteurs. Pour chacun des anticorps, différents ensembles de trois groupes hydroxyles incluant les C-2 et C-4 du tyvelose ainsi que le groupe acétamido GalNAc du 18H1 fournissent les interactions polaires clés avec les sites de liaison de l'anticorps. Une carte des sites obtenue par le remplacement des groupes fonctionnels a permis de réaliser qu'un patron semblable existe pour la reconnaissance du didésoxyhexose par les deux MAbs alors que chacun d'eux reconnaît des surfaces distinctes du résidu GalNAc. En conséquence, même si les deux anticorps ensevelissent le 4-OH du tyvelose, le principal contact de surface se produit sur les faces opposées du 3,6-didésoxyhexose.

Mots clés : β-tyveloside, 3,6-didésoxy-D-*arabino*-hexose, hydrate de carbone antigène du *Trichinella*, carte de l'anticorps, *Trichinella spiralis*, *N*-glycanes, reconnaissance moléculaire des hydrates de carbone, topologie des antigènes, remplacement d'un groupe fonctionnel.

[Traduit par la Rédaction]

Introduction

The causative agent of trichinosis a parasitic nematode, *Trichinella spiralis*, has an exceptionally large host range and is endemic in many carnivorous animals. The parasite establishes itself in the intestinal epithelia of the host animal, following consumption of infected tissue and causes acute muscle pain, fatigue, fever, and in severe cases, death (1). During invasion, *T. spiralis* secretes an array of glycoproteins that are key to successful colonization of the intestine by the parasite. Antibodies against the glycan portion of the glycoproteins can prevent parasitic invasion and cause expulsion of the *T. spiralis* larvae from the intestine (2, 3). Here the syntheses of congeners of the native, terminal disaccharide β-D-Tyv*p*(1→3)β-D-GalNAc*p* are reported. The inhibitory activities of these ligands are used to define the precise specificity and topology of the epitope's contact surface with the binding sites of two protective rat

monoclonal antibodies (MAbs) produced from lymphocytes of rats infected with *T. spiralis*.

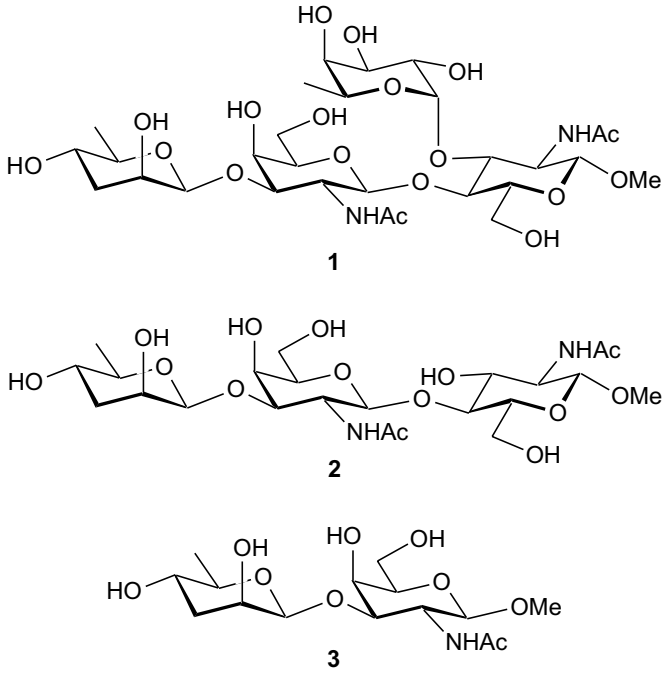
In common with many other nematodes (4), *Trichinella* secretes and displays on its cuticle a large number of proteins that display a rich repertoire of *N*-linked glycans (5, 6). Complex-type *N*-glycans in eukaryotes are characterized by the presence of variable numbers of antennae (usually two, three, or four, called bi-, tri-, and tetraantennary, respectively). In mammals the antennae stubs are usually elongated by the addition of β-Gal to give β-Gal(1→4)GlcNAc or "LacNAc". In a restricted number of mammalian glycoproteins, β-GalNAc is added to the GlcNAc stubs in place of β-Gal and thus they have β-GalNAc(1→4)GlcNAc or "LacdiNAc" antennae. Both types of antennae are found in vertebrates but LacdiNAc is the preferred antennae building block in many helminths including *Trichinella* (5, 6). The L1 stage of *T. spiralis* modifies LacdiNAc with phosphorylcholine moieties or by substitution with 3,6-dideoxy-D-*arabino*-hexose (D-tyvelose), a sugar normally confined to the cell wall lipopolysaccharide (LPS) of gram-negative bacteria. Both modifications create highly immunogenic epitopes.

Trichinella spiralis faces an aggressive immune response from its animal host, but avoids extinction by changing its expression of antigenic molecules as it changes life stages (7, 8) and by residing in intracellular habitats (9, 10). Antibody responses induced by L1 stage larvae in the intestine and in the muscle are largely directed at *N*-glycans unique to this stage (11–14). Glycans capped by tyvelose are the target of protective immunity against *T. spiralis* and antibodies specific for one of these glycans protect rats against reinfection with *T. spiralis* (3, 15, 16). The structure of the antennae of the protective antigen is shown (**1**, Fig. 1). The most striking and unusual feature is the presence of tyvelose as its β-pyranoside form rather than the α-anomer, which previously was the only naturally occurring form to have been observed in bacterial LPS antigens of pathogenic *Salmonella* (17).

Some monoclonal tyvelose-specific antibodies that bind the *T. spiralis* glycan provide protection to passively immunized rats (3, 5). Antibody 9D4 has high protective efficacy in rats and exhibits high affinity for tetrasaccharide **1**. Another tyvelose specific antibody 18H1, also shows poor protective efficacy (3, 15). It fails to cause expulsion of larvae from the intestines of rats, even though it exhibits most of the inhibitory effects shown by antibody 9D4.

No structural details of these antibody binding sites are available, although preliminary crystallographic data has been collected for MAb 9D4, and both antibody Fv regions have been partially sequenced (18). The 3,6-dideoxy arabinohexose was inferred to be linked to the *N*-glycans via the rare β-linkage based on binding studies with di- (16, 19), tri- (20, 21), and tetrasaccharides (22, 23). MAb 9D4 showed the highest affinity for tetrasaccharide **1**, while trisaccharide **2** had five times weaker affinity than the tetrasaccharide, and three times higher affinity than the disaccharide **3** (Table 1) (21, 24). This indicates the binding site of this antibody has contacts to all four sugars of the tetrasaccharide **1**, while the majority of its binding energy is focused around the dideoxyhexose containing disaccharide, an observation that has been found for other antibodies recognizing glycans containing dideoxyhexoses (25). MAb 18H1 unexpectedly recognized the trisaccharide **2** with an affinity comparable to that of the tetrasaccharide **1** and recognized the disaccharide **3** with six times higher affinity. This data is clearly inconsistent with earlier rationalization of the poor protective efficacy of MAb 18H1 that hypothesized it had been raised against a non-fucosylated linear arm of the glycan (16), and that the linear trisaccharide **2** was the preferred epitope. This would require that trisaccharide **2** be bound more tightly than the branched tetrasaccharide **1**. Consistent with the mapping data from the three different sized ligands (**1**–**3**), MAb 9D4 shows a higher affinity for its complementary ligand **1** than 18H1 shows for its smaller and complementary disaccharide epitope **3** (Table 1).

Fig. 1. The structure of the terminal tetrasaccharide **1** of the *N*-glycan expressed by the L1 stage larvae of the *T. spiralis* parasite, and its component terminal trisaccharide **2** and disaccharide **3**.



Chemical mapping by functional group replacement has proven to be a very successful tool to acquire information about carbohydrate-binding sites of antibodies (26–30), enzymes (31, 32), and lectins (26, 33). The strategy as devised by Lemieux and co-workers (34) involves the use of monodeoxy and mono-*O*-methyl congeners to identify the most important polar contacts between the carbohydrate epitope and protein. When the binding data of the modified epitopes with protein are combined with computer-assisted modeling, an overall picture of the binding site emerges, and the carbohydrate surface located in the site vs. that exposed to solvent water as well as the complementary interacting surfaces can be identified.

Results and discussion

The methyl glycoside of β-D-Tyv*p*(1→3)β-D-GalNAc*p* **3**, together with 11 other synthetic targets (Fig. 2) are used in this chemical mapping study. Disaccharides **4** and **5** are used to probe the importance of the 2-acetamido-2-deoxy group for binding, while analogs **6**–**8** contain modifications to probe the 4-position of GalNAc and disaccharides **9** and **10**,

the 6-position of GalNAc. Modifications were made to the tyvelose residue to investigate the contributions of the hydroxyl groups at the C-2′ and C-4′ positions. Compounds **11** and **12** are 2′-monodeoxy and 2′-*O*-monomethyl congeners while compounds **13** and **14** are 4′-monodeoxy and 4′-*O*-monomethyl analogues.

Initially, disaccharides **5** and **6** were prepared from an easily accessible tyvelose donor **15** (22) (Scheme 1), using insoluble silver zeolite as promoter. When reacting with galactosyl acceptor **16** (35) or glucosamine acceptor **17**, the disaccharides **18** and **19** were obtained in only poor yields (→**18** (15%), →**19** (26%)). These are typical and representative yields in the preparation of β-mannopyranosides using insoluble silver salt and halides as donors. Both the disaccharides **18** and **19** were deprotected by hydrogenation to give targeted compounds **5** (89%) and **6** (97%).

In our synthesis of several targets, differentiation between the hydroxyl group OH-4′ and OH-2′ of the tyvelose residue was essential. Obviously the donor **15** was not satisfactory since both positions are protected by benzyl groups. Even though the synthetic scheme seems short, the fact that the glycosylations proceeded in low yields also prevented us from obtaining final products in reasonable amounts, especially when an extended reaction sequence was involved. This necessitated an alternative route for creation of the β-tyveloside linkage.

Use of a 3,6-dideoxy-D-ribohexopyranose (paratose) derivative as a precursor of the target tyvelosides became the strategy of choice, since the anomeric β-linkage is easily introduced by exploiting a C-2 participating group. The C-2 hydroxyl group can be inverted to its C-2 epimer through an oxidation–reduction sequence (36, 37). It was reported that by carefully choosing the reducing agent, the axial OH-2 epimer could be obtained in high yield. Recently, we published a new methodology to allow the preparation of 3,6-dideoxy-D-hexopyranoses (abequose and paratose) on a large scale and in high yields (38); furthermore, this methodology permits the facile introduction of different protecting groups at the C-2 and C-4 positions. For this purpose we employed a previously prepared paratose thioglycoside **20** as starting material (38).

Since benzoyl and pivaloyl protecting groups are superior participating groups when compared to the corresponding acetate ester, we converted **20** to the 2-OH derivative **21** and then prepared the corresponding benzoylated and pivaloylated donors **22** and **23** (Scheme 2). In our preliminary investigation, it was found that **22** and **23** gave similar yields when reacted with 2-azido galactosyl acceptor **24** (39). Due to the relative ease with which the benzoate group can be removed, the benzoylated donor **22** was used for all glycosylations. Using *N*-iodosuccinimide – triflic acid as the activation conditions, the disaccharide **25** was obtained in 83% yield. After removal of benzoate (→**26**, 94%), the 2′-hydroxyl group was oxidized to the corresponding ketone **27** by DMSO–Ac_2O. The intermediate ketone **27** was not isolated but immediately reduced. When excess L-selectride was used as the reducing reagent, the corresponding β-tyveloside was obtained in excellent stereoselectivity (→**28**, 92%), no paratose derivative was detected by NMR,

and the 2-azido group was simultaneously reduced to the amine. The amino disaccharide **4** (90%) was obtained from **28** following removal of benzyl and benzylidene groups by Birch reduction. The fully protected 2-amino disaccharide **28** was acetylated using acetic anhydride in methanol (→**29**, 93%), and the protecting groups were successfully removed by hydrogenation to afford the native disaccharide **3** (88%). When compound **3** was subjected to a dibutyltin-oxide-assisted

methylation, the corresponding 6-*O*-methyl ether derivative **10** was obtained in moderate yield (44%).

With compound **29** in hand, the 2′-hydroxyl group was methylated using sodium hydride (Scheme 3) and a controlled amount of methyl iodide as reagent, the methylated derivative **30** was obtained (37%). The poor yield reflected incomplete methylation which results from the conditions employed which are designed to avoid *N*-methylation. The benzyl and benzylidene were removed by hydrogenation to give the 2′-OMe disaccharide **12** (93% yield). To prepare the corresponding 2′-deoxgenated disaccharide **11**, **29** was transformed to **31** (98%) by reaction with 1,1′-thiocarbonyldiimidazole, and 2′-deoxygenation was realized after subjecting **31** to reaction with tributyltin hydride (→**32**, 95%) (40). After hydrogenation, the desired 2′-deoxy compound **11** was obtained in excellent yield (95%).

The 4′-deoxygenated disaccharide **13** was prepared from disaccharide **29** (Scheme 4). Benzoylation of **29** gave **33**

(87%), and the 4′-benzyl group was selectively removed by transfer hydrogenation in the presence of the benzylidene acetal using ammonium formate – Pd-C conditions (→**34**, 78%). The 4′-OH was deoxygenated via a similar sequence to that described for the synthesis of compound **32**, (→**35** (92%), →**36** (83%)), and the final disaccharide **13** was obtained after removing the protecting groups by Zemplen transesterification and hydrogenation (→**13**, 88%).

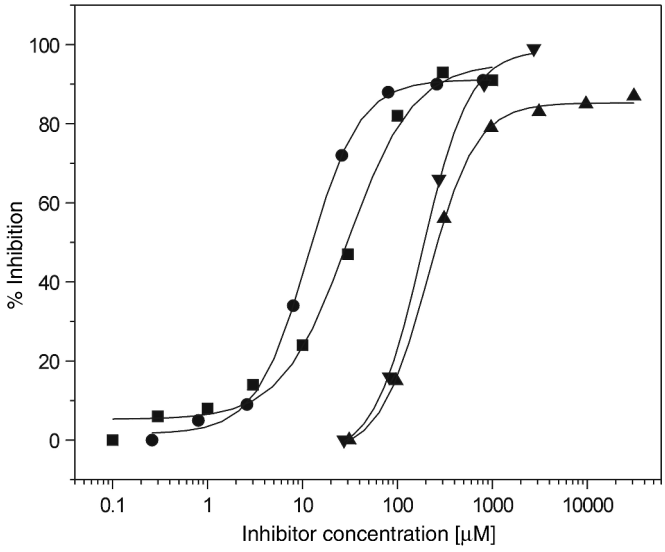
The synthesis of 6-deoxyGalNAc disaccharide **9** also started from compound **29** (Scheme 5). The benzyl ether was removed selectively in the presence of the benzylidene acetal in a manner similar to the conversion of **33** to **34** to give **37** (79%), together with **3** (11%) resulting from loss of the benzylidene acetal. The diol **37** was benzoylated (→**38**, 89%), and the acetal was removed under standard hydrogenation conditions using palladium hydroxide on charcoal as catalyst (→**39**, 89%). The 6-OH was reduced through a sequence of tosylation (→**40**), displacement by bromide to give **41**, and reduction using tributyltin hydride (→**42**). The intermediates **40**–**42** were not isolated, and after transesterification of the 2′,4′-dibenzoate **42**, the targeted compound **9** was obtained in moderate yield (49% from **39**).

Initially it was planned to obtain the 4′-OMe disaccharide **14** by methylation of intermediate **34**. However, when **34** was methylated using methyl triflate and 2,6-di-*tert*-butyl-4-methylpyridine, no methylated product was isolated. It was then decided to use a 4-*O*-methylated paratose donor **47** as starting material (Scheme 6). The paratose thioglycoside **47** was obtained in several transformation steps. Thus, starting from compound **43** (38), the 4-OH was methylated (→**44**, 92%), and the 1,2-propylidene acetal was hydrolyzed and the diol **45** benzoylated (→**46**, 96%). The anomeric benzoate was converted to the mixture of anomeric thioglycosides **47** (89%) using $PhSSiMe_3$–TMSOTf as reagents. Disaccharide **48** was obtained in good yield (78%) after coupling **47** with acceptor **24** using *N*-iodosuccinimide – triflic acid as promoter. After removing the 2′-benzoate (→**49**, 94%), the 4′-*O*-methylated disaccharide **10** was obtained by oxidation to the keto compound **50** followed by reduction and deprotection (→**51** (76%), →**14** (94%)).

To prepare the 4-*O*-monomethylated disaccharide **8**, we decided to use compound **56** as an acceptor (Scheme 7). Compound **56** has a methyl group preinstalled at the 4-position, and was prepared starting from 2-azido galactopyranosyl derivative **52** (39). Thus, by heating a solution of triol **52** with bis(tributyltin)oxide, the 3,6-positions were benzoylated to give **53** in very good yield (86%) and selectivity. The 4-OH was methylated (→**54**, 94%) using methyl triflate as reagent in the presence of the bulky base, 2,6-di-*tert*-butyl-4-methylpyridine. The benzoates were removed (→**55**, 97%) and the primary hydroxyl group was selectively silylated using *tert*-butyldimethylsily chloride as reagent to give the acceptor **56** (84%). Glycosylation of **56** with donor **22** afforded the disaccharide **57** in 71% yield. After removing the 2′-*O*-benzoate (→**58**, 98%), the 2′-equatorial hydroxyl group was inverted to the corresponding 2′-axial configuration by an oxidation–reduction sequence as describe above (→**60**, 76%), and the disaccharide **8** (88%) was obtained following deprotection.

The synthesis of 4-mono-deoxygenated disaccharide **7** (Scheme 8) started with glucosamine alcohol **17**. The 3-hydroxyl group was protected as a benzoate (→**61**, 96%), and the 4,6-*O*-benzylidene acetal was regioselectively opened to afford the alcohol **62** in excellent yield (95%). The 4-OH position was deoxygenated through a two-step Barton–McCombie deoxygenation reaction (40) as describe above (→**63** (94%), →**64** (88%)). After removing the 3-*O*-benzoate (→**65**, 94%), the acceptor **65** was glycosylated by donor **22** to produce the disaccharide **66** in moderate yield (54%).

Fig. 3. Representative inhibition curves obtained with the monoclonal antibody 9D4 and the following disaccharides: disaccharide **10** (6-*O*-methyl GalNAc congener) (●), disaccharide **4** (2-amino GalNAc congener) (■), native disaccharide **3** (▼), disaccharide **5** (2-hydroxy GalNAc congener) (▲). Microtiter plates were coated with [β-D-Tyv(1→3)β-D-GalNAc]$_8$-BSA glycoconjugate and diluted monoclonal antibody solutions containing increasing amounts of inhibitor were added to the plate. Bound antibody was detected by a species-specific antibody–horseradish peroxidase conjugate and percentage inhibitions are expressed relative to wells that contained no inhibitor. Each point is the average of three values and the standard deviation on each point was ±5% or better.



Compound **66** was debenzoylated to give the alcohol **67** (91%). Oxidation gave the keto derivative **68**, which was reduced to give **69.** The protecting groups were finally removed by Birch reduction to afford the pure 4-deoxy-disaccharide **7** (overall 23% yield from **67**).

We have described the synthesis of a comprehensive set of disaccharide congeners **4**–**14** (Fig. 2) related to the *T. spiralis* epitope β-D-Tyv*p*(1→3)β-D-GalNAc*p* (**3**). The congeners are modified at each position bearing a hydroxyl or acetamido group. The ability of these disaccharides to inhibit binding of the monoclonal antibodies 9D4 and 18H1 to a β-D-Tyv*p*(1→3)β-D-GalNAc*p* BSA glyconconjugate (16) was assayed in a solid-phase ELISA format. Briefly the disaccharide conjugate was coated on ELISA plates and incubated with antibody in the presence of increasing amounts of inhibitor. Bound antibody was detected by a goat anti-rat IgG antibody and percentage inhibition was calculated relative to wells that contained no inhibitor. The structure activity data was used to infer a topological map of the epitope surface for each antibody binding site. The quality of the inhibition data obtained in this work is illustrated in Fig. 3 and the inhibitory activities for compounds **1**–**14** with both monoclonal antibodies 9D4 and 18H1 are recorded in Tables 1–3.

In designing the set of congeners we followed the approach pioneered by Lemieux and co-workers (34) for detecting intermolecular hydrogen bonds present in a protein–oligosaccharide complex. The inhibitory power of mono-deoxy and mono-*O*-methyl congeners identifies hydroxyl

groups that are buried and involved in key polar interactions with the protein, as well as those hydroxyl groups exposed to solvent water. Hydroxyl groups that are positioned around the periphery of the complex may also be identified from the relative inhibitory power of monodeoxy and mono-*O*-methyl congeners thus providing a detailed topology of the interacting surface. Inactive monodeoxy and mono-*O*-methyl congeners pinpoint hydroxyl groups that are buried and involved in key polar interactions. When these modifications are made to solvent exposed hydroxyl groups only minor changes are registered in their binding activity. However, when mono-*O*-methylation or monodeoxygenation replaces hydroxyl groups that lie at the periphery of the protein–oligosaccharide complex large swings in activity for either one or both of the derivatives can be observed. Frequently the changes may result in enhanced binding energy. In general, binding at the periphery is indicated when the deoxy congener is active but the mono-*O*-methyl compound is inactive (41). However, if a hydroxyl at the periphery is an acceptor of a hydrogen bond the *O*-methyl derivative may be even more active than the deoxy congener (42, 43).

At first appearance the recognition of the dideoxyhexose residue by both antibodies is similar. The C-4 hydroxyl group is buried in the binding site and makes essential polar contacts. The hydroxyl group at C-2 appears to make much weaker polar contacts perhaps via a hydrogen bond either from the protein or via a water molecule. Mono-*O*-methyl disaccharide **12** is five to eight times more active than **3** with each antibody, whereas, with the antibody 9D4, the deoxy compound is almost as active as the native disaccharide **3**, while with 18H1 the same compound is fourfold less active. In both cases this suggests that this hydroxyl group resides close to the periphery of the binding site. When interacting with 18H1 **12** may either accept a hydrogen bond or the methyl group can make favourable contacts with the protein, and (or) displace a water molecule.

It is immediately obvious that the two monoclonal antibodies recognize the GalNAc residue via completely different surfaces. The 2-acetamido group is of major importance for MAb 18H1, since disaccharides modified at C-2 (**4** and **5**) are inactive. The C-4 hydroxyl group is clearly not involved in protein contacts since the C-4 epimer **6** is more active than **3**, and the 4-deoxy and mono-*O*-methyl disaccharides **7** and **8** have activities close to that of **3**. The C-6 hydroxyl must reside close to the periphery of the binding site since the methyl ether **10** is twice as active as **3**.

The recognition of GalNAc by MAb 9D4 is quite distinct. The acetamido group is not important to binding, since Gal may substitute for GalNAc without impact, and in fact the free amino disaccharide **5** is almost six times more active than **3**. Steric changes at C-4 are prohibitive since the C-4 epimer **6** is inactive, as is the mono-*O*-methyl disaccharide **8**. However, the 4-deoxy disaccharide **7** is almost unchanged compared to **3.** The 6-deoxy disaccharide **9** is only slightly less active than **3**, while the methyl ether **10** is 18 times more active than **3**. This suggests that both C-4 and C-6 hydroxyl group reside at the edge of the binding site and the C-6 *O*-methyl group is able to make a productive interaction at the periphery of the binding site via van der Waal contacts or by replacing a water molecule.

These data (Table 3) may be integrated with the initial inhibition data for tetra, tri, and disaccharides **1**–**3** (Table 1) and lead to the conclusion that the poorly protective MAb 18H1 only interacts with the terminal disaccharide of the *T. spiralis N*-glycan chains. There are no antibody contacts with the proximal branching fucose residue, since the underside of the Tyv and GalNAc residues contact the binding site leaving Tyv O-2 at the periphery and the major polar contacts being O-4 (Tyv) and the 2-acetamido group of GalNAc. This is consistent with the noninvolvement of GalNAc 4-OH. The key polar groups and those at the periphery of the binding site are shown in the stereo plots as CPK plots and as a Connolly surface (44) (Fig. 4).

While the recognition of Tyv by MAb 9D4 initially appeared to be similar to that by 18H1, the most deeply buried surface of the Tyv likely extends around the opposite face involving the C-6 methyl group and ring oxygen atoms. For 9D4 the involvement of its binding site with the GalNAc residue is almost the exact opposite of the situation with 18H1, and must involve the top face of the GalNAc residue. Whereas, the acetamido group can be replaced by OH without significant loss of binding, both O-4 and O-6 are close to the periphery of the site, and since the fucose residue is adjacent to these groups and protrudes from this upper face,

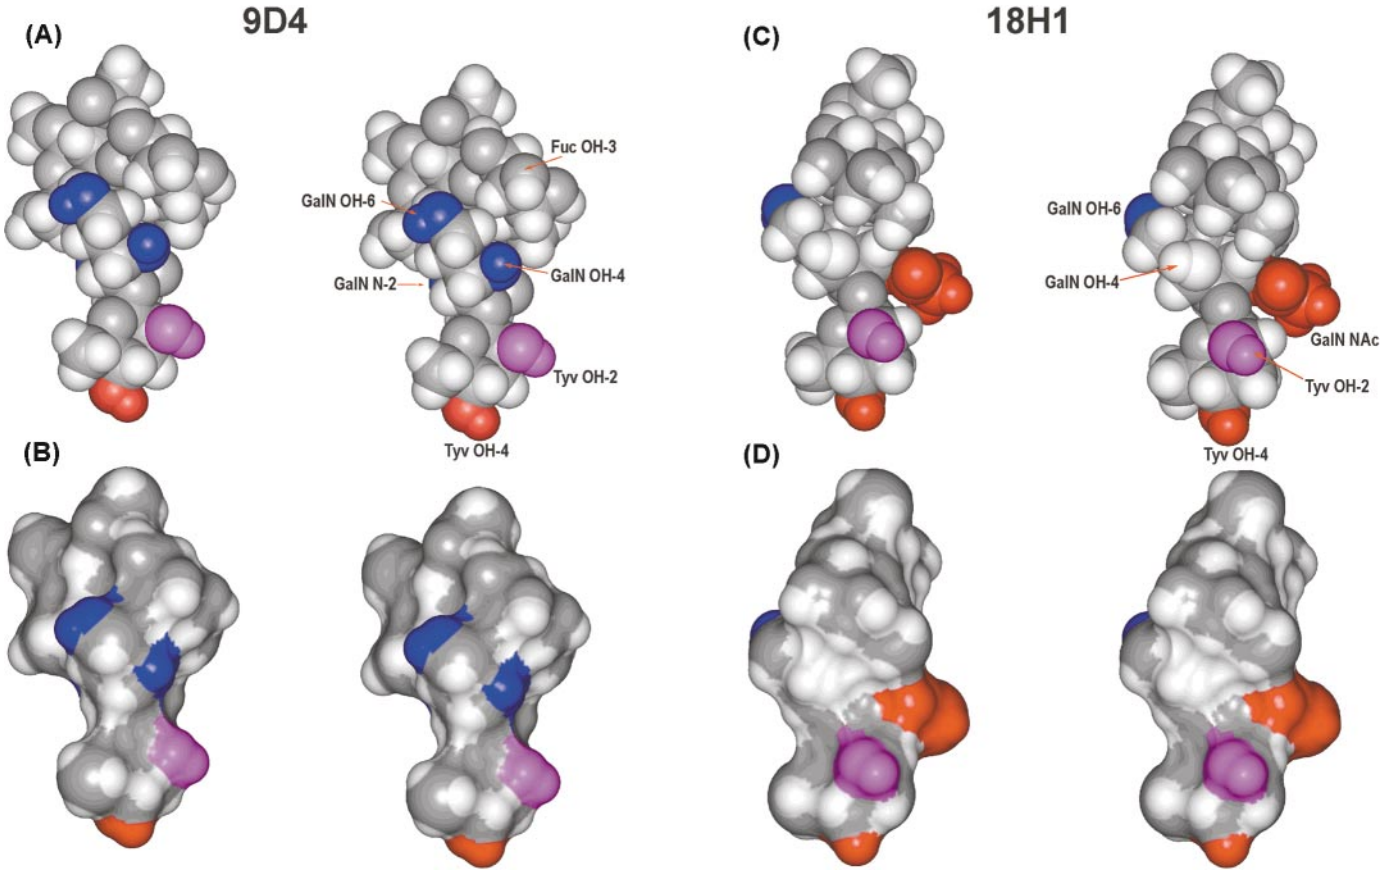
Fig. 4. Stereo drawings of the epitopes recognized by antibodies 9D4 and 18H1. Functional groups shown in red make crucial hydrogen bonds with the binding sites. Groups shown in pink are involved in contacts at the periphery of the binding site. Groups shaded blue are also located at the periphery. (*a*) Space-filling model showing the epitope residues Tyv O-4 and O-2 and GalNAc O-4 that create the contact surface for the 9D4 epitope. (*b*) Connolly surface of the 9D4 epitope. (*c*) Space-filling model showing the epitope residues Tyv O-4 and O-2 and GalNAc acetamido groups that create the contact surface for the 18H1 epitope. (*d*) Connolly surface of the 18H1 epitope.



its involvement in binding together with a minor contribution from the GlcNAc residue are readily appreciated (Fig. 4, Tables 1 and 2).

Investigation of a number of antibody binding sites by functional group replacement studies has shown that a small number of hydroxyl groups, and where appropriate, acetamido groups provide from two to four key polar contacts. Without these complex formation does not occur. The binding of *T. spiralis N*-glycans to antibody 18H1 conforms to this pattern, where O-4 of tyvelose and the acetamido group of GalNAc are involved in crucial polar interactions and to a lesser extent O-2 of tyvelose. Monoclonal 9D4 is quite different and its recognition of the disaccharide involves only one key polar contact, which is again O-4 of tyvelose. The tyvelose residue is recognized from the opposite face, which would require its 6-deoxy group to be buried and involved in hydrophobic contacts. Involvement of GalNAc O-4 and O-6 at the periphery is consistent with this, as is the ability to modify the acetamido function without penalty. The complete recognition surface of the carbohydrate epitope for 9D4 must extend to include the GlcNAc and Fuc residues since both trisaccharide **2** and tetrasaccharide **1** are more active inhibitors than the disaccharide **3** (Table 1). One or both of these residues may provide additional polar contacts. At this stage we would infer that this is most likely to be O-2 or O-3 of fucose.

The superior protective ability of MAb 9D4 correlates with the higher affinity for its larger tetrasaccharide target epitope, which is about 20 times the affinity of the poorly protective MAb 18H1 for its smaller disaccharide target epitope (Table 1) (21, 24). Although the key recognition element in both cases is the terminal disaccharide, the surface of the oligosaccharide epitope that is buried determines the degree to which the buried surface area can be extended. For MAb 9D4 the inclusion of the fucose residue can be contrasted with the restriction of MAb 18H1 to contacts that do not extend beyond the terminal disaccharide and involve polar contacts with O-4 and O-2 (Tyv) and NHAc (GalNAc) and possible non-polar interactions with this group. It appears that the additional specificity element and larger surface area of interaction lead to tighter binding and that this is essential for full bioactivity.

Experimental

General methods

Optical rotations were measured with a PerkinElmer 241 polarimeter for samples in a 10-cm cell at 22 ± 2°C and $[\alpha]_D$

values are given in units of 10^{-1} deg cm^2 g^{-1}. Analytical TLC was performed on plates of Silica Gel 60-F_{254} (Merck, Darmstadt) with detection by quenching of fluorescence and (or) by charring with 5% sulfuric acid in water. All commercial reagents were used as supplied and chromatography solvents were distilled prior to use. Column chromatography was performed on Silica Gel 60 (Silicycle, Quebec, Canada). ^{1}H NMR spectra were recorded on Varian Unity 300, 500, or 600 MHz. The first-order proton chemical shifts δ_H are referenced to either residual $CHCl_3$ (δ_H 7.24, $CDCl_3$) or residual CD_2HOD (δ_H 3.30, CD_3OD), or internal acetone (δ_H 2.225, D_2O). First order coupling constants are given in Hz. HMQC-NMR spectra were recorded on Varian spectrometers operating at 300, 500, or 600 MHz. The ^{13}C chemical shifts (δ_C) are referenced to internal $CDCl_3$ (δ_C 77.00, $CDCl_3$). Organic solutions were dried prior to concentration under vacuum at <40°C (bath). Final compounds were purified by reverse-phase chromatography performed on a Waters 600 HPLC system, using a Beckman semipreparative C-18 column (10 × 250 mm, 5 μ), and the products were detected with a Waters 2487 UV detector or a Waters 2410 refractive index monitor. Microanalyses and electrospray mass spectra were performed by the analytical services of this department. Reaction yields were not optimized.

Enzyme immunoassay

Inhibition assays were performed in triplicate in 96 well microtiter plates with the previously described rat monoclonal antibodies 18H1 (IgG_1) and 9D4 (IgG_{2c}) (3). Microtiter plates were incubated for 18 h at 4°C with a solution of [β-D-Tyv(1→3)β-D-GalNAc]$_8$-BSA glycoconjugate (100 μL/well) dissolved in 0.01 M phosphate-buffered saline solution at a concentration of 1 μg mL^{-1} (16). The plate was washed with PBST (5×) and blocked for 1 h at room temperature by incubation with 2% BSA in PBS (100 μL). After the plate had been washed with PBST (3×), antibody solution with or without inhibitor was added (100 μL) to the plate incubated for 18 h at room temperature. Monoclonal antibody 18H1 was used from ascites fluid at a final dilution of 5×10^{-5} and 9D4 at a dilution of 1.5×10^{-3}. The plate was washed with PBST (5×), and goat anti-rat IgG antibody conjugated to horse radish peroxidase (Kirkegaard and Perry Lab, Mandel, Guelph, ON) solution (100 μL) diluted (1:5000) in PBS was incubated for 1 h at room temperature. The plate was washed with PBST (5×), 3,3′,5,5′-tetramethylbenzidine (TMB, 100 μL) was added, and after 2 min the colour reaction was stopped by the addition of 1 M phosphoric acid (100 μL). Absorbance was read at 450 nm and percent inhibition was calculated using wells containing no inhibitor as the reference point. Triplicate samples typically exhibited OD values with a standard deviation of ±5% or better. Wells with OD values outside this error range were discarded and eliminated from the data analysis. Inhibition curves were drawn using the software package Origin 5.0 (OriginLab, Northampton, MA), and the IC_{50} value was computed by the software.

Methyl 2-*O*-benzyl-4,6-*O*-benzylidene-3-*O*-(2,4-di-*O*-benzyl-3,6-dideoxy-β-D-*arabino*-hexopyranosyl)-β-D-galactopyranoside (18)

A mixture of acceptor **16** (35) (105 mg, 0.28 mmol), silver zeolite (300 mg), and 4 Å molecular sieves (300 mg) in anhyd CH_2Cl_2 (3 mL) was stirred for 30 min at room temperature, and cooled to −40°C. A solution of tyvelosyl chloride **15** (125 mg, 0.36 mmol, prepared by reacting the corresponding hemi-acetal with oxalyl chloride (22)) in anhyd CH_2Cl_2 (2.5 mL) was added dropwise and the mixture was slowly warmed to room temperature and stirred for 24 h. The mixture was filtered off, and the filtrate was concentrated. The disaccharide **18** was obtained by chromatography on silica gel using 15% EtOAc – toluene as eluent (29 mg, 15%), $[\alpha]_D$ + 27.3 (*c* 2.1, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 7.51–7.58 (m, 2H, Ar), 7.10–7.36 (m, 18H, Ar), 5.56 (s, 1H, PhCH), 4.83 (d, 1H, *J* = 11.2 Hz, Bn), 4.77 (d, 1H, *J* = 13.2 Hz, Bn), 4.75 ("s", 1H, H-1′), 4.68 (d, 1H, *J* = 13.2 Hz, Bn), 4.55 (d, 1H, *J* = 11.5 Hz, Bn), 4.27–4.37 (m, 4H, H-1, H-6a, H-4, Bn), 4.06 (dd, 1H, *J* = 1.6, 12.3 Hz, H-6b), 3.76–3.84 (m, 2H, H-2, H-3), 3.57 (s, 3H, OMe), 3.28–3.52 (m, 4H, H-5, H2′, H-4′, H-5′), 2.23 (d′t′, 1H, *J* = 4.0, 13.4 Hz, H-3e′), 1.31 (d, 3H, *J* = 6.1 Hz, H-6′), 1.18 (m, 1H, H-3a′). Anal. calcd. for $C_{41}H_{46}O_9$: C 72.12, H 6.79; found: C 72.19, H 6.49.

Methyl 3-*O*-(3,6-dideoxy-β-D-*arabino*-hexopyranosyl)-β-D-galactopyranoside (5)

A mixture of disaccharide **18** (26 mg, 0.038 mmol) and 10% $Pd(OH)_2$ on charcoal (20 mg) in MeOH (10 mL) was hydrogenated overnight. The catalyst was filtered and the filtrate was concentrated, and the residue was purified by reverse phase HPLC using H_2O–MeOH (linear gradient 0 → 20%) as eluent to afford **5** (11 mg, 89%), $[\alpha]_D$ –21.2 (*c* 0.6, MeOH). ^{1}H NMR (CD_3OD) δ: 4.76 (d, 1H, *J* = 1.1 Hz, H-1′), 4.16 (m, 1H, H-1, high order), 4.03 (m, 1H, H-4), 3.96 (m, 1H, H-2′), 3.69–3.79 (m 2H, H-6a, H-6b), 3.59–3.61 (m, 2H, H-2, H-3), 3.45–3.57 (m, 6H, H-5, H-4′, OMe, H-4), 3.30 (dq, 1H, *J* = 6.1, 9.3 Hz, H-5′), 2.14 (ddd, 1H, *J* = 3.3, 4.6, 13.6 Hz, H-3e′), 1.55 (ddd, 1H, *J* = 2.9, 11.4, 13.6 Hz, H-3a′), 1.27 (d, 3H, *J* = 6.1 Hz, H-6′). HR-ES-MS *m/e* calcd. for $C_{13}H_{24}O_9$ (MNa^+): 347.13180; found: 347.131922.

Methyl 2-acetamido-3-*O*-(2,4-di-*O*-benzyl-3,6-dideoxy-β-D-*arabino*-hexopyranosyl)-4,6-*O*-benzylidene-2-deoxy-β-D-glucopyranoside (19)

A mixture of acceptor **17** (45) (88 mg, 0.27 mmol), silver zeolite (300 mg), and 4 Å molecular sieves (400 mg) in anhyd CH_2Cl_2 (3 mL) was stirred for 30 min at room temperature, and cooled to −40°C. A solution of tyvelosyl chloride **15** (173 mg, 0.50 mmol, prepared by reacting the corresponding hemi-acetal with oxalyl chloride (22)) in anhyd CH_2Cl_2 (2.5 mL) was added dropwise and the mixture was slowly warmed to room temperature and stirred for 24 h. The mixture was filtered off, and the filtrate was concentrated. The disaccharide **19** was obtained by chromatography on silica gel using 35% EtOAc – toluene as eluent (44 mg, 26%), $[\alpha]_D$ –0.8 (*c* 1.7, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 7.47–7.52 (m, 2H, Ar), 7.23–7.37 (m, 13H, Ar), 5.52 (s, 1H, PhCH), 5.45 (d, 1H, *J* = 7.1Hz, NH), 4.86 (d, 1H, *J* = 8.2 Hz, H-1), 4.70 (d, 1H, *J* = 1.2 Hz, H-1′), 4.64 (d, 1H, *J* = 12.5 Hz, Bn), 4.58 (d, 1H, *J* = 12.5 Hz, Bn), 4.38–4.50 (m, 3H, 2 × Bn, H-3), 4.32 (dd, 1H, *J* = 4.9, 10.4 Hz, H-6a), 3.76 (t, 1H, *J* = 10.2 Hz, H-4), 3.65 (t, 1H, *J* = 9.2 Hz, H-6b), 3.59 (m, 1H, H-2′), 3.47 (s, 3H, OMe), 3.36–3.53 (m, 3H, H-5, H-4′, H-5′), 3.13 (m, 1H, H-2), 2.27 (ddd, 1H,

Methyl 2-amino-3-*O*-(4-*O*-benzyl-3,6-dideoxy-β-D-*arabino*-hexopyranosyl)-4,6-*O*-benzylidene-2-deoxy-β-D-galactopyranoside (28)

The alcohol **26** (289 mg, 0.548 mmol) was dissolved in a mixture of anhyd DMSO (4 mL) and Ac_2O (2 mL) at 0°C. The reaction was left at ambient temperature overnight. After removing the solvents under reduced pressure, the mixture was filtered through a thin bed of silica gel using 40% EtOAc–hexane as eluent to give the intermediate ketone **27** (235 mg, 82% yield) which was divided in two parts for the preparation of both compound **28** and **29**.

A portion of **27** (40 mg, 0.076 mmol) was dissolved in anhyd THF (3 mL) at 0°C, a solution of L-selectride in THF (1.0 M, 300 μL, 0.3 mmol) was added dropwise and the reaction was continued for 1 h. Water (1 mL) was added and the reaction mixture was concentrated. The syrupy mixture was dissolved in CH_2Cl_2 (50 mL), washed with a 10% aqueous solution of $Na_2S_2O_3$ (20 mL) and saturated brine (20 mL), dried and concentrated. The mixture was purified by chromatography on silica gel using 5% MeOH–CH_2Cl_2 as eluent to afford the amine **28** (35 mg, 92% yield), $[\alpha]_D$ +40.2 (*c* 1.5, $CHCl_3$). ^1H NMR ($CDCl_3$) δ: 7.49 (m, 2H, Ar), 7.22–7.36 (m, 8H, Ar), 5.53 (s, 1H, PhCH), 4.76 (d, 1H, *J* = 1.0 Hz, H-1′), 4.59 (d, 1H, *J* = 11.5 Hz, Bn), 4.44 (d, 1H, *J* = 11.5 Hz, Bn), 4.31 (dd, 1H, *J* = 1.4, 12.4 Hz, H-6a), 4.25 ("d", 1H, *J* = 3.1 Hz, H-4), 4.12 (d, 1H, *J* = 7.8 Hz, H-1), 4.05 (dd, 1H, *J* = 1.7, 12.4 Hz, H-6b), 3.94 (m, 1H, H-2′), 3.65 (dd, 1H, *J* = 3.9, 10.5 Hz, H-3), 3.53 (s, 3H, OMe), 3.48 (m, 2H, H-4′ +H-5′), 3.41 (m, 1H, H-5), 3.26 (dd, 1H, *J* = 7.9, 10.4 Hz, H-2), 2.43 (d′t′, 1H, *J* = 3.9, 13.7 Hz, H-3e′), 1.52 (m, 1H, H-3a′), 1.32 (d, 3H, *J* = 5.7 Hz, H-6′). Methyl 2-amino-3-*O*-(3,6-dideoxy-β-D-arabino-hexopyranosyl)-2-deoxy-β-D-galactopyranoside (4)

With the help of a dry ice – acetone condenser, liquid ammonia (25 mL) was collected in a flask containing the amine **28** (35 mg, 0.07 mmol). A small piece of sodium (100 mg) was added, and reaction was continued for 4 h. During this time, the reaction mixture remained dark blue. The condenser was removed and MeOH (0.5 mL) was added. The colour of the reaction mixture turned white and the ammonia was allowed to evaporate. After the evaporation of NH_3, the residue was purified by reverse-phase chromatography using a gradient of H_2O–MeOH (0 → 30%) as eluent to yield compound **4** (20.5 mg, 90% yield), $[\alpha]_D$ –7.1 (*c* 0.2, MeOH). ^1H NMR (D_2O) δ: 4.84 (d, 1H, *J* = 0.7 Hz, H-1′), 4.60 (d, 1H, *J* = 8.6 Hz, H-1), 4.28 ("d", 1H, *J* = 2.9 Hz, H-4), 4.10 (m, 1H, H-2′), 4.03 (dd, 1H, *J* = 2.9, 10.8 Hz, H-3), 3.84 (dd, 1H, *J* = 7.9, 11.7 Hz, H-6a), 3.78 (dd, 1H, *J* = 4.2, 11.7 Hz, H-6b), 3.76 (m, 1H, H-5), 3.61 (s, 3H, OMe), 3.58 (ddd, 1H, *J* = 4.8, 9.34, 11.5 Hz, H-4′), 3.48 (dq, 1H, *J* = 6.0, 9.3 Hz, H-5′), 3.32 (dd, 1H, *J* = 8.6, 10.6 Hz, H-2), 2.20 (ddd, 1H, *J* = 3.5, 4.6, 13.9 Hz, H-3e′), 1.69 (ddd, 1H, *J* = 2.9, 11.5, 14.1 Hz, H-3e′), 1.28 (d, 3H, *J* = 6.1 Hz, H-6′). HR-ES-MS *m*/*e* calcd. for $C_{13}H_{25}O_8N$ (MNa^+): 346.14779; found: 346.148284.

Methyl 2-acetamido-3-*O*-(4-*O*-benzyl-3,6-dideoxy-β-D-*arabino*-hexopyranosyl)-4,6-*O*-benzylidene-2-deoxy-β-D-galactopyranoside (29)

The intermediate ketone **27** (106 mg, 0.2 mmol) was dissolved in anhyd THF (3 mL) at 0°C, a solution of L-selectride in THF (1.0 M, 1.5 mL, 1.5 mmol) was added dropwise, and the reaction was continued at 0°C for 1 h. Water (0.3 mL) was added, after 10 min, Ac_2O (2 mL) was added dropwise, the reaction was continued for 30 min. After concentration, the mixture was dissolved in CH_2Cl_2 (100 mL), the organic solution was washed with a 10% aqueous solution of $Na_2S_2O_3$ (1 × 50 mL) and saturated brine (50 mL), dried, and evaporated. The mixture was purified by chromatography on silica gel using 2.5% MeOH–CH_2Cl_2 as eluent to afford compound **29** (102 mg, 93% yield), $[\alpha]_D$ +56.5 (*c* 0.6, $CHCl_3$). ^1H NMR ($CDCl_3$) δ: 7.46–7.52 (m, 2H, Ar), 7.22–7.36 (m, 8H, Ar), 5.95 (d, 1H, *J* = 7.0 Hz, NH), 5.52 (s, 1H, PhCH), 5.02 (d, 1H, *J* = 8.2 Hz, H-1), 4.73 (dd, 1H, *J* = 3.4, 11.1 Hz, H-3), 4.57 (d, 1H, *J* ~ 1 Hz, H-1′), 4.56 (d, 1H, *J* = 11.5 Hz, Bn), 4.42 (d, 1H, *J* = 11.5 Hz, Bn), 4.26–4.36 (m, 2H, H-6a, H-4), 4.04 (dd, 1H, *J* = 1.6, 12.4 Hz, H-6b), 3.83 (br m, 1H, H-2′), 3.51 (br, 4H, OMe, H-5), 3.38–3.50 (m, 3H, H-2, H-4′, H-5′), 2.33–2.39 (m, 2H, H-3e′, OH-2′), 1.85 (s, 3H, Ac), 1.38 (m, 1H, H-3a′), 1.30 (d, 3H, *J* = 5.6 Hz, H-6′). Methyl 2-acetamido-3-*O*-(3,6-dideoxy-β-D-*arabino*-hexopyranosyl)-2-deoxy-6-*O*-methyl-β-D-galactopyranoside (10)

A mixture of tetraol **3** (31.6 mg, 0.0865 mmol) and dibutyltin oxide (26 mg, 0.104 mmol) in anhydrous methanol (4 mL) was refluxed for 2 h. The mixture was concentrated and coevaporated with toluene (2 × 15 mL), and dried under high vacuum. The mixture was dissolved in anhyd DMF (2 mL). CsF (40 mg, 0.259 mmol) and MeI (16 μL, 0.259 mmol) were added, and the reaction was heated to 50°C overnight. The solution was concentrated under reduced pressure and the desired 6-*O*-methyl disaccharide **10** was obtained by reverse-phase HPLC using a gradient of H_2O–MeOH (0 → 20%) as eluent (14.5 mg, 44% yield), $[\alpha]_D$ –34.8 (*c* 0.3, MeOH). Starting material **3** (18 mg) was also recovered. ^{1}H NMR (D_2O) δ: 4.68 ("s", 1H, H-1′), 4.45 (d, 1H, *J* = 8.6 Hz, H-1), 4.10 ("d", 1H, *J* = 3.2 Hz, H-4), 4.01 (dd, 1H, *J* = 8.6, 10.8 Hz, H-2), 3.89 (m, 1H, H-2′), 3.87 (dd, 1H, *J* = 3.1, 10.8 Hz, H-3), 3.83 (m, 1H, H-5), 3.72 (dd, 1H, *J* = 7.7, 10.8 Hz, H-6a), 3.68 (dd, 1H, *J* = 4.0, 11.0 Hz, H-6b), 3.55 (ddd, 1H, *J* = 4.6, 9.2, 11.4 Hz, H-4′), 3.52 (s, 3H, OMe), 3.44 (dq, 1H, *J* = 6.0, 9.3 Hz, H-5′), 3.42 (s, 3H, OMe), 2.17 (ddd, 1H, *J* = 3.7, 4.6, 13.9 Hz, H-3e′), 2.03 (s, 3H, Ac), 1.65 (ddd, 1H, *J* = 3.1, 11.5, 14.3 Hz, H-3a′), 1.28 (d, 3H, *J* = 6.2 Hz, H-6′). HR-ES-MS *m/e* calcd. for $C_{16}H_{29}O_9N$ (MNa^+): 402.17400; found: 402.174490.

Methyl 2-acetamido-3-*O*-(4-*O*-benzyl-3,6-dideoxy-2-*O*-methyl-β-D-*arabino*-hexopyranosyl)-4,6-*O*-benzylidene-2-deoxy-β-D-galactopyranoside (30)

Alcohol **29** (42 mg, 0.077 mmol) was dissolved in anhyd DMF (1 mL) at 0°C, NaH (9 mg, 0.38 mmol) was added, and the mixture was stirred for 15 min. MeI (5.2 μL, 0.085 mmol) was added, and the reaction was continued for another 1 h. Methanol (100 μL) was added, and the mixture was concentrated. Chromatography on silica gel using 5% MeOH–CH_2Cl_2, gave the desired disaccharide **30** (16 mg, 37% yield), $[\alpha]_D$ +42.6 (*c* 0.5, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 7.44–7.53 (m, 2H, Ar), 7.21–7.33 (m, 8H, Ar), 5.78 (d, 1H, *J* = 6.4 Hz, NH), 5.55 (s, 1H, PhCH), 5.02 (d, 1H, *J* = 8.2 Hz, H-1), 4.67 (br d, 1H, *J* ~ 1 Hz, H-1′), 4.59 (dd, 1H, *J* = 3.3, 11.1 Hz, H-3), 4.55 (d, 1H, *J* = 11.6 Hz, Bn), 4.44 (d, 1H, *J* = 11.6 Hz, Bn), 4.34 (d, 1H, *J* = 3.1 Hz, H-4), 4.30 (dd, 1H, *J* ~ 1, 12.4 Hz, H-6a), 4.06 (dd, 1H, *J* = 1.4, 12.3 Hz, H-6b), 3.35–3.58 (m, 5H, H-5′, H-2′, H-4′ H-2, H-5), 3.50 (s, 3H, OMe), 3.40 (s, 3H, OMe), 2.35 (ddd, 1H, *J* = 4.4, 4.4, 13.5 Hz, H-3e′), 1.93 (s, 3H, Ac), 1.43 (dd, 1H, *J* = 3.0, 10.3, 13.3 Hz, H-3a′), 1.31 (d, 3H, H-6′). Methyl 2-acetamido-3-*O*-(2-*O*-benzoyl-4-*O*-benzyl-3,6-dideoxy-β-D-*arabino*-hexopyranosyl)-4,6-*O*-benzylidene-2-deoxy-β-D-galactopyranoside (33)

Disaccharide **29** (50 mg, 0.092 mmol) was dissolved in a 1:1 mixture of pyridine–CH_2Cl_2 (3 mL) at –30°C, benzoyl chloride (12 μL, 0.101 mmol) was added and the reaction was stirred at ambient temperature for 7 h. TLC revealed that the starting material was not completely consumed. The reaction mixture was cooled to –30°C and more benzoyl chloride (8 μL, 0.068 mmol) was added. The reaction was allowed to warm to –10°C over 30 min, at which point TLC showed the starting material to be completely transformed. Methanol (200 μL) was added, and the mixture was concentrated under reduced pressure. Chromatography on silica gel using 2% MeOH–CH_2Cl_2 as eluent gave compound **33** (52 mg, 87% yield), $[\alpha]_D$ +44.3 (*c* 0.7, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 7.98 (m, 2H, Bz), 7.46 (m, 1H, Bz), 7.08–7.36 (m, 7H, Ar), 5.88 (d, 1H, *J* = 6.8 Hz, NH), 5.51 (s, 1H, PhCH), 5.34 (m, 1H, H-2′), 5.05 (d, 1H, *J* = 8.2 Hz, H-1), 4.81 (s, 1H, H-1′), 4.68 (dd, 1H, *J* = 3.4, 11.1 Hz, H-3), 4.55 (d, 1H, *J* = 11.5 Hz, Bn), 4.41 (d, 1H, *J* = 11.5 Hz, Bn), 4.33 (d, 1H, *J* = 3.1 Hz, H-4), 4.29 (dd, 1H, *J* = 1.2, 12.3 Hz, H-6a), 4.04 (dd, 1H, *J* = 1.6, 12.3 Hz, H-6b), 3.57 (m, 1H, H-5′), 3.48 (s, 1H, H-5′), 3.47 (s, 4H, OMe, H-5), 3.31–3.46 (m, 2H, H-4′, H-2), 2.46 (d′t′, 1H, *J* = 4.0,, 14.0 Hz, H-3e′), 1.95 (s, 3H, Ac), 1.70 (ddd, 1H, 3.2, 11.2, 14.1 Hz, H-3a′), 1.36 (d, 1H, *J* = 6.1 Hz, H-6′). Anal. calcd. for $C_{36}H_{41}O_{10}N$: C 66.76, H 6.38, N 2.16; found: C 66.38, H 6.28, N 2.05.

Methyl 2-acetamido-3-*O*-(2-*O*-benzoyl-3,6-dideoxy-β-D-*arabino*-hexopyranosyl)-4,6-*O*-benzylidene-2-deoxy-β-D-galactopyranoside (34)

A mixture of disaccharide **33** (52 mg, 0.08 mmol), HCO_2NH_4 (25 mg, 0.40 mmol) and 5% Pd-C (34 mg) in MeOH (10 mL) was heated to reflux for 1 h. The catalyst was filtered off and the filtrate was concentrated. Disaccharide **34** was obtained by chromatography on silica gel using 2% MeOH – CH_2Cl_2 as eluent (35.2 mg, 78% yield), $[\alpha]_D$ +32.6 (*c* 0.5, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 7.98 (m, 2H, Bz), 7.45 (m, 1H, Bz), 7.07–7.34 (m, 7H, Ar), 6.08 (d, 1H, *J* = 7.1 Hz, NH), 5.50 (s, 1H, PhCH), 5.31 (m, 1H, H-2′), 5.00 (d, 1H, *J* = 8.2 Hz, H-1), 4.78 ("s", 1H, H-1′), 4.65 (dd, 1H, *J* = 3.3, 11.1 Hz, H-3), 4.10 (d, 1H, *J* = 3.3 Hz, H-4), 4.27 (dd, 1H, *J* ~ 1.0, 12.3 Hz, H-6a), 4.02 (dd, 1H, *J* = 1.3, 12.3 Hz, H-6b), 3.61 (m, 1H, H-4′), 3.46 (s, 4H, OMe, H-5), 3.34–3.45 (m, 2H, H-5′, H-2), 2.29 (d′t′, 1H, *J* = 5.1, 14.0 Hz, H-3e′), 1.96 (s, 3H, Ac), 1.66 (ddd, 1H, 3.2, 11.2, 14.1 Hz, H-3a′), 1.34 (d, 1H, *J* = 6.1 Hz, H-6′). Anal. calcd. for $C_{29}H_{35}O_{10}N$: C 62.47, H 6.33, N 2.51; found: C 62.26, H 6.34, N 2.33.

Methyl 2-acetamido-3-*O*-(2-*O*-benzoyl-3,6-dideoxy-4-*O*-imidazoylthiocarbonyl-β-D-*arabino*-hexopyranosyl)-4,6-*O*-benzylidene-2-deoxy-β-D-galactopyranoside (35)

To a solution of disaccharide **34** (30 mg, 0.055 mmol) in anhydrous toluene (3 mL), was added 1,1′-thiocarbonyldiimidazole (35 mg, 0.18 mmol), and the mixture was heated to reflux for 8 h. After cooling, the mixture was concentrated, and the disaccharide **35** was obtained by chromatography on silica gel using 2.5 → 5% MeOH – CH_2Cl_2 as eluent (32.9 mg, 92% yield), $[\alpha]_D$ +5.2 (*c* 0.5, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 8.29 (t, 1H, *J* = 0.8 Hz, imidazole), 8.03 (m, 2H, Bz), 7.56 (t, 1H, 1.6 Hz, imidazole), 7.51 (m, 1H, Bz), 7.13–7.38 (m, 7H, Ar), 7.03 (dd, 1H, *J* = 0.8, 1.6 Hz, imidazole), 6.00 (d, 1H, *J* = 7.1 Hz, NH), 5.56 (m, 1H, H-4′), 5.53 (s, 1H, PhCH), 5.43 (m, 1H, H-2′), 4.96 (d, 1H, *J* = 1.5 Hz, H-1′), 4.93 (d, 1H, *J* = 8.2 Hz, H-1), 4.69 (dd, 1H, *J* = 3.4, 11.2 Hz, H-3), 4.27–4.36 (m, 2H, H-4, H-6a), 4.06 (dd, 1H, *J* = 1.6, 12.4 Hz, H-6b), 3.94 (dq, 1H, *J* = 6.1, 9.0 Hz, H-5′), 3.53 (m, 1H, H-2), 3.49 (m, 1H, H-5), 3.48 (s, 3H, OMe), 2.67 (d′t′, 1H, *J* = 4.5, 13.8 Hz, H-3e′), 1.93 (s, 3H, Ac), 1.84 (ddd, 1H, 3.4, 10.5, 13.8 Hz, H-3a′), 1.37 (d, 1H, *J* = 6.2 Hz, H-6′). Anal. calcd. for $C_{33}H_{37}O_{10}N_3S$: C 59.36, H 5.59, N 6.29; found: C 59.01, H 5.33, N 6.24.

Methyl 2-acetamido-3-*O*-(2-*O*-benzoyl-3,4,6-trideoxy-β-D-threo-hexopyranosyl)-4,6-*O*-benzylidene-2-deoxy-β-D-galactopyranoside (36)

To a refluxing solution of disaccharide **35** (32.9 mg, 0.061 mmol) in anhydrous toluene (2 mL) was added dropwise a solution of tributyltin hydride (41 μL, 0.15 mmol) in toluene (0.75 mL), and a catalytic amount of AIBN (~2 mg) was added, the reaction was continued to reflux for 3 h. After concentration, the mixture was chromatographed on silica gel using 2% MeOH – CH_2Cl_2 as eluent to give disaccharide **36** (22 mg, 83% yield), $[\alpha]_D$ +36.2 (*c* 0.6, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 8.01 (m, 2H, Bz), 7.46 (m, 1H, Bz), 7.09–7.36 (m, 7H, Ar), 5.85 (d, 1H, *J* = 6.9 Hz, NH), 5.53 (s, 1H, PhCH), 5.16 (m, 1H, H-2′), 5.03 (d, 1H, *J* = 8.2 Hz, H-1), 4.71 (d, 1H, *J* = 1.1 Hz, H-1′), 4.63 (dd, 1H, *J* = 3.4, 11.2 Hz, H-3), 4.35 (d, 1H, *J* = 3.3 Hz, H-4), 4.29 (dd, 1H, *J* = 1.5, 12.3 Hz, H-6a), 4.04 (dd, 1H, *J* = 1.4, 12.3 Hz, H-6b), 3.64 (m, 1H, H-5′), 3.47 (m, 4H, H-5+ OMe), 3.41 (m, 1H, H-2), 2.07 (m, 1H, H-3e′), 1.96 (s, 3H, Ac), 1.72 (m, 1H, H-3a′), 1.30–1.68 (m, 2H, H-4a′, H4e′), 1.27 (d, 3H, *J* = 6.2 Hz, H-6′). Anal. calcd. for $C_{29}H_{35}O_9N$: C 64.31, H 6.51, N 2.59; found: C 64.00, H 6.42, N 2.56.

Methyl 2-acetamido-3-*O*-(3,4,6-trideoxy-β-D-threo-hexopyranosyl)-2-deoxy-β-D-galactopyranoside (13)

Compound **36** (22 mg, 0.0406 mmol) was dissolved in anhyd MeOH (3 mL), and a solution of NaOMe in MeOH (1.5 M, 400 μL) was added. After 1 h, the mixture was neutralized with Amberlite IR-120 (H^+), the solution was filtered and evaporated to dryness. The residue was hydrogenated in a similar fashion as compound **5** and disaccharide **13** (12.5 mg, 88% yield) was purified by reverse-phase HPLC using a gradient of H_2O–MeOH (0 → 30%) as eluent. $[\alpha]_D$ –34 (*c* 0.5, MeOH). ^{1}H NMR (D_2O) δ: 4.60 (d, 1H, *J* = 0.9 Hz, H-1′), 4.45 (d, 1H, *J* = 8.6 Hz, H-1), 4.12 ("d", 1H, *J* = 3.1 Hz, H-4), 4.02 (dd, 1H, *J* = 8.6,

Methyl 2-acetamido-3-O-(3,6-dideoxy-β-D-arabino-hexopyranosyl)-2,6-dideoxy-β-D-galactopyranoside (9)

Tolunesulfonyl chloride (12.5 mg, 0.066 mmol) was added to a solution of compound **39** (34.7 mg, 0.06 mmol) in anhydrous pyridine (2 mL), and the reaction was stirred at room temperature for 3 h. Water (0.3 mL) was added to quench the reaction. The mixture was diluted with EtOAc (50 mL), washed with brine (1 × 25 mL), dried and concentrated. Lithium bromide (34.2 mg, 0.39 mmol) and KI (6 mg, 0.036 mmol) were added to a solution of the residue in DMF (1.5 mL), and the resulting solution was heated to 100°C for 1 h. The reaction mixture was diluted with EtOAc (75 mL), washed with brine (sat., 2 × 25 mL), dried and evaporated. Tributyltin hydride (330 μL, 0.12 mmol) and AIBN (5 mg, 0.03 mmol) were added to a refluxing solution of bromide **41** (25 mg, 0.04 mmol) in anhydrous toluene (2 mL). After 1 h, the reaction was cooled to room temperature and concentrated. The syrupy mixture was dissolved in anhyd MeOH (5 mL), and a solution of MeONa in MeOH (1.5 M, 50 μL) was added. After stirring for 1 h, the reaction was neutralized with Amberlite IR-120 (H^+) resin, filtered and concentrated. Disaccharide **9** was obtained by reverse-phase HPLC using a gradient of H_2O–MeOH (0 → 30%) as eluent (10.5 mg, 49% yield), $[\alpha]_D$ –38.4 (*c* 0.5, MeOH). ^{1}H NMR (D_2O) δ: 4.68 (d, 1H, *J* = 0.9 Hz, H-1′), 4.42 (d, 1H, *J* = 8.6 Hz, H-1), 3.97 (dd, 1H, *J* = 8.6, 10.8 Hz, H-2), 3.94 ("d", 1H, *J* = 3.1 Hz, H-4), 3.89 (m, 1H, H-2′), 3.86 (dd, 1H, *J* = 3.1, 10.8 Hz, H-3), 3.80 (dq, 1H, *J* = 0.7, 6.6 Hz, H-5), 3.55 (ddd, 1H, *J* = 4.8, 9.3, 11.5 Hz, H-4′), 3.49 (s, 3H, OMe), 3.43 (dq, 1H, *J* = 6.1, 9.3 Hz, H-5′), 2.17 (ddd, 1H, *J* = 3.5, 4.8, 14.1 Hz, H-3e′), 2.02 (s, 3H, Ac), 1.65 (ddd, 1H, *J* = 2.9, 11.5, 14.3 Hz, H-3e′), 1.29 (d, 3H, *J* = 6.4 Hz, H-6), 1.27 (d, 3H, *J* = 6.0 Hz, H-6′). Phenyl 2-*O*-benzoyl-3,6-dideoxy-4-*O*-methyl-1-thio-α,β-D-ribo-hexopyranoside (47)

A solution of **46** (185 mg, 0.50 mmol) in anhydrous toluene (3 mL) was stirred with molecular sieves 4 Å (400 mg) for 30 min at 0°C. Me_3SiSPh (244 μL, 1.25 mmol) was added, followed by TMSOTf (97 μL, 0.5 mmol). Reaction was continued at room temperature overnight. Triethylamine (0.5 mL) was added, and the insoluble material was filtered off. After evaporation, the thioglycoside **47** was obtained by chromatography of the residue on silica gel using 5% EtOAc – hexane as eluent (α/β 4:6, 160 mg, 89%). ^1H NMR ($CDCl_3$) for α-anomer δ: 8.09 (m, 2H, Bz), 7.57 (m, 1H, Bz), 7.45 (m, 2H, Bz), 7.17–7.28 (m, 5H, Ph), 5.75 (d, 1H, *J* = 5.1 Hz, H-1), 5.29 (d′t′, 1H, *J* = 5.1, 12.4 Hz, H-2), 4.18 (dq, 1H, *J* = 6.2, 9.2 Hz, H-5), 3.40 (s, 3H, OMe), 3.07 (ddd, 1H, *J* = 4.5, 9.3, 10.9 Hz, H-4), 2.52 (dd′t′, 1H, *J* = 0.7, 4.5, 11.9 Hz, H-3e), 1.87 (d′t′, 1H, *J* = 12.1, 12.1 Hz, H-3a), 1.26 (d, 3H, *J* = 6.2 Hz, H-6); β-anomer δ: 8.04 (m, 2H, Bz), 7.57 (m, 1H, Bz), 7.46 (m, 2H, Bz), 7.26 (m, 5H, Ph), 4.90 (d′t′, 1H, *J* = 4.8, 9.9 Hz, H-21), 4.80 (d, 1H, *J* = 9.9 Hz, H-1), 3.42 (dq, 1H, *J* = 6.2, 9.2 Hz, H-5), 3.36 (s, 3H, OMe), 3.02 (m, 1H, H-4), 2.82 (d′t′, 1H, *J* = 4.5, 12.0 Hz, H-3e), 1.53 (d′t′, 1H, *J* = 12.1, 12.1 Hz, H-3a), 1.36 (d, 3H, *J* = 6.2 Hz, H-6). Anal. calcd. for $C_{20}H_{22}O_4S$: C 67.02, H 6.19; found: C 67.34, H 6.16.

Methyl 2-azido-3-*O*-(2-*O*-benzoyl-3,6-dideoxy-4-*O*-methyl-β-D-ribo-hexopyranosyl)-4,6-*O*-benzylidene-2-deoxy-β-D-galactopyranoside (48)

A mixture containing thioglycoside **47** (140 mg, 0.40 mmol), alcohol **24** (39) (95 mg, 0.31 mmol) and 4 Å molecular sieves (500 mg) in CH_2Cl_2 was stirred for 30 min and *N*-iodosuccinimide (146 mg, 0.62 mmol) was added. After the reaction mixture had been cooled to –60°C, TfOH (6 μL, 0.067 mmol) was added, and the reaction was continued for 3 h. Triethylamine (0.5 mL) was added to quench the reaction, and disaccharide **48** was obtained in a similar fashion to that described above (134.7 mg, 78% yield), $[\alpha]_D$ –14.7 (*c* 0.8, $CHCl_3$). ^1H NMR ($CDCl_3$) δ: 8.02–8.08 (m, 2 H, Bz), 7.20–7.57 (m, 8H, Ar), 5.50 (s, 1H, PhCH), 4.82–4.96 (m, 2H, H-1′ + H-2′), 4.30 (dd, 1H, *J* = 1.6, 12.4 Hz, H-6a), 4.23 (br d, 1H, *J* = 3.1 Hz, H-4), 4.21 (d, 1H, *J* = 8.0 Hz, H-1), 4.04 (dd, 1H, *J* = 1.6, 12.4 Hz, H-6b), 3.77 (dd, 1H, *J* = 8.0, 10.6 Hz, H-2), 3.55 (s, 3H, OMe), 3.51 (dd, 1H, *J* = 3.5, 10.6 Hz, H-3), 3.43 (dq, 1H, *J* = 6.1, 9.0 Hz, H-5′), 3.39 (m, 1H, H-5), 3.35 (s, 3H, OMe), 3.04 (ddd, 1H, *J* = 4.5, 9.0, 10.8 Hz, H-4′), 2.79 (d′t′,1H, *J* = 4.4, 12.1 Hz, H-3e′), 1.45 (d′t′, 1H, *J* = ~11.5, 11.5 Hz, H-3a′), 1.31 (d, 3H, *J* = 6.1 Hz, H-6′). Anal. calcd. for $C_{28}H_{33}O_9N_3$: C 60.53, H 5.99, N 7.56; found: C 60.64, H 6.00, N 7.32.

Methyl 2-azido-3-*O*-(3,6-dideoxy-4-*O*-methyl-β-D-ribo-hexopyranosyl)-4,6-*O*-benzylidene-2-deoxy-β-D-galactopyranoside (49)

Compound **48** (140 mg, 0.25 mmol) was transesterified as described above to give the disaccharide **49** (107 mg, 94% yield), $[\alpha]_D$ +22.7 (*c* 1.1, $CHCl_3$). ^1H NMR ($CDCl_3$) δ: 7.51 (m, 2H, Ph), 7.31–7.38 (m, 3H, Ph), 5.52 (s, 1H, PhCH), 4.43 (d, 1H, *J* = 7.3 Hz, H-1′), 4.31 (dd, 1H, *J* = 1.5, 12.4 Hz, H-6a), 4.24 ("d", 1H, *J* = 3.4 Hz, H-4), 4.22 (d, 1H, *J* = 8.0 Hz, H-1), 4.04 (dd, 1H, *J* = 1.7, 12.4 Hz, H-6b), 3.85 (dd, 1H, *J* = 8.1, 10.5 Hz, H-2), 3.58 (s, 3H, OMe), 3.53 (dd, 1H, *J* = 3.5, 10.6 Hz, H-3), 3.52 (dq, 1H, *J* = 6.1, 9.0 Hz, H-2′), 3.32–3.42 (m, 5H, H-5, H-5′, OMe), 3.35 (s, 3H, OMe), 2.92 (ddd, 1H, *J* = 4.4, 8.8, 10.9 Hz, H-4′), 2.49 (d′t′, 1H, *J* = 4.7, 12.3 Hz, H-3e′), 1.36 (d′t′, 1H, *J* ~ 11.5, 11.5 Hz, H-3a′), 1.28 (d, 3H, *J* = 6.1 Hz, H-6′). Methyl 2-acetamido-3-*O*-(3,6-dideoxy-β-D-arabino-hexopyranosyl)-2-deoxy-4-*O*-methyl-β-D-galactopyranoside (8)

Compound **60** (35 mg, 0.06 mmol) was hydrogenated in a similar fashion as compound **5**. After evaporation, the residue was dissolved in anhyd THF (2 mL), a solution of TBAF in THF (1.0 M, 50 μL) was added and reaction was continued for 5 h. After concentration, disaccharide **8** was obtained by reverse-phase HPLC using a gradient of H_2O–MeOH (0 → 30%) as eluent (20 mg, 88% yield), $[\alpha]_D$ –47.6 (*c* 0.2, MeOH). ^1H NMR (D_2O) δ: 4.62 (d, 1H, *J* = 0.6 Hz, H-1′), 4.41 (d, 1H, *J* = 8.6 Hz, H-1), 3.97 (dd, 1H, *J* = 8.4, 10.8 Hz, H-2), 3.87 (dd, 1H, *J* = 3.1, 11.0 Hz, H-3), 3.86 (m, 2H, H-2′, H-3), 3.82 ("d", 1H, J = 3.1 Hz, H-4), 3.77–3.81 (m, 2H, H-6a, H-6b), 3.67 (m, 1H, H-5), 3.55 (m, 1H, H-4′), 3.50 (s, 3H, OMe), 3.42 (dq, 1H, *J* = 6.2, 9.2 Hz, H-5′), 2.17 (ddd, 1H, *J* = 3.5, 4.8, 13.9 Hz, H-3e′), 2.02 (s, 3H, Ac), 1.65 (ddd, 1H, *J* = 3.1, 11.7, 14.3 Hz, H-3a′), 1.29 (d, 3H, *J* = 6.2 Hz, H-6′). HR-ES-MS *m*/*e* calcd. for $C_{16}H_{29}O_9N$ (MH^+): 402.17400; found: 402.174200.

Methyl 2-acetamido-3-*O*-benzoyl-4,6-*O*-benzylidene-2-deoxy-β-D-glucopyranoside (61)

Benzoyl chloride (646 μL, 5.57 mmol) was added dropwise to an ice-cold solution of alcohol **17** (45) (1.5 g, 4.6 mmol) in a mixture of anhyd CH_2Cl_2 (10 mL) and pyridine (8 mL), and the mixture was stirred at room temperature for 5 h. Methanol (1 mL) was added, the mixture was concentrated and dissolved in CH_2Cl_2 (100 mL), washed with 5% $NaHCO_3$ (2 × 50 mL), saturated brine (1 × 50 mL), dried and evaporated. The benzoylated acetal **61** was obtained by chromatography on silica gel using 5% MeOH–CH_2Cl_2 as eluent (1.90 g, 96%), $[\alpha]_D$ –99.2 (*c* 0.8, $CHCl_3$). ^1H NMR ($CDCl_3$) δ: 8.03 (m, 2H, Bz), 7.56 (m, 1H, Bz), 7.43 (m, 2H, Bz), 7.40 (m, 2H, Ph), 7.26–7.32 (m, 3H, Ph), 6.05 (d, 1H, *J* = 9.5 Hz, NH), 5.58 (t, 1H, *J* = 9.8 Hz, H-3), 5.53 (s, 1H, PhCH), 4.47 (d, 1H, *J* = 8.4 Hz, H-1), 4.37 (dd, 1H, *J* = 5.0, 10.5 Hz, H-6a), 4.32 (d′t′, 1H, *J* = 10.0 Hz, 10.0 Hz, H-2), 3.86 (t, 1H, *J* = 9.4 Hz, H-4), 3.83 (t, 1H, *J* = 10.3 Hz, H-6b), 3.67 (m, 1H, H-5), 3.42 (s, 3H, OMe), 1.89 (s, 3H, Ac). Anal. calcd. for $C_{23}H_{25}O_7N$: C 64.63, H 5.90, N 3.28; found: C 64.56, H 5.88, N 3.21.

Methyl 2-acetamido-3-*O*-benzoyl-6-*O*-benzyl-2-deoxy-β-D-glucopyranoside (62)

To a mixture containing compound **61** (1.0 g, 2.34 mmol), $NaBH_3CN$ (1.8 g, 28 mmol), and 4 Å molecular sieves (1.5 g) in anhyd THF (20 mL), was added a trace amount of methyl orange (~1 mg). A saturated solution of HCl in anhydrous ether (30 mL) was added dropwise until the color of the reaction became slightly pink. The reaction was continued for 2 h, the mixture was diluted with EtOAc (50 mL), and filtered. After concentration, the residue was dissolved in EtOAc (120 mL), and the solution was washed with 2 M HCl (2 × 50 mL), 10% $NaHCO_3$ aqueous solution (2 × 50 mL), dried, and evaporated. The alcohol **62** was obtained by chromatography on silica gel using 7.5% MeOH – CH_2Cl_2 as eluent (950 mg, 95%), $[\alpha]_D$ –13.2 (*c* 0.3, $CHCl_3$). ^1H NMR ($CDCl_3$) δ: 8.03 (m, 2H, Bz), 7.57 (m, 1H, Bz), 7.44 (m, 2H, Bz), 7.40 (m, 2H, Ph), 7.25–7.36 (m, 5H, Ph), 5.56 (d, 1H, *J* = 9.2 Hz, NH), 5.27 (dd, 1H, *J* = 9.0, 10.7 Hz, H-3), 4.64 (d, 1H, *J* = 11.9 Hz, Bn), 4.58 (d, 1H, *J* = 11.9 Hz, Bn), 4.48 (d, 1H, *J* = 8.3 Hz, H-1), 4.11 (d′t′, 1H, *J* = 8.8, 10.7 Hz, H-2), 3.90 (t, 1H, *J* = 9.3 Hz, H-4), 3.86 (dd, 1H, *J* = 4.9, 10.3 Hz, H-6a), 3.83 (dd, 1H, *J* = 4.8, 10.3 Hz, H-6b), 3.62 (m, 1H, H-5), 3.50 (s, 3H, OMe), 1.86 (s, 3H, Ac). Anal. calcd. for $C_{23}H_{27}O_7N$: C 64.32, H 6.34, N 3.26; found: C 64.16, H 6.12, N 3.01.

Methyl 2-acetamido-3-*O*-benzoyl-6-*O*-benzyl-2-deoxy-4-imidazoylthiocarbonyl-β-D-glucopyranoside (63)

1,1′-Thiocarbonyldiimidazole (538 mg, 2.72 mmol) was added to a solution of compound **62** (585 mg, 1.36 mmol) in anhydrous toluene (10 mL) and the mixture was heated to 90°C overnight. The solution was diluted with EtOAc (75 mL), washed with brine (1 × 25 mL), dried and concentrated to dryness to give **63** (691 mg, 94%), $[\alpha]_D$ –21.0 (*c*

0.8, $CHCl_3$). ^1H NMR ($CDCl_3$) δ: 8.13 (s, 1H, imidazole), 7.90 (m, 2H, Bz), 7.62 (s, 1H, imidazole), 7.51 (m, 1H, Bz), 7.17–7.40 (m, 7H, Ar), 7.02 (s, 1H, imidazole), 6.08 (t, 1H, *J* = 9.5 Hz, H-4), 5.86 (d, 1H, *J* = 8.8 Hz, NH), 5.78 (t, 1H, *J* = 10.5 Hz, H-3), 4.76 (d, 1H, *J* = 8.4 Hz, H-1), 4.46 (s, 2H, Bn), 4.08 (m, 1H, H-2), 3.96 (m, 1H, H-5), 3.71 (dd, 1H, *J* = 3.8, 10.6 Hz, H-6a), 3.65 (dd, 1H, *J* = 5.0, 10,8 Hz, H-6b), 3.54 (s, 3H, OMe), 1.86 (s, 3H, Ac), Anal. calcd. for $C_{27}H_{29}O_7N_3S$: C 60.10, H 5.42, N 7.79; found: C 60.21, H 5.33, N 7.72.

Methyl 2-acetamido-3-*O*-benzoyl-6-*O*-benzyl-2,4-dideoxy-β-D-xylo-hexopyranoside (64)

A solution of **63** (321.4 mg, 0.60 mmol) in anhydrous toluene (15 mL) was heated to reflux, a solution of tributyltin hydride (535 μL, 1.93 mmol) in anhydrous toluene (5 mL) and a catalytic amount of AIBN (~10 mg) were added. After 4 h, the deoxygenation was complete. Compound **64** was obtained by chromatography on silica gel using 3% MeOH – CH_2Cl_2 as eluent (217 mg, 88% yield), $[\alpha]_D$ –8.2 (*c* 0.7, $CHCl_3$). ^1H NMR ($CDCl_3$) δ: 7.99 (m, 2H, Bz), 7.54 (m 1H, Bz), 7.41 (m, 2H, Bz), 7.24–7.35 (m, 5H, Bn), 5.42 (br, 1H, NH), 4.57 (s, 2H, Bn), 4.43 (d, 1H *J* = 8.4 Hz, H-1), 4.02 (d′t′, 1H, *J* = 8.9, 10.3 Hz, H-2), 3.80 (m, 1H, H-5), 3.63 (dd, 1H, *J* = 5.7, 10.2 Hz, H-6a), 3.54 (dd, 1H, *J* = 4.6, 10.2 Hz, H-6b), 3.50 (s, 3H, Ome), 2.22 (ddd, 1H, *J* = 1.8, 5.1, 12.6 Hz, H-4e), 1.87 (s, 3H, Ac), 1.72 (d′t′, 1H, *J* = 11.5, 11.5 Hz, H-3a). Anal. calcd. for $C_{23}H_{27}O_6N$: C 66.81, H 6.58, N 3.39; found: C 66.59, H 6.41, N 3.02.

Methyl 2-acetamido-6-*O*-benzyl-2,4-dideoxy-β-D-xylo-hexopyranoside (65)

A solution of NaOMe in MeOH (1.5 M, 200 μL) was added to a solution of compound **64** (400 mg, 0.967 mmol) in anhyd MeOH (50 mL), and the reaction was stirred at room temperature for 2 h. After neutralization with Amberlite IR-120 (H^+), the organic solution was evaporated, and the acceptor **65** was obtained by chromatography on silica gel using 5% MeOH – CH_2Cl_2 as eluent (280 mg, 94% yield), $[\alpha]_D$ –63.3 (*c* 0.5, $CHCl_3$). ^1H NMR ($CDCl_3$) δ: 7.23–7.34 (m, 5H, Bn), 6.08 (d, 1H, *J* = 4.6 Hz, NH), 4.57 (d, 1H, *J* = 12.1 Hz, Bn), 4.52 (d, 1H, *J* = 12.1 Hz, Bn), 4.21 (d, 1H, *J* = 8.1 Hz, H-1), 3.77 (m, 1H, H-3), 3.65 (m, 1H, H-5), 3.58 (dd, 1H, *J* = 6.0, 10.3 Hz, H-6a), 3.51 (dd, 1H, *J* = 4.3, 10.2 Hz, H-6b), 3.48 (s, 3H, OMe), 3.30 (m, 1H, H-2), 2.05 (m, 1H, H-4e), 2.02 (s, 3H, Ac), 1.46 (d′t′, 1H, *J* = 11.6, 11.6 Hz, H-4a). Anal. calcd. for $C_{16}H_{23}O_5N$: C 62.12, H 7.49, N 4.53; found: C 61.87, H 7.37, N 4.29.

Methyl 2-acetamido-3-*O*-(2-*O*-benzoyl-4-*O*-benzyl-3,6-dideoxy-β-D-ribo-hexopyranosyl)-6-*O*-benzyl-2,4-dideoxy-β-D-xylo-hexopyranoside (66)

N-Iodosuccinimide (125 mg, 0.52 mmol) was added to a mixture of donor **22** (230 mg, 0.52 mmol), acceptor **65** (82 mg, 0.26 mmol), and 4 Å molecular sieves (350 mg) in anhyd CH_2Cl_2 (5 mL) The reaction was cooled to –60°C, and TfOH (5.0 μL) was added. After 3 h, the reaction was neutralized with Et_3N (0.5 mL), diluted with EtOAc (75 mL), and filtered. The organic solution was washed with a 10% aqueous solution of $Na_2S_2O_3$ (1 × 30 mL), and the mixture was purified by repeated chromatography on silica gel using 5% MeOH – CH_2Cl_2 to afford the disaccharide **66** (91 mg, 54% yield) in pure form, $[\alpha]_D$ +38.2 (*c* 0.5, $CHCl_3$). ^1H NMR (CDCl3) δ: 8.10 (m, 2H, Bz), 7.57 (m, 1H, Bz), 7.44 (m, 2H, Bz), 7.25–7.33 (m, 10H, Bn), 5.41 (d, 1H, *J* = 6.7 Hz, NH), 4.96 (m, 1H, H-2′), 4.90 (d, 1H, *J* = 8.2 Hz, H-1), 4.64 (d, 1H, *J* = 7.6 Hz, H-1′), 4.61 (d, 1H, *J* = 11.5 Hz, Bn), 4.57 (d, 1H, *J* = 12.1 Hz, Bn), 4.53 (d, 1H, *J* = 12.1 Hz, Bn), 4.46 (m, 1H, H-3), 4.45 (d, 1H, *J* = 11.7 Hz, Bn), 3.72 (m, 1H, H-5), 3.56 (dd, 1H, *J* = 5.9, 10.1 Hz, H-6a), 3.45–3.55 (m, 2H, H-5′, H-6b), 3.43 (s, 3H, OMe), 3.24 (m, 1H, H-4′), 2.76 (m, 1H, H-2), 2.65 (d′t′, 1H, *J* = 4.9, 12.0 Hz, H-3e′), 2.24 (m, 1H, H-4e), 1.62 (d′t′, 1H, *J* = 11.7, 11.7 Hz, H-3a′), 1.56 (s, 3H, Ac), 1.50 (d′t′, 1H, *J* = 11.6, 11.6 Hz, H-4a), 1.30 (d, 3H, *J* = 6.1 Hz, H-6′). HR-ES-MS *m*/*e* calcd. for $C_{36}H_{43}O_9N$ (MNa^+): 656.28355; found: 656.283345.

Methyl 2-acetamido-3-*O*-(4-*O*-benzyl-3,6-dideoxy-β-D-ribo-hexopyranosyl)-6-*O*-benzyl-2,4-dideoxy-β-D-xylo-hexopyranoside (67)

Disaccharide **66** (70 mg, 0.11 mmol) was dissolved in anhyd MeOH (15 mL), and a solution of NaOMe in MeOH (1.5 M, 200 μL) was added, the reaction was stirred at room temperature overnight. After neutralization with Amberlite IR-120 (H^+), the mixture was concentrated to dryness. The alcohol **67** was obtained (53 mg, 91% yield) by chromatography on silica gel using 7.5% MeOH – CH_2Cl_2 as eluent, $[\alpha]_D$ +3.3 (*c* 0.6, $CHCl_3$). ^1H NMR (CDCl3) δ: 7.22–7.34 (m, 10H, Bn), 5.58 (d, 1H, *J* = 7.9 Hz, NH), 4.57 (d, 1H, *J* = 11.3 Hz, Bn), 4.56 (d, 1H, *J* = 12.1 Hz, Bn), 4.53 (d, 1H, *J* = 12.1 Hz, Bn), 4.43 (d, 1H, *J* = 9.3 Hz, H-1), 4.41 (d, 1H, *J* = 11.8 Hz, Bn), 4.21 (d, 1H, *J* = 7.5 Hz, H-1′), 3.88 (m, 1H, H-3), 3.68 (m, 1H, H-5), 3.59 (dd, 1H, *J* = 6.0 Hz, 10.1 Hz, H-6a), 3.45–3.55 (m, 5H, H-2, H-6b, OMe), 3.34–3.42 (m, 2H, H-2′, H-5′), 3.10 (m, 1H, H-4′), 2.46 (d′t′, 1H, *J* = 4.6, 12.2 Hz, H-3e′), 2.19 (ddd, 1H, *J* = 1.8, 5.2, 13.4 Hz, H-4e), 1.99 (s, 3H, Ac), 1.57 (d′t′, 1H, *J* = 11.5, 11.4 Hz, H-4a), 1.38 (d′t′, 1H, *J* = 11.6, 11.6 Hz, H-3a′), 1.25 (d, 3H, *J* = 6.1 Hz, H-6′). HR-ES-MS *m*/*e* calcd. for $C_{29}H_{39}O_8N$ (MNa^+): 552.25734; found: 552.257502.

Methyl 2-acetamido-3-*O*-(3,6-dideoxy-β-D-*arabino*-hexopyranosyl)-2,4-dideoxy-β-D-xylo-hexopyranoside (7)

A solution of alcohol **67** (25 mg, 0.047 mmol) in anhyd DMSO (2 mL) and Ac_2O (1 mL) was stirred at 0°C for 30 min, and the reaction was left at room temperature overnight. After evaporation, the residue was partitioned in a mixture of EtOAc – 10% aqueous NaCl solution, and the organic solution was evaporated and dissolved in anhyd THF (3 mL) at 0°C. A solution of L-selectride in THF (1.0 M, 200 μL, 0.20 mmol) was added and the reaction was left at 0°C for 1 h. Water (0.3 mL) was added and the mixture was diluted with EtOAc (50 mL), washed with $Na_2S_2O_3$, brine, dried and concentrated to give crude **69**. Liquid ammonia (25 mL) was collected in a flask containing compound **69** (15 mg, 0.028 mmol) equipped with a dry ice condenser. Sodium (50 mg, 0.97 mmol) was added to this solution, and reaction was continued for 4 h. Methanol (0.5 mL) was added, and the condenser was removed to allow ammonia to evaporate. The residue was dissolved in H_2O (3 mL), and neutralized with a saturated aqueous solution of NH_4Cl and

© 2002 NRC Canada

evaporated. The desired disaccharide **7** was obtained by reverse-phase HPLC using a gradient of H_2O–MeOH (0 → 30%) as eluent (4.0 mg, 23%), $[\alpha]_D$ –55.5 (*c* 0.4, MeOH). ^1H NMR (D_2O) δ: 4.67 ("s", 1H, H-1′), 4.40 (d, 1H, *J* = 8.6 Hz, H-1), 3.89 (ddd, 1H, *J* = 5.1, 10.6, 10.6 Hz, H-3), 3.84 (m, 1H, H-2′), 3.63–3.72 (m, 3H, H-5, H-6a, H-6b), 3.62 (dd, 1H, *J* = 8.6, 10.1 Hz, H-2), 3.56 (ddd, 1H, *J* = 4.6, 9.3, 11.4 Hz, H-4′), 3.51 (s, 3H, OMe), 3.43 (dq, 1H, *J* = 6.1, 9.3 Hz, H-5′), 2.13–2.18 (m, 2H, H-3e′, H-4e), 2.02 (s, 3H, Ac), 1.64 (ddd, 1H, *J* = 3.1, 11.5, 14.3 Hz, H-3a′), 1.50 (d′t′, 1H, *J* = 11.5, 11.5 Hz, H-4a), 1.27 (d, 3H, *J* = 6.2 Hz, H-6′). HR-ES-MS *m/e* calcd. for $C_{15}H_{27}O_8N$ (MNa^+): 372.16344; found: 372.163817.

Characterization of some mesogenic alkyl 1-thioglycosides

B. Henrissat, G.K. Hamer, M.G. Taylor, and R.H. Marchessault

Abstract: A series of dodecyl 1-thio-β-D-glycosides has been synthesized and characterized (DSC, NMR, CP MAS, X-ray diffraction) as possible new marking materials with liquid-crystalline properties. These compounds undergo solid to liquid crystal phase transitions at various temperatures, which depend on the nature of the carbohydrate part of the structure. Their liquid-crystalline phases show extreme shear thinning behaviour.

Key words: liquid crystal, powder X-ray diffraction, phase transition, thioglycoside, solid-state NMR, marking material

Résumé : On a effectué la synthèse et on a caractérisé (DSC, RMN, CP MAS, diffraction des rayons X) une série de 1-thio-β-D-glycosides de dodécyle, de nouveaux marqueurs potentiels ayant des propriétés de cristaux liquides. Ces composés subissent des transitions de solide à cristal liquide à diverses températures qui dépendent de la nature de la portion hydrate de carbone de la structure. Leurs phases cristal liquide présentent un comportement extrême de fluidisation par cisaillement.

Mots clés : cristal liquide, diffraction de rayons X par des poudres, transition de phase, thioglycoside, RMN à l'état solide, marqueur.

[Traduit par la Rédaction]

Introduction

Alkyl glycosides have been shown to be thermotropic mesogens when the alkyl chain ranges from heptyl upwards (1). Because of the great variety of possible carbohydrates, alkyl chain length, type of linkage and its position of attachment to the sugar molecule, it has been predicted that several million carbohydrate liquid crystals could be obtained (2). A few of these amphiphilic carbohydrates have found biochemical applications as non-ionic detergents for membrane protein extraction (3). As part of a research program concerned with the evaluation of their liquid-crystalline phase as potential materials with advanced properties, we report here synthesis and the characterization of some dodecyl 1-thioglycosides.

Experimental

General methods

Solutions were evaporated below 45°C under diminished pressure. TLC was performed on silica gel F254 (Aldrich), eluent was ethyl acetate – hexane (1:2, v/v) and detection was done with 5% sulfuric acid in ethanol followed by heating. The ^{1}H and ^{13}C NMR spectra were recorded at 250 and 62.5 MHz, respectively, on a Bruker AM 250 spectrometer. Chemical shifts are given with respect to external tetramethylsilane. Differential scanning calorimetry was carried out with a PerkinElmer DSC-2C calorimeter on 12 mg samples sealed in aluminum capsules. The heating and cooling rates were 20°C min^{-1}. Powder X-ray diagrams were obtained in a Warhus flat-film camera by using Ni-filtered Cu Kα radiation on the sample loaded in 0.5-mm capillary tubes.

Solid-state ^{13}C NMR

High resolution ^{13}C NMR spectra were acquired at 50.3 MHz with a Bruker CXP 200 instrument. Cross-polarization (CP) was performed with Hartmann–Hahn matched radio-frequency fields of about 60 Hz. Spectra were collected with a 1 ms contact time and 6 s recycle delay over a sweep width of 10 kHz. Magic-angle spinning (MAS) at about 2.5 kHz was achieved in a probe from Doty Scientific. A small chip of linear polyethylene (NBS Standard Reference Material 1475) was added to the samples to provide a chemical shift reference at 32.9 ppm (4) with respect to tetramethylsilane. The spectrum of the liquid-crystalline phase was not recorded because cross-polarization was ineffective due to high molecular mobility. Furthermore, the

Table 1. ^{1}H NMR data for ring protons of 1-thio-β-D-glycosides **4**, **9**, **14**, and **15**.

Compound	Chemical shifts (ppm) and coupling constants (Hz)						
	H-1	H-2	H-3	H-4	H-5	H-6a	H-6b
4	4.48 d ($J_{1,2}$ = 10.0)	5.23 t ($J_{2,3}$ = 10.0)	5.09 t ($J_{3,4}$ = 10.0)	5.03 t ($J_{4,5}$ = 10.0)	3.71 m ($J_{5,6a}$ = 5.0)	4.25 dd ($J_{6a,6b}$ = 12.0)	4.14 dd ($J_{5,6b}$ = 2.5)
9	4.48 d ($J_{1,2}$ = 10.0)	5.24 t ($J_{2,3}$ = 10.0)	5.05 dd ($J_{3,4}$ = 4.0)	5.43 dd ($J_{4,5}$ = 1.0)	3.93 dt ($J_{5,6a}$ = 8.0)		
	H-1	H-2	H-3	H-4	H-5a	H-5b	
14	4.51 d ($J_{1,2}$ = 10.0)	5.28 t ($J_{2,3}$ = 10.0)	4.97 t ($J_{3,4}$ = 10.0)	4.95 m ($J_{4,5a}$ = 10.0)	4.23 dd ($J_{5a,5b}$ = 13.0)	3.38 dd ($J_{4,5b}$ = 6.0)	
15	4.24 d ($J_{1,2}$ = 10.0)	3.04 t ($J_{2,3}$ = 10.0)	3.18 t ($J_{3,4}$ = 10.0)	3.34 m ($J_{4,5a}$ = 10.0)	3.78 dd ($J_{5a,5b}$ = 12.0)	3.08 dd ($J_{4,5b}$ = 6.0)	

Notes: For each compound: 1st line, chemical shift; 2nd line, multiplicity; 3rd line, coupling constant (in parenthesis). d= doublet; t = triplet; dd = doublet of doublets; m = multiplet.

sample flowed under the rapid spinning conditions, leading to imbalance in the rotor and to magic angle spinning instabilities.

Syntheses

Syntheses of the 2-thiopseudourea derivatives **2**, **7**, and **12** from the corresponding glycosyl bromides **1**, **6**, and **11** were done as previously described (5). *S*-alkylation was adapted from a classical procedure (6). In a typical experiment, the 2-thiopseudourea derivative (40 g) and potassium carbonate (70 g) in water (60 mL) are stirred with dichloromethane at room temperature, the extract is concentrated, and the residue is alkylated with an appropriate alkyl halide (75 mL). De-*O*-acetylation was effected with sodium methoxide in methanol.

Results and discussion

Tetra-*O*-acetyl-α-D-glucopyranosyl bromide (7) **1** was converted into 2-*S*-(tetra-*O*-acetyl-β-D-glucopyranosyl)-2-thiopseudourea hydrobromide **2** according to standard procedures (5). 2,3,4,6-Tetra-*O*-acetyl-1-thio-β-D-glucopyranose **3** was generated from **2** and was *S*-alkylated in situ with 1-bromododecane in the presence of potassium carbonate (6). Treatment of the resulting dodecyl 2,3,4,6-tetra-*O*-acetyl-1-thio-β-D-glucopyranoside **4** with a catalytic amount of sodium methoxide gave the expected dodecyl 1-thio-β-D-glucopyranoside **5**. An identical synthetic route was followed for the synthesis of dodecyl 1-thio-β-D-galacto- **10** and -xylo-pyranoside **15** starting, respectively, from tetra-*O*-acetyl-α-D-galactopyranosyl bromide (8) **6** and tri-*O*-acetyl-α-D-xylopyranosyl bromide (9) **11**.

^{1}H NMR (e.g., Table 1) has been used to characterize the stereochemistry of the synthetic intermediates **4**, **9**, and **14** as well as of the final products **5**, **10**, and **15**. The anomeric β configuration is unambiguously confirmed by the large coupling constants $J_{H\text{-}1,H\text{-}2}$ of about 10 Hz (Table 1).

The three dodecyl 1-thioglycosides **5**, **10**, and **15** have been examined under polarized light with an optical microscope equipped with a heating stage. Upon heating, all samples undergo melting to a birefringent liquid characteristic of a liquid-crystalline phase. When further heating is applied, they change to isotropic fluids and loose their birefringence. Upon cooling, the reverse succession of events is observed, i.e., the appearance of a liquid-crystalline phase and then, at lower temperatures, crystallization to a solid. The melting behavior of **5**, **10**, and **15** was examined by differential scanning calorimetry. A typical thermogram is shown in Fig. 1. The transition temperatures of the three dodecyl 1-thioglycosides **5**, **10**, and **15** are reported in Table 2. It is interesting to note that the crystal – liquid crystal transitions (K2-LC) occur at significantly higher temperatures on heating than on cooling. Also, while 1-thio-glycosides **10** and **15** both exhibit crystal-to-crystal transitions (K1-K2), glycoside **5** does not. It is possible that such a transition also occurs for the latter compound, but at a temperature lower than ambient.

A solid-state ^{13}C NMR study was done with dodecyl 1-thio-β-D-xylopyranoside **15** because the two transitions of

interest (K-K2 and K2-LC) occur at temperatures (80 and 105°C, respectively) compatible with the heating stage of our spectrometer. Figures 2A and 2B show the solid-state spectra recorded at 25 and 90°C, i.e., under and above the K1-K2 transition. In both forms, there are indications of multiple resonance for individual chemically equivalent carbons. This effect is more pronounced in the spectrum of the K1 form, where obvious splittings are observed for many resonances, especially for the terminal methyl group at 15 ppm and for the sugar C-1 carbon at 90 ppm. Specific resonance assignments are difficult since the peak positions change dramatically in the two forms. The peaks in the 87–95 ppm region can, however, be assigned with confidence to the C-1 carbon of the sugar ring. By analogy with the solution NMR spectrum, the remaining peaks can probably be assigned in order of decreasing chemical shift: C-3, C-2, C-4, C-5.

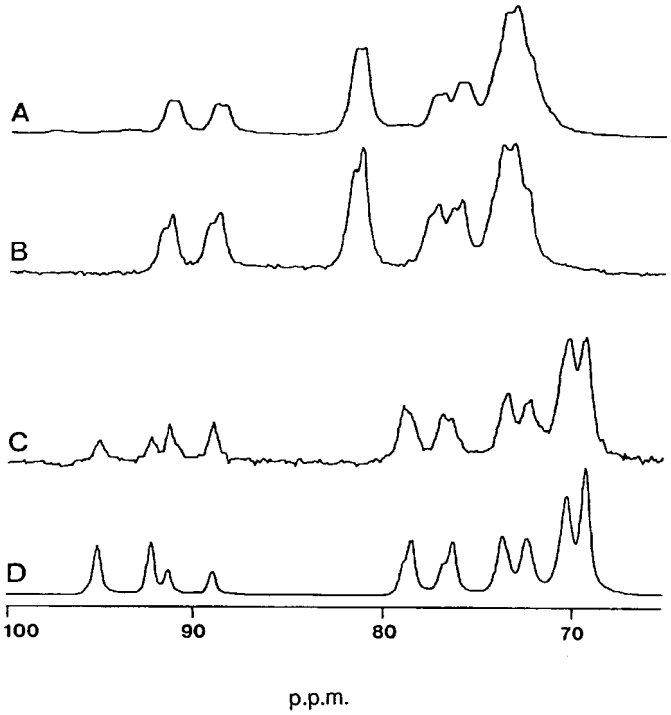
In the K1 form, the resonance assigned to C-1 of compound **15** clearly consists of four lines between 88 and 95 ppm with relative intensities of about 2:2:1:1. A similar situation is noted for the peaks at 77 and 79 ppm, each of which has a shoulder. Application of resolution enhancement shows four lines in this region with relative intensities of about 1:2:1:2. These observations indicate that there are four magnetically non-equivalent environments for the sugar ring in this crystal form. It is interesting to note that the X-ray crystal structure of octyl 1-thio-β-D-xylopyranoside (a lower homologue of compound **15** but with a shorter alkyl chain) shows a disordered structure where the carbohydrate moiety has two orientations with equal occupancy (10). The solid-state NMR results here show that a disordered structure could also be valid for dodecyl 1-thio-β-D-xylopyranoside **15**. A mixture of crystal polymorphs could also explain the peak multiplicity observed for **15**; however, in such a case the differential scanning calorimetry thermogram would show a more complex melting profile. The spectrum of the higher temperature form (K2), although of lower definition, also shows peak multiplicity, indicating at least two non-equivalent environments in the crystal (Fig. 2B).

The cooling behavior of the 1-thio-glycoside **15** was also investigated by solid-state NMR. Although it was not possible to record the spectrum of the material in the liquid crystal form, it was, however, heated in the spectrometer for one hour at 110°C and then cooled to 27°C. The differential scanning calorimetry data (Fig. 1 and Table 2) indicated that on cooling from the liquid-crystalline phase, **15** underwent only one transition to the intermediate crystal form (K2). Figure 3A shows the spectrum of the sugar-ring carbons obtained immediately after cooling the material. This spectrum clearly corresponds to the K2 form as seen by comparison with the spectrum obtained at 90°C (Fig. 3B). The sample was allowed to equilibrate at room temperature for 24 h before another spectrum was acquired at 27°C. In this case (Fig. 3C), it is seen that the material has returned to the K1 form by comparison with the original room temperature spectrum (Fig. 3D). It is interesting to note that the same number of lines is observed as in the original spectrum (Fig. 2A), but that there are differences in the relative intensities. These intensity variations may originate from a non-isotropic orientation of the crystals during the thermal transitions, which occurred under high-speed magic angle spinning conditions in the magnetic field of the NMR spectrometer.

Powder X-ray diffraction diagrams of **15** were recorded to characterize its crystal-to-crystal transition at 80°C and to further identify the crystalline form obtained after standing 24 h at room temperature. Table 3 lists the main *d* spacings

© 2002 NRC Canada

Fig. 3. Solid-state ^{13}C NMR spectra of the carbohydrate part of dodecyl 1-thio-β-D-xylopyranoside **15** after different heat treatments. (A) Spectrum obtained at 27°C immediately after 1 h of treatment at 110°C; (B) spectrum of the K2 form obtained at 90°C; (C) same as (A) but after 24 h at room temperature; (D) spectrum of the K1 form (never heated).



measured for compound **15** at room temperature (A), immediately after heating two hours at 90°C (B), and 24 h later (C). One clearly observes different *d* spacings after heating above the transition temperature. After 24 h standing at room temperature, the material returns to its low temperature polymorph.

Conclusions

This work covers part of an extensive program at Xerox Corporation on marking materials. The subject herein is described as hot-melt inks suitable for ink jet printing. A set of examples in a United States patent (11) makes use of the research described herein. The carbohydrate chemistry leading to synthesis of these liquid-crystalline materials is outlined schematically in the above referenced patent and their characterization was inspired by published data. However, while this work was in progress a related study by van Doren et al. (12) appeared, which reminded us of how Jeffrey (2) pioneered the field of carbohydrate mesogens. His basic crystal-line-packing model, for liquid-crystalline alkyl 1-glycosides, which can be applied to the compounds in this study, is a hydrogen-bonded layer of carbohydrate moieties with the alkyl chains pointing outwards in parallel arrangement (2). The latter are the first to melt, while the hydrogen-bonded layers resist the thermal motion up to a higher temperature. Jeffrey (2) predicted a staggering potential for easily available liquid-crystalline compounds from carbohydrate molecules.

Type I interferon structures: Possible scaffolds for the interferon-alpha receptor complex

Tattanahalli L. Nagabhushan, Paul Reichert, Mark R. Walter, and Nicholas J. Murgolo

Abstract: The structures of several type I interferons (IFNs) are known. We review the structural information known for IFN alphas and compare them to other interferons and cytokines. We also review the structural information known or proposed for IFN–cell receptor complexes. However, the structure of the IFN – cell receptor – IFN receptor2 (IFNAR2) and IFN receptor1 (IFNAR1) complex has not yet been determined. This paper describes a structural model of human IFN-IFNAR2/IFNAR1 complex using human IFN-α_{2b} dimer as the ligand. Both the structures of recombinant human IFN-α_{2b} and IFN-β were determined by X-ray crystallography as zinc-mediated dimers. Our proposed model was generated using human IFN-α_{2b} dimer docked with IFNAR2/IFNAR1. We compare our model with the receptor complex models proposed for IFN-β and IFN-γ to contrast similarities and differences. The mutual binding sites of human IFN-α_{2b} and IFNAR2/IFNAR1 complex are consistent with available mutagenesis studies.

Key words: three dimensional structure, antiviral activity, receptor, interferon.

Résumé : On connaît les structures de plusieurs interférons (IFN) de type I. On passe en revue les informations structurales connues pour les IFN alpha et on les compare à celles connues pour d'autres interférons et cytokines. On passe aussi en revue les informations structurales connues ou proposées pour les complexes IFN–cellule réceptrice. Toutefois, les structures du complexe INF – cellule réceptrice – IFN récepteur 2 (IFNAR2) et IFN récepteur 1 (IFNAR 1) n'a pas encore été déterminée. Dans ce travail, utilisant le dimère interféron humain-α_{2b} comme ligand, on décrit un modèle structural du complexe humain IFN-IFNAR2/IFNAR1. Faisant appel à la diffraction des rayons X sur des dimères reliés au zinc, on a déterminé les structures des recombinants humains humain-α_{2b} ainsi que IFN-β. Notre modèle proposé a été généré en utilisant le dimère humain IFN-α_{2b} arrimé au IFNAR2/IFNAR1. On a comparé notre modèle avec les modèles du complexe récepteur proposés pour IFN-β et IFN-γ pour mettre en relief les similarités et les différences. Les sites de fixation mutuels du dimère humain IFN-α_{2b} et du IFNAR2/IFNAR1 sont en accord avec les études disponibles de mutagénèse.

Mots clés : structure tridimensionnelle, activité antivirale, récepteur, interféron.

Introduction

General

The diverse and multiple biological properties of interferons (IFNs) have driven the need for an understanding of their activity at the molecular level. In 1957, Issacs and Lindenmann (1) discovered IFNs as antiviral agents. IFNs are a family of structurally and functionally related proteins that exhibit antiviral and antiproliferative effects on various cell types. They have been shown to exhibit various potent immunomodulatory effects including regulation of natural killer cell activity and modulation of major histocompatability antigen expression as well as antiproliferative activity against malignant cells (1–5).

Classification of interferons

IFNs were historically classified according to the cells of origin (i.e., leukocyte, fibroblast, and immune IFN). More modern designations are based on immunogenic properties and gene sequences. The major classes of IFNs are IFN-α, -β, -τ, and -ω, which are also designated type I (acid stable), and IFN-γ designated type II (acid labile). The IFN-α gene family is known to consist of at least 14 distinct human members that encode 12 different proteins (6). Sequencing

of mammalian genomes has led to identification of additional classes including limitin (7) and IFN-κ (8). A number of synthetic and hybrid genes have been expressed to produce unnatural proteins including consensus IFN (9). Consensus IFN is a synthetic IFN-α designed by assembling each of the most frequently observed amino acids in several IFN-α subtypes (9). The human IFN-α species are particularly homologous in amino acid sequence (about 78%) and generally display a high level of species specificity in their biological activities. Primary amino acid comparisons of the IFN-α subtypes with human IFN-β and IFN-γ reveal sequence identities of about 30% and 10%, respectively, (10). The type I IFN-α family contains proteins of 166 amino acid residues except for IFN-α_2, which has 165 residues, and IFN-ω with 172 residues. All the IFN-α subtypes contain two disulfide bridges with Cys1–Cys99 and Cys29–Cys138, except IFN-α_2, which lacks position 44 and forms the disulfide bridges with Cys1–98 and Cys29–Cys138 and for IFN-α_8, which forms the first disulfide bridge with Cys1–Cys100. IFN-β has only one disulfide bridge at Cys31–Cys141 (11). The most biophysical information has been reported for recombinant *E. coli* derived human α- and β-interferon. The homogeneity of human recombinant IFN-α_{2b} has been analyzed using various physio–chemical methods developed to analyze the quality of interferon preparations including gel electrophoresis, reverse phase HPLC, NMR, various mass spectral methods, and circular dichroism (12).

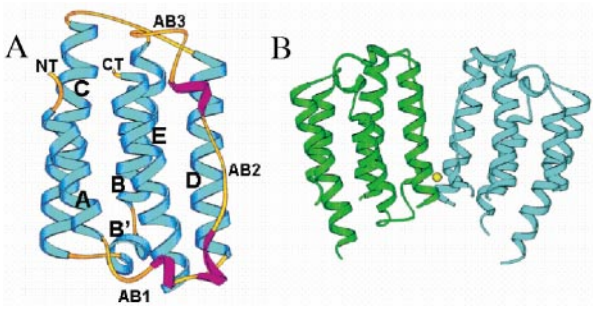
IFN-α and IFN-β interact with two receptor components on cell surfaces, interferon alpha receptor 1 (IFNAR1) and interferon alpha receptor 2 (IFNAR2), which belong to the class II cytokine receptor superfamily (13). Both subunits of the receptor are required for selective ligand recognition and the receptors recognize distinct ligand epitopes (14). IFNAR1 contains four extracellular Ig-like domains, while IFNAR2 contains two extracellular Ig-like domains. Sequence similarity to tissue factor and IFN-γ receptors (both of which contain two Ig-like extracellular domains) suggest IFNAR1 and IFNAR2 will adopt similar folds. The availability of high-resolution structures of these receptors has facilitated homology modeling of IFNAR1 and IFNAR2. Such models are useful for mapping ligand and antibody epitopes.

Structural information on IFN-α, -β, and -γ and interleukin-10

IFN-α

Although crystallization of human recombinant IFN-α_{2a} was first reported in 1982 (15), high quality crystals of the zinc-mediated non-covalent dimer of human recombinant IFN-α_{2b} were not reported until 1996 (16). The crystallographic asymmetric unit contains three non-covalent dimers of the IFN-α_{2b} monomer shown in complimentary orientations in Fig. 1. The zinc-binding site is formed from adjacent glutamic acid residues (Glu41 and Glu42) located on the 3_{10} helix at the C-terminal end of the AB loop of each monomer. The overall fold of IFN-α_{2b} is similar to the previously determined structure of murine recombinant IFN-β (17). Each monomer of IFN-α_{2b} is composed of five α-helices, labeled A–E, linked by one overhand connection (AB loop) and three short segments (BC, CD, and DE loops). The topology of IFN-α_{2b} resembles the classical up-up-down-down four helix bundle motif: helices A, B, C, and E comprise the

Fig. 1. Molecular structure of IFN-α_{2b}. (A) Ribbon diagram; (B) dimer. (A) Helices A–E are in cyan, A–B loop 3_{10} helices are in magenta. (B) Independent monomers are in cyan and green; zinc is indicated by a yellow sphere.



helix bundle (Fig. 1). IFN-α_{2b} is distinguished from the classical topology by helix D (consisting of 20 residues) that replaces the second extended overhand loop (CD loop) observed in class 1 long chain cytokines (18).

Multidimensional heteronuclear NMR spectroscopy was used to determine the solution structure of recombinant human IFN-α_{2a} at pH 3.5 at 2–2.2 mM protein concentration (19). The lower pH was required for structure determination because unspecific aggregation at higher pH led to low-quality solution ^{1}H NMR spectra with broad resonance lines. As observed for the crystal structure of IFN-α_{2b}, IFN-α_{2a} consists of five α-helices, four of which are arranged to form a left handed helix bundle with an up-up-down-down topology and two overhead connections. Among the structurally related four helical bundle cytokines, the structure of IFN-α_{2a} is most similar to that of IFN-α_{2b}, murine IFN-β, and human IFN-β. The crystal structure of ovine IFN-τ (20) is similar to the crystal structures of IFN-α_{2b}, human IFN-β, and murine IFN-β and the NMR solution structure of IFN-α_{2a}.

IFN-β

To date, X-ray crystallographic structures have been determined for murine *E. coli* derived IFN-β (17) and CHO cell derived glycosylated human IFN-β (21). The overall topology of both murine and human recombinant IFN-β monomeric structures is most similar to IFN-α_{2b}. Interestingly, human IFN-β and IFN-α_{2b} both crystallize as zinc-mediated dimers (Fig. 2B). However, the human IFN-β zinc-mediated dimer forms a different dimer interface compared with the IFN-α_{2b} crystal structure. The dimer interface of human IFN-β contains a zinc atom that is coordinated by histidine residues from adjacent monomers. A water molecule completes the tetrahedral zinc coordination between His121 (helix D) and Glu43 (AB loop) of one monomer and Gln94 (AB loop) and His97 (helix C) of the complimentary monomer. Dimerization has been observed for other helical cytokines and in some cases has been correlated with receptor activity (18). The biological significance of dimer formation of human IFN-β and IFN-α_{2b} is unclear.

IFN-γ

In 1991, the first human interferon structure determined was of recombinant human *E. coli* derived IFN-γ (22) (Fig. 2C). Human IFN-γ is a homodimer in solution and crystallizes with two dimers related by non-crystallographic twofold axis in the asymmetric unit. The protein was primarily

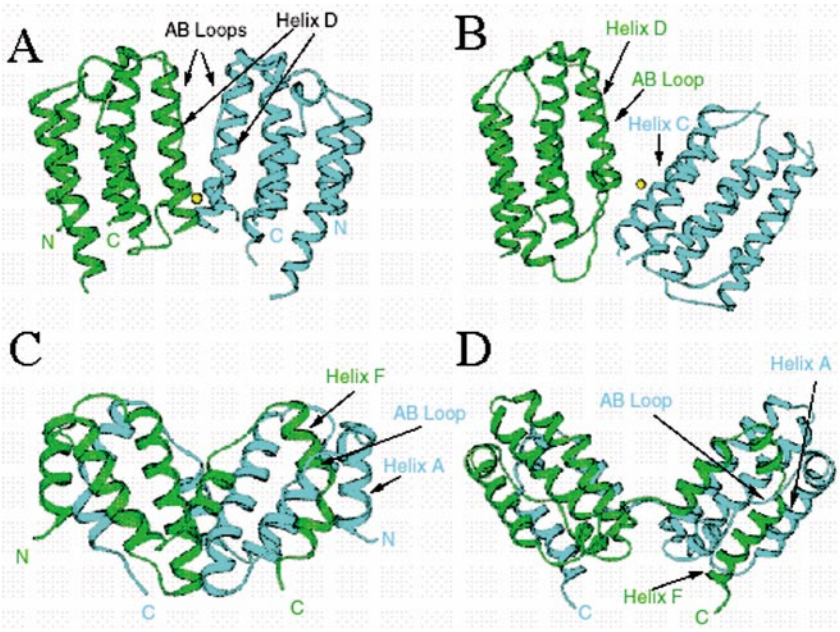
Fig. 2. Comparison of dimer structures of (A) IFN-α_{2b}; (B) IFN-β; (C) IFN-γ; and (D) IL-10. Each independent monomer is either in cyan or green. For IFN-α_{2b} and IFN-β the coordinate zinc is indicated by a yellow sphere.



α-helical with six helices in each subunit. Subsequently, the recombinant rabbit IFN-γ structure was reported to be topologically identical to human IFN-γ (23). Both structures were predominantly α-helical with extensive interdigiation of the α-helical segments of the two polypeptide chains. The high resolution structure (2 Å) of bovine IFN-γ reported in 2000 was most similar in overall topology to the human IFN-γ (3.5 Å) (24). The structure of a biologically active single chain mutant of human IFN-γ was reported in 2000 (25). The single-chain mutant was derived by linking the two peptide chains of the IFN-γ dimer by a seven-residue linker and changing His111 in the first chain to an aspartic acid residue.

Interleukin-10

Interleukin-10 (IL-10) is a cytokine that inhibits production of pro-inflammatory cytokines including IFN-γ and TNF-α. Physiochemical studies on recombinant human IL-10 indicate that human IL-10 is predominately a non-covalent dimer at neutral pH with two disulfide bridges (26). The crystal structure of recombinant human CHO cell derived IL-10 is a dimer composed of identical polypeptide chains related by a twofold axis (27) (Fig. 2D). Each IL-10 monomer consists of six α-helices. The main-chain folds resemble IFN-γ in which the structural integrity of each domain is dependent on the intertwining of helices from each peptide chain. IL-10 and IFN-γ structures have comparable overall topology (v shape), interdomain angle (129° in both structures), and five amino acid sequences conserved in all amino acid sequences in the core. The high resolution crystal structure of refolded *E. coli* derived human IL-10 (28) has overall topology most similar to the recombinant CHO cell derived IL-10.

Dimer interactions

IFN-α_{2b}, human IFN-β, IL-10, and IFN-γ have dimeric units in their crystal structures (Figs. 2A–D). Both IFN-α_{2b} and human IFN-β crystallized as zinc-mediated dimers; however, IL-10 and IFN-γ crystallize as non-covalent intercalated dimers. All of these cytokines bind to class 2 cytokine receptors. The dimeric form of IL-10 and IFN-γ are important for optimal receptor activation, whereas there is no evidence that IFN-α or IFN-β dimers are important for activating their receptors.

IFN-α_{2b} zinc-mediated dimer is most similar to human IFN-β at the monomer level in the overall topology, folds, and elements of secondary structure. The major structural differences of the main chain reside in the exposed loops. Differences include (*i*) helix B in IFN-α_{2b} is kinked, which is absent in human IFN-β; (*ii*) helix E in IFN-α_{2b} is rotated around its axis relative to the orientation in human IFN-β; (*iii*) and human IFN-β is glycosylated at a single site Asn80 at the end of helix C, whereas IFN-α_{2b} is non-glycosylated. All the alpha interferons except for one species are glycosylated. Glycoslation does not interfere with dimer formation in human IFN-β.

IL-10 and human IFN-β display the best overall structural identity with each other; however, they do not share any significant sequence homology. While each domain of IL-10 resembles the long chain monomeric cytokines, the dimer fold of IL-10 (Fig. 2D) is most like IFN-γ (Fig. 2C). The two notable differences in the dimers are the size (length of helices) and orientation of the domains. In IL-10 the helix bundles are perpendicular to one another, while in IFN-γ the domains are oriented at an angle of about 60°. The domains of IL-10 are constrained to exhibit the 90° interdomain angle due to the conformations of the crossover connections that are formed. Analysis of interactions in the core of IL-10 and IFN-γ shows a close structural correspondence of a five residue cluster (IFN-γ motif). IL-10 and IFN-γ both contain similar flexible regions.

Members of the type I IFN family have homology to each other, bind to the same cell surface receptors (type II), and have overlapping function (6, 29–31). This review is specific

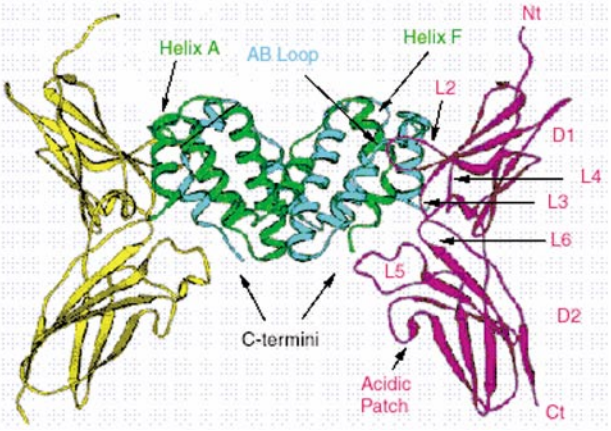
Fig. 3. Molecular structure of IFN-γ and its soluble high-affinity receptor. The ligand dimer is colored as in Fig. 2; IFN-γR1 molecules are in yellow and magenta.



to interferon and interferon-like structures. Several broad reviews on type I and type II cytokines are available (32).

Currently, crystal structures are not available for any type I interferon receptor complex. Here we review structural features on the related IFN-γ and IL-10 receptor complexes. Based on this analysis, we propose a model for the interferon/interferon-receptor complex.

Comparison of the structures of IFN-γ and IL-10 receptor complexes

The crystal structure of IFN-γ bound to its high affinity receptor (IFN-γR1) was first completed in 1995 (33). The complex contains two IFN-γR1s that bind the identical twofold related surfaces of IFN-γ to form a 2:1 IFN-γR1/IFN-γ complex (Fig. 3). Formation of this complex on the cell surface requires that the twofold of IFN-γ be approximately parallel to the cell membrane. Although IFN-γ oligomerizes two IFN-γR1s, the receptors do not interact with one another and are separated by ~100 Å, where they are predicted to enter the cell membrane.

The α-helical core of IFN-γ bound to IFN-γR1 is essentially identical to the previously determined crystal structure of unbound IFN-γ; however, significant structural differences are observed for the AB loop of IFN-γ, which makes extensive contacts with IFN-γR1. These contacts result in well-ordered AB loops that contain one turn of 3_{10} helix. In contrast, the AB loops in the crystal structure of unbound IFN-γ exhibit highly variable conformations. The conformational flexibility of this region is also supported by NMR studies. Although the mobility of the AB loop is influenced by IFN-γR1 binding, the positively charged C-terminal tail of IFN-γ remains flexible and is not observed in the structure of the complex (22, 33, 34).

Although it is not observed in the structure, this region of IFN-γ is likely involved in receptor binding. It has been demonstrated to affect receptor recognition and heparin sulfate binding by BIAcore (35). Antibodies raised against this region of IFN-γ block STAT1 alpha nuclear translocation, a requirement for biological activity (36). Mutation or deletion of the C-terminus affects receptor binding, dsRNA cleavage, and antiviral activity (37, 38). Peptides corresponding to the C-terminus compete with IFN-γ for receptor binding (39).

The extracellular fragment of IFN-γR1 folds into two domains to form a narrow rod-like molecule with overall dimensions of 75 × 25 × 15 Å. The N-terminal (D1) and C-terminal (D2) domains are connected by a short linker that adopts one turn of an α-helix. Unique to IFN-γR1, D1 and D2 are linked by a disulfide bond between Cys108 in the helical linker and Cys153 in D2. Approximately 1090 Å of surface area is buried in the D1–D2 interface that consists mostly of hydrophobic residues. The interdomain angle between D1 and D2 is approximately 120°. The IFN-γ binding site is located in a crevice between D1 and D2.

The domains of IFN-γR1 are structurally similar to fibronectin type III domains (FBNIII). D1 adopts a FNBIII β-sandwich fold that is characterized by two β-sheets comprised of β-strands A, B, and E and G, F, C, and C′. Although D1 of IFN-γR1 adopts a standard FBNIII topology, D2 contains an additional three residue β-strand (strand D) that is linked to β-strand E by a buried disulfide bond between Cys181 and Cys186. β-Strand D forms part of the A, B, and E β-sheet, and with the exception of Cys181, its residues display five solvent accessible glutamic and aspartic acid residues on the receptor surface. The BC loop contributes an additional five acidic residues that combine with β-strand D to form an acidic patch near the domain interface (Fig. 3). This patch has been hypothesized to form a transient binding site for the basic C-terminal tail of IFN-γ.

The structure of IFN-γR1 provided the first opportunity to compare the three-dimensional structures of class 1 and class 2 cytokine receptors as defined by Bazan (31). Comparison of IFN-γR1 with growth hormone receptor (GHR), the prototypical class 1 cytokine, revealed IFN-γR1 and GHR exhibit different domain angles of 120° and 90°, respectively. The functional consequence of the different domain angles is that GHR displays six ligand binding loops compared with five for IFN-γR1. Thus, the AB loop from D1 participates in growth hormone binding in the GHR but is buried in the domain interface in IFN-γR1.

Residues of IFN-γ in the binding interface are located on two discontinuous polypeptide segments. The first is comprised of helix A, the AB loop, and helix B, while the second contains helix F. IFN-γ is oriented with its N- and C-termini near the D1–D2 interface with the AB loop interacting with the L2 loop on D1. A total of 960 $Å^2$ of accessible surface is buried in each binding interface. The aromatic receptor residues Tyr52 loop 2 (144 $Å^2$), Trp210 loop 6 (95 $Å^2$), and Trp85 loop 3 (75 $Å^2$), contribute almost one third of the total buried surface area. Tyr52 and Trp85 form a large protruding surface that makes extensive contacts with the AB loop, His111, and Glu112 of IFN-γ. Of the eleven hydrogen bonds and salt bridges identified in the interface, five involve mainchain atoms of the AB loop. Near the end terminus of the molecule, IFN-γ residues Val5 N termini, Ile114 helix F, and Ala118 helix F, pack against Trp210 loop 6 and Val209 loop 6 of the receptor. In 2000, the crystal structure of the complex of human IFN-γ with the soluble glycosylated extracellular part of IFN-γRα revealed the presence of a third receptor molecule not directly associated with the IFN-γ dimer (40).

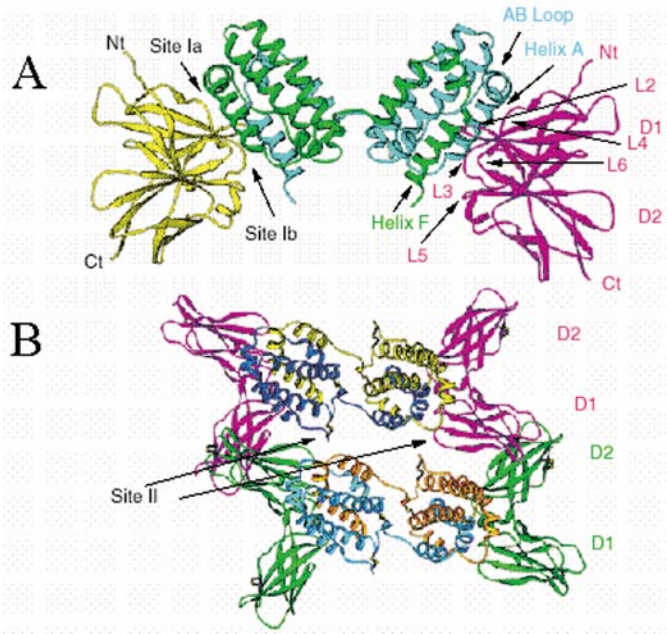
Fig. 4. Molecular structure of IL-10/sIL-l0R1 (A) 1:2 and (B) 2:4 complexes. In plate (A) IL-10 monomers in cyan and green, while the sIL-10R1 molecules are in yellow and magenta. In plate (B) IL-10 monomers are in yellow, blue, cyan, and magenta, and sIL-10R1 molecules are in cyan and green.



The IL-10/IL-10R1 complex

The crystal structure of the IL-10/IL-10R1 complex shares many similarities with the IFN-γ/IFN-γR1 complex (41). Like IFN-γ, IL-10 uses the same surfaces comprised of helix A, AB loop, and helix F to bind two IL-10R1s and form a 1:2 IL-10/IL-10R1 complex (Fig. 4). Despite differences in the domain orientations of IL-10 and IFN-γ, the separation between the C-terminal ends of the twofold related IL-10R1s is very similar to the IFN-γ/IFN-γR1 complex (~110 Å vs. 100 Å).

Comparison of bound and unbound IL-10 reveals a conserved α-helical core that does not change its structure upon receptor binding. As observed for IFN-γ, the AB loop of unbound IL-10 is flexible but adopts a rigid conformation due to several contacts with IL-10R1 in the receptor complex. Despite receptor binding the N-terminal ten and C-terminal two residues are not observed in the IL-10/IL-10R1 complex and are assumed to be flexible.

IL-10R1 folds into two FBN-III domains to form an L-shaped molecule. The individual domains of IL-10R1 and IFN-γR1 are structurally similar. Comparison of D1 and D2 domains results in root-mean-square deviations of 1.2 Å (81 Cα atoms) and 1.6 Å (71 Cα atoms), respectively. Despite similar domain structures, IL-10R1 and IFN-γR1 exhibit markedly different interdomain angles of 90° and 120°, respectively. Despite the different domain angles, IL-10R1 and IFN-γR1 still use the same five loops (L2–L6) to bind their respective ligands; however, the positions of the L2–L3 D1 loops change relative to the L5–L6 loops on D2. For IL-10R1, these loops are separated by ~20 Å, while in IFN-γR1 the distance is only 12 Å. These differences allow IFN-γR1 to bind the short A and F helices in IFN-γ, while IL-10R1 is more suited to bind to the longer A and F helices of IL-10.

As a result, IL-10R1 contacts IL-10 at two distinct surfaces labeled Ia and Ib. Site Ia occurs where the A–B loop crosses helix F, while site Ib is located near the N-terminus of helix A and the C-terminus of helix F. Receptor binding loops L2–L4 interact exclusively with site Ia, while loops L5 and L6 in D2 interact with site Ib. As previously observed for IFN-γR1, IL-10R1 residue Tyr43 located on loop 2 buries the most surface area of any residue (~105 $Å^2$) into a shallow cavity created by helix F and the AB loop.

Unique to the IL-10 system, IL-10 and sIL-10R1 form a complex consisting of two IL-10 dimers and four IL-10R1 molecules in solution. A 2:4 complex is also formed in the IL-10/IL-10R1 crystals by two adjacent 1:2 complexes that separated by unit cell translation of 46 Å and offset an additional ~21 Å in a direction approximately perpendicular to the unit cell translation (Fig. 4). Contacts in the interface (site II) between the complexes are formed between IL-10R1 D1 from one complex with IL-10 and IL-10R1 D2 of the adjacent complex. The location of the L2 loop in the site II as well as the site I interface suggests that assembly of the 2:4 is dependent on the initial formation of the site I interface (e.g., 1:2 complex). Sequence similarities between IL-10R1 and IL-10R2 suggest both receptors may bind such that IL-10R2 may bind to the IL-10R1 binding site. This 2:4 complex provides a model for how IL-10R1 and IL-10R2 may associate to form a biologically active IL-10/IL-10R1/IL-10R2 complex.

Molecular models for IFN/IFN receptor complexes

IFNAR1 and IFNAR2 are members of the class 2 cytokine receptor family (31) permitting modeling of their extracellular domains from the crystal structure of human IFN-γ receptor 1 (33, 40) or tissue factor (42). Several prior models of IFNAR1 and IFNAR2 based upon IFN-γ receptor 1 and tissue factor have been presented (37–41).

Homology models were constructed for human IFNAR2 and IFNAR1 based on the crystal structure of IFN-γ receptor 1 (33). Models were constructed for the two extracellular domains of IFNAR2 (residues 1–202), extracellular domains 1–2 of IFNAR1 (residues 1–202), and extracellular domains 3–4 of IFNAR1 (residues 203–407). The alignment of IFNAR1 domains and IFN-γ receptor 1 was previously described by Cutrone and Langer (43). IFNAR2, IFNAR1 domain 1–2, and IFNAR1 domain 3–4 models were constructed by the Segment Match Modeling Approach (44) and refined with the Encad program as implemented in the Look (Molecular Applications Group, formerly of Palo Alto, CA) program. The models were further refined by molecular mechanics minimization with the InsightII/Discover program (Accelrys, San Diego, CA).

The molecular model of IFNAR2 was docked manually with the InsightII program to the zinc dimer crystal structure of IFN-$α_{2b}$ (16) using the site and orientation previously suggested from mutational analysis (45–48). Prior mutational analysis suggested key IFN-$α_{2b}$–IFNAR2 interactions are D35–K50, R144–E79, R149–E79, S152–H78, R144–M48, and R22–Y45. Based on our docked orientation the last interaction is likely indirect.

Fig. 5. The IFN-α_{2b}/IFNAR1/IFNAR2 complex. IFN-α_{2b} is shown in cyan, IFNAR1 in green, and IFNAR2 in red.

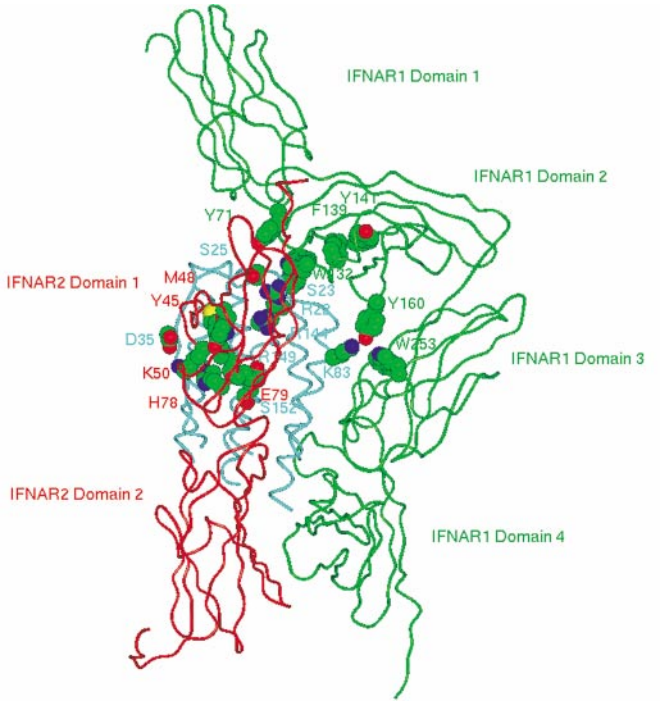

Fig. 6. The IFN-α_{2b}/IFNAR1/IFNAR2 dimer model. Coloring as in Fig. 5; zinc is indicated by a yellow sphere.

The molecular models of the IFNAR1 domain 1–2 and domain 3–4 were first docked to the IFN-α_{2b} crystal structure independently and were later annealed to form a peptide bond between domains 2 and 3 with residues mapped by mutagenesis as forming the IFNAR1 binding site on the same side of the model as suggested from prior modeling (43). Mapping of bovine IFNAR1 binding residues in that work demonstrated the importance of IFNAR1 domains 2 and 3 (49). Domain 2 residues mapped by loss of binding mutations included W132, F139, Y141, and Y160, while a single domain 1 residue Y71 and a single domain 3 residue W253 appeared important as well. Of residues previously noted to form the IFNAR1/IFN-α recognition site, Y71, W132, and Y160 of the first two domains appear to form an available surface for docking, with F139 and Y141 propping up these positions. Prior IFN-α chimers and mutations suggest the IFNAR1 recognizes IFN-α AB loop residues 16–28 as well as K83 and Y90 (50). Given the expected similar orientation of IFNAR1 and IFNAR2 transmembrane segments, we oriented the IFNAR1 domain 1–2 model along the AB loop and the domain 3–4 model against IFN-α K83 and Y90. Specific interactions could be formed in docking between IFN-α_{2b}–IFNAR1 S23 and S25–Y71, R22–W132, K83–Y160, and K83–W253. The resulting annealed IFNAR1 model contain an approximately perpendicular angle between domains 2 and 3. The resulting IFN-α_{2b} zinc dimer IFNAR1/IFNAR2 complex model was subject to further refinement by molecular mechanics minimization with InsightII/Discover.

The docked orientation of the IFN-α_{2b}/IFNAR1/IFNAR2 complex is presented in Fig. 5. IFNAR1 and IFNAR2 do not have a significant contact region excepting the N-terminus of IFNAR2. The association of IFNAR1 and IFNAR2 does not require IFN-α_{2b} dimer formation in this orientation. Chimeric constructs using the extracellular domain of the EPO receptor and transmembrane and intracellular regions of IFNAR1 demonstrate receptor dimerization is required for induction of effector genes (51). A similar construct with the extracellular domain of IFN-γR1 and transmembrane and intracellular regions of IFNAR2 shows receptor dimerization is sufficient to induce biological activity (52). Thus, ligand dimerization, perhaps mediated by zinc, may permit a complex to form with two molecules of IFNAR1 and IFNAR2. These receptors could recognize identical sites on the dimer in a manner analogous to IFN-γR1 (33).

IFNAR2 dimerization may be a requirement for antiviral activity. Both IFNAR2 and IFNAR1 are subject to alternative splicing, producing soluble-receptor isoforms. Differential regulation of IFNAR2 isoform expression has been recently suggested as a means of modulating type I IFN responses (53). While the intracellular domain of IFNAR2 is required for signal transduction, interaction of its soluble isoform, containing only the extracellular domain, with its membrane anchored isoform is sufficient to confer antiviral activity even in the absence of type I IFN (54). The nature of this interaction is unclear as direct contact between IFNAR2 extracellular domains is not seen in our proposed model (see Fig. 6).

Although, it is perceived that IFN-α_2 exists as a monomer at physiologically relevant concentrations, local concentration at the receptor or receptor mediated association may obligate dimer formation. NMR and dynamic light-scattering studies have shown IFN-α_2 exists in a oligomeric rather than monomeric state at neutral pH (19, 55). Since IFN-γ and

© 2002 NRC Canada

IL-10 activate their respective receptors as dimers, we used the dimer of IFN-α_{2b} to generate symmetrical counterparts for IFNAR1 and IFNAR2 on the IFN-α_{2b} dimer. This orientation is shown in Fig. 6. From this model, it is evident IFN-α_{2b} dimers could recognize two copies of IFNAR1 and IFNAR2.

IFN-β can form a dimer with zinc as well, although the monomer orientation differs from IFNA2 (56). The IFNAR1/IFNAR2 complex also appears to recognize IFN-β at a different location on the ligand framework (56).

Conclusion

The proposed IFN-α_{2b}/IFNAR1/IFNAR2 model of a dimer ligand binding to a pair of receptors on each of the chains of the ligand is consistent with the model proposed for the binding of cytokines to class 2 receptors.

Acknowledgments

We thank Gideon Schrieber for providing Proofs of the IFN-α_{2b}/IFNAR2 complex paper prior to publication. We thank Patricia Weber and Johanthan Greene for help in the preparation of this manuscript.

Novel substrates for efficient enzymatic transglycosylation by *Bacillus circulans*

Shiro Komba and Yukishige Ito

Abstract: To develop transglycosylation for efficient preparation of *N*-acetyllactosamine (Galβ(1→4)GlcNAc, LacNAc), β-galactosidase mediated transglycosylation using novel substrates *Bacillus Circulans* was explored. To make transglycosylation entropically favorable over hydrolysis, donor (lactose or galactose) and acceptor (*N*-acetylglucosamine, GlcNAc) components were connected to a single molecule. For that purpose, 1,2- and 1,3-benzenedimethanol and 2-hydroxy-5-nitro- and 5-hydroxy-2-nitro-benzyl alcohol were screened as linkers and enzymatic transglycosylation was examined under several conditions. In the case of 2-hydroxy-5-nitro-benzyl connected substrate **40**, an indication of the occurrence of intramolecular transglycosylation was observed, and the desired product (**58**) was obtained in 26% isolated yield. The same reaction in the presence of CMP sialic acid and α-(2→6)-sialyltransferase gave sialyl LacNAc **87** in one pot in 39% isolated yield. Additionally, the effect of the *C*-2 substituent of the acceptor component was briefly examined using substrates containing NHAlloc (**72**), NHTroc (**73**), and N_3 (**74**) groups. Although the occurrence of intramolecular transglycosylation was not clear in these cases, disaccharides **81**–**83** were obtained in reasonable yields.

Key words: galactosidase, intramolecular transglycosylation, *N*-acetyllactosamine, sialyltransferase.

Résumé : Faisant appel à de nouveaux substrats *Bacillus circulan*, on a étudié la réaction de transglycolisation catalysée par une β-galactosidase dans le but de développer une méthode de transglycosylation permettant de préparer la *N*-acétyllactosamine (Galβ(1→4)GlcNAc, LacNAc) d'une façon efficace. Afin de rendre la réaction de transglycosylation entropiquement favorable et de la rendre plus favorable que l'hydrolyse, on a relié les blocs donneur (lactose ou galactose) et accepteur (*N*-acétylglucosamine, GlcNAc) dans une seule molécule. À cette fin, on a utilisé les benzène-1,2- et 1,3-diméthanols ainsi que les alcools 2-hydroxy-5-nitro et 5-hydroxy-2-nitrobenzyliques comme connecteurs et on a étudié les réactions de transglycosylation sous plusieurs conditions. Dans le cas du substrat **40**, faisant appel à l'alcool 2-hydroxy-5-nitrobenzylique comme connecteur, on a observé des indications à l'effet de l'existence d'une réaction de transglycosylation intramoléculaire et on a obtenu le produit désiré, **58**, avec un rendement de 26% de produit isolé. La même réaction effectuée en présence de CMP de l'acide sialique et d'α-(2→6)-sialyltransférase dans une réaction monotope conduit à la formation de la LacNAc sialyée, **87**, avec un rendement de 39% en produit isolé. De plus, on a fait une brève étude de l'effet du substituant en *C*-2 du composant accepteur en utilisant des substrats portant des groupes NHAlloc (**72**), NHTroc (**73**) et N_3 (**74**). Même si les possibilités de réactions de transglycosylation intramoléculaire ne sont pas claires dans ces cas, on a obtenu les disaccharides **81**–**83** avec des rendements raisonnables.

Mots clés : galactosidase, transglycosylation intramoléculaire, *N*-acétyllactosamine, sialyltransférase.

[Traduit par la Rédaction]

Introduction

N-Acetyllactosamine (LacNAc) is a widespread component of glycoproteins (1), glycolipids (2), and glycosaminoglycans (3). It is particularly important as a core structure of ligands for cell adhesion molecules, for instance selectin (4) and CD22 (5). It was first isolated from porcine gastric mucin as a growth factor for *Lactobacillus bifidus var. pennysylvanicus* by Tomarelli et al. (6). A number of chemical approaches toward LacNAc have been reported (7–11). Most typically, it can be prepared from lactose (Lac) via lactal using azidonitration, developed by Wong and Lemieux (12) and Lemieux and Ratcliff (13), as the key transformation.

On the other hand, Wong et al. (14) developed a highly efficient LacNAc producing system, by using β-(1→4)-galactosyltransferase (EC 2.4.1.90), in combination with multiple enzymes for UDP–galactose recycling. This landmark achievement opened the way for glycosyltransferase catalyzed preparative scale oligosaccharide synthesis (15). Limitations in terms of the cost, availability, and stability of the enzymes and sugar nucleotides are still not negligible, however.

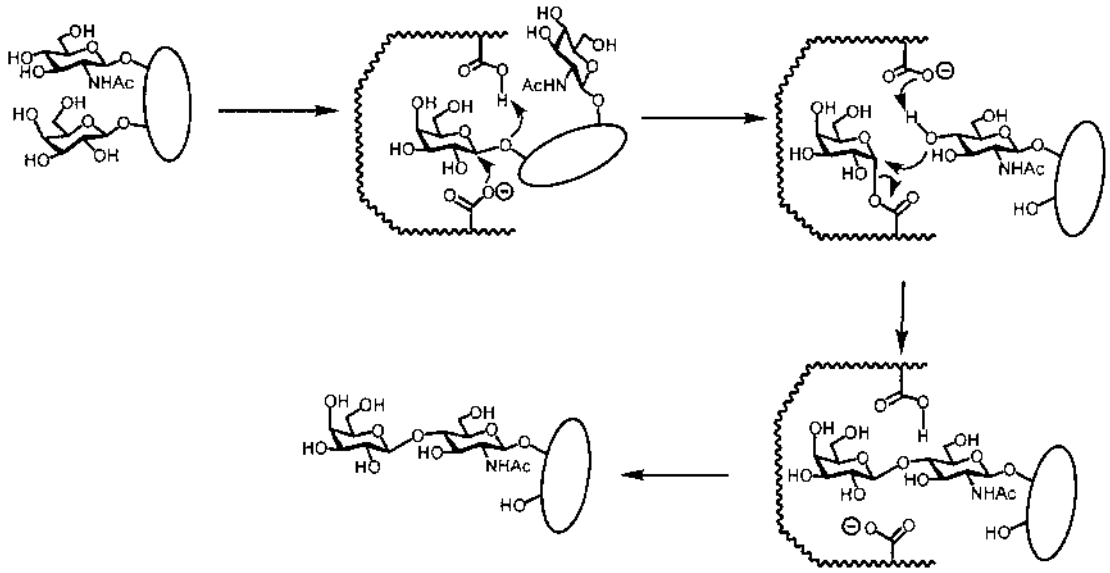
Scheme 1.



The glycosidase-based approach is attractive due to the following reasons: (*i*) an inexpensive (e.g., lactose) or easily obtainable (e.g., aryl β-D-galactoside) donor can be used; (*ii*) compared with glycosyltransferases, this group of enzymes are much more stable, easier to handle, and generally cheaper. Zilliken et al. (16) reported the first enzymatic synthesis of LacNAc from lactose and *N*-acetylglucosamine (GlcNAc) in the presence of extracts from *Lactobacillus bifidus*, although the yield was low from the standpoint of practical use. More recently, quite extensive studies on the use of β-D-galactosidase (EC 3.2.1.23) from *Bacillus circulans* have been reported by several groups (17–22).

Although these pioneering works clearly revealed the potential of galactosidase as a valuable tool for the synthesis of biologically relevant oligosaccharides, attainable yields have not been satisfactory. In most cases, a large excess of either glycosyl donor (e.g., lactose) or acceptor (*N*-acetylglucosamine) was used in order that the transglycosylation can compete with hydrolysis. It would be extremely difficult to suppress the hydrolysis to an extent that transglycosylation using an equimolar amount of glycosyl donor–acceptor can be achieved in a synthetically useful efficiency. One potential solution would be to perform the glycosyl transfer in an intramolecular manner by connecting the donor and acceptor components together into a single molecule (Scheme 1). Transglycosylation may be favorable over hydrolysis on the condition that the donor and acceptor portions of the substrate fit simultaneously into the binding pocket of the enzyme. In this paper, the first success in finding the substrate that, in part, fulfills these demands, is reported (23).

Results and discussion

As a tether to connect donor and acceptor components, our initial attention was focused on (**2**) 1,2-(*ortho*)-, and (**3**) 1,3-(*meta*)-benzenedimethanol, and substrates **9** and **10** were designed. These substrates were synthesized in a straightforward manner as depicted in Scheme 2. Although rather forcing conditions (75°C, 12 h) were required, the reactions of **2** and **3** with oxazoline **1** (24) selectively gave **4** and **5** in 59 and 74% yield, respectively, without noticeable contamination with diglycosylated products. Subsequent glycosylation with lactosyl trichloroacetimidate **6** (25) was effected in the presence of TMSOTf to afford **7** and **8** in 75 and 79% yield, respectively. Finally, *O*-acyl protecting groups were removed by sodium methoxide, and the designed substrates **9** and **10** were obtained in quantitative yield. These compounds were then examined as substrates for enzymatic transglycosylation using β-galactosidase from *B. circulans*, and the courses of the reactions were monitored by analytical HPLC (Fig. 1). Based on MALDI-TOF-MS and NMR analysis, peaks assignable as the desired products **15** and **16** (MALDI-MS *m*/*z*: ([M + Na]$^+$, 688) were identified, and their structures were rigorously confirmed by NMR analysis of corresponding acetates **17** and **18**. The yields of transglycosylated products **15** and **16** were rather low (~5%), however. While hydrolysis toward **11** and **12** was the overwhelmingly major pathway, it was noteworthy that the formation of bis-disaccharides **13** and **14** was dominant over **15** and **16** throughout the reaction.[2] Since the formation of **13** and **14** is possible only by intermolecular pathway, it is most probable that the intramolecular pathway made only a minor contribution, if any, to the formation of **15** and **16** (Scheme 3). Their formation would most likely be a result of sequential intermolecular transglycosylation and deglycosylation (i.e., (**9**, **10**)→(**13**, **14**)→(**15**, **16**)). This conclusion was supported by the extremely similar profiles of the *ortho* (**9**) and *meta* (**10**) isomers.

The above negative results obtained by **9** and **10** implied that the topological relationship of Gal and GlcNAc residues

[2] In addition, products that, based on MALDI-TOF mass, are assignable as multiply galactosylated, were detected. Their structures were not rigorously confirmed, however (see Figs. 1–5).

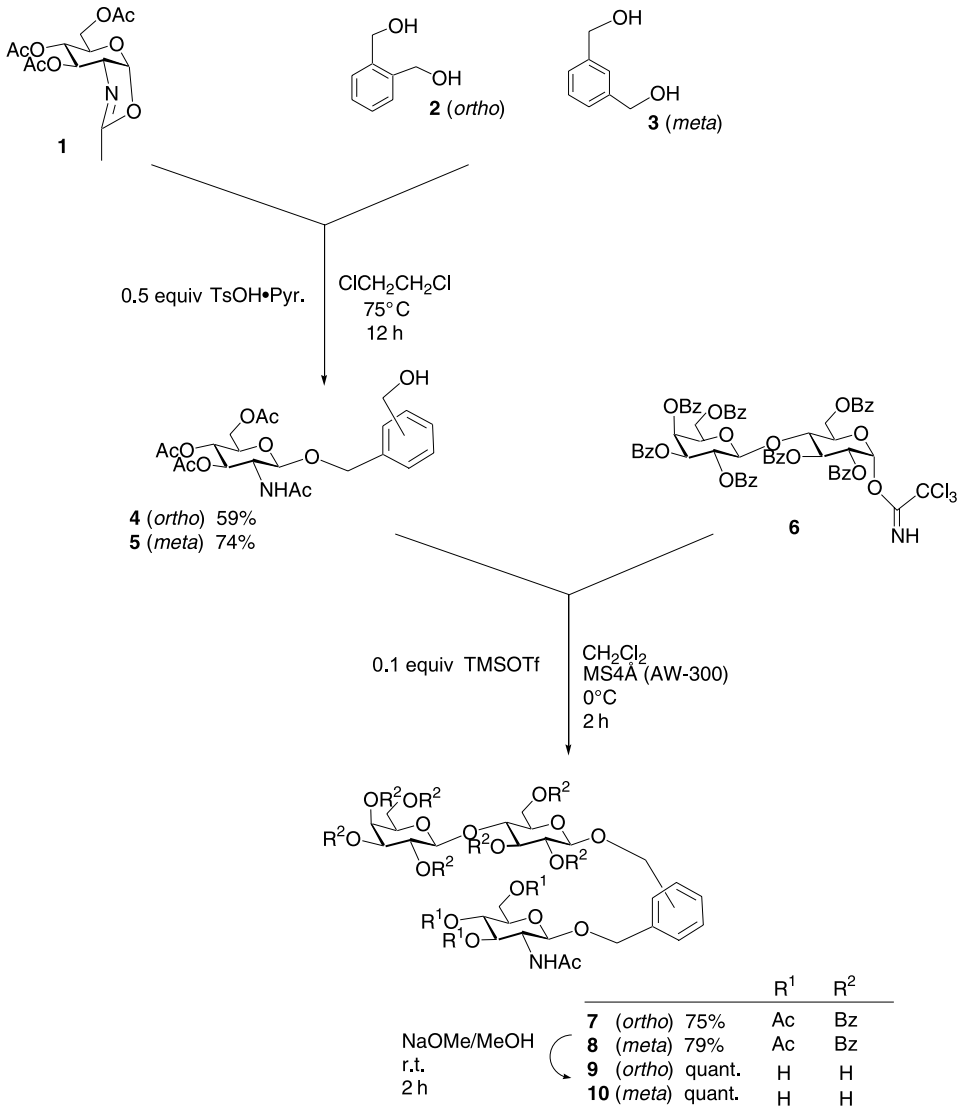
Scheme 2.



of these compounds does not fit the binding pocket of β-galactosidase. We therefore decided to attenuate the distance between these residues by changing the linker. To that end, 2-hydroxy-5-nitrobenzyl (*ortho*) (**20**) and 5-hydroxy-2-nitrobenzyl (*meta*) alcohol (**21**) were chosen, which each have one less methylene unit compared with **2** and **3**. Because they are unsymmetrical diols, regioisomers can be produced simply by changing the order of glycosylation (i.e., **36**–**37** and **38**–**39**). Additional diversity of the substrate can be generated by incorporating the galactose residue, instead of lactose, directly on the phenolic oxygen (i.e., **40** and **41**). In the latter case, the substrates can be viewed as derivatives of *p*-nitrophenyl galactoside, a well explored reactive donor for enzymatic transglycosylation.

Preparation of these substrates was achieved in a concise and divergent manner as depicted in Scheme 4. It commenced with a $BF_3{\cdot}OEt_2$-mediated chemoselective glycosylation of the primary hydroxy groups of **20** and **21**, with either lactosyl (**19**) (26) or glucosaminyl (**24**) (27) acetate to give **22** and **23** or **25** and **26**, respectively, in 67–85% yield. For the glycosylation of the unreactive phenolic hydroxy group, trichloroacetimidates **27** (28), **30** (25), and **33** (25) gave highly satisfactory results. To our surprise, addition of molecular sieves (MS), a common practise in glycosylation to ensure anhydrous conditions, deteriorated the efficiency of these particular reactions. Namely, when **22** and **23** were reacted with **27** in the presence of MS AW-300, the yields of **28** and **29** were less than 40%, while the same products were obtained in excellent yields in their absence. Reactions of **25** and **26** with **30** and **31** were likewise performed to give **31**, **32**, **34**, and **35** in 85–97% yield. Somewhat unexpectedly, in the case of the preparation of **34**, a significant amount of the corresponding α-isomer was also synthesized (α:β = 1:3.3). The obtained products were then subjected to deprotection, uneventfully, to give **36**–**41**.

These compounds were examined as substrates for transglycosylation in a similar manner as that described for **15** and **16**. Namely, each substrate (8 mM) was incubated with *B. circulans* β-galactosidase in 50 mM acetate buffer (pH 5.0), and the reactions were followed by analytical HPLC (Fig. 2).

In the case of substrates carrying lactose as a donor component (**36**–**39**), severe peak overlaps retarded the interpretation

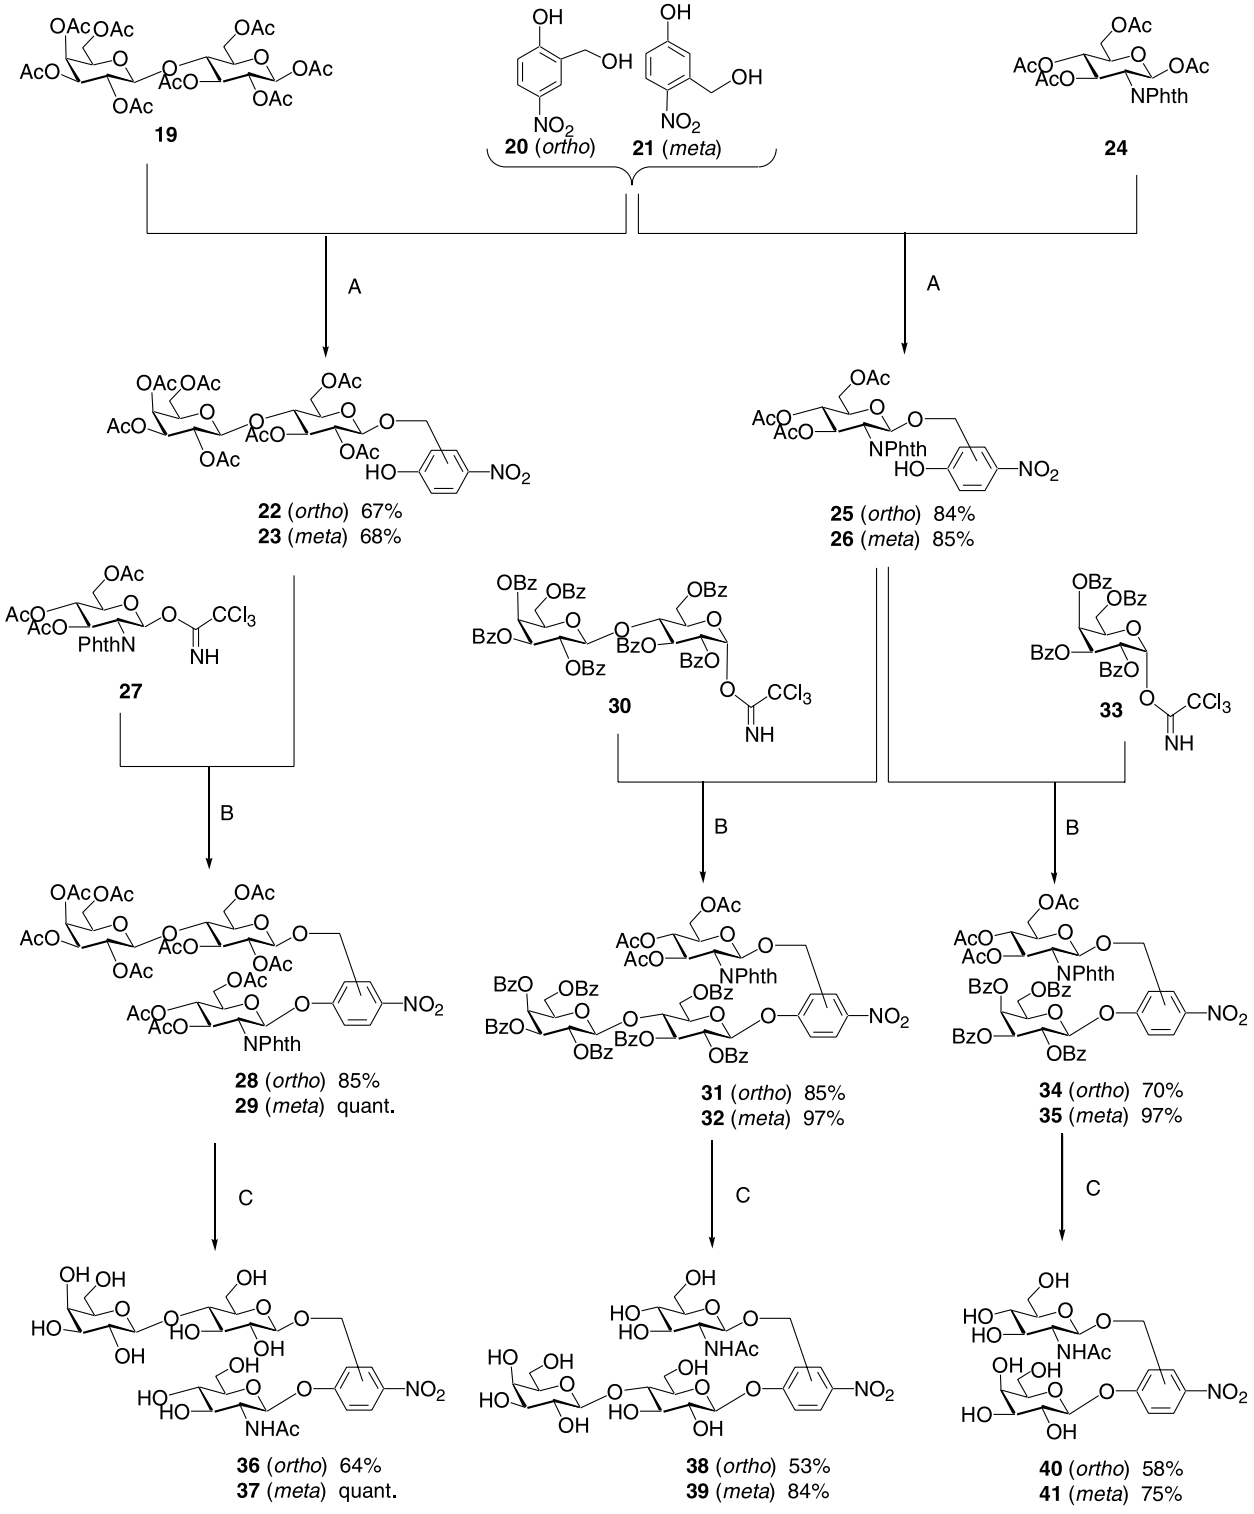
Scheme 4. Reagents and conditions: (*a*) 2 equiv $BF_3{\cdot}OEt_2$ in CH_2Cl_2 at rt for 1 h; (*b*) 0.5 equiv $BF_3{\cdot}OEt_2$ in CH_2Cl_2 at rt for 1 h; (*c*) (*i*) 75 equiv NH_2NH_2 in EtOH at 90°C for 3 h, (*ii*) Ac_2O in MeOH at rt for 8 h.



of the HPLC profiles. To enhance the peak assignments, aliquots of the mixtures were treated with β-*N*-acetylglucosaminidase from Jack beans (Sigma Co., Ltd.). After this treatment, galactosylated products, including the desired products (**54**–**57**) and bis-disaccharides (**48**–**51**), were readily distinguished from substrates and hydrolyzed products (**42**–**45**) by their resistance. In any event, no indication of intramolecular glycosyl transfer was obtained from these substrates; that is, at the early stage of incubation, the formation of **48**, **49**, **50**, and **51** was dominant over **54**, **55**,

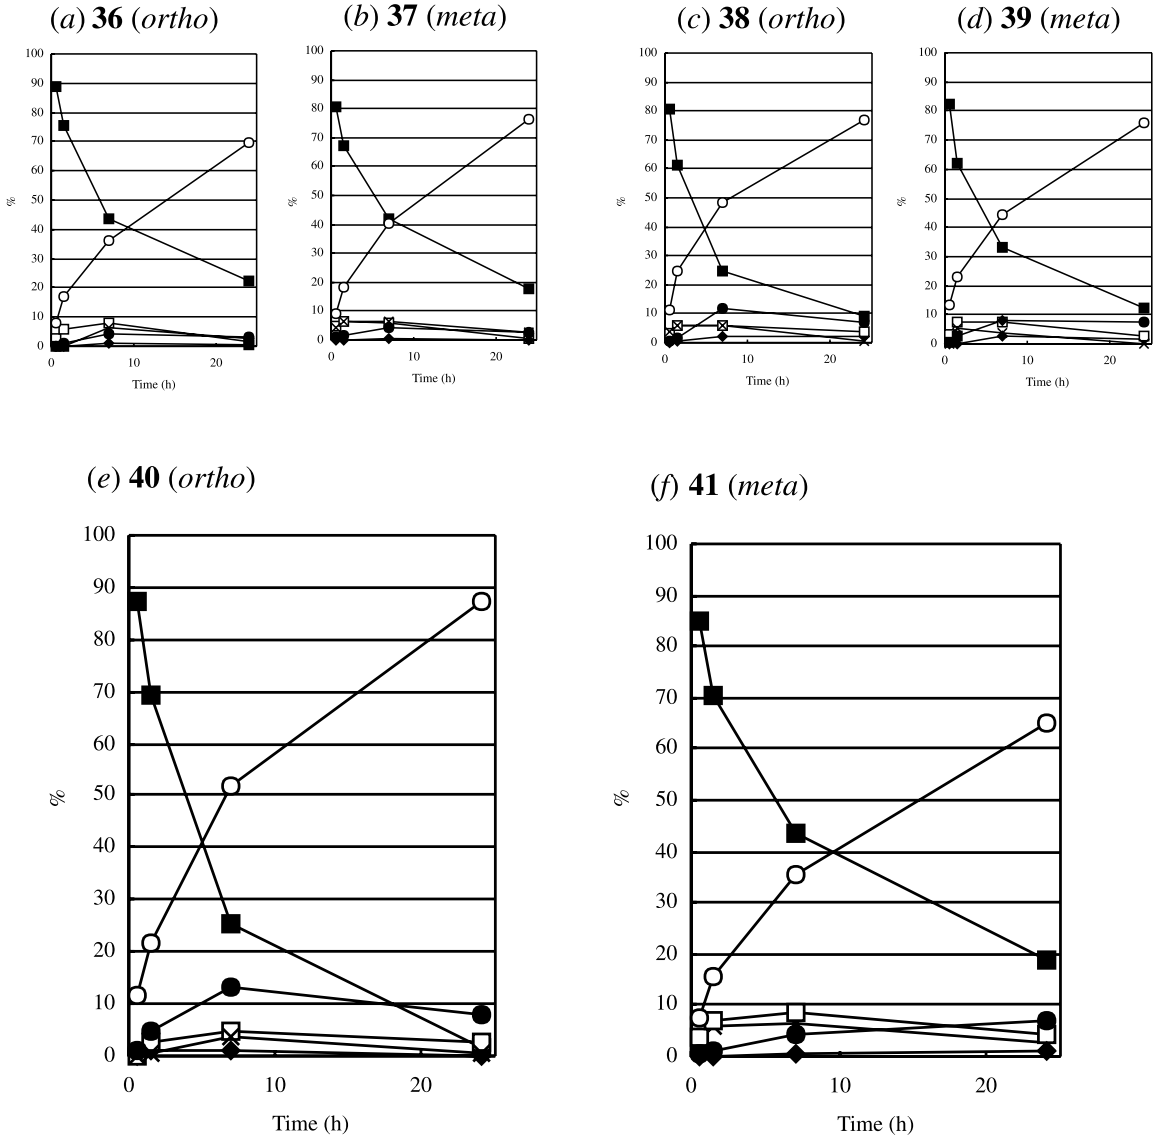
Fig. 2. Time course of β-galactosidase catalyzed reactions using substrates derived from the nitro-containing linker (Scheme 4). (*a*) Compound **36** (8 mM) was incubated with 0.34 U of β-galactosidase in 1.8 mL of acetate buffer (50 mM, pH 5.0) at 36°C; (*b*) compound **37** (8 mM) was incubated with 0.34 U of β-galactosidase, under identical conditions as (*a*) aliquots of the mixture were analyzed by HPLC. Peaks were assigned as follows based on MALDI-TOF-MS analysis: ■ starting material (**36** and **37**); ○ GlcNAcGlc (**42** and **43**); ● LacNAcGlc (**54** and **55**); □ LacNAcLac (**48** and **49**); × GlcNAcGalLac (regioisomer of **48** and **49**, structure not confirmed); ◆ $GlcNAcGal_2Lac$ (structure not confirmed); (*c*) compound **38** (8 mM) was incubated with 0.34 U of β-galactosidase in 1.8 mL of acetate buffer (50 mM, pH 5.0) at 36°C; (*d*) compound **39** (8 mM) was incubated with 0.10 U of β-galactosidase, under identical conditions as (*c*). Aliquots of the mixture were analyzed by HPLC. Peaks were assigned as follows based on MALDI-TOF-MS analysis: ■ starting material (**38** and **39**); ○ GlcNAcGlc (**44** and **45**); ● LacNAcGlc (**56** and **57**); □ LacNAcLac (**50** and **51**); × GlcNAcGalLac (regioisomer of **50** and **51**, structure not confirmed); ◆ $GlcNAcGal_2Lac$ (structure not confirmed).; (*e*) compound **40** (8 mM) was incubated with 0.13 U of β-galactosidase in 0.70 mL of acetate buffer (50 m M, pH 5.0) at 36°C; (*f*) compound **41** (8 mM) was incubated with 0.44 U of β-galactosidase under idential conditions as in (*e*). Aliquots of the mixture were analyzed by HPLC. Peaks were assigned as follows based on MALDI-TOF-MS analysis: ■ starting material (**40** and **41**); ○ GlcNAc (**46** and **47**); ● LacNAc (**58** and **59**); □ LacNAcGal (**52** and **53**); × $Gal_2GlcNAc$ (regioisomer of **52** and **53**, structure not confirmed); ◆ $Gal_3GlcNAc$ (structure not confirmed).

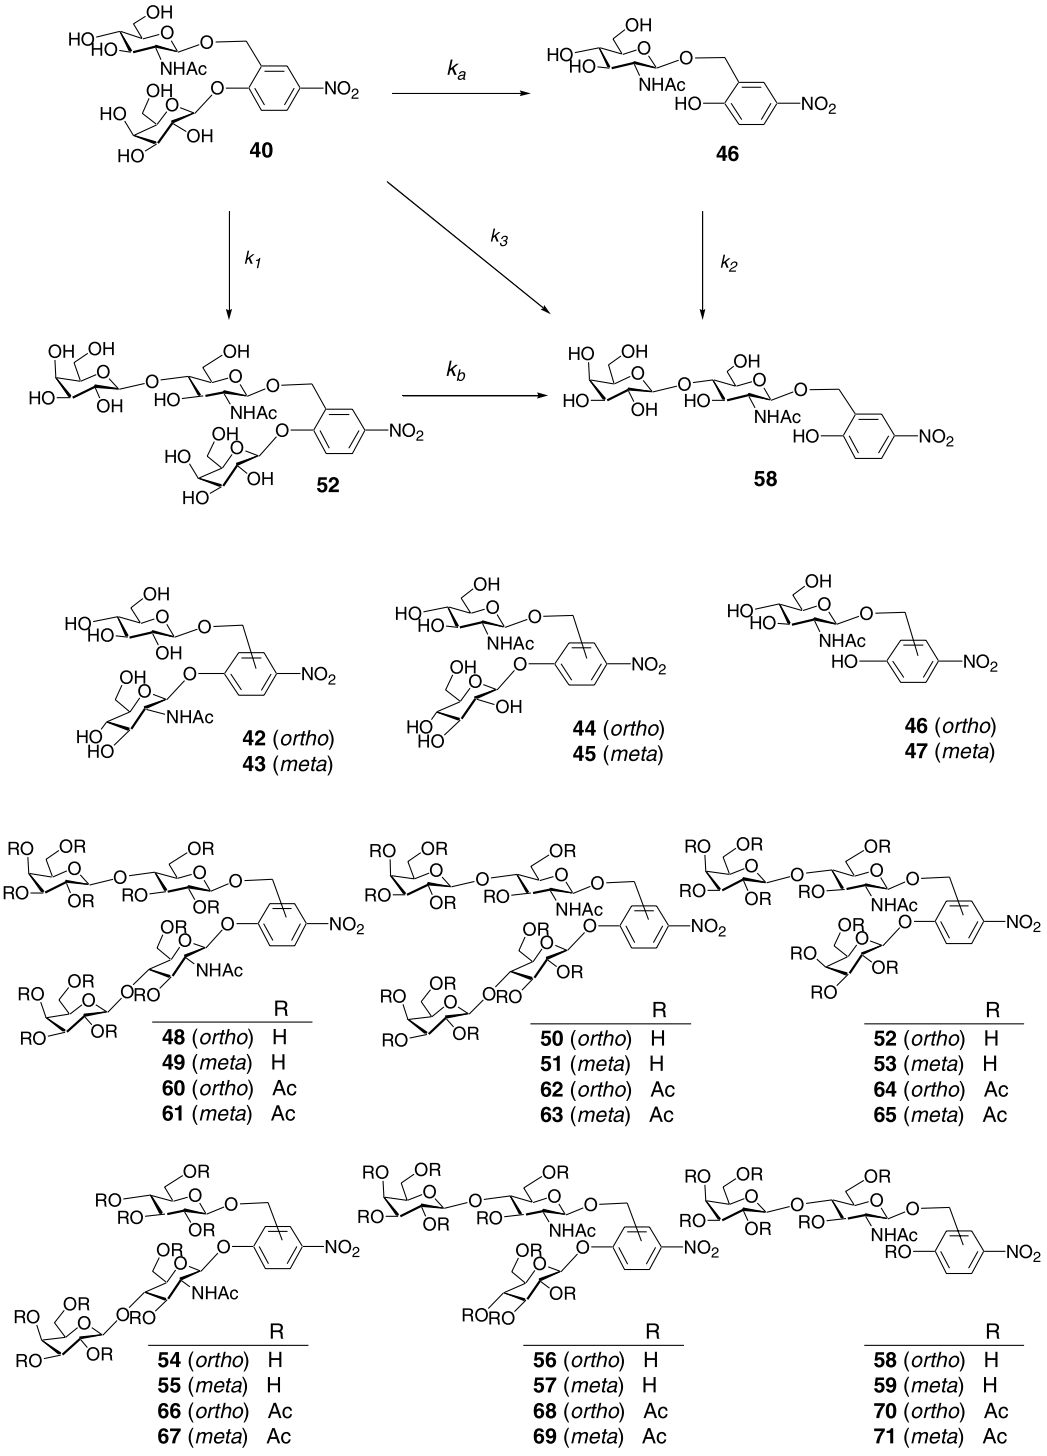


56, and **57**.[2] Nevertheless, it was observed that a significant amount of the transglycosylated product (**56**) was formed from *ortho* substrate **38**.

On the other hand, the profile of substrate **40** was markedly different. In this particular case, the formation of the LacNAc derivative (closed circle) was dominant over that of **52** even at the early stage of incubation ([**40**] > [**46**]).[2] Since the rates of intermolecular glycosyl transfer are likely to be similar between **40** and **46** ($k_1 \approx k_2$), it was inferred that the intramolecular pathway is functional ($k_3 > k_1, k_2$) (Scheme 5). By contrast, when starting from the *meta* oriented substrate **41**, it was found that the transglycosylation was far less efficient.

© 2002 NRC Canada

Scheme 5.



The formation of intermolecularly glycosylated product **53** preceded that of **59**, which means that the direct pathway was insignificant.

Using the preferred substrate **40**, the effects of substrate concentration (i.e., Table 1, entries 1–4), organic solvents (entries 6–12), and buffer pH (entry 5) were briefly examined. Contrary to several precedents on enzymatic transglycosylation (17, 20, 21), the beneficial effect of organic solvent was not observed (entries 6–12). A preparative scale reaction was performed at 20 mM concentration in acetate buffer (entry 3). Thus, using 50 mg (94 μmol) of compound **40**, incubation with β-galactosidase (430 mU) for 3 h afforded 26% yield (13.1 mg) of **58**, the structure of which was rigorously confirmed by NMR analysis of the corresponding acetate **70**. Subsequently, the effect of the glucosamine *C*-2 substituent was examined. Considering the potential synthetic utility of the expected products, three types of substrates were prepared, namely *N*-allyloxycarbonyl (Alloc) protected **72**,

N-trichloroethoxycarbonyl (Troc) protected **73**, and *C*-2 azide **74**. To synthesize these substrates, compound **34** was used as the common intermediate. Thus, **34** was treated with hydrazine hydrate in EtOH to remove *N*-phthalimido and *O*-acyl groups. The resultant amine was treated with either allyl chloroformate – $NaHCO_3$, trichloroethyl chloroformate – $NaHCO_3$, or TfN_3–Cu_2SO_4–K_2CO_3 (29), to afford **72**, **73**, and **74** in 64, 80, and 53% yield, respectively (Scheme 6).

Enzymatic transglycosylations were examined under conditions optimized for **40** (20 mM substrates in 50 mM acetate buffer, pH 5.0, Fig. 3 (Scheme 7). In these cases, the dominancy of intramolecular transglycosylation was not as clear as **40**, because the formation of the expected products (**81**–**83**) was slightly behind the initial formation of intermolecularly transferred products (**78**–**80**);[2] nonetheless, carbamate-protected lactosamine derivatives **81** and **82** were formed with an efficiency comparable with **58**. These products were quite resistant to galactosidase mediated hydrolysis. Preparative scale reactions using **72** (17.3 μmol), **73** (15 μmol), and **74** (9.6 μmol) were performed, in the same manner as described for **40**, to give **81**, **82**, and **83** in 21, 21, and 11%, respectively (Scheme 8), the structures of which were rigorously confirmed by NMR analysis of the corresponding acetates (**84**, **85**, and **86**). Since *N*-Alloc- (30) and *N*-Troc-protected derivatives (31) and *C*-2 azide (13, 32) are useful as glycosyl donors for the β- and α-selective glycosylation of 2-amino sugars, respectively, this procedure may be useful for the chemoenzymatic synthesis of complex oligosaccharides.

We then turned our attention to the synthesis of sialyl LacNAc by using galactosidase mediated transglycosylation, in combination with sialyltransferase. Since it is obvious that the LacNAc product **58** is susceptible to further digestion by β-galactosidase (to provide **46**), its yield under standard conditions does not reflect the relative rates of intramolecular transglycosylation and hydrolysis (i.e., k_3 vs. k_a). In fact, the yield of **58** (26%) dropped to 18% after 4 h incubation (Table 1, entries 3 and 4). To minimize the extent of post-transglycosylation hydrolysis, and to gain a more accurate estimation of the efficiency of transglycosylation, α-(2→6)-sialyltransferase (rat, recombinant, *Spodoptera frugiperda*) (Calbiochem Co., Ltd.) (33, 34) and CMP sialic acid were added to the system to trap **58** as a galactosidase resistant product **87** (Scheme 9, Figs. 4 and 5). As expected, smooth formation of sialyl-α-(2→6)-LacNAc **87** (□) was observed, and its amount did not decrease after prolonged incubation. In a preparative scale run, substrate **40** was used (25 mg, 47 μmol), incubated in 200 mM HEPES buffer (2.4 mL, pH 7.5) in the presence of β-galactosidase (100 mU), α-(2→6)-sialyltransferase (60 mU), and CMP-sialic acid (30 mg,

46 μmol). After 17 h, successive purification by Sephadex LH-20 and preparative HPLC afforded sialyl-α-(2→6)-LacNAc **87** in 39% yield (15.4 mg).

In conclusion, a novel method for the preparation of LacNAc and sialyl LacNAc was developed using β-galactosidase mediated intramolecular transglycosylation,

using substrates that have glycosyl donor and aglycon portions connected by a tether.

Experimental[3]

General methods

Column chromatography was performed on Silica Gel 60N (spherical, neutral) (Kanto chemical Co., Inc.). Preparative reverse-phase HPLC was performed on a Waters HPLC system (Millennium[32] operation system), using a Mightysil RP-18 GP 250–20 (5 μm) (Kanto chemical Co., Inc.), with a flow rate of 10 mL min^{-1}, and detected at 256 nm with a photodiode array detector (Waters 996). The solvent systems were: (*a*) TFA–water (1:1000) and (*b*) TFA–acetonitrile–water (1:900:100). Analytical reverse phase HPLC separations were performed on a Waters HPLC system, using a Mightysil RP-18 GP 250–3.0 (5 μm) (Kanto chemical Co., Inc.), with a flow rate of 0.6 mL min^{-1}, and detected at 256 nm with the same detector as above, using the same solvent system as above. MALDI-TOF-MS was performed in the positive ion mode on a Kompact MALDI IV tDE (Shimadzu Co., Ltd.), using a matrix of 2,5-dihydroxybenzoic acid or α-cyano-4-hydroxycinnamic acid, and an angiotensin I (MW = 1296.5) as a standard. FAB-MS was performed in the positive ion mode on a JMS-HX110 (JEOL), using a matrix mixture of glycerol and 3-nitrobenzyl alcohol. Optical rotations were measured with a DIP-370 digital polarimeter (Japan spectroscopic Co., Ltd.) at 22°C. ^{1}H NMR spectra were recorded at 400 MHz (JEOL JNM-AL400), or at 500 MHz (JEOL JNM-ECP500), in $CDCl_3$ (internal Me_4Si, δ: 0.00), DMSO-d_6, CD_3OD, or D_2O. ^{13}C NMR spectra were recorded at 100 or 125 MHz, respectively, on the same instruments in $CDCl_3$, DMSO-d_6, CD_3OD, or D_2O (internal MeOH, δ: 49.0). β-Galactosidase from *Bacillus circulans* was purchased from Daiwa Kasei K.K. (Japan). α-(2→6)-Sialyltransferase from rat, recombinant, *Spodoptera frugiperda* was purchased from Calbiochem Co., Ltd. β-*N*-Acetylglucosaminidase from Jack beans was purchased from Sigma Co., Ltd. All solvents and reagents were reagent grade and were used without further purification.

Enzymatic transglycosylation: typical procedure 1

A solution of substrate **9** (13.7 mg, 20.5 μmol, 8 mM) in 50 mM sodium acetate buffer (2.5 mL, pH 5.0) was incubated with β-D-galactosidase (0.5 U) at 36°C. After 30 min, 1 h, 4.5 h, and 8 h, aliquots of the reaction mixture were taken (ca. 200 μL) and terminated by heating at 95°C for 10 min. Each of them was separated by HPLC, first using 90% solvent A and 10% solvent B for 10 min, then the linear gradient 10–100% solvent B for 170 min. The eluted peaks were detected 254 nm UV absorption and the

[3] Experimental details for preparation of substrates were provided as Supplementary Material. Fig. 4. HPLC profiles of β-galactosidase – α-sialyltransferase reaction of **40**: (*a*) 1.5 h, (*b*) 6.5 h. Retention times of starting material (**40**), $Gal_2GlcNAc$ (**52**), NeuAcGalGlcNAc (**87**), and GlcNAc (**46**) are 17.87, 18.34, 22.25, and 22.53 min, respectively.

composition was calculated by integral curves. The fractions containing products were analyzed by MALDI-TOF-MS and each product was acetylated for extensive ^1H NMR analysis.

Enzymatic transglycosylation: typical procedure 2

A solution of substrate **36** (10 mg, 14.3 μmol, 8 mM) in 50 mM sodium acetate buffer (1.8 mL, pH 5.0) was added to β-D-galactosidase (0.34 U) and incubated at 36°C. After 30 min, 1.5 h, 7 h, and 24 h, aliquots of the reaction mixture were taken and terminated by heating at 95°C for 10 min, and part of them were analyzed by analytical HPLC, first using 100% solvent A for 5 min, then the linear gradient 0–30% solvent B for 30 min.

Residual aliquots (180 μL) were treated with β-*N*-acetylglucosaminidase (62.5 mU) at 36°C for 2 days, then the reaction mixtures were terminated by heating at 95°C for 10 min. Each of them was analyzed by HPLC, 90% solvent A and 10% solvent B as isocratic mode. The eluted peaks were detected at 254 nm using UV absorption and the composition was calculated by integral curves.

Combined transglycosylation–sialylation: preparation of compound 87

To a solution of **40** (25 mg, 46.7 μmol, 20 mM) and CMP-Neu5Ac (30.8 mg, 46.7 μmol) in 200 mM HEPES buffer (2.3 mL, pH 7.5) containing 20 mM $MgCl_2$, 5.3 mM $MnCl_2$, and 20 mM KCl, was added α-(2→6)-sialyltransferase (60 mU), followed by β-D-galactosidase (2.2 U). The mixture was incubated at 36°C for 18 h, and terminated by heating at 95°C for 10 min. After concentration, the mixture was roughly purified by Sephadex LH-20 gel filtration column chromatography (H_2O). Fractions containing **87** were concentrated and the mixture was purified by preparative HPLC, first using 100% solvent A for 5 min, then the linear gradient 0–30% solvent B for 30 min to give sialylated compound **87** (15.4 mg, 39%), together with hydrolyzed compound **46** (10.8 mg, 61%). Compound **87**: ^1H NMR (500 MHz, D_2O and MeOH) δ: 8.06 (d, 1H, $J_{Ph4,Ph5}$ = 3.2 Hz, Ph6), 8.01 (dd, 1H, $J_{Ph3,Ph4}$ = 9.2 Hz, $J_{Ph4,Ph6}$ = 3.2, Ph4), 6.49 (d, 1H, $J_{Ph3,Ph4}$ = 9.2 Hz, Ph3), 4.75 (d, 1H, J_{gem} = 12.8 Hz, PhCH),

Fig. 5. Time course of β-galactosidase – α-sialyltransferase reaction of **40**. Compound **40** (20 mM) was incubated with 86 mU of β-galactosidase and α-(2→6)-sialyltransferase (2.4 mU) in 95 μL of HEPES (200 mM, pH 7.5), 20 mM $MgCl_2$, 5.3 mM $MnCl_2$, 20 mM KCl, and CMP-sialic acid (20 mM), at 36°C. Peaks were assigned as follows based on MALDI-TOF-MS analysis: ◆ starting material (**40**); × GlcNAc (**46**); □ NeuAcGalGlcNAc (**87**); ■ $Gal_2GlcNAc$ (**52**).

Professor Raymond U. Lemieux

The following excerpt from David Bundle's excellent biography of Ray Lemieux for an upcoming volume of *Advances in Carbohydrate Chemistry and Biochemistry*, says it all: "His work was a dominating factor in converting this field from an academic specialization to one of great practical importance in chemistry, biology and medicine. He provided the area….with….[so many]….conceptual and experimental tools….[that it] shows a very rare and special degree of insight into chemical problems." In a nomination letter for an award (that Ray incredulously did not receive), this writer noted that Ray "entered an area where the practices relied on….in-house expertise and trade secrets. He rebelled at the notion that these vagaries had to be accepted as…."the strange world of carbohydrate chemistry"….[for]….such a view relegated the matter to the realm of magic." Lemieux's attempts to transform the "magic"….into…."science" provided spin-off materials that are so well blended into the fabric of chemistry that their origins are undetectable — and frequently unattributed.

Foremost among these is the use of NMR for structure elucidation. The writer once listened as Ray recalled the 1957 realization that the low-field signals with large and small spacings in the 40 MHz spectra were from the anomeric α and β protons, which led to the immediate epiphany that organic structure proof would thereafter be forever changed. Indeed, a young theoretical chemist who had listened to one of Lemieux's lectures about these observations returned to Harvard and the result was the Karplus equation.

But there is more to this landmark event that also provides another glimpse into Ray's modus operandi — the seemingly arrogant advice that "you never learn much by talking to people who are doing the same thing you are". Appropos, the major co-authors on the 1957 paper were NRC physical chemists, for in those days NMR was the playground of physicists. This cunning, prospector's intuition was to propel Ray into "molecular recognition" long before that sobriquet had been coined, and thence into the nettlesome world of immunology, and as his final triumph, a postulate about the source of binding energy between proteins and carbohydrate epitopes.

In his Wolf Prize address in 1999, Ray expressed satisfaction at accomplishing what he had set out to. If so he must have been aware of Yogi Berra's famous advice, "when you come to a fork in the road, take it," for his perennial concern with the anomeric centre brought him into 1950s conflict with the giants of organic chemistry. After all, he had the temerity to suggest that the thermodynamically stable anomers of glucose had the aglycon in the axial orientation, not equatorial as Barton's fledgling comformational analysis demanded.

Indeed, therein lay the impetus for the landmark NMR study that was to prove him right, and thence provide fodder for the anomeric effect, a phenomenon that has now returned to enrich its physical organic chemistry roots.

Professor Raymond U. Lemieux

L'extrait qui suit, tiré de la superbe biographie de Ray Lemieux, signée par David Bundle et destinée à une prochaine parution de *Advances in Carbohydrate Chemistry and Biochemistry*, est on ne peut plus éloquente : « Ses travaux ont significativement contribué à transformer ce secteur de facture résolument théorique en un domaine de forte incidence pratique pour la chimie, la biologie et la médecine. Il a livré au secteur une pléiade d'outils conceptuels et expérimentaux... qui reflètent une profonde compréhension des problèmes chimiques. » Dans une lettre de mise en candidature de Ray (pour un prix que Ray n'a pas remporté, à l'étonnement général), l'auteur écrivait que « Ray a abordé la profession à une époque où les pratiques étaient jalousement gardées. Or, il n'était pas prêt à accepter cet obscurantisme de la chimie des glucides, qui ne faisait que cultiver le mystère entourant la matière ». Ce désir de Lemieux de lever le voile du mystère grâce à la science a révélé des principes aujourd'hui si fondamentaux pour la chimie que leur origine est souvent passée sous silence, voire oubliée.

Le recours à la RMN pour déterminer la structure des matériaux est une pratique qui offre un bon exemple. En effet, l'auteur se souvient avoir écouté Ray lui raconter comment ce dernier a conclu, en 1957, que les signaux de champ à faible intensité ponctués de longues et de courtes chutes caractéristiques du spectre de 40 MHz avaient pour origine les protons anomériques α et β, et comment il a alors compris que cette découverte allait à jamais changer la façon de déterminer les structures organiques. De fait, un jeune chimiste théoricien d'alors, inspiré par un exposé de Lemieux au cours duquel ce dernier partageait ses conclusions, est retourné à Harvard et a formulé la fameuse équation de Karplus.

Si ces circonstances sont en soi marquantes, elles ont aussi frayé les voies à une vision, parfois qualifiée d'arrogante, que Ray allait épouser : « On apprend bien peu en se contentant de ne discuter qu'avec ses confrères. » Il importe de mentionner que les principaux coauteurs de l'article de 1957 étaient des physicochimistes du CNRC puisque, à cette époque, la RMN était le joujou des physiciens. Son audacieuse intuition allait faire de Ray une véritable tête d'affiche de la « reconnaissance des molécules » et de l'épineux domaine de l'immunologie et allait lui inspirer son postulat sur la source de l'énergie de liaison entre les protéines et les épitopes glucidiques, dernière note triomphale de sa carrière.

Dans le discours qu'il a prononcé lorsqu'on lui a remis le prix Wolf en 1999, Ray s'est dit satisfait de son parcours professionnel. Qu'il l'ait su ou non, il vivait au diapason du fameux aphorisme de Yogi Berra : « Quand on arrive à un embranchement, il ne faut pas hésiter à le prendre. » À preuve, son insatiable intérêt pour le centre anomérique a hérissé, en 1950, les grands de la chimie organique d'alors. Rien de surprenant : n'avait-il pas osé avancer que les anomères du glucose stables du point de vue de la thermodynamique portaient l'aglicone en position axiale plutôt qu'équatoriale, contrairement à ce que dictait la nouvelle analyse conformationnelle de Barton?

De fait, c'est à cette témérité que l'on doit la publication du rapport phare sur la RMN qui a prouvé la justesse de l'instinct de Ray et qui a mis en lumière l'effet anomérique, phénomène qui a ensuite largement été mis à profit dans le secteur de la chimie organique physique.

© 2002 NRC Canada

Ray's birth on June 16, 1920 to a homesteading family at Lac la Biche, behind God's back in Northern Alberta, is hardly the beginning for such a storied career, but it does exemplify the nexus between education and social mobility. Fortunately, his oldest sister and surrogate mother — for the real one died when he was seven — was "going with" a physics undergrad at the University of Alberta, and this culminated in Ray coming under the tutelage of Ruben Sandin, U of A's legendary mentor of young chemists. Rube sent him to Clifford Purves at McGill's Pulp and Paper Institute, where he was introduced to the vagaries of carbohydrate chemistry.

Purves sent Ray to Ohio State, where Melvin Wolfrom was engrossed in structure elucidation of streptomycin. He was thus introduced to the emerging "amino sugar" antibiotics that challenged penicillin's pre-eminence, and brought him into competition with the Umezawa brothers of Japan. Indeed the α-glucosaminide motif of these antibiotics may have been the well-spring of the elegant methodologies for anomeric stereocontrol that poured forth from his lab in the 1960–1970s.

Two side issues at Ohio State deserve mention, the more important of which will conclude this tribute. The less important is that Ray, in Wolfrom's lab, correlated the absolute stereochemistries of sugars and amino acids. In so doing he completed a bridge that led Emil Fischer to his "lock and key" theory, because enzyme action on anomeric sugars provided the impetus for the theory. Ray's tribute to Fischer is worthwhile reading.

No biography of Ray would be complete without mention of his visceral commitment to Canada. His valiant attempts in the 1960s at start-up companies to capitalize upon results from academic labs was two generations too soon, and they foundered even with the help of his wealthy industrialist brother. And while he greatly admired, probably even envied, the U.S.A.'s caution-be-damned attitude, the idea of going south was completely anathema to him. He preferred to light a candle rather than curse the dark, and the candle that shone most brightly was Chembiomed, which commercialized the immunoabsorbents that were leveraged from the chemical synthesis, and monumental molecular recognition studies of the blood group oligosaccharides.

Not surprisingly, Ray's elevation to Canada's highest civilian accolade, Companion of the Order of Canada in 1996, was a crowning adornment that went well with the King Faisal International Prize and the Albert Einstein World Award that preceeded it. The celebrated Wolf Prize for Chemistry was to follow it three years later — one year before his death.

Finally, the second "side issue" from Ohio State transcends all of the above, for Ray clearly shared the sentiments of Jacqueline Kennedy-Onassis: "It doesn't matter how successful you are if you mess up with your children." It was at Ohio State that Ray met a physical chemistry graduate student who was to become his wife. Jeannie's remarkable sense of humour must surely have been the perfect foil to harness Ray's boundless energy.

Si la naissance de Ray, le 16 juin 1920, dans une famille pionnière de Lac la Biche, dans le nord de l'Alberta, est un début bien humble pour celui qui allait devenir un si grand homme, elle témoigne de l'intime relation entre l'instruction et la mobilité sociale. En effet, la soeur aînée de Ray, qui jouait aussi le rôle de mère de famille puisque la mère de Ray est décédée lorsque celui n'avait que sept ans, était inscrite au baccalauréat en physique à l'Université de l'Alberta. Dans son sillage, Ray a gagné les rangs de cette université et a eu la chance d'être supervisé par Ruben Sandin, réputé pour l'encadrement qu'il offrait à ses disciples. Ruben a ensuite confié Ray à Clifford Purves, à l'Institut de pâtes et papiers de McGill, ce qui a constitué son introduction au mystérieux monde de la chimie des glucides.

Ensuite, Purves a cru bon de recommander Ray à Melvin Wolfrom, qui s'appliquait alors à élucider la structure de la streptomycine, à l'Université d'état de l'Ohio. Ray a ainsi abordé l'étude de ce nouvel antibiotique aminosucre susceptible de détrôner la pénicilline et, ce faisant, est entré dans l'arène avec les frères Umezawa du Japon. De fait, il y a fort à parier que le motif structural de l'α-glucosaminide de ces antibiotiques est au coeur des élégantes méthodologies de stéréocontrôle anomérique enfantées par le laboratoire de Ray au cours des années 1960 et 1970.

Deux autres réalisations à l'Université de l'état de l'Ohio sont dignes de mention ici, la plus marquante étant réservée à la fin du présent article. La première est l'établissement par Ray, dans le laboratoire de Wolfrom, de la corrélation de la stéréochimie absolue des glucides et des acides aminés. Ses efforts ont donné le coup d'envoi à la théorie « de la clé et de la serrure » d'Emil Fischer, inspirée par l'idée de l'action des enzymes sur les glucides anomériques. L'hommage flatteur que Ray rend à Fischer mérite lecture.

Nul ne peut parler de Ray sans souligner son affection pour le Canada. Ses vaillants efforts, au cours des années 1960, pour mettre sur pied des entreprises susceptible de tirer profit des résultats des laboratoires de recherche étaient trop visionnaires pour l'époque (Après tout, on parle d'un avant-gardisme de deux générations!) et se sont soldés par l'échec, malgré l'appui financier du frère de Ray, un industriel fortuné. Et bien que Ray ait admiré, peut-être envié, la vision de mépris du danger cultivée aux États-Unis, il n'a jamais voulu emporter ses pénates chez nos voisins du Sud. Il préférait allumer une bougie plutôt que maudire l'obscurité. Et sa bougie la plus brillante a été Chemibiomed, société qui a commercialisé les immunoadsorbants ayant découlé de la synthèse chimique et d'études de reconnaissances moléculaires marquantes des oligosides des groupes sanguins.

Il n'y a donc rien eu de surprenant à ce que Ray reçoive en 1996 le plus éminent honneur civil du Canada, soit le titre de Compagnon de l'Ordre du Canada, joyau qui allait s'ajouter au prix international King Faisal et au prix mondial Albert Einstein dont on l'avait déjà décoré. Trois ans plus tard, un an avant son décès, il allait aussi recevoir le prix Wolf, particulièrement convoité dans le domaine de la chimie.

La seconde « réalisation » que Ray attribuait à l'Université de l'état de l'Ohio dominait toutes les autres à ses yeux. En effet, Ray partageait l'opinion de Jacqueline Kennedy-Onassis, soit que le succès professionnel ne compte pour rien si sa famille est mise à mal. C'est donc à l'Université de l'état de l'Ohio que Ray a fait la connaissance d'une étudiante en chimie, Jeannie, qui allait devenir son épouse. Le fin sens de l'humour de Jeannie

Their five daughters and one son were his pride and joy, and he rejoiced in their impressive accomplishments ranging from the university professoriat to the Canadian national soccer team. How remarkable that in his ACS-sponsored autobiography *How Sweet it Was*, he cited his family as his proudest achievement.

Bert O. Fraser-Reid

s'est sans nul doute avéré le complément idéal à l'ardent caractère de Ray. Ray éprouvait une vive fierté pour ses cinq filles et pour son fils et s'enorgueillissait de leurs admirables réalisations, depuis l'enseignement universitaire jusqu'à la participation à l'équipe nationale canadienne de soccer. De fait, dans son autobiographie intitulée « *How sweet it was* », Ray affirmait que sa famille était de loin sa plus enviable réussite.

Thermolysis of a spiro-fused oxadiazoline: The carbonyl ylide–cyclic carbene–diradical sequence

Nadine Merkley and John Warkentin

Abstract: Thermolysis of spiro-fused oxadiazoline **1** in benzene led to loss of N_2 to form a carbonyl ylide intermediate. Most of the ylide fragmented to acetone and 4-phenyl-1,3-dioxane-2-ylidene, which could be trapped with *tert*-butyl alcohol. In the absence of the trapping agent, the major pathway followed by the carbene was fragmentation to a diradical, 5-phenyl-2-oxa-1-oxo-1,5-pentanediyl. The latter diradical coupled to α-phenyl-γ-butyrolactone and decarboxylated to afford cyclopropylbenzene. Other products from the reaction were those of *apparent* insertion of the carbene into a C–H bond of the benzene solvent and into a C–H bond of acetone. Such reactions appear to be without precedent — alternative, non-carbene mechanisms are proposed.

Key words: dioxacarbene, carbonyl ylide, cyclopropylbenzene, diradical, lactone, oxadiazoline.

Résumé : La thermolyse de l'oxadiazoline à fusion spiro, **1**, dans le benzène, conduit à une perte d'azote et à la formation d'un intermédiaire carbonyl-ylure. L'ylure se fragmente principalement en acétone et en 4-phényl-1,3-dioxane-2-ylidène que l'on peut piéger avec de l'alcool *tert*-butylique. En absence de piège, la voie réactionnelle principale suivie par le carbène en est une de fragmentation en biradical, le 5-phényl-2-oxa-1-oxopentane-1,5-diyle. Ce dernier radical peut se coupler à l'α-phényl-γ-butyrolactone et il se décarboxyle pour former du cyclopropylbenzène. Parmi les autres produits de la réaction, on a observé ceux résultant de l'insertion *apparente* du carbène dans une liaison C–H du benzène agissant comme solvant et dans une liaison C–H de l'acétone. De telles réactions ne semblent pas avoir été observées antérieurement et on propose des mécanismes alternatifs n'impliquant pas de carbène.

Mots clés : dioxacarbène, carbonyl-ylure, cyclopropylbenzène, biradical, lactone, oxadiazoline.

[Traduit par la Rédaction]

Introduction

Thermolysis of oxadiazolines (**1**) is now a well-established method for the generation of alkoxy- or dialkoxycarbenes (1). Fragmentation of alkoxy- or dialkoxycarbenes to radicals was reported many years ago, primarily for gas phase conditions (2), and computations for model systems followed (3). Such fragmentations of dialkoxycarbenes to radical pairs, in solution under relatively mild conditions, have recently been studied experimentally (4) and modeled (without solvation) with smaller analogues (3). Fragmentation of cyclic oxy- or dioxycarbenes to corresponding diradicals appears to be limited to a theoretical study by Borden and Hoo (5).

We now report the synthesis and thermolysis of oxadiazoline **1** in benzene at 110°C. The thermolysis occurs through a number of intermediates that are formed sequentially including a carbonyl ylide (**2**), a carbene (**3**), and diradicals **4** and **5** (Scheme 1).

Methods

Oxadiazoline **1** was synthesized by means of the sequence of reactions shown in Scheme 2. Ring opening of **6** was selective, leading primarily to **7**, which was saponified to **8**. The hydrazinolysis of **9** was also selective, affording primarily **10**, which crystallized from solution during the reaction. Oxidation of **11** with $Pb(OAc)_4$ led to a mixture of **1** and **12**. The intramolecular acid catalyzed substitution, leading from **12** to **1** to complete the cyclization, was modeled after intermolecular analogues (6).

A sample of **1** in benzene-d_6, in a sealed tube, was heated at 110°C for 72 h before an ^{1}H NMR spectrum of the crude mixture of products was acquired. The solvent and volatile products were then evaporated and the residue was chromatographed on SiO_2.

Results and discussion

Evidence for an ylide intermediate (**2**) came from the finding that a minor product was ketone **15** (Scheme 3). The yield of that product was not affected by inclusion of acetone (1.1 M) in the benzene solution of **1**, indicating that it could not have arisen from insertion of **3** into a C–H bond of acetone. Moreover, it could not have arisen from *any* reaction of free acetone.

We suggest that **15** arose from **2** through **13**, which came from a 1,4-sigmatropic H-shift in **2**. Such rearrangements of carbonyl ylides are known (7). Apparently, a fully concerted

fragmentation of the oxadiazoline, to the carbene, N_2, and acetone, as suggested by Smith (8) on the basis of computation, is not general. Rearrangement of **13** to **15** is unprecedented, to the best of our knowledge, but it is reasonable, given that both fragments of ion pair **14** that are proposed for the rearrangement are stabilized. A good model system is the 2-acetoxy acetal **16**, thermolysis of which at 120°C affords the mixed diester **18** in 68% yield (9). The reaction can be understood in terms of reversible formation of an ion pair and nucleophilic substitution at carbon (Scheme 4). Return of the ion pair to **16** presumably scrambles the oxygen atoms of the acetoxy group whereas the enolate fragment in Scheme 3 would bond to carbon to form **15** irreversibly.

The formation of diastereomers **19** from thermolysis of **1** in benzene containing *tert*-butyl alcohol is evidence for carbene **3**, whereas the formation of lactone **20** and cyclopropylbenzene (**21**) in the absence of *tert*-butyl alcohol indicates that **3** fragments to diradical **4** (Scheme 5). There is analogy for the fragmentation of **3** to diradical **4** in the fragmentation of cinnamyloxy(methoxy)carbene to cinnamyl and methoxycarbonyl radicals and of benzyloxy(methoxy)carbene to benzyl and methoxycarbonyl radicals (4).

Cyclopropylbenzene (**21**) is an expected product from **5**, which is an intermediate from decarboxylation of **4**. We were unable to detect (by GC, with authentic samples for reference) either 1- or 3-propenylbenzene, which might also have arisen from **5** by means of intra- or intermolecular H-transfer. Reversal of **4** to **3** is speculative but, because **4** must be born with the geometry shown and because the barrier to radical coupling cannot be large, the reversal step (**4a**→**3**) is a probable, albeit invisible, reaction.

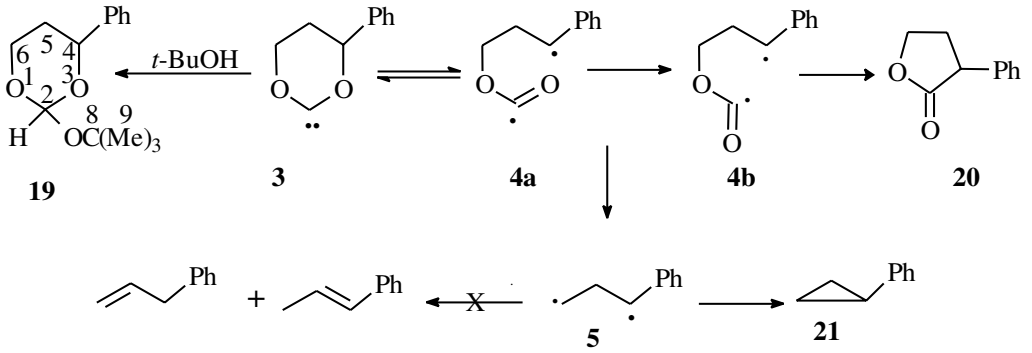
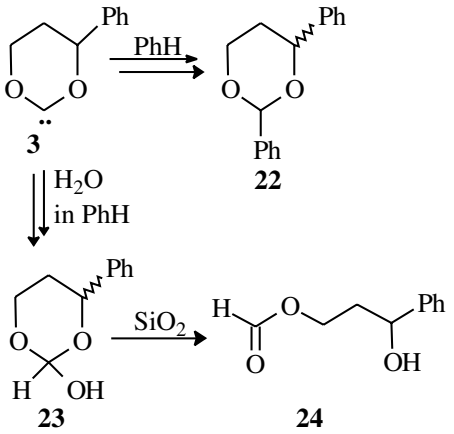
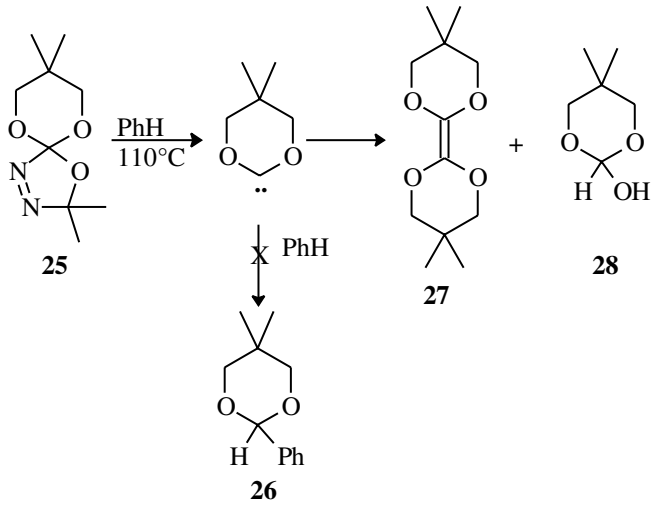
Scheme 5.



Scheme 6.



Scheme 7.



The formation of **20** and **21** in roughly equal amounts means that the rate constants for cyclization and decarboxylation of **4** at 110°C are very similar. The rate constant for decarboxylation was estimated as follows. From the Arrhenius equation of Newcomb (10) we obtained the rate constant k_H at 110°C for the reaction of RCH_2OCO radicals with $HSnBu_3$ ($k_H = 1.77 \times 10^6$ M^{-1} s^{-1}). The ratio k_H/k_{CO2} was available from the product ratio RCH_3:RCH_2OCHO = 38:25 for the reaction of RCH_2OCO radicals with $HSnBu_3$ (average concentration 0.025 M) in toluene at 110°C (11). Thus, the rate constant for decarboxylation came to $k_{CO2} \sim 6.8 \times 10^4$ s^{-1}, and the upper limit of the rate constant for cyclization of **4**, to form **20**, could be set at about 1×10^5 s^{-1}. That estimated rate constant is smaller than might have been expected, given that the process is an intramolecular coupling of a diradical to a five-membered ring. The reason for the small rate constant must lie in the fact that the initial conformation **4a** is the wrong one for coupling to **20**. Rotation into conformation **4b**, over a barrier of about 9 kcal mol^{-1}, is required (12) before lactone **20** can form. Such a barrier could limit the rate of coupling considerably, because the conformations **4a** and **4b** are only two of many conformations of the diradical. Rotations about the other single bonds of **4a** have barriers (13) smaller than 4 kcal mol^{-1} and therefore other conformations of the diradical will be populated before conformation **4b** is reached. Moreover, when **4b** is reached it will have only about a one-in-four chance of being in the singlet state (14). With these features in consideration, the relatively slow coupling of **4** to lactone **20** becomes understandable.

Additional products, not shown in the previous Schemes, were diastereomeric 2,4-diphenyl-1,3-dioxanes (**22**) (12) and diastereomeric hemiorthoformates (4-phenyl-1,3-dioxan-2-ols) (**23**). The latter products are readily accounted for in terms of capture of carbene **3** by adventitious water. Hemiorthoformates (**23**) were thermally stable, but an attempt at isolation by chromatography on silica led to 1-phenyl-1,3-propanediol-3-formate (**24**) (Scheme 6).

We were surprised to find **22** (12%, 6:1 ratio of diastereomers), because dialkoxycarbenes have never been shown to insert into a C–H bond of benzene. In fact, the more nucleophilic imidazolidene-2-ylidene does not appear to react with toluene, although products from apparent insertions into the acidic C–H bonds of acetylene and of a sulphone had been observed (15*a*). 1,3,4-Triphenyl-4,5-dihydro-1*H*-1,2,4-triazole-5-ylidene undergoes many reactions but not insertion into C–H bonds (15*b*). A possible reason for the apparently higher reactivity of **3**, relative to that of acyclic dialkoxycarbenes, was thought to be the enforced 0°, 0° conformation. For allyloxyhydroxycarbene, the 0°, 0° conformation was calculated to be 11.7 kcal mol^{-1} higher in energy than the most stable (180°, 180°) conformation (3*c*). A reduction of the stability of the carbene, as a result of raising the energy of the ground state, would reduce the barrier to insertion if the transition state for insertion were affected less, or not at all, by the conformational restriction. This attractive explanation was abandoned when it was found that

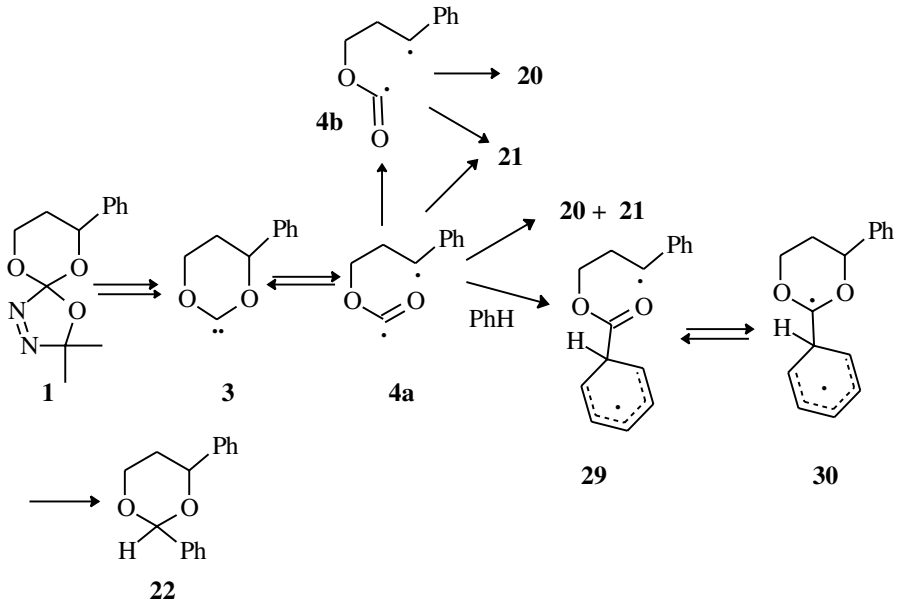
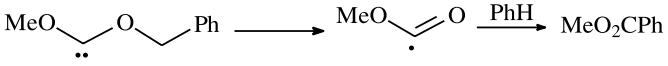
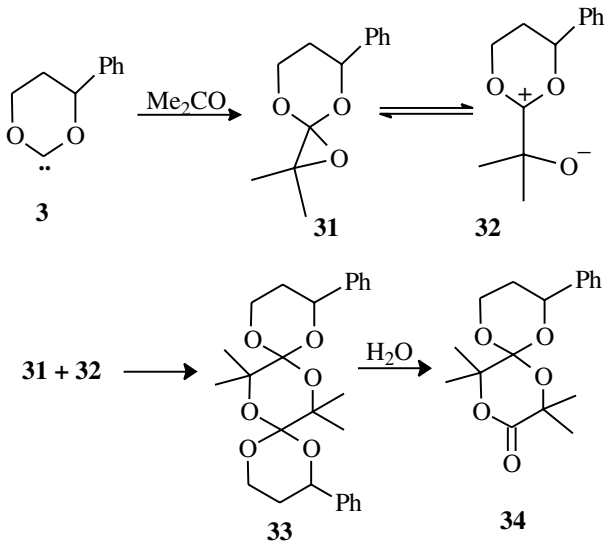


Scheme 9.



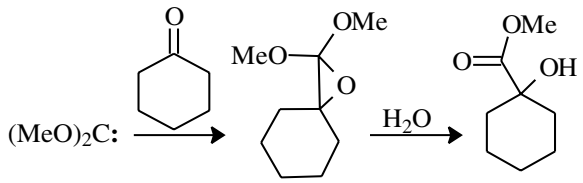
Scheme 10.



thermolysis of **25** in benzene (16) gave the carbene dimer **27** (20%) and 5,5-dimethyl-1,3-dioxan-2-ol (**28**, 21%), the latter being the result of reaction of the carbene with adventitious water (Scheme 7). There were additional products, but **26** could not be detected. With the results in Scheme 7, it is hard to ascribe **22** (Scheme 6) to insertion of **3** into benzene.

The only alternative mechanism that we could conceive of is radical substitution on benzene through the sequence of Scheme 8. Both intra- and intermolecular additions of acyl radicals to double bonds are known (17), as is radical aromatic substitution (18), and relatively slow closure of **4** (above) could permit aromatic substitution, via **29** and **30**, to

Scheme 11.



compete. The carbene from **25** does not fragment to a radical pair and attack on benzene was therefore not observed.

Having estimated the rate constant for decarboxylation and coupling, we were able to estimate the rate constant for attack on benzene by **4a** and (or) **4b** as follows. Knowing that the rates of coupling and decarboxylation are about twice as large as that of attack on benzene (from yields of the products) we could set $k_{CO_2} = 2k_{benzene}$[benzene]. The concentration of benzene is about 10 M and k_{CO_2} has an upper limit of 1×10^5 s^{-1} (above). Thus $k_{benzene}$ would not need to have a value greater than about 5×10^4 M^{-1} s^{-1} for aromatic substitution to compete. Aromatic substitution occurred when methoxycarbonyl radicals, generated in benzene by thermolysis of methyl azodicarboxylate at 130°C, gave methyl benzoate in 13% yield (19). Support for the postulate that aromatic substitution with **4** occurred also came from the discovery of methyl benzoate (3%) in the product mixture formed when benzyloxy(methoxy)carbene was generated in benzene (Scheme 9). We had not recognized that minor product previously (4*b*).

The cyclization step, **29→30**, is a 6-endo process for which there are now many examples, although we were unable to find a very close analogue (20). Subsequent formation of diastereomers **22** by a radical mechanism is not surprising, because kinetic control could apply in the migration step that forms the new C–H bond. There is ample precedent for the postulated H-migration in **30**. Analogous migrations from C-2 of 1,3-diyls are well known (21) although mono-radicals do not rearrange in that way. Synthesis

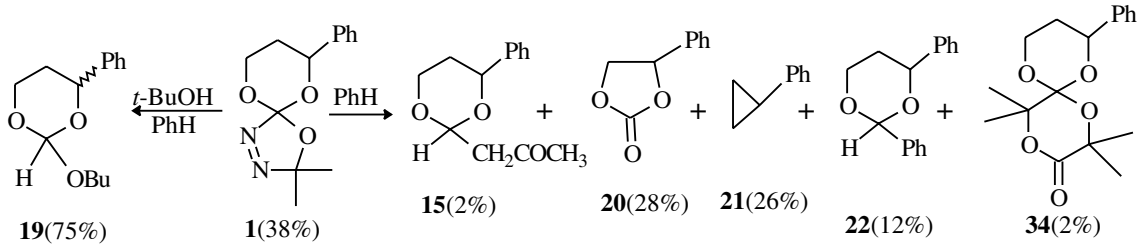
Scheme 12.



of authentic **22** by acid-catalyzed reaction of 1-phenyl-1,3-propanediol with benzaldehyde gave only one diastereomer, which we assume was the more stable *cis*-isomer, formed under thermodynamic control.

Spiro-fused ester **34** was also obtained, in 2% yield. The structure is not in doubt, but the source of it is not known. Addition of acetone (initial concentration 1.1 M) before thermolysis raised the yield of **34** to 28%! We have not developed an attractive explanation for its formation. A partial solution to the problem involves attack of the carbene (**3**) on acetone to afford **32**, which, like **2**, should be equilibrated with the oxirane **31** (Scheme 10). The postulated reaction of the carbene with acetone is in keeping with the observation that dimethoxycarbene reacts with cyclohexanone to afford an oxirane (22). Coupling of two units of **32** is unlikely, because **32** is a reactive intermediate that must be formed very slowly from **1**. However, a reaction between **31** and **32** is plausible, given that **31** is expected to be quite polar. Only two 2,2-dialkoxyoxiranes have been reported to date (22, 23) and they are sensitive materials that hydrolyse readily, as shown for one of them in Scheme 11. A bimolecular reaction between **31** and **32** would be expected to lead to **33**, and partial hydrolysis of **33** after the reaction tube was opened would yield the observed **34** (Scheme 10). Water in the added acetone cannot be a major contributor because the acetone was dried carefully and because the yield of hemiorthoformate (**23**) did not rise as a result of adding acetone to the benzene solvent prior to thermolysis.

In summary, the thermolysis chemistry of oxadiazoline **1** is exceptionally rich. It loses N_2 to form carbonyl ylide **2** that undergoes 1,4-sigmatropic rearrangement to afford **15** via **13**. The major fate of **2** is fragmentation to carbene **3** that can be trapped efficiently in a bimolecular reaction with *tert*-butyl alcohol. If **3** is not intercepted, it undergoes ring opening to diradical **4,** which undergoes three reactions at comparable rates. The diradical attacks benzene through a sequence of unprecedented reactions that lead to substitution product **22**. Diyl **4** also cyclizes to lactone **20** and it decarboxylates to afford phenylcyclopropane via cyclization of diyl **5**. Finally, the formation of **34** suggests that oxirane **31** is an undetected intermediate from the reaction of **3** with acetone. The products, accounted for individually above, are listed in Scheme 12.

Experimental

General

NMR spectra were collected with Bruker AV-300 or AV-500 NMR spectrometers, with samples in $CDCl_3$. The chemical shifts, in ppm, are referenced to the ^1H signal from residual $CHCl_3$ at 7.26 ppm or to the ^{13}C signal at 77.0 ppm. The coupling constants of the first-order multiplets are in Hz. Chemical shift assignments are based on analysis of ^1H–^1H COSY, ^1H–^{13}C HSQC, and ^1H–^{13}C HMBC spectra. Connectivities of the atoms were determined with the aid of both ^1H–^{13}C HMBC and ^1H–^{13}C HSQC 2-D NMR experiments. Assignments of signals to axial (ax) and equatorial (eq) ^1H atoms are based on good analogy (24).

4-Phenyl-1,3-dioxane (6) (25)

Styrene (100 g, 0.96 mol) was dissolved in 200 mL (2.5 mol) of 37% formaldehyde. Concentrated H_2SO_4 (8.0 mL, 0.14 mol) was added, the round-bottom flask was fitted with a reflux condenser, and the mixture was refluxed for 7 h. After cooling, the solution was washed twice with 160 mL of benzene and the combined benzene layers were washed twice with 250 mL of water. Most of the benzene was removed by distillation (80°C) at atmospheric pressure. The pressure was then reduced to 2 mm Hg (1 mm Hg = 133.322 Pa), and 4-phenyl-1,3-dioxane was collected as a clear oil (83.9 g, 0.51 mol, 57%), boiling between 96 and 130°C. ^1H NMR (200 MHz, $CDCl_3$) δ: 1.71 (m, 1H), 2.10 (ddd, ^3J = 4.9 Hz, ^3J = 12.2 Hz, ^3J = 12.4 Hz, ^2J = 12.4 Hz, 1H), 3.87 (ddd, ^3J = 2.5 Hz, ^3J = 11.8 Hz, ^2J = 11.8 Hz, 1H), 4.19 (dd, ^3J = 4.8 Hz, ^2J = 11.4 Hz, 1H), 4.64 (dd, ^3J = 2.5 Hz, ^2J = 11.2 Hz, 1H), 4.89 (d, ^2J = 6.3 Hz, 1H), 5.22 (d, ^2J = 6.3 Hz, 1H), 7.26–7.39 (m, 5H).

1,5-Diacetoxy-5-phenyl-2-oxapentane (7) (26)

Concentrated HCl (1 mL) was added to 4-phenyl-1,3-dioxane (**6**) (80 g, 0.49 mol) dissolved in acetic anhydride (138 mL, 1.46 mol) and the solution was heated to 80°C for 20 h. The solution was cooled, neutralized with 10% NaOH to pH 7 (as determined with universal litmus paper), and then washed twice with ether (50 mL). The ether layer was dried with magnesium sulfate. After vacuum filtration the ether was removed with a rotary evaporator leaving **7** (108.4 g, 0.41 mol, 83%) as an orange oil. ^1H NMR (500 MHz, $CDCl_3$) δ: 1.87 (s, 3H), 1.90–1.96 (m, 1H), 1.99 (s, 3H), 2.05–2.12 (m, 1H), 4.01–4.06 (m, 1H), 4.13–4.18 (m, 1H), 4.65 (m, 1H), 5.01 (d, ^3J = 2.6 Hz, 1H), 5.28 (d, ^3J = 2.6 Hz, 1H), 7.24–7.32 (m, 5H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 20.49, 20.60, 36.70, 60.80, 78.01, 86.81, 126.36, 127.82, 128.35, 140.81, 170.17, 170.58. EI-MS *m/z*: 206 (1), 177 (4), 163 (3), 146 (17), 133 (6), 117 (29), 107 (25), 91 (6), 77 (8), 43 (100). CI-MS (NH_3) *m/z*: 284 ($[M + NH_4]^+$, 28), 177 (100), 146 (17), 117 (95), 75 (4).

1-Phenyl-1,3-propanediol (8) (27)

To a solution of **7** (15.62 g, 0.058 mol) in 10 mL of ether was slowly added a saturated solution of KOH in methanol

© 2002 NRC Canada

(30 mL). The solution was stirred for 3 h before it was neutralized with 5% HCl. The aqueous–methanol layer was extracted twice with 30 mL of ether. Evaporation of most of the ether and subsequent distillation of the residue gave 1-phenyl-1,3-propanediol (4.7 g, 0.031 mol, 54%), boiling at 119°C, 0.5 mm Hg (1 mm Hg = 133.322 Pa) (lit. (28) value bp 117 to 118°C at 0.25 mm Hg). ^{1}H NMR (200 MHz, CD_3OD) δ: 1.68–1.91 (m, 2H), 3.62–3.41 (m, 2H), 4.83 (dd, ^3J = 2.6 Hz, ^3J = 5.4 Hz, 1H), 7.22–7.52 (m, 5H). ^{13}C NMR (50 MHz, CD_3OD) δ: 42.71, 65.50, 75.92, 126.73, 128.20, 129.40, 146.33. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.86 (m, 2H), 3.76 (m, 2H), 4.83 (dd, ^3J = 4.7 Hz, ^3J = 7.9 Hz, 1H), 7.22–7.52 (m, 5H). ^{13}C NMR (50 MHz, $CDCl_3$) δ: 40.34, 60.44, 73.08, 125.55, 127.25, 128.25, 144.19. EI-MS *m/z*: 152 ([M]$^+$, 14), 133 (9), 105 (50), 107 (100), 91 (16), 79 (78), 51 (23), 43 (16). CI-MS (NH_3) *m/z*: 170 ([M + NH_4]$^+$, 21), 152 (100), 135 (56), 117 (86), 91 (16).

4-Phenyl-1,3-dioxan-2-one (9) (29)

1,1′-Carbonyldiimidazole (3.51 g, 0.022 mol) in 100 mL of dichloromethane was added dropwise (ca. 1 h) to a solution of **8** (3.0 g, 0.02 mol) and pyridine (4.4 mL, 0.054 mol) in 180 mL of dichloromethane. After stirring overnight the solution was washed three times with 5% HCl (250 mL), and once each with water (250 mL) and brine (250 mL). The dichloromethane layer was dried with $MgSO_4$ and, after filtration, the solvent was removed with a rotary evaporator to leave **9** as white crystals (2.49 g, 0.014 mol, 70%) after recrystallization from hot ethanol; mp 53–54°C. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 2.20–2.38 (m, 2H), 4.46–4.51 (m, 2H), 5.51 (dd, ^3J = 3.8 Hz, ^3J = 9.6 Hz, 1H), 7.26–7.44 (m, 5H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 29.42, 66.87, 80.15, 125.67, 127.83, 129.0 137.90, 148.77 (C=O). EI-MS *m/z*: 178 ([M]$^+$, 12), 117 (82), 104 (100), 91 (11), 77 (51), 56 (48), 51 (36). CI-MS (NH_3) *m/z*: 196 ([M + NH_4]$^+$, 100), 179 ([M + H]$^+$, 30), 134 (9), 117 (89), 104 (8). HR-MS calcd. for $C_{10}H_{10}O_3$: 178.0629; found: 178.0657.

Synthesis of 10 by hydrazinolysis of 9

Hydrazine monohydrate (7.1 mL, 0.15 mol) was added, with stirring, to 4-phenyl-1,3-dioxan-2-one (**9**) (3.96 g, 0.022 mol) in 70 mL of dichloromethane under nitrogen. In about 2 h a white precipitate had formed. The heterogeneous mixture was filtered leaving the product as white crystals (3.63 g, 0.017 mol, 77%). ^{1}H NMR (200 MHz, CD_3OD) δ: 1.92 (m, 2H), 4.00–4.12 (m, 2H), 4.66 (m, 1H), 7.17–7.26 (m, 5H). ^{13}C NMR (50 MHz, CD_3OD) δ: 39.50, 63.39, 71.73, 126.93, 128.38, 129.38, 145.96, 160.69 (C=O). EI-MS *m/z*: 211 ([M + H]$^+$, 1), 192 (7), 134 (9), 118 (11), 117 (100), 91 (11), 79 (16), 57 (11), 43 (12). CI-MS (NH_3) *m/z*: 211 ([M + H]$^+$, 3), 193 (100), 152 (13), 135 (8), 117 (100), 105 (8), 76 (11), 69 (19), 43 (52).

3-Isopropylidene carbazic acid 3-hydroxy-3-phenylpropyl ester (11)

To a solution of **10** (1.10 g, 5.23 mmol) in dichloromethane (10 mL) was added 1 mL of acetone. After the **10** had dissolved, Na_2SO_4 (0.24 g, 1.4 mmol) was added, and the mixture was stirred for 2 h. The Na_2SO_4 was removed by filtration and the solvent was removed with a rotary evaporator. Compound **11** was obtained as a white solid (0.78 g, 3.1 mmol, 60%); mp 109–110°C. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.82 (s, 3H), 2.03 (s, 3H), 2.07–2.11 (m, 2H), 4.24–4.27 (m, 1H), 4.45–4.53 (m, 1H), 4.81 (dd, ^3J = 4.2 Hz, ^3J = 4.5 Hz, 1H), 7.27–7.38 (m, 5H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 16.24, 25.49, 38.62, 63.30, 71.36, 125.89, 127.69, 128.64, 144.10, 151.37, 154.45. EI-MS *m/z*: 251 ([M + H]$^+$, 1), 144 (15), 117 (100), 91 (17), 72 (38), 56 (31), 43 (38). CI-MS (NH_3) *m/z*: 251 ([M + H]$^+$, 29), 233 (23), 193 (48), 117 (100), 99 (12), 72 (19). HR-MS calcd. for $C_{13}H_{19}N_2O_3$: 251.1395; found: 251.1382.

3,4-Diaza-2,2-dimethyl-7-phenyl-1,6,10-trioxaspiro[5.4]dec-3-ene (1)

To an ice-cooled solution of lead(IV) acetate (4.43 g, 0.010 mol) in dichloromethane (25 mL) under nitrogen was added, dropwise, over a period of 1 h, a solution of **11** (1 g, 0.004 mol) in dichloromethane (5 mL). After addition, stirring was continued for 2 days. The solution was filtered through Celite, washed four times with 25 mL of 5% $NaHCO_3$ solution and dried over Na_2SO_4. ^{1}H NMR spectroscopy of an aliquot indicated that the product was probably a mixture of **1** and **12**. The solvent was evaporated and the residue was dissolved in dichloromethane (20 mL) before trifluoroacetic acid (0.01 mL) was added. After 90 min the cyclization of **12** to **1**, monitored with TLC, was complete. The solution was washed with aqueous NaOH and dried over $MgSO_4$. Evaporation of the solvent and radial chromatography of the residue (Chromatotron, 10% EtOAc – hexanes) gave **1**, a white solid, as a mixture of two diastereomers in 1:1 ratio (0.38 g, 1.5 mmol, 38%). ^{1}H NMR (composite spectrum, 300 MHz, $CDCl_3$) δ: 1.48 (s, 3H), 1.52 (s, 3H), 1.53 (s, 6H), 1.90–2.03 (m, 2H), 2.18–2.39 (m, 2H), 4.23–4.31 (m, 2H), 4.35 (ddd, ^3J = 3.5 Hz, ^3J = 11.3 Hz, ^2J = 11.3 Hz, 1H) 4.81 (ddd, ^3J = 2.8 Hz, ^3J = 11.8 Hz, ^2J = 11.9 Hz, 1H), 5.24 (dd, ^3J = 3.1 Hz, ^3J = 11.6 Hz, 1H), 5.73 (dd, ^3J = 2.7 Hz, ^3J = 11.6 Hz, 1H), 7.23–7.40 (m, 10H). ^{13}C NMR (composite spectrum, 75 MHz, $CDCl_3$) δ: 24.49, 24.64, 31.74, 31.92, 63.02, 65.16, 74.62, 77.09, 119.81, 120.44, 125.92, 128.18, 128.54, 140.21 (analogous, but not spirocyclic, oxadiazolines typically have a C-5 signal at δ 118.7–119.4 and a C-2 signal at δ 136.7–137.9) (30). EI-MS *m/z*: 162 ([M–N_2–Me_2CO]$^+$, 1), 116 (72), 117 (100), 104 (12), 91 (19), 65 (3), 43 (19).

Thermolysis of 1 in the presence of *tert*-butyl alcohol

A solution of oxadiazoline **1** (27.4 mg, 0.11 mmol) and *tert*-butyl alcohol (82.2 mg, 1.1 mmol) in 2 mL of benzene was flame sealed into an NMR tube. The tube was heated for 72 h at 110°C with a constant-temperature oil bath. Two diastereomers of 2-*tert*-butoxy-4-phenyl-1,3-dioxane (**19**) (75% combined yield) were obtained in a ratio of 3:1, as determined by integration of clean singlets at δ 5.64 and 6.03. The crude sample was not purified but the signals corresponding to the major diastereomer could be assigned. Some integrations are approximate, because of partial overlap with signals from the minor diastereomer.

^{1}H NMR (major diastereomer, 500 MHz, C_6D_6) δ: 1.59 (s, 9H, CH_3), 1.48–1.73 (dm, 1H, H5-eq), 1.96 (ddd, ^3J = 5.0 Hz, ^3J = 12.6 Hz, ^3J = 12.4 Hz, ^2J = 12.4 Hz, 1H, H5-ax), 3.36–3.50 (m, 1H, H6-ax), 3.57 (dd, ^3J = 1.4 Hz, ^3J = 4.0 Hz, ^2J = 11.0 Hz, 1H, H6-eq), 5.32 (dd, ^3J =

© 2002 NRC Canada

2.4 Hz, ^3J = 11.7 Hz, 1H, H4-ax), 6.03 (s, 1H), 7.03–7.37 (m, 5H). ^{13}C NMR (125 MHz, C_6D_6) δ: 28.74 (C9), 33.77 (C5), 58.32 (C6), 69.44 (C4), 77.13 (C8), 105.21 (C2), 125.91, 128.08, 128.32, 142.90. EI-MS *m/z*: 152 (6), 134 (31), 107 (100), 79 (84), 59 (14), 51 (30). CI-MS (NH_3) *m/z*: 196 (8), 179 (8), 152 (24), 134 (17), 117 (100), 105 (19).

Thermolysis of 1 in benzene

Oxadiazoline **1** (0.1515 g, 0.61 mmol), and the internal standard 1,4-dimethoxybenzene (0.0205 g, 0.148 mmol) were dissolved in 6 mL of benzene and sealed into a thermolysis tube after three cycles of freeze-pump-thaw degassing. The tube was then kept in an oil bath at 110°C for 72 h. The crude mixture of products was injected into the GC–FID to determine the product yields. The peak areas were corrected for the detector response and products were identified by coinjection of authentic compounds. The remainder of the mixture was freed from solvent and the residue was separated by radial chromatography (Chromatotron, 100% hexanes) to afford the following products.

*Cyclopropylbenzene (**21**) (31)*

26%. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 0.85 (m, 2H), 1.11 (m, 2H), 2.02 (m, 1H), 7.19–7.43 (m, 5H). EI-MS *m/z*: 118 ($[M]^+$, 54), 117 (100), 115 (48), 91 (74), 77 (22).

*4-Phenyl-1,3-dioxan-2-one (**9**) (29)*

5%.

*α-Phenyl-γ-butyrolactone (**20**) (32, 33)*

28%. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 2.40 (dddd, ^3J = 8.2, 9.2, 10.1 Hz, ^2J = 12.6 Hz, 1H), 2.71 (dddd, ^3J = 3.4, 6.8, 9.1 Hz, ^2J = 12.6 Hz, 1H), 3.80 (dd, ^3J = 9.7 Hz, ^3J = 9.9 Hz, 1H), 4.34 (ddd, ^3J = 6.7, 9.1 Hz, ^2J = 9.1 Hz, 1H), 4.46 (ddd, ^3J = 3.4, 8.2 Hz, ^2J = 9.1 Hz, 1H), 7.27–7.40 (m, 5H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 31.62, 45.54, 66.56, 127.71, 127.98, 129.00, 136.79, 177.43. EI-MS *m/z*: 162 ($[M]^+$, 22), 117 (100), 103 (16), 91 (48), 77 (24), 63 (14), 51 (15). HR-MS calcd. for $C_{10}H_{10}O_2$: 162.0681; found: 162.0675.

*4-Phenyl-1,3-dioxan-2-ol (**23**)*

19% (not isolable, structure assignment tentative, diastereomer ratio not known). EI-MS *m/z*: 163 ($[M - OH]^+$, 1), 133 (2), 117 (100), 105 (30), 91 (20), 77 (39).

*1-Phenyl-1,3-propanediol-3-formate (**24**) (34)*

^{1}H NMR (300 MHz, $CDCl_3$) δ: 2.02–2.19 (m, 2H), 4.23 (ddd, ^3J = 5.9 Hz, ^3J = 5.7 Hz, ^3J = 5.7 Hz, ^2J = 11.3 Hz, 1H), 4.43 (ddd, ^3J = 5.9 Hz, ^3J = 5.7 Hz, ^3J = 5.7 Hz, ^2J = 11.3 Hz, 1H), 4.83 (dd, ^3J = 5 Hz, ^3J = 7.6 Hz, 1H), 7.35–7.36 (m, 5H), 8.08 (s, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 37.93, 61.27, 71.31, 125.85, 128.04, 128.80, 143.90, 161.22. EI-MS *m/z*: 180 ($[M]^+$, 3), 163 (4), 152 (7), 134 (52), 107 (96), 91 (20), 79 (100), 51 (21), 43 (17). HR-MS calcd. for $C_{10}H_{12}O_3$: 180.0786; found: 180.0778.

*1-(4-Phenyl-1,3-dioxan-2-yl)-2-propanone (**15**)*

2%. Apparently only one diastereomer was isolated. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.70 (ddd, ^3J = 2.5 Hz, ^3J = 3.5 Hz, ^2J = –13.4 Hz, 1H, H5-eq), 1.99 (dddd, ^3J = 4.6 Hz, ^2J = –13.3 Hz, ^3J = 11.9 Hz, ^3J = 11.9 Hz, 1H, H5-ax), 2.22 (s, 3H), 2.84 (d, ^3J = 5.1 Hz, 2H), 3.94 (ddd, ^3J = 2.6 Hz, ^3J = 11.7 Hz, ^2J = –11.9 Hz, 1H, H6-ax), 4.20 (ddd, ^3J = 1.3 Hz, ^3J = 4.9 Hz, ^2J = –11.5 Hz, 1H, H6-eq), 4.72 (dd, ^3J = 2.5 Hz, ^3J = 11.4 Hz, 1H, H4-ax), 5.17 (t, ^3J = 5.1 Hz, 1H, H2), 7.28–7.4 (m, 5H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 31.51, 33.17, 49.33, 67.02, 78.93, 99.06, 125.95, 127.98, 128.61, 141.49, 205.21. CI-MS (NH_3) *m/z*: 238 ($[M + NH_4]^+$, 25), 221 ($[M + H]^+$, 58), 187 (31), 152 (30), 135 (44), 117 (100), 91 (14), 78 (10), 43 (14).

*8,8,11,11-Tetramethyl-2-phenyl-1,5,7,10-tetraoxa-9-oxospiro[5.5]undecane (**34**)*

2%. Connectivity determined by means of ROESY 2-D NMR spectroscopy. IR (NaBr, neat) (cm^{-1}): 1739. ^{1}H NMR (500 MHz, C_6D_6) δ: 1.15 (dddd, ^3J = 1.5, 2.6, 2.6 Hz, ^2J = 13.4 Hz, 1H, H3-eq), 1.48 (s, 3H, H11′), 1.50 (s, 3H, H11″), 1.53 (s, 3H, H8′), 1.56 (s, 3H, H8″), 1.62 (dddd, ^3J = 4.9, 11.7, 12.9 Hz, ^2J = 13.1 Hz, 1H, H3-ax), 3.41 (ddd, ^3J = 1.6, 4.9 Hz, ^2J = 11.1 Hz, 1H, H4-eq), 3.97 (ddd, ^3J = 2.5, 12.8 Hz, ^2J = 11.1 Hz, 1H, H4-ax), 5.00 (dd, ^3J = 2.7, 11.7 Hz, 1H, H10-ax), 7.08–7.12 (m, 5H). ^{13}C NMR (125 MHz, C_6D_6) δ: 24.07 (C11′), 24.20 (C11′), 28.58 (C8′), 28.72 (C8′), 32.47 (C3), 60.34 (C4), 71.65 (C2), 76.74 (C11), 84.16 (C8), 109.07 (C6), 128.85, 128.39, 128.15, 141.42, 171.06 (C=O). EI-MS *m/z*: 204 (4), 179 (4), 117 (100), 104 (18), 70 (70), 43 (37). CI-MS (NH_3) *m/z*: 307 ($[M + H]^+$, 18), 134 (18), 117 (100), 70 (32). The yield of this product rose to 28% in an experiment in which the starting solvent was 1.1 M in acetone.

*2,4-Diphenyl-1,3-dioxane (**22**)*

12%. Diastereomers in 6:1 ratio (by NMR, after chromatography, which failed to separate them and may have altered the initial diastereomer ratio). ^{1}H NMR (major diastereomer, 500 MHz, $CDCl_3$) δ: 1.81 (ddd, ^3J = 2.5, 4.0 Hz, ^2J = 13.4 Hz, 1H, H5-eq), 2.14 (dddd, ^3J = 4.9, 12.2, 11.9 Hz, ^2J = 13.4 Hz, 1H, H5-ax), 4.14 (ddd, ^3J = 2.5, 11.9 Hz, ^2J = 11.9 Hz, 1H, H6-ax), 4.37 (ddd, ^3J = 1.3, 4.9 Hz, ^2J = 11.5 Hz, 1H, H6-eq), 4.92 (dd, ^3J = 2.6, 11.4 Hz, H4-ax), 5.73 (s, 1H, H2-ax), 7.28–7.58 (m, 10H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 33.63 (C5), 67.48 (C6), 79.29 (C4), 101.79 (C2), 126.03, 126.38, 127.89, 128.38, 128.59, 128.95, 131.04, 138.88, 141.86. EI-MS *m/z*: 239 ($[M - H]^+$, 1), 134 (7), 117 (61), 105 (100), 78 (35), 77 (82), 51 (32). CI-MS (NH_3) *m/z*: 241 ($[M + H]^+$, 24), 152 (16), 134 (40), 117 (100), 91 (24). The minor diastereomer was inferred from the presence of a singlet at 5.23 ppm, upfield from that of the major diastereomer by 0.55 ppm. In the two diastereomers formed from trapping of the carbene with *tert*-butyl alcohol the minor diastereomer gave rise to a singlet 0.39 ppm upfield from the signal for the orthoformyl H of the major diastereomer.

Thermolysis of 1 in the presence of added acetone

A solution of oxadiazoline **1** (0.1684 g, 0.679 mmol) and acetone (0.5 mL) in benzene (5.5 mL) was sealed into a thermolysis tube after three cycles of freeze–pump–thaw degassing. The tube was kept in an oil bath at 110°C for 72 h. After thermolysis the internal standard, 1,4-dimethoxybenzene (6.8 mg, 0.1218 mmol), was added and the crude solution was injected into the GC–FID for determination of product yields. Detector response factors were applied to obtain the corrected yields below.

© 2002 NRC Canada

Cyclopropylbenzene (**21**) (4%), α-phenyl-γ-butyrolactone (**20**) (5%), 2-hydroxy-4-phenyl-1,3-dioxane (**23**) (21%), 1-(4-phenyl-1,3-dioxan-2-yl)-2-propanone (**15**) (2%), 8,8,11,11-tetramethyl-2-phenyl-1,5,7,10-tetraoxa-9-oxospiro[5.5]undecane (**34**) (28%), 2,4-diphenyl-1,3-dioxane (diastereomers) (**22**) (13%), 4-phenyl-1,3-dioxan-2-one (**9**) (7%).

Synthesis of *cis*-2,4-diphenyl-1,3-dioxane

The procedure was modeled after one (35) for making an analogue. To 1-phenyl-1,3-propanediol (5 g, 0.032 mol) and benzaldehyde (3.4 g, 0.036 mol) in dichloromethane (50 mL) was added *p*-toluenesulfonic acid (0.5 g, 2.9 mmol). The solution was stirred overnight before it was washed with 10 mL of $NaHCO_3$ and dried over Na_2SO_4. The residue obtained upon removal of the solvent was purified by means of column chromatography (10% EtOAc – hexanes) yielding **22** (5.65 g, 73%). The *cis* configuration was assigned on the basis of the known preference for the C-2 phenyl group to be in the equatorial position (36). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.83 (m, 1H, H5-eq), 2.18 (dddd, ^3J = 4.9, 12.2, 12.2 Hz, ^2J = 12.3 Hz, 1H, H5-ax), 4.16 (ddd, ^3J = 2.3, 11.8 Hz, ^2J = 11.8 Hz, 1H, H6-ax), 4.40 (ddd, ^3J = 1.0, 4.5 Hz, ^2J = 11.4 Hz, 1H, H6-eq), 4.98 (dd, ^3J = 2.4, 11.2 Hz, 1H, H4-ax), 5.73 (s, 1H, H2), 7.33–7.66 (m, 10H).

3,4-Diaza-2,2,8,8-tetramethyl-1,6,10-trioxaspiro[5.4]dec-3-ene (25)

The synthesis and properties of **25** have been described (16).

5,5-Dimethyl-1,3-dioxan-2-ol (28)

Unstable material, isolated in 21% yield by preparative GC (OV-17, 6′ × 1/4″, He at 40 mL min^{-1}) and tentatively identified as **28**. ^{1}H NMR (200 MHz, C_6D_6) δ: 1.02 (s, 3H), 1.76 (s, 3H), 3.13 (d, ^2J = 10.6 Hz, 2H), 3.81 (d, ^2J = 10.6 Hz, 2H), 5.97 (s, 1H).

Carbene dimer (27)

Yield 20%, isolated by preparative GC (conditions above). ^{1}H NMR (300 MHz, C_6D_6) δ: 0.067 (s, 12H), 3.43 (s, 8H). ^{13}C NMR (75 MHz, C_6D_6) δ: 21.86, 30.95, 78.36, 136.69. EI-MS *m/z*: 229 ([M + H]$^+$, 4), 191 (8), 161 (13), 132 (32), 115 (92), 69 (100), 56 (78). HR-MS calcd. for $C_{12}H_{21}O_4$ [M + H]$^+$: 229.1439; found: 229.1453.

Synthesis, structure, and electrochemistry of cobalt(III) complexes with bis(benzoylacetone)-ethylenediimine Schiff base

Mehdi Amirnasr, Rasoul Vafazadeh, and Amir H. Mahmoudkhani

Abstract: A series of complexes of the type *trans*-$[Co((BA)_2en)(amine)_2]ClO_4$ — where $(BA)_2en$ is the bis(benzoylacetone)ethylenediimine dianion and the amines are morpholine (mrpln) **1**, aniline (aniln) **2**, benzylamine (bzlan) **3**, piperidine (pprdn) **4**, *p*-toluidine (*p*-toldn) **5**, and pyrrolidine (prldn) **6** — has been synthesized and characterized by elemental analysis, UV–vis, ^1H NMR, and ^{13}C NMR spectroscopy. The crystal and molecular structure of *trans*-$[Co((BA)_2en)(mrpln)_2]ClO_4$ (**1**) has been determined by X-ray crystallography. The electrochemical reduction of these complexes at a glassy-carbon electrode, in the potential range of 0.5 to –2.0 V (vs. Ag/AgCl), in acetonitrile solution, indicates that the first reduction potential of Co(III/II) is irreversible, which is accompanied by the dissociation of the axial amine–cobalt bonds. This potential is dependent on the pK_a of the axial amines. The second reduction potential of Co(II/I) shows reversible behavior and is also independent of the axial amine pK_a. These results indicate the loss of the axial amines in the first redox process and the involvement of a four-coordinate species in the second redox step.

Key words: Schiff base, cobalt(III), axial amine, electrochemical properties, crystal structure.

Résumé : On a synthétisé une série de complexes du type *trans*-$[Co(BA)_2en)(amine)_2]ClO_4$ dans lesquels $(BA)_2en$ = dianion bis(benzoylacétone)éthylènediimine et amine = morpholine (mrpln) **1**; aniline (aniln) **2**; benzylamine (bzlan) **3**; pipéridine (pprdn) **4**; *p*-toluidine (*p*-toldn) **5** et pyrrolidine (prldn) **6** et on les a caractérisés par analyse élémentaire et spectroscopies UV–vis et RMN du ^1H et du ^{13}C. On a étudié les structures cristallines et moléculaires du *trans*-$[Co(BA)_2en)(mrpln)_2]ClO_4$ (**1**) par diffraction des rayons X. La réduction électrochimique de ces complexes au niveau d'une électrode de carbone vitreux, à un potentiel allant de 0,5 à –2,0 V (vs. Ag/AgCl), en solution dans l'acétonitrile, indique que le premier potentiel de réduction de Co(III/II) est irréversible et qu'il est accompagné d'une dissociation des liaisons amine–cobalt axiales. Ce potentiel varie avec le pK_a des amines axiales. Le deuxième potentiel de réduction de Co(II/I) met en évidence un comportement réversible et il est aussi indépendant du pK_a de l'amine axiale. Ces résultats indiquent que la perte des amines axiales se produit dans le premier processus redox et que les quatre espèces coordinées sont impliquées dans la deuxième étape.

Mots clés : base de Schiff, cobalt(III), amine axiale, propriétés électrochimiques, structure cristalline.

[Traduit par la Rédaction]

Introduction

The chemistry of transition-metal complexes with Schiff base ligands continues to be the subject of growing interest (1–3). Many of these compounds are relevant to the biochemistry of vitamins, enzymes, and coenzymes (4–6). The remarkable chemical similarity between cobalamines and cobaloximes is now well recognized to be a consequence of the fortuitous near-identicality of the effective coordinating strengths of these chemically unrelated ligand systems. The conjugated tetradentate ligands are chelating agents that coordinate to the four equatorial positions of square pyramidal or octahedral structures of metal centers. The resulting compounds are known to serve as models for the natural Corrine ring complexes, and thus for vitamin B_{12} and its co-enzyme (6–11). The properties of the model complexes are strongly dependent on the nature of the axial ligands. The mutual interdependence of the properties of the two axial ligands can be assessed by structural, spectroscopic, thermodynamic, and kinetic methods (7, 8, 12–17). Limited comparisons of properties determined by many of these methods suggest that cobalamines and various models have the same type of dependence on the *trans*-ligands.

In this paper we report the synthesis of *trans*-$[Co((BA)_2en)(amine)_2]ClO_4$ complexes with primary and secondary amines as axial ligands, where the amines are morpholine (mrpln) **1**, aniline (aniln) **2**, benzylamine (bzlan) **3**, piperidine (pprdn) **4,** *p*-toluidine (*p*-toldn) **5**, and

pyrrolidine (prldn) **6** (Fig. 1). These cobalt(III) Schiff base complexes are among the few reported cases containing neutral *N*-donor axial ligands (18, 19).

Experimental

Caution! Transition-metal complex perchlorate salts are known to be hazardous and must be treated with care, especially in the presence of organic solvents.

Materials

Bis(benzoylacetone)ethylendiimine $H_2(BA)_2$en was prepared as described in the literature (20). $Co(OH)_2$ was freshly prepared prior to each synthesis by adding an aqueous solution of NaOH to a solution of $Co(NO_3)_2 \cdot 6H_2O$ in water (with a molar ratio of 2:1), filtering the precipitate immediately, and washing it with acetone. Bis(benzoylacetone)ethylendiiminocobalt(II) ([Co((BA)$_2$en)]) was synthesized by the method of McCarty et al. (20).

Piperidine (Aldrich), benzylamine, morpholine, pyrrolidine, and aniline (Merck) were distilled under reduced pressure. All other chemicals were commercial reagent grade and used as received from Aldrich and Merck.

Physical measurements

Electronic absorption spectra were measured by a Shimadzu UV-240 spectrophotometer. ^{1}H and ^{13}C NMR spectra were obtained on a Bruker Avance DRX500 (500 MHz) NMR spectrometer in CD_3OD solvent. Proton chemical shifts are reported in parts per million (ppm) relative to an internal Me_4Si standard. All measurements were made at 20°C. Elemental analyses were performed using a Heraeus CHN-O-RAPID elemental analyzer. The IR spectra were recorded on a Shimadzu 435 spectrophotometer using the KBr pellet technique.

Cyclic voltammetry studies were carried out by using an EG&G Princeton Applied Research Model 384B. An Ag/AgCl electrode containing 3 M NaCl served as the reference electrode, a Pt wire as the counter electrode, and a glassy-carbon electrode as the working electrode. Cyclic voltammetric measurements were performed in acetonitrile with 50 mM tetra-*n*-butylammonium percholorate (TBAP) as the supporting electrolyte, under nitrogen atmosphere.

Synthesis of *trans*-[diaminebis(benzoylacetone)ethylenediiminatocobalt(III)] perchlorate complexes (*trans*-[Co((BA)$_2$en)(amine)$_2$]ClO$_4$) (1–6)

The appropriate amine (30 mmol) was added to a stirring suspension of 10 mmol (4.05 g) of the [Co((BA)$_2$en)] complex in 150 mL acetone and air was bubbled slowly through the reaction mixture for 4 h. To the resulting clear brown solution was added 15 mmol (1.84 g) of solid $NaClO_4$ and the solution was stirred for an additional period of 1 h. The resulting solution was left overnight to give a brown precipitate. The solid product was filtered off and recrystallized from an acetone–ethanol (2:1 v/v) mixture. The brown crystals were isolated by filtration, washed with cold ethanol and then dried in vacuum.

X-ray crystallography

Brown crystals of *trans*-[Co((BA)$_2$en)(mrpln)$_2$]ClO$_4$ suitable for X-ray crystallography were obtained by slow evaporation of its solution in acetone–ethanol (1:1 v/v) at room temperature. Data were collected on a Siemens SMART CCD diffractometer using graphite-monochromated Mo Kα (λ = 0.71073 Å) radiation. A full sphere of the reciprocal lattice was scanned by 0.3° steps in ω with a crystal-to-detector distance of 3.97 cm. The preliminary orientation matrix was obtained from the first frames using SMART (21). The frames were integrated using the preliminary orientation matrix, which was updated every 100 frames. Final cell parameters were obtained by refinement on the positions of reflections with $I > 10\sigma(I)$, after integration of all the frames using SAINT (21). The data were empirically corrected for absorption and other effects using SADABS (22). The structure was solved by direct methods and refined by the full-matrix least-squares method on F^2 data using SHELXTL (23). All non-H atoms were refined anisotropically, except oxygen atoms of the perchlorate ion, which were found to be disordered over two positions with site occupancy factors of 0.71 and 0.29. They were refined isotropically with the restrain bond distances of 1.42 Å. The H atoms were constrained to idealized geometries and refined isotropically.

[a] $R_1 = \Sigma||F_o| - |F_c|| / \Sigma|F_o|$. $wR_2 = \{\Sigma[w(F_o^2 - F_c^2)^2] / \Sigma[w(F_o^2)^2]\}^{1/2}$.
[b] $w = 1/[\sigma^2(F_o^2) + (xP)^2 + yP]$. $P = (F_o^2 + 2F_c^2)/3$.

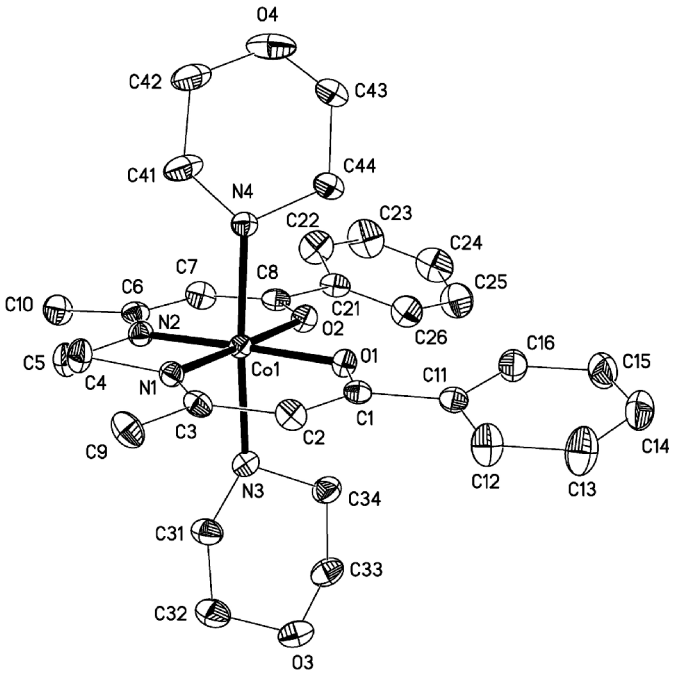
The crystallographic and refinement data are summarized in Table 1.[2]

Results and discussion

Synthesis

H_2(BA)en was prepared by the condensation of benzoylacetone with ethylenediamine as reported in the literature (20). This compound was further characterized by IR, UV–vis, ^{1}H, and ^{13}C NMR spectroscopy. Six Co(III) complexes (**1**–**6**) were prepared by air oxidation of [Co^{II}((BA)$_2$en)] in the presence of the appropriate amine (Fig. 1). A slow stream of air was passed through a stirring suspension of [Co^{II}((BA)$_2$en)] in acetone, to which was added excess amine. The air oxidation was continued for a period of 4 h, during which time the solution changed from red to brown. Dark brown crystals of these complexes were obtained in good yield (55–78%). All complexes reported here are diamagnetic, as expected for a low-spin d^6-configuration.

Fig. 2. ORTEP diagram of the cation of complex **1** showing the atom-labeling scheme. Displacement ellipsoids are shown at the 20% probability level (H atoms and the ClO_4 group are not shown for clarity).



Structure of the cobalt(III) complex with morpholine

The molecular structure of the *trans*-[Co((BA)$_2$en)(mrpln)$_2$]ClO_4 complex is shown in Fig. 2. Selected bond lengths and angles are listed in Table 2. The octahedral coordination of Co(III) is slightly distorted, the (BA)$_2$en Schiff base ligand (ONNO ligand) coordinates the cobalt ion in four equatorial positions, and the two amine molecules occupy the two axial positions of the octahedral complex. The Co—O and Co—N bond distances of the (BA)$_2$en ligand in the equatorial plane are symmetric within the limits of experimental error. The Co—O(1) and Co—O(2) bond lengths are 1.893(2) and 1.900(2) Å, respectively, and compare well with the Co—O distances found in *trans*-[Co(acacen)(piperidine)$_2$]NCS (1.894(2), 1.900(2) Å) and *trans*-[Co(3-Cl-acacen)(NH$_3$)$_2$]BPh_4 (1.881(4) Å) (18, 19). The Co—N(1) and Co—N(2) bond lengths are 1.899(3) and 1.905(3) Å, respectively, which is in good agreement with the Co—N distances found in *trans*-[Co(acacen)(piperidine)$_2$]NCS (1.899(2), 1.905(2) Å) and *trans*-[Co(3-Cl-acacen)(NH$_3$)$_2$]BPh_4 (1.8918(9) Å) (18, 19).

The average cobalt—nitrogen bonds in the axial positions (Co—N$_{av}$ = 2.04 Å) compare well with the Co—N distances found in cobalt–amine (e.g., [Co(NH$_3$)$_6$]Cl_3, Co—N = 1.963 Å) (24) and cobalt–amine complexes of different derivatives of acacen (2.042 Å (18) and 1.960 Å (19)). The Co—N$_{eq}$ are shorter than Co—N$_{ax}$ by approximately 0.133 to 0.149 Å due to the presence of π-backbonding in Co—N$_{imine}$ of the

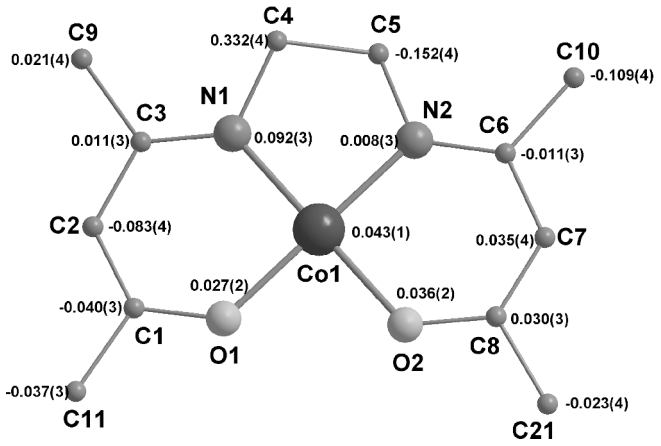
ϕ_7 (O2-C8-C21-C26)	18.7(4)

Fig. 3. Deviation (Å) of atoms from the basal skeleton for complex **1**.



equatorial ligand. Those differences are 0.135 to 0.145 Å and 0.059 to 0.068 Å in *trans*-[Co(acacen)(piperidine)$_2$]NCS and *trans*-[Co(3-Cl-(acacen)(NH$_3$)$_2$]BPh$_4$, respectively.

All angles around the Co center deviate significantly from 90° indicating a rectangular distortion. The ligand-cobalt-ligand bond angles in the equatorial plane consist of two that are larger than 90° (O(1)-Co-N(1) (93.89(10)°), O(2)-Co-N(2) (94.26(11)°)) and two smaller angles (O(1)-Co-O(2) (86.10(9)°)) and N(1)-Co-N(2) (85.87(11)°)) (see Table 2) that are close to the corresponding values in *trans*-[Co(acacen)(piperidine)$_2$]NCS (94.1(1)°, 95.2(1)°, 84.6(1)°, 86.2(1)°) (18) and *trans*-[Co(3-Cl-acacen)(NH$_3$)$_2$]BPh$_4$ (94.06(14)°, 94.06(14)°, 84.3(3)°, 87.58(5)°) (19).

The diagonal angles of 178.75(11)° and 178.40(11)° are indicative of a slight tetrahedral distortion of the basal coordination of Co(III), which in the case of perfect planarity have values of 180°. This distortion is also reflected by the torsion angles of ~3° in the six-membered rings of basal coordination (see Table 3) and the angle between the best least-squares planes (Co1-O1-C1-C2-C3-N1) and (Co1-O2-C8-C7-C6-N2) being 3.36(10)°. Deviations of atoms from the least-squares plane (χ^2 = 3379) defined by the main basal skeleton are illustrated in Fig. 3.

The (N-)H atoms of the morpholine axial ligands are involved in hydrogen bonds with the oxygen atoms of the perchlorate anions, forming chains along the *c* axis. This behavior has also been seen in the IR spectrum of the compound (vide infra). The geometry of these hydrogen bonds is given in Table 4.

Spectral studies

The octahedral geometry of complex **1** is evident from the X-ray structural analysis (Fig. 2). An octahedral *trans*-structure for the other complexes (**2**–**6**) can be inferred based on the similarity of the ^{1}H and ^{13}C NMR spectra of these complexes with those of complex **1**. The signal appearing at ~6 ppm in the ^{1}H NMR spectrum **1** is assigned to the two =C*H* groups (Table 5) and indicates that the equatorial coordination sites are occupied by the (BA)$_2$en ligand, leading to the magnetically equivalent =C*H* protons (25). The methyl protons adjacent to the nitrogen (C*H*$_3$(N)) appear as a singlet at 2.4 to 2.6 ppm and the four ethylenediamine protons give a multiplet at ~3.31 ppm. The aromatic protons of the phenyl rings in the Schiff base ligand appear as a complex multiplet at ~7.4 to 8.2 ppm. The axially coordinated amine (N*H*) proton(s) appear at ~3.29 to 4.13 ppm (depending on the type of amine). The chemical shifts of the aromatic and aliphatic protons of the axial amines are listed in Table 5.

In the ^{13}C NMR spectrum a signal appears at 22.37 to 22.66 ppm due to the methyl carbon of the equatorial ligand NC(*C*H$_3$). The two signals at ~170 and ~175 ppm are assigned to (O*C*)Ph and (N*C*)CH$_3$, respectively (25). The ethylene carbons appear at 52.70 to 53.61 ppm and the signal at 93.67 to 94.30 ppm corresponds to -H*C*= groups in different complexes. The ^{13}C NMR signals of the axial amines are shown in Table 6. The signals at 45.64 and 20.04 ppm correspond to Ph-*C*H$_2$-NH$_2$ and H$_2$N-C$_6$H$_4$-*C*H$_3$, respectively, in the benzylamine and *p*-toluidine complexes. Other signals, corresponding to the aromatic carbons of benzylamine, *p*-toluidine, and aniline as axial ligands, appear in a narrow range close to the aromatic carbons of the Schiff base (Table 6).

The IR spectrum of the ligand exhibits a strong band at 1540 cm^{-1} due to ν C=N (26, 27). This band in the IR spectra of the complexes is shifted to a lower frequency by ~30 cm^{-1} and appears at 1508 cm^{-1}. The fairly broad band of medium intensity appearing at 1278 cm^{-1}, which corresponds

to the intramolecular hydrogen bonding in the free ligand (27), is absent in the complexes. The bands corresponding to the axial amine N—H stretching vibrations appear in the range of 3200–3300 cm^{-1}. These bands, as expected, are shifted to lower frequencies by ~150 cm^{-1} relative to the uncoordinated amines, and are broadened due to the formation of hydrogen bonds with the oxygen atoms of the perchlorate anions.

The absorption spectrum of the H$_2$(BA)$_2$en ligand exhibits two bands in the regions of 350 nm ($\varepsilon \approx 3400$ M^{-1} cm^{-1}) and 243 nm ($\varepsilon \approx 19000$ M^{-1} cm^{-1}) (28). The band at lower energy ($\lambda = 350$ nm) involves a $\pi \rightarrow \pi^*$ transition, which includes the π orbital functions of the azomethine chromophore. This $\pi \rightarrow \pi^*$ transition involves molecular orbitals that originate from the C=N group. The other band ($\lambda = 243$ nm) arises from $\pi \rightarrow \pi^*$ transitions involving the phenyl rings. However, no $n \rightarrow \pi^*$ band is observed in the H$_2$(BA)$_2$en spectrum (19).

The first $\pi \rightarrow \pi^*$ transitions in *trans*-[Co((BA)$_2$en)(amine)$_2$]ClO$_4$ complexes are red-shifted approximately 20 nm relative to that of the free ligand (Table 7). In contrast to the cobalt(III)–acacen complexes, the $\pi \rightarrow \pi^*$ transitions in **1**–**6** are more intense, because of the extended conjugate system (19). The nature of the axial ligand (amine) does not show any significant influence on the position of this band.

Electrochemistry

The cyclic voltammograms (CV) of *trans*-[Co((BA)$_2$en)(X)$_2$]ClO$_4$ complexes ((*a*) X = prldn, $c = 4 \times 10^{-3}$ M; (*b*) X = bzlan, $c = 8 \times 10^{-3}$ M), in the potential range between 0.70 and –2.00 V (vs. Ag/AgCl) in acetonitrile solution, and with 50 mM tetra-*n*-butylammonium perchlorate (TBAP) as the supporting electrolyte at a glassy carbon electrode, are shown in Fig. 4.

E1ectrochemistry in the absence of amines

A scan in the negative direction in the absence of a coordinating amine ligand indicates that the first irreversible reduction wave at ca. 0.75 V is due to the following process (eq. [1]) (9, 19):

[1] *trans*-[Co^{III}((BA)$_2$en)]$^+$ + 2X $\rightarrow$ *trans*-[Co^{III}((BA)$_2$en)(X)$_2$]$^+$

Since the electron is added to the antibonding d_{z^2} orbital the reduction of the Co(III) complex is accompanied by the loss of its axial ligands in the absence of coordinating ligands and in weakly coordinating solvents (19).

The second wave at –1.69 V has the peak potential difference of ca. 70 mV with the same anodic (i_{pa}) and cathodic (i_{pc}) peak currents. This is an indication of the following reversible one-electron-transfer process (eq. [2]):

[2] *trans*-[Co^{II}((BA)$_2$en)] + e$^-$ $\rightarrow$ *trans*-[Co^{I}((BA)$_2$en)]$^-$

When the direction of scanning is reversed and carried out in the positive region, at much higher potentials between 0.2 and –0.2 V, the Co(II) complex is reoxidized to the octahedral Co(III) complex *trans*-[Co^{III}((BA)$_2$en)(X)$_2$]$^+$, i.e. the (*trans*-[Co^{II}((BA)$_2$en)] $\leftrightarrow$ *trans*-[Co^{III}((BA)$_2$en)]$^+$ + e$^-$) electron

[c]Formal potential for the reversible process $[Co^{II}((BA)_2en)] + e^- \leftrightarrow [Co^{II}((BA)_2en)]^-$.
[d]References 28 and 29.

transfer process is followed by the following chemical reaction (eq. [3]):

[3] *trans*-$[Co^{III}((BA)_2en)]^+ + 2X \rightarrow$ *trans*-$[Co^{III}((BA)_2en)(X)_2]^+$

The reduction potential data of the cobalt complexes are summarized in Table 8. The results show that the nature of the axial ligand (amine) has a strong influence on the anodic peak potentials (i_{pa}) for the first reduction process $Co^{III} + e^- \rightarrow Co^{II}$ (differing by almost 290 mV), which is related to the basicity strength of the respective amine. The electron affinity of cobalt(III) in the complexes increases with increasing pK_b (decreasing basicity strength) of the axial ligand; therefore, the corresponding reduction potentials shift to more negative values. In fact, there is a linear relation between the pK_b of the axial amine ligand (29, 30) and the first cathodic potential (E_{pc}) of the complexes. These results are in accord with those obtained for similar Co(III) complexes reported in the literature (9, 19).

The second reduction potential corresponding to Co(II/I) was not influenced by the basicity strength of the axial amine, which indicates the absence of the axial ligands and the involvement of a four-coordinate square-planar species in this redox process.

Electrochemistry in the presence of the amines

The Co(III/II) couple dependence on exact axial ligation shows chemical reversibility, but has a much slower rate of electron transfer than the Co(II/I) couple (9). In an attempt to achieve reversible electrochemical behavior of *trans*-$[Co((BA)_2en)(pprdn)_2]ClO_4$ (**4**) the cyclic voltammetry (CV) was carried out in the presence of excess piperidine (pprdn). The cyclic voltammogram of the *trans*-$[Co((BA)_2en)(pprdn)_2]ClO_4$ complex in the presence of excess pprdn is shown in Fig. 5. In the absence of additional pprdn in the solution, the first reduction process of Co(III/II) is irreversible. Upon addition of excess piperidine, the oxidation wave of Co(II) is shifted towards more negative potentials (by almost 400 mV). By increasing the piperidine concentration (to an [amine]:[complex] ratio of ~100:1), the Co(III/II) redox couple becomes quasireversible, with ΔE_p = 110 mV and a value of 0.9 for the ratio of anodic to cathodic peak currents (i_{pa}/i_{pc}). In contrast to Co(III/II), the redox potential of the Co(II/I) couple is not significantly changed by the addition of excess amine to the solution.

Fig. 5. Changes in the cyclic voltammogram of the *trans*-$[Co((BA)_2en)(pprdn)_2]ClO_4$ complex at different piperidine concentration ratios: (*a*) 0, (*b*) 10, (*c*) 50, (*d*) 100.

Conclusion

The combination of spectral, structural, and electrochemical measurements we have described has illustrated the main features of the coordination and redox chemistry of the trans-[Co((BA)$_2$en)(amine)$_2$]ClO_4 complexes. The coordination geometry around the Co(III) center in **1**–**6** is a distorted octahedron of N_2O_2 + N_2. Electrochemical studies have revealed that the first reduction process Co(III/II) is irreversible and strongly influenced by the nature of the axial amines. A 290 mV change in the Co(III)/Co(II) cathodic peak is observed when the axial ligands are changed from pyrrolidine to aniline. This process becomes quasi-reversible upon the addition of excess amine. The Co(II)/Co(I) couple is reversible and insensitive to moderate concentrations of axial ligands.

The observed trends in the electrochemical behavior and reactivity of these complexes are along the same line as those reported for closely related Schiff base cobalt complexes, with potential biological applications.

Acknowledgments

The authors are grateful to the Isfahan University of Technology and Tarbiat Modarres University Research Council for partial support of this work. We also thank Dr. A. Salimy for his assistance in the electrochemical measurements and Mr. Bijanzadeh for obtaining the ^1H and ^{13}C NMR spectra. We wish to thank the Division of Inorganic Chemistry, Department of Chemistry, Göteborg University for providing X-ray structure determination facilities.

Thermal oscillations in the bromate – oxalic acid – $MnSO_4$ – H_2SO_4 – acetone system: A calorimetric study

Sudeshna Biswas, Kallol Mukherjee, Dulal Chandra Mukherjee, and Satya Priya Moulik

Abstract: The oscillatory reaction of potassium bromate, oxalic acid, and $MnSO_4$ in the presence of acetone in aq H_2SO_4 solutions has been studied calorimetrically at different concentrations of substrates. Acetone and oxalic acid have been found to accelerate the reaction by increasing the oscillation frequency. On the other hand, $MnSO_4$ has a retarding effect; the frequency of oscillation decreases systematically with increasing concentration of $MnSO_4$. Potassium bromate shows mixed behavior in this respect. The total heat evolved during the reaction per mol of oxalic acid consumed has been evaluated, which can be used to calculate the concentrations of the various reactants at different stages of the reaction. The effects of different electrolytes (KCl, NaCl, $BaCl_2$, $CaCl_2$, $SrCl_2$, NaBr, NaI, KNO_3, $NaNO_3$, and $Ca(NO_3)_2$) and solvents (dimethylformamide, 1,4-dioxane, acetonitrile, and tetrahydrofuran) on the extents of oscillation and the enthalpy change for the process have been also examined.

Key words: Belousov–Zhabotinsky reaction, oscillatory reaction, oxalic acid, calorimetry, acetone.

Résumé : Faisant appel à la calorimétrie et opérant à diverses concentrations de substrat, on a étudié la réaction oscillatoire du bromate de potassium, avec l'acide oxalique et le $MnSO_4$, en présence d'acétone, en solutions aqueuses de H_2SO_4. On a observé que l'acétone et l'acide oxalique accélèrent la réaction en augmentant la fréquence d'oscillation. D'autre part, le $MnSO_4$ ralentit la réaction; la fréquence de l'oscillation diminue de façon systématique avec une augmentation de la concentration du $MnSO_4$. De ce point de vue, le comportement du bromate de potassium est mixte. On a évalué la chaleur totale dégagée au cours de la réaction, par mol d'acide oxalique et on peut utiliser cette valeur pour calculer les concentrations des divers réactifs à différents stages de la réaction. On a aussi examiné les effets de divers électrolytes (KCl, NaCl, $BaCl_2$, $SrCl_2$, NaBr, NaI, KNO_3, $NaNO_3$ et $Ca(NO_3)_2$) ainsi que celles de divers solvants (diméthylformamide, 1,4-dioxane, acétonitrile et tétrahydrofurane) sur l'oscillation et le changement d'enthalpie pour ce processus.

Mots clés : réaction de Belousov–Zhabotinsky, réaction oscillatoire, acide oxalique, calorimétrie, l'acétone.

[Traduit par la Rédaction]

Introduction

Studies of the Belousov–Zhabotinsky (B-Z) oscillatory chemical reaction (1) have been the subject of growing importance and interest. The fundamental chemistry of the B-Z system has been clarified by the FKN (Field, Körös, and Noyes) mechanism (2) and by mathematical models (3–5). The methodologies that have been liberally employed so far for studying the B-Z reaction are based on potentiometric and spectrophotometric measurements. The results of calorimetric measurements (6, 7) are also being used to understand the oscillatory phenomena with the objective of getting straightforward information about the thermochemical behavior of the system.

Noszticzius and Bódiss (8) have studied the B-Z reaction with oxalic acid in place of malonic acid, and others (9–13) have studied the reaction in the presence of acetone (a bromine scavenger). This complex oscillatory system has been monitored by voltage oscillations as well as by absorbance oscillations. But so far, this system has not been studied by following temperature oscillations. In our earlier communications, (6, 14, 15) we have reported calorimetrically measured temperature oscillations of the bromate – gallic acid – sulfuric acid B-Z system as a function of bromate concentration, with and without ferroin as a catalyst, in the presence of mixed solvents and electrolytes. As studies of the temperature oscillation of the B-Z reaction involving oxalic acid as the organic substrate are not very common in the literature, we have undertaken an investigation of the thermochemical behavior of the bromate – oxalic acid – $MnSO_4$ – H_2SO_4 – acetone B-Z oscillatory system. As solvents (14, 16, 17) and added electrolytes (15, 17–19) are found to have marked effects on the B-Z system, we have also investigated their

effects on the oscillatory process, and have attempted to rationalize the results.

Experimental section

Materials

Potassium bromate, sulfuric acid, oxalic acid (OA), acetone (AC), manganous sulfate, and tetrahydrofuran (THF) were products of Merck (Germany). The electrolytes used in this study were A.R. grade products of Merck (India). The solvents dimethylformamide (DMF), acetonitrile (ACN), and 1,4-dioxane (DX) were A.R. grade products of S.D. Fine Chemicals (India). Doubly distilled conductivity water was used in all preparations.

Method

The reaction was studied in a TRONAC 458 isoperibol titration calorimeter at 303 K. A solution (18 mL) with a composition of 0.155 mol dm^{-3} $KBrO_3$, 1.1 mol dm^{-3} acetone, and 1.25 equiv dm^{-3} H_2SO_4 were loaded into the reaction vessel of the calorimeter. A mixture (2 mL) of 0.625 mol dm^{-3} oxalic acid and 0.013 mol dm^{-3} manganous sulfate in H_2SO_4 was added from a burette into the reaction vessel. The change in heat during the oscillations was recorded with a Houston Omniscribe stripchart recorder. The heat produced during the reaction was evaluated from the peak height and slope values of the produced thermograms (Figs. 1 and 2) following the procedure described earlier (6). The effect of concentration of a component on the oscillatory reaction was studied by changing its concentration at constant concentrations of the other components.

Results and discussion

The oscillatory reaction process

The BrO_3^-–$MnSO_4$–H_2SO_4–OA–AC mixed-substrate B-Z system is a complex one. The overall reaction is (8):

[1] $HBrO_3 + 2(COOH)_2 + CH_3COCH_3 \rightarrow 4CO_2 + 3H_2O + BrCH_2COCH_3$

Br_2 inhibits the process whereas CO_2 does not. CH_3COCH_3 scavenges Br_2 and the oscillation persists longer in the presence of CH_3COCH_3 (10).

$HBrO_2$ is a vital component for the deceleration and acceleration of the oscillatory process (8).

The following reaction steps for the mechanism have been proposed (20):

[2] $BrO_3^- + Br^- + 2H^+ \rightleftharpoons HBrO_2 + HOBr$

[3] $Br^- + HBrO_2 + H^+ \rightleftharpoons 2HOBr$

[4] $Br^- + HOBr + H^+ \rightleftharpoons Br_2 + H_2O$

[5] $BrO_3^- + HBrO_2 + H^+ \rightleftharpoons 2BrO_2\bullet + H_2O$

[6] $Mn^{2+} + BrO_2\bullet + H^+ \rightleftharpoons Mn^{3+} + HBrO_2$

[7] $BrO_2\bullet + (COOH)_2 \rightarrow HBrO_2 + CO_2 + HCO_2\bullet$

[8] $HOBr + (COOH)_2 \rightarrow H_2O + CO_2 + HCO_2\bullet + Br\bullet$

The Br_2 is removed from the system by the following reactions:

[9] $Br\bullet + CH_3COCH_3 \rightarrow Br^- + CH_3COCH_2\bullet + H^+$

[10] $CH_3COCH_2\bullet + Br_2 \rightarrow BrCH_2COCH_3 + Br\bullet$

[11] $CH_3COCH_2\bullet + CH_3COCH_2\bullet \rightarrow CH_3COCH_2CH_2COCH_3$

[12] $CH_3COCH_3 + H^+ \rightleftharpoons CH_2{=}COHCH_3 + H^+$

[13] $CH_2{=}COHCH_3 + Br_2 \rightarrow BrCH_2COCH_3 + H^+ + Br^-$

General thermal behavior of the oscillatory process

Addition of mixed solutions of $MnSO_4$ and oxalic acid from the burette into the potassium bromate solution in the calorimeter vessel released a large amount of initial heat for several minutes, which was estimated by a previously reported procedure (6). After that, regular (also irregular) oscillations of the released heat were observed. A large induction period before the beginning of oscillations was reported by Guedes and Faria (10). The release of appreciable initial heat was also observed in the bromate – gallic acid – H_2SO_4 – ferroin system studied by us (14, 15). The results are exemplified in Figs. 1 and 2. The number of oscillation (n) and the enthalpy of reaction expressed in kJ mol^{-1} (ΔH_R) were evaluated. This ΔH_R includes the initial heat and the heat released in the oscillatory regime, and is expressed per mol of oxalic acid based on the consideration that all the other reaction components are in excess compared to oxalic acid, so that at the end of the reaction, all the oxalic acid is consumed. From the ΔH_R values, the consumption of a component during the different stages of the reaction can be estimated. In this calculation, ΔH_R at a certain stage becomes proportional to the oxalic acid consumed and is thus related to the consumption of other reacting species, acetone and bromoacetone by way of the necessary mass balance equations. It is observed from the results given in Tables 1–6 that the ΔH_R values have shown a direct correlation only with the acetone concentration ([AC]); the other components, oxalic acid, salts, and mixed solvents have not shown an observable correlation. The oscillations also are found to increase with the concentration of acetone and not with the concentrations of the other components. This reflects the clear Br_2 scavenging effect of acetone; the ΔH_R–[AC] profile has been found to be fairly linear. The same physical quantities of n and ΔH_R were also estimated at different concentrations of the reagents (OA, AC, $MnSO_4$, and $KBrO_3$), salts (chlorides of K, Na, Ba, Sr, and Ca; nitrates of K, Na, and Ca; NaBr and NaI), and solvents (DX, ACN, THF, and DMF).

Effect of substrate concentration

The oscillatory process was examined as a function of the concentration of each of AC, OA, $MnSO_4$, and $KBrO_3$ at fixed concentrations of the other components.

With increasing acetone concentration, the number of oscillations increased. No oscillation was observed at 0.2 mol dm^{-3} acetone concentration calorimetrically, though Wittmann et al. (9) reported oscillations from potentiometric studies below 0.21 mol dm^{-3} of acetone. At 0.3 mol dm^{-3}, only a single oscillation was observed. At 0.4 mol dm^{-3} acetone, there was a lag period of 8 min between two oscillations. This lag period was reduced to 3 min at 0.5 mol dm^{-3} acetone (Fig. 1). Above 0.5 mol dm^{-3} acetone, no such distinct halt was observed. Wittmann et al. (9) also potentiometrically observed a pause of oscillation in the OA–AC mixed-substrate B-Z system, at 0.21 to 1.4 mol dm^{-3} acetone (Table 1).

With increasing OA concentration, the number of oscillation increased. Oscillation was not observed below 0.04 mol dm^{-3} OA. At 0.05 mol dm^{-3} and 0.04 mol dm^{-3} OA, a combination of high- and low-amplitude oscillations was observed. At 0.04 mol dm^{-3} OA, three high-amplitude initial oscillations were followed by two low-amplitude oscillations. At 0.05 mol dm^{-3} OA, six high-amplitude oscillations were followed by four low-amplitude oscillations. This type of mixed high- and low-amplitude oscillations was also reported by Guedes and Faria (10) from spectrophotometric studies. In the present study, mixed high- and low-amplitude oscillations were not observed at >0.05 mol dm^{-3} OA (see Fig. 2 and Table 2).

With increasing $MnSO_4$ concentration, the number of oscillation decreased. We could not increase the indicator concentration above 0.0015 mol dm^{-3} due to the Br_2 liberation in acid solution. Interestingly, no oscillation was observed in the absence of $MnSO_4$ or in the presence of ferroin indicator. (Table 3).

With increasing $KBrO_3$ concentration, the number of oscillations decreased. Also, >0.22 mol dm^{-3} $KBrO_3$ could not be used here because of the Br_2 liberation in acid solution (Table 4).

Though with increasing concentration of substrate the rates of chemical reactions generally increase, the opposite effect may be explained due to complex formation of the added reactants in the activated state, thereby inhibiting the formation of products. Increased concentrations of $KBrO_3$ and Mn^{2+} lead to increased formation of $HBrO_2$ and HOBr through rxns. [2]–[6] and that causes the increase in the bromine concentration. As the acetone concentration is kept fixed in those experiments, some unscavenged Br_2 may be present to inhibit the process. In this complex chemical reaction, understanding of the inhibition by the substrate may require information on the different activated states, which at present is not known. OA, on the other hand, offered an activating effect in the reaction up to a certain concentration

above, which n did not change. Such a saturation point was reached at ~0.08 mol dm^{-3} of OA. AC produced a good activating effect on the reaction by its bromine scavenging ability (10, 20). The presence of Br_2 inhibits oscillations, as has been pointed by other authors (8–11, 20). Acetone reacts with bromine to produce bromoacetone (eq. [13]) and consequently reduces the Br_2 concentration. All the results discussed above are presented in Tables 1–4.

Effect of mixed solvents

DX and ACN showed similar inhibitory effects on the OA–$KBrO_3$–AC–$MnSO_4$ system. In both the cases, the number (n) of oscillations decreased with increasing volume fraction of the organic component. In the case of DX, the oscillation ceased at 20 volume% DX, and for ACN at 15%. For THF, n also decreased and the decrease was very rapid compared to DX and ACN. Addition of very small amounts of THF increased n by almost a factor of two relative to the aqueous medium. With increasing volume fraction of THF, n decreased sharply and the oscillatory behavior ended at 3% THF. DMF showed completely different behavior. The number of oscillations (n) initially increased from 0.5 to 4% DMF, then started decreasing from 5 to 10% DMF. Higher percentages of DMF could not be used due to the liberation of Br_2.

Lalitha and Ramaswamy (16) have studied the bromate – gallic acid – ferroin system at a fixed composition (20 volume%) of the organic solvents (DX, THF, ACN, and DMF) in water. For these systems, n increased in the order DMF > THF > ACN > DX. In this study, we have used variable compositions, thereby obtaining variable n values. A comparison of the results at a fixed composition (1 volume% organic solvents) gives the order THF > DMF > DX ≈ ACN. This sequence fails, however, at higher proportions of the organic solvents.

It is considered by Lalitha and Ramaswamy (16) and Jha et al. (17) that the bromination of the active methylene compound is an important factor for an oscillatory reaction (where malonic acid or related organic substrates are used), and it occurs through the electrophilic substitution by bromonium ion (Br^+). As a result of poor solvation of this Br^+ in mixed solvent media, it performs faster bromination, thereby decreasing the frequency of oscillation. But this generalization is not possible for the present system where the organic substrate is oxalic acid with no active methylene group. The solvents can react with very reactive intermediates of the B-Z system (like bromine dioxide, bromous acid, hypobromous acid, etc.). How these and other factors affect the course of the reaction is difficult to assess and decipher. The results are presented in Table 5.

Effect of added electrolytes

Jacobs and Epstein (18) have studied the effect of chloride on the oscillations in the bromate – cerium – malonic acid system. The effect of chloride on the above-mentioned system under a variety of conditions has been reported and a mechanism has been proposed. The chloride inhibition mechanism involves the oxidation of chloride to chlorous acid which reduces Ce(IV) to Ce(III), preventing oscillation. The oscillations resume when the chlorous acid has been

1×10^{-5}	10	257

Note: $[H_2SO_4]$ = 1.25 equiv dm^{-3}, [OA] = 0.0625 mol dm^{-3}, [AC] = 1.0 mol dm^{-3}, $[MnSO_4]$ = 0.0013 mol dm^{-3}, $[KBrO_3]$ = 0.14 mol dm^{-3}. ΔH_R is expressed per mol of OA.
[a]At 1×10^{-5} equiv dm^{-3}.

completely oxidized to chlorate. The inhibitory effect of iodide ion on the B-Z system (19) and bromide ion on the Briggs–Rauscher (21) reaction have also been studied. Nitrate, sulfate, and perchlorate salts have been shown (18) not to affect the malonic acid – bromate – Ce^{3+}(catalyst) – H_2SO_4 B-Z reaction. However, Jha et al. (17) observed inhibitory effects on this B-Z reaction at high $NaNO_3$ concentrations. We also observed inhibitory effects of chloride and nitrate salts on the bromate – gallic acid – H_2SO_4 – ferroin oscillatory process (15).

In the present study, experiments were performed with five chloride salts (KCl, NaCl, $BaCl_2$, $SrCl_2$, and $CaCl_2$). Inhibition was almost insignificant; the n values remained unaltered up to electrolyte concentrations of about 1×10^{-2} equiv dm^{-3}. The oscillatory process was also not inhibited by KNO_3, $NaNO_3$, and $Ca(NO_3)_2$ up to 1×10^{-2} equiv dm^{-3}. With NaBr and NaI, a slight inhibition was observed with increasing concentration of the electrolyte from 1×10^{-7} to 1×10^{-2} equiv dm^{-3}.

The effects of added electrolytes up to 1×10^{-5} equiv dm^{-3} on n are presented in Table 6. We studied this effect up to electrolyte concentrations of 1×10^{-2} equiv dm^{-3}. As the values of n remain more or less the same with increasing electrolyte concentration beyond 1×10^{-5} equiv dm^{-3}, the results for this concentration range are not shown in the table.

This insignificant inhibitory effect of the above-mentioned electrolytes is in sharp contrast to other oscillatory reaction processes (15, 18) where distinct reduction of n was observed, even with electrolyte concentrations as low as 1×10^{-7} equiv dm^{-3}. In our previous work (15), we reported inhibitory effects of chloride and nitrate salts on the bromate – gallic acid – H_2SO_4 – ferroin reaction, studied by both calorimetry and potentiometry. A probable mechanism of the inhibitory effects of the chloride ion on the bromate – gallic acid – H_2SO_4 – ferroin reaction was presented (15), but an explanation of the effect of nitrate salts could not be proposed. For the present system, calorimetric studies have not shown any significant inhibition and it may be assumed that potentiometric observation should give the same result. Why chloride and nitrate ions do not contribute to the process by way of interaction with $HBrO_2$ and $\bullet BrO_2$, which are vital products (15), requires further examination.

Conclusions

Increasing the concentration of different components of the oscillatory system individually, keeping others constant, has marked effects on n. $KBrO_3$ and $MnSO_4$ have shown decreasing effects on n, whereas acetone has shown an increasing effect. Oxalic acid has produced a hyperbolic saturation effect.

ΔH_R values for the overall heat evolved in the oscillatory reaction per mol of oxalic acid consumed has been found to be linearly related with the acetone concentration. Based on ΔH_R, the consumption of the reacting components at different stages of oscillation can be estimated.

THF, ACN, and DX have retarding effects on n. A maximum for n has been observed for DMF.

Electrolytes have practically no effect on the oscillatory process.

Cyclodextrin-, UV-, and high pH-induced fluorescence enhancement of the pesticide azinphos-methyl: Applications to its trace analysis

Brian D. Wagner, Adam C. Sherren, and Matthew A. Rankin

Abstract: Various methods for the enhancement of the fluorescence of the pesticide azinphos-methyl are reported. The addition of hydroxypropyl-β-cyclodextrin was found to moderately enhance the fluorescence by a factor of three, presumably via inclusion of the pesticide into the cyclodextrin cavity. This complexation was found to occur with an association constant of 690 ± 140 M^{-1}. This enhancement was found to be too low to be useful in a fluorescence-based analytical method for this pesticide. Exposure of azinphos-methyl to UV light was also found to result in enhanced fluorescence, with much larger enhancement than in the case of addition of cyclodextrins. This enhancement was presumed to occur via photolysis of azinphos-methyl to a more fluorescent photoproduct. However, the difficulty of providing a constant UV dosage prevents its useful application as a fluorescence-based analytical method. Finally, it was found that base hydrolysis of azinphos-methyl resulted in a very large fluorescence enhancement. Although this enhancement was previously reported in the literature, it was found that contrary to the published reports, the hydrolysis occurred rapidly at room temperature, with no need for carrying out the reaction at increased temperature. Fluorescence enhancements of a factor of 300 were obtained by simply adding the appropriate amount of an aqueous NaOH solution to the aqueous azinphos-methyl sample. This procedure was used as the basis of a simple fluorescence-based analytical method for azinphos-methyl in water, with excellent linear calibration curves obtained down to concentrations of 5 ppb.

Key words: fluorescence spectroscopy, pesticides, azinphos-methyl, fluorescence enhancement, host–guest inclusion.

Résumé : On a développé diverses méthodes permettant de rehausser la fluorescence du pesticide « azinphos-méthyle ». On a trouvé que l'addition d'hydroxypropyl-β-cyclodextrine augmente la fluorescence par un facteur de trois, probablement par l'inclusion du pesticide dans la cavité de la cyclodextrine. On a observé que la complexation se fait avec une constante d'association de 690 ± 140 M^{-1}. On a trouvé que cette augmentation est trop faible pour être utile dans une méthode analytique de ce pesticide faisant appel à la fluorescence. On a observé que l'exposition du pesticide à de la lumière UV provoque aussi une augmentation de la fluorescence qui est beaucoup plus grande que celle observée avec les cyclodextrines. On a fait l'hypothèse que ceci résulte d'une photolyse de l'« azinphos-méthyle » en un photoproduit plus fluorescent. Toutefois, la difficulté de fournir un dosage constant d'UV rend difficile son application à une méthode analytique de ce pesticide faisant appel à la fluorescence. Enfin, on a trouvé que l'hydrolyse de l'« azinphos-méthyle » par une base conduit à une très importante augmentation de la fluorescence. Même si cette élévation a été rapportée dans la littérature antérieurement, on a trouvé que contrairement à ce qui avait alors été rapporté l'hydrolyse de produit rapidement à la température ambiante, sans qu'il soit nécessaire d'augmenter la température de la réaction. On a obtenu des facteurs d'augmentation de la fluorescence de l'ordre de 300 en ajoutant simplement la quantité appropriée d'une solution aqueuse de NaOH à un échantillon d'« azinphos-méthyle ». On a utilisé cette méthode comme base d'une méthode faisant appel à la fluorescence qui permet de faire simplement l'analyse de l'« azinphos-méthyle » dans l'eau, avec d'excellentes courbes de calibration linéaires jusqu'à des concentrations aussi faibles que 5 ppb.

Mots clés : spectroscopie de fluorescence, pesticides, « azinphos-méthyle », augmentation de la fluorescence, inclusion hôte–invité.

Introduction

Prince Edward Island (PEI) has a very high proportion of cultivated land. In 1998, there were a total of 404 000 acres of land used for agriculture (1), representing 29% of the total land area of the province. As a consequence, PEI has one of the highest uses of pesticides per total land area in Canada. In 1998, a total of 886 218 kg of pesticides were purchased on PEI, including herbicides, insecticides, and fungicides (1). The use of pesticides in agricultural applications has led to a great deal of controversy and debate on the

environmental impact of this high pesticide usage, including its impact on human health, drinking water, and ecosystems. Although most of these issues remain unresolved, one easily identifiable negative consequence of pesticide use in this province is the recent epidemic of fish kills in PEI rivers and streams. These incidents have occurred every summer since 1994 (with the exception of 1997), with nine fish kills reported in 1999 alone.[2] Each of these incidents involve the deaths of at least hundreds of fish. Pesticides have been identified as the cause of many of these fish kills; water samples collected from affected areas have shown levels of various pesticides well above the toxic level for fish.[2,3] Many of these incidents occur after heavy rains, which in combination with long-sloping fields and lack of significant buffer zones between cultivated fields and natural waterways, results in large run-offs of pesticide-laden water into rivers and streams.[2,3]

One pesticide which has been identified in the river water samples taken after most of these fish kill incidents is azinphos-methyl (AZM), the structure of which is shown in Fig. 1*a*. AZM is an organophosphorus insecticide, with a relatively long persistence for this type of pesticide (2, 3). It is a highly efficient insecticide and acaricide, and works as both a contact insecticide and a stomach poison (2, 3). It is also highly toxic to nontarget species, with an oral LD_{50} of 4.4–16 mg kg^{-1} for male rats (3). It is a potentially significant contaminant in natural waters, owing to its solubility of 30 ppm (2), and its extremely high toxicity to aquatic organisms. For example, it has a 96 h LC_{50} of 3 ppb for rainbow trout (3). By comparison, in one of the fish-kill incidents studied, which occurred in August 2000, the water sampled after the incident was found to contain AZM at the level of 73.2 ppb[3], well above the toxic threshold. AZM is classed as a Group C pesticide on PEI, with annual sales between 1000 and 9999 kg (compared to Group A pesticides with annual sales over 50 000 kg) (1). Although AZM is not one of the most heavily used pesticides on PEI, its importance in fish kills is a result of its high toxicity to aquatic organisms and its relatively high solubility. In a report entitled *Relative ranking of acute pesticide risks to fish*, published by the PEI Department of Technology and Environment (4), AZM has a rating description of EH (Extremely hazardous), the highest risk ranking. It should be noted that AZM is used not only on PEI, but throughout Canada, for example as an insecticide in apple orchards. The Canadian Environmental Quality Guideline for AZM in water is 20 ppb.

The current method for determination of AZM in natural waters on PEI involves extraction into CCl_4, followed by HPLC. This method has three major disadvantages: the use of an environmentally harmful chlorinated solvent, the relatively high cost of analysis, and the fact that the analysis must be performed in a laboratory. There would be a great advantage to a technique which could be done on-site. Fluorescence has found significant application as the basis for the analysis of other pesticides (5, 6). Furthermore, the recent development of portable, hand-held fluorimeters provides the potential for the development of a fluorescent-based analytical field technique. However, AZM is only weakly fluorescent in aqueous solution. Thus, to use a fluorescence-based analytical technique, sensitive in the ppb region in which AZM can have an environmental impact in natural waters, it is necessary to include some method for enhancing its natural fluorescence. Fluorescence enhancement by cyclodextrins has been previously applied to other pesticides (7–9); this method might also be useful for AZM. There have also been reports of fluorescence enhancement of other pesticides upon exposure to UV radiation, via photolysis to a more fluorescent photoproduct (10–12), as well as a report of decreased fluorescence from a number of aromatic pesticides upon UV irradiation (13). In terms of AZM itself, the only reports of its fluorescence enhancement have been upon base hydrolysis, involving the heating of AZM solutions at high pH and at 85°C for 10 min (14), or at 90°C for 30 min (15). This requirement of heating the solutions at high temperature severely limits the applicability of this fluorescence enhancement method as a field technique.

In this paper we describe three methods by which the weak natural fluorescence of AZM can be enhanced: addition of modified β-cyclodextrins, UV exposure, and high pH (with no heating). Furthermore, we show that the measurement of AZM fluorescence at high pH provides a sensitive and accurate quantitative analytical method with no need for prior heating of the sample, and propose its use in the trace analysis of this pesticide in natural waters, and as the basis for a fluorescence-based field analysis method for AZM.

Experimental

AZM, β-CD, and HP-β-CD were obtained from Aldrich Chemical Company. HP-β-CD is available with various degrees of substitution; the highest substitution available was

[2] Sharrat, S. Deadly combination seen as main reason for fish kills. *The Guardian*. (Charlottetown, PEI). September 18, 1999.
[3] Pesticides blamed for recent fish kills. *The Guardian*. (Charlottetown, PEI). September 1, 2000.

© 2002 NRC Canada

used, namely 1.8 (an average of 1.8 hydroxyls out of the 3 per monomer unit were substituted). All compounds were used as received. Tests of the water content of the CDs showed values of 11.8 and 3.3% for β-CD and HP-β-CD, respectively (based on mass loss after heating for 4 h in a vacuum oven at 180°C). The CDs were not dried before use, however the calculated CD concentrations were corrected using the determined water content values.

Solutions for fluorescence studies were prepared using nanopure distilled and deionized water. Unless otherwise indicated, the concentration of the AZM solutions was 7.6×10^{-6} M; this concentration was chosen as the lowest that would still give a reasonably measurable absorbance at the excitation wavelength used for the fluorescence measurements (see below) and a well-defined fluorescence spectrum. It should be noted that this concentration corresponds to 2.43 ppm, a value much higher than that found for AZM in natural water samples. Nevertheless, this concentration was deemed to be best for these tests of AZM fluorescence enhancement, as it is essential to be able to accurately measure the fluorescence spectrum of AZM in water at neutral pH in the absence of any added cyclodextrin or other treatment for use as a reference. Solutions for studies of the pH dependence of AZM fluorescence were prepared using appropriate aqueous buffer solutions. Solutions for the analysis studies at pH 12 were prepared by adding 0.20 mL of 0.10 M aq NaOH solution to 1.8 mL of the AZM test solution in a fluorescence cuvette, shaking thoroughly, and letting stand for 5 min before measuring the fluorescence spectrum.

Absorption spectra were measured on a Cary 50 Bio UV–vis spectrophotometer. Fluorescence spectra were obtained on a Photon Technology International LS-100 luminescence spectrometer using 1×1 cm^2 quartz fluorescence cells, with an excitation wavelength of 320 nm. This excitation wavelength was chosen as the longest wavelength at which AZM shows a significant absorption band. Excitation at lower wavelengths would be slightly absorbed by added cyclodextrins at high concentrations, and would also be more likely to be absorbed by other species present in natural water samples. The 7.6×10^{-6} M AZM solutions had an absorbance of 0.04 at this wavelength. All spectra were obtained at 21 ± 2°C. Solutions were not oxygen-purged, as preliminary investigations showed a negligible effect of purging on the observed fluorescence intensity (<5%). All fluorescence spectra were baseline corrected by subtraction of the spectrum of a water blank; this procedure also served to remove a water Raman scattering band at ca. 360 nm, which was significant in spectra with low intensity. Fluorescence enhancements (F/F_o) were determined as the ratio of the integrated area under the corrected fluorescence spectrum (I_F vs. wavenumber) of treated AZM (added CD, UV-exposed, or high pH) relative to that of untreated AZM solution.

Results and discussion

Fluorescence enhancement by hydroxypropyl β-cyclodextrin

The fluorescence enhancement of guest molecules upon inclusion into cyclodextrins has been well documented (16). Cyclodextrins (CDs) are cyclic oligosaccharides of glucopyranose (17); a general structure of β-cyclodextrin (the oligomer containing seven glucopyranose units) is shown in Fig. 1*b*, with R = H in the case of the parent β-cyclodextrin. CDs are highly soluble in aqueous solution. More importantly, they have a truncated cone structure in aqueous solution, with a well-defined internal cavity (17). Hydrophobic guest molecules can become included within the relatively less polar CD cavity, forming a supramolecular host–guest inclusion complex. The fluorescence of CD-included guest molecules is often significantly enhanced relative to the fluorescence of the free guest in aqueous solution. This can be the result of a number of factors, the most important being the effect of the decreased polarity of the environment of the guest within the CD cavity, but also including hindrance of rotational motion within the guest molecule, and protection from external quencher species.

Cyclodextrins can be chemically modified, by replacing some or all of the hydroxyl hydrogens by other groups (18). Such chemically modified CDs often have improved properties over their unmodified parents, for example improved solubility, and greater abilities to enhance fluorescence. Recent work in our laboratory has been focused on the enhancement of guest fluorescence by alkyl- and hydroxyalkyl-substituted CDs; we have shown that hydroxypropyl-β-cyclodextrin (HP-β-CD, R = $CH_2CHOHCH_3$ in Fig. 1*b*) in particular provides significantly larger fluorescence enhancement of polarity-sensitive fluorescent probes (in this case anilinonaphthalene sulfonates) than does β-CD itself (19, 20). We proposed this enhancement to be a result of the hydroxypropyl substituents on the rims providing an extended nonpolar cavity, which can therefore bind hydrophobic guests more strongly, as well as providing an even less polar cavity relative to aqueous solution.

In this work, the ability of HP-β-CD to significantly enhance the fluorescence of AZM was investigated, with the goal of using any observed significantly CD-enhanced fluorescence in a trace analysis scheme. Figure 2 shows the fluorescence spectrum of 7.6×10^{-6} M AZM in the absence (*a*) and presence (*b*) of 10 mM HP-β-CD. As can be seen from this figure, significant fluorescence enhancement was observed, with a value of F/F_o of 2.7 in this case, and an

Fig. 2. The fluorescence spectrum of AZM in: (*a*) the absence, and (*b*) the presence of 10 mM HP-β-CD.

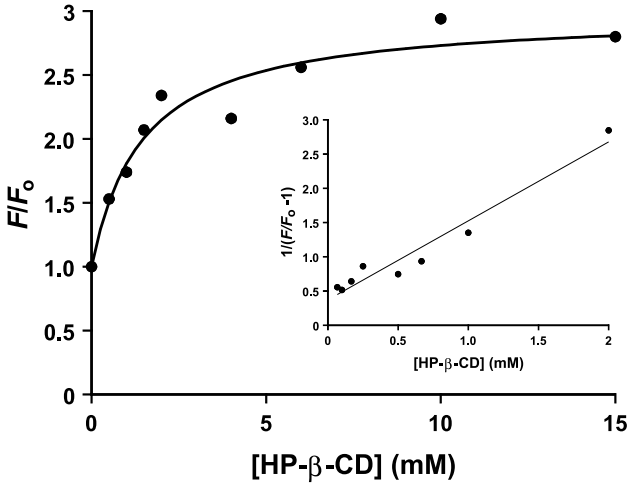
Fig. 3. The fluorescence enhancement F/F_o of M AZM as a function of HP-β-CD concentration. The solid line shows the fit of the experimental data to eq. [1], with F_{max}/F_o = 2.98 and K = 687 M^{-1}. The inset shows the reciprocal–reciprocal plot with a linear fit.



accompanying small red-shift of ca. 15 nm. This result suggests that AZM has become included in the HP-β-CD cavity. Similar studies were also performed using unmodified β-CD: fluorescence enhancement of AZM was also observed, but at lower values, with F/F_o ranging from 1.2 to 1.6. These results confirm our expectation that modified HP-β-CD would provide better enhancement results than the parent β-CD.

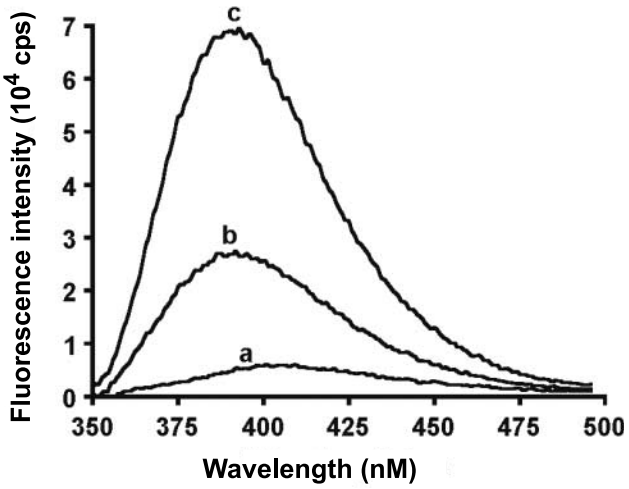
The association constant K for the formation of the host–guest inclusion complex from the free host and guest molecules can be obtained by measuring the fluorescence enhancement F/F_o as a function of host concentration, using the equation (21, 22)

$$[1] \qquad F/F_o = 1 + (F_{max}/F_o - 1)\,\frac{[CD]_o K}{1 + [CD]_o K}$$

where F_{max}/F_o is the fluorescence enhancement when all of the guests have been included. Equation [1] assumes that only 1:1 host–guest inclusion complexes are formed. This assumption can be tested using the double-reciprocal plot (or Benesi–Hildebrand plot (23)) of $1/(F/F_o - 1)$ vs. $1/[CD]$; this plot will be linear if only 1:1 complexes form, but will be nonlinear if higher-order complexes form. The double-reciprocal plot, shown as an inset in Fig. 3, is linear, indicating that higher-order complexes are not involved. The fit of the data in Fig. 3 to eq. [1] using the non-linear least-squares method yielded a value of K = 690 ± 140 M^{-1}, and F_{max}/F_o = 2.98 ± 0.30. In terms of reported values of K for other guests in HP-β-CD, this is a moderate to low value.

The maximum enhancement of a factor of 3.0 obtained with HP-β-CD is much too small to be useful for a trace analysis method for AZM in the ppb region. We estimate that significant fluorescence signals could be measured down to ca. 500 ppb at best using this enhanced fluorescence; this is well above the low ppb region required for natural water samples. Furthermore, as can be seen from Fig. 3, there was a fair degree of scatter in the measured values of F/F_o; this scatter is also noticeable in the double-reciprocal plot. Although decent values of F/F_o were obtainable by averaging a number of trials (from 3–5 trials at each CD concentration), this variability was not observed in such experiments performed in our lab with other guests (19, 20). This variability would also limit the applicability of this method in a trace analysis scheme.

Fig. 4. The fluorescence spectrum of AZM recorded immediately upon insertion into the fluorimeter (*a*), and (*b*) after 80 minutes and (*c*) 120 minutes in the fluorimeter.



Fluorescence enhancement by UV exposure

It was observed that if the measurement of the fluorescence spectrum of an AZM solution was repeated (i.e. using the same solution in the cuvette), then the subsequently measured fluorescence intensity was larger than that initially measured. It was further noted that the longer the solution was left in the fluorimeter (continuously exposed to the 320 nm excitation light), the larger the fluorescence intensity measurement. This result is illustrated in Fig. 4, which shows the fluorescence spectrum of a single sample of AZM that was left sitting in the fluorimeter sample holder, measured initially and after 80 and 120 min. This figure indicates that a very large enhancement of the AZM fluorescence occurs upon extended absorption of the UV excitation light, much larger than that obtained in the presence of HP-β-CD (as shown in Fig. 2), with a significant blue-shifting of the emission spectrum by ca. 20 nm. These observations were consistent and reproducible. Figure 5 shows a plot of the UV-induced fluorescence enhancement F/F_o (integrated fluorescence intensity relative to that measured initially) of another AZM solution under constant illumination by the fluorimeter excitation lamp at 320 nm, measured over the course of just over 7 hours. As can be seen, the AZM fluorescence intensity was found to increase steadily (except for a spike at 20 min), then level off after ca. 5 hours. This was followed by a slow but continual decrease in intensity. The maximum fluorescence enhancement of 13.1 is significantly larger than the maximum fluorescence enhancement of 3.0 obtained by adding HP-β-CD.

We propose that AZM is photolyzed by UV light, generating a more fluorescent unidentified photoproduct with a blue-shifted spectrum. This hypothesis agrees with the literature reports of UV-induced fluorescence enhancement of

© 2002 NRC Canada

Fig. 5. The integrated fluorescence intensity of AZM as a function of time of exposure to the UV excitation light in the fluorimeter.

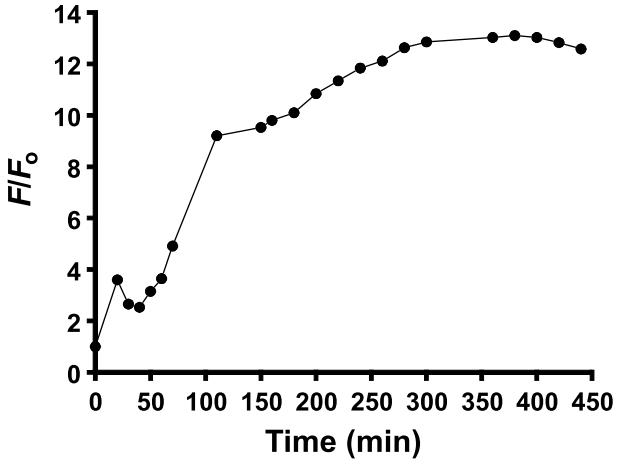


Fig. 6. The peak fluorescence intensity of AZM as a function of pH.

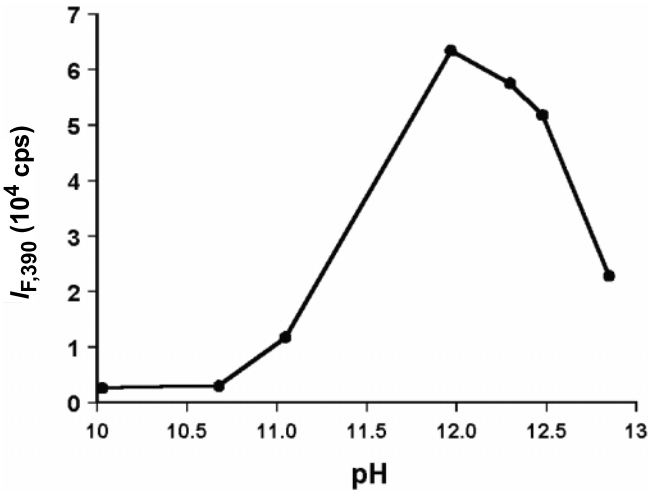


other pesticides (10–12) that also invoke the photochemical formation of a more fluorescent product as the explanation for the observed fluorescence enhancement. The eventual decrease in fluorescence after prolonged UV exposure suggests that this more fluorescent photoproduct is itself subsequently photolyzed. This subsequent photolyzation is also suggested by attempts to enhance the fluorescence of AZM solutions using a hand-held UV lamp. In all cases, no fluorescence was measurable from these solutions, even after short exposures. This lack of fluorescence must be a result of complete photolysis of the AZM to non-fluorescent photoproducts upon exposure to this relatively high intensity UV source. Such complete photolysis clearly takes much longer to occur upon exposure to the much weaker and more monochromatic UV light from the fluorimeter excitation lamp.

The values of the fluorescence enhancements of AZM observed by UV exposure are much larger than those observed by cyclodextrin inclusion, and would potentially be useful in a trace analysis technique for AZM. However, an accurate fluorescence method based on UV-irradiation would require every sample and standard solution to be exposed to exactly the same amount of UV irradiation. This uniformity would be very difficult for a number of reasons, including lamp stability and water transparency (in the case of natural water samples), and would especially be difficult in a field application. Furthermore, the fluorescence signal is actually destroyed if the AZM solution is exposed to too high an amount of UV. For these reasons, application of this observed UV-induced fluorescence enhancement of AZM is considered to be impractical, and was not pursued. However, we do plan to undertake photochemical product and laser flash photolysis studies, to identify the structure of the more fluorescent photoproduct of AZM, as well as the final non-fluorescent photoproducts.

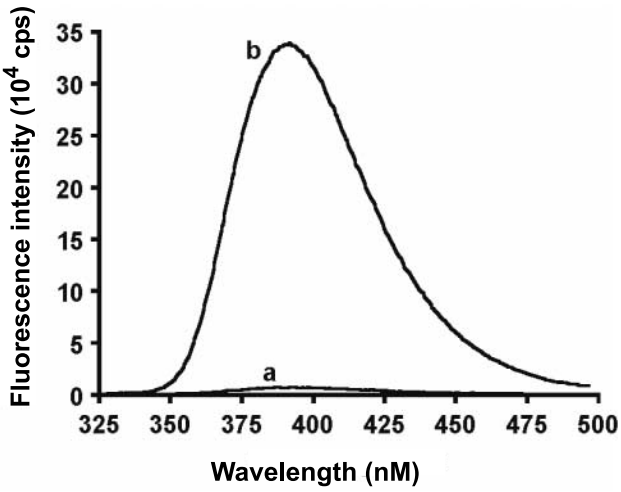
Fluorescence enhancement at high pH

As a final attempt to obtain analytically useful fluorescence enhancement of AZM, the effect of increasing the pH to basic conditions was investigated. This attempt was mainly motivated by the literature reports of significantly enhanced AZM fluorescence at high pH after heating of the AZM solutions at high temperatures (14, 15). This enhanced fluorescence was proposed to be the result of base hydrolysis of AZM to the much more fluorescent compound anthranilic acid, a reaction which was reported to be too slow to be useful at room temperature (14). Our goal was to see whether heating of the samples is in fact required for base hydrolysis and its associated fluorescence enhancement to occur.

Figure 6 shows a plot of the peak fluorescence intensity (at 390 nm) of AZM as a function of pH at room temperature using various buffered solutions. This figure clearly shows a dramatic increase in fluorescence as pH is increased to basic conditions. However, this increased fluorescence begins to decline if the pH is too high. The optimum pH for enhanced AZM fluorescence is shown to be ca. pH 12. Figure 7 shows the fluorescence spectrum of AZM in pure water at neutral pH and at pH 12. In this case (and for all subsequent measurements at pH 12), the solutions were prepared by adding NaOH solution to obtain $[OH^-] = 0.0100$ M (an identical volume of pure water was added to the neutral pH solution), giving pH = 12, with the expected pH confirmed using a pH meter. This method of pH adjustment is more convenient than using a buffer solution, and more importantly can be applied directly to natural water samples. This figure indicates the dramatic fluorescence increase that can be obtained by simply adding the appropriate amount of NaOH to an AZM solution at room temperature. This result is contrary to the literature report described above, which claims that the hydrolysis of AZM is too slow to be useful at room temperature. It is not clear why a different result was obtained in the present study. A comparison of the two spectra in Fig. 7 gives a fluorescence enhancement F/F_o of 300. The emission at pH 12 is also slightly blue-shifted with respect to that at pH 7, by ca. 12 nm. This is a much larger enhancement than was obtained by either CD addition or UV exposure. More importantly, this enhancement is large enough to be potentially useful as the basis for a fluorescence trace analysis method for AZM, as it should result in significant and easily measurable fluorescence signals from AZM, even in the low ppb range.

© 2002 NRC Canada

Fig. 7. The fluorescence spectrum of AZM at: (*a*) pH = 7.0, and (*b*) pH = 12.0.



To test the usefulness of this NaOH-hydrolyzed AZM technique, calibration plots of peak fluorescence intensity (I_F at 390 nm) as a function of AZM concentration in the ppb range were constructed. Solutions were carefully prepared using the protocol described in the experimental section. Typical results are shown in Fig. 8 for the 100–500 ppb and 5–100 ppb ranges. Analysis of these calibration plots using linear regression gave the following results:

[2] 100–500 ppb plot: I_F = 596.5 cps/ppb × [AZM] + 5447 cps, r = 0.9997

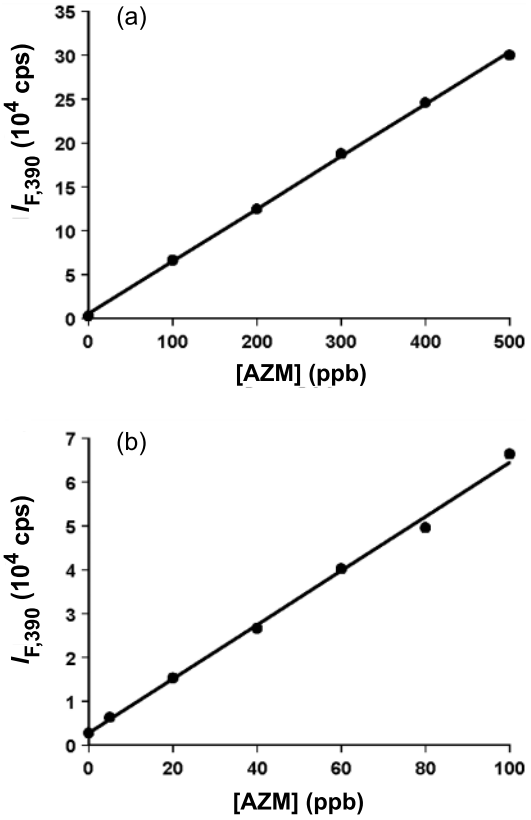
[3] 5–100 ppb plot: I_F = 616.1 cps/ppb × [AZM] + 2786 cps, r = 0.998

The excellent linearity in these plots throughout the 5 to 500 ppb range shows that this method of fluorescence enhancement could be used to determine AZM concentrations in this range, and thus is potentially useful as the basis for a fluorescence trace analysis method for AZM in natural waters. For example, the concentration of 73.2 ppb reported in a river water sample after a particular fish kill incident could easily and accurately be determined using the calibration plot shown in Fig. 8*b*.

It should be noted that we chose a standard waiting time of 5 min for the solution to hydrolyze before measurement of the fluorescence spectrum, mainly for experimental convenience. Some further fluorescence signal increase was observed past this time, with the intensity leveling off after approximately 30 min. Calibration curves with higher signals were obtained when samples were allowed to hydrolyze for 30 min before the spectrum was measured; however, we did not feel that the higher signals obtained warranted the greatly increased waiting time in the experiment, especially considering the excellent results obtained with the shorter waiting time.

We are currently investigating the application of this NaOH-induced fluorescence enhancement method to the development of a trace analysis method for AZM determination in natural waters. This application will present an additional potential complication, namely unknown fluorescence background signals, which could vary from sample to sample with natural water samples. Thus, comprehensive studies of the fluorescence signal measured from "clean" (i.e. AZM-free) natural water samples must be undertaken first, to see if such background fluorescence of waters from PEI streams will be significant compared to the signals obtained from enhanced AZM fluorescence. It should be noted that there have been numerous reports in the literature of fluorescence detection of various pollutants, including pesticides, in natural waters, in which background fluorescence was found to be insignificant (7–12).

Fig. 8. Calibration curves for the peak intensity of AZM as a function of concentration upon addition of NaOH over two different AZM concentration ranges: (*a*) 100–500 ppb, and (*b*) 5–100 ppb. The solid line is the linear fit of the data, with parameters given in the text.



Conclusions

AZM fluorescence is moderately enhanced by the addition of hydroxypropyl-β-cyclodextrin, by a factor of ca. three. However, this enhancement is far too small to be applicable to a fluorescence-based analytical method. AZM fluorescence was found to be more significantly enhanced by exposure to UV radiation (320 nm), presumably by photolysis to a more fluorescent product. However, difficulties in exposing samples to equal UV dosage, especially in the field, would be expected to severely limit the practicality of this enhancement method. Finally, an extremely large AZM fluorescence enhancement of a factor of 300 was obtained at an increased pH of 12.0. This method did not require heating of

© 2002 NRC Canada

the solution as was previously reported in the literature; in fact, the large enhancement could be obtained simply by adding a specific amount of NaOH solution to the sample, mixing, and measuring the fluorescence spectrum. This method was shown to produce calibration curves with excellent linearity, even in the range of 5–100 ppb, the concentration range in which AZM has been shown to exist in natural waters during and just after fish kill incidents. The next phases in this project will involve the application of this high pH-enhanced fluorescence to natural water samples, followed by investigations into the use of a portable fluorimeter for the development of a fluorescence-based field technique for this pesticide. Although the additional complication of unknown levels of background fluorescence from the chemically complicated natural water samples will be present, fluorescence-based techniques for other pesticides have been successfully applied to river water samples.

Synthesis and reactivity of palladium and platinum diimine complexes containing boronate esters

Arienne S. King, Liliya G. Nikolcheva, Christopher R. Graves, Anna Kaminski, Christopher M. Vogels, Robert H.E. Hudson, Robert J. Ireland, Stephen J. Duffy, and Stephen A. Westcott

Abstract: Condensation of α-diketones (2,3-butanedione, benzil, and acenaphthenequinone) with 3-$H_2NC_6H_4Bpin$ (pin = 1,2-$O_2C_2Me_4$) gave the corresponding boron-containing α-diimines. The addition of these ligands to $[MCl_2(coe)]_2$ (coe = *cis*-cyclooctene, M = Pd or Pt) gave complexes of the type *cis*-MCl_2(α-diimine) in moderate to high yields. The platinum complexes have been examined for their ability to bind to DNA using enzyme digest studies. These complexes were found to bind to single-stranded DNA as well as, or better than, the non-boron containing controls, and showed binding similar to that of cisplatin (*cis*-$PtCl_2(NH_3)_2$).

Key words: boronate esters, diazabutadienes, DNA-binding, platinum.

Résumé : La condensation d'α-dicétones (butane-2,3-dione, benzile, et acénaphtènequinone) avec le 3-$H_2NC_6H_4Bpin$ (pin = 1,2-$O_2C_2Me_4$) conduit à la formation d'α-diimines contenant du bore. L'addition de ces ligands au $[MCl_2(coe)]_2$ (coe = *cis*-cyclooctène; M = Pd, Pt) fournit des complexes du type *cis*-MCl_2(α-diimine) avec des rendements allant de modérés à élevés. Faisant appel à des études de digestion d'enzymes, on a évalué la capacité de ces complexes du platine à se fixer sur l'ADN. Vis-à-vis de l'ADN à brin unique, ces complexes se fixent aussi bien, ou mieux, que les contrôles ne contenant pas de bore et leur taux de fixation est semblable à celui du cisplatine, *cis*-$PtCl_2(NH_3)_2$.

Mots clés : esters de l'acide boronique, diazabutadiènes, fixation de l'ADN, platine.

[Traduit par la Rédaction]

Introduction

Interest in compounds containing boronic acids $[RB(OH)_2]$ or boronate esters $[RB(OR')_2]$ arises from their remarkable versatility in organic synthesis (1) as well as from their potent biological activities (2–11). As part of our ongoing program generating novel boron compounds (12), we decided to examine the synthesis and reactivity of a series of α-diimines containing boronate esters.

1,4-Diazabutadienes (α-diimines) have both been used extensively as ligands for transition metals, owing to their ease of preparation and ability to fine-tune both steric and electronic properties (13). The resulting coordination complexes have been utilized in organic synthesis and catalysis (13–20) and as luminescence labels for the detection and photochemical cleavage of DNA (21). Diazabutadienes have also been used in dehalosilylation – ring-closure reactions of $SbCl_3$ and $BiCl_3$ to give the corresponding 1,2,5-pnictadiazoles (22). Some of the unique chemical and physical properties observed for metal diimine complexes have been attributed to the relatively strong π-acceptor ability of the diazabutadiene ligands, resulting from an energetically low-lying LUMO (23). Although fluorinated α-diimines have recently been prepared (24), to the best of our knowledge no such systems containing boronate esters have been reported. Diimines containing these electron-withdrawing groups would be expected to possess low lying LUMOs, and consequently, be strong π-acceptors. The results of our initial investigations into preparing these compounds, and the corresponding palladium and platinum complexes, are presented herein.

Experimental

The reagents and solvents used were obtained from Aldrich Chemicals. NMR spectra were recorded on a JEOL JNM-GSX270 FT-NMR spectrometer. ^{1}H NMR chemical shifts are reported in ppm and referenced to residual protons in deuterated solvent at 270 MHz. ^{11}B NMR chemical shifts are referenced to external $F_3B{\cdot}OEt_2$ at 87 MHz. ^{13}C NMR chemical shifts are referenced to solvent carbon resonances as internal standards at 68 MHz. Multiplicities are reported as (s) singlet, (d) doublet, (t) triplet, (q) quartet, (m) multiplet, (br) broad, and (ov) overlapping. Infrared spectra were obtained using a Mattson Genesis II FT-IR spectrometer, and are reported in cm^{-1}. Melting points were measured (uncorrected) with a Mel-Temp apparatus. Microanalyses for C, H, and N were carried out at Desert Analytics (Tucson,

AZ) and CMA (Vancouver, BC). All reactions were carried out in ambient conditions and the products were found to be stable indefinitely under those circumstances. Polymerization experiments were done by Dr. Marc Kristen (Basell Polyolefin GmbH).[2]

Synthesis

1,4-Bis[3-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)-phenyl]-2,3-dimethyl-1,4-diaza-1,3-butadiene (1a)

An EtOH solution (5 mL) of 3-$H_2NC_6H_4$Bpin (3-APBpin (pin = 1,2-$O_2C_2Me_4$)) (1.67 g, 7.62 mmol) was added dropwise to 2,3-butanedione (0.30 g, 3.48 mmol) in EtOH (3 mL). Following the addition of formic acid (1 drop), the reaction was heated at reflux (4 h) and then stored at 0°C, whereupon a beige precipitate formed, which was collected by suction filtration and washed with hexane (3 × 10 mL). Yield: 1.10 g (65%); mp 225–227°C. IR (Nujol) (cm^{-1}): 2937, 2912, 2856, 1637, 1599, 1570, 1483, 1464, 1417, 1358, 1321, 1265, 1201, 1140, 1076, 966, 901, 881, 849, 804, 779, 714, 706, 671. ^{1}H NMR ($CDCl_3$) δ: 7.54 (d, *J* = 8 Hz, 2H, Ar), 7.36 (ov dd, *J* = 8 Hz, 2H, Ar), 7.22 (br s, 2H, Ar), 6.85 (br d, *J* = 8 Hz, 2H, Ar), 2.11 (s, 6H, N=C(CH_3)), 1.34 (s, 24H, BO_2(CH_3)$_4$). ^{13}C NMR δ: 168.3, 150.5, 130.2, 130 (br, C-B), 128.5, 124.9, 121.6, 83.9, 25.0, 15.5. ^{11}B NMR δ: 31 (br).

1,4-Bis[3-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)-phenyl]-2,3-diphenyl-1,4-diaza-1,3-butadiene (1b)

A CH_2Cl_2 solution (10 mL) of 3-APBpin (1.17 g, 5.35 mmol) was added dropwise to benzil (0.50 g, 2.38 mmol) in methylene chloride (10 mL). Activated molecular sieves (10 g) were added and the reaction was heated at reflux for 24 h. The molecular sieves were removed by suction filtration and washed with CH_2Cl_2 (3 × 10 mL). Removal of the solvent under vacuum gave an oil that was triturated with cold Et_2O (10 mL) to afford a yellow solid. Yield: 0.87 g (60%); mp 224°C. IR (Nujol) (cm^{-1}): 2915, 2856, 1620, 1461, 1376, 1315, 1268, 1142, 1071, 965, 899, 853, 785, 697. ^{1}H NMR ($CDCl_3$) δ: 7.88 (br d, *J* = 8 Hz, 4H, Ar), 7.46–7.35 (ov m, 8H, Ar), 7.06 (ov dd, *J* = 8 Hz, 2H, Ar), 6.97 (br s, 2H, Ar), 6.56 (br d, *J* = 8 Hz, 2H, Ar), 1.26 (s, 12H, BO_2(CH_3)$_4$), 1.22 (s, 12H, BO_2(CH_3)$_4$). ^{13}C NMR δ: 164.4, 148.8, 138.0, 131.0, 130.9, 130 (br, C-B), 128.7, 128.4, 127.8, 126.7, 122.9, 83.6, 24.9, 24.8. ^{11}B NMR δ: 31 (br).

1,4-Bis[3-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)-phenyl]-2,3-acenaphthene-1,4-diaza-1,3-butadiene (1c)

A CH_2Cl_2 solution (10 mL) of 3-APBpin (1.20 g, 5.49 mmol) was added dropwise to acenaphthenequinone (0.50 g, 2.74 mmol) in CH_2Cl_2 (10 mL), in the presence of activated molecular sieves (10 g). The reaction was allowed to proceed at room temperature for 12 days, at which point the sieves were removed by suction filtration and the solution was washed with CH_2Cl_2 (3 × 10 mL). Removal of the solvent under vacuum gave an oily mixture that was triturated with Et_2O (3 × 5 mL) to afford an orange solid. Yield: 1.11 g (70%); mp 245°C. IR (Nujol) (cm^{-1}): 2974, 2882, 2843, 1666, 1644, 1594, 1568, 1461, 1415, 1359, 1315, 1271, 1231, 1143, 1098, 1072, 1045, 964, 943, 871, 850, 783, 703. ^{1}H NMR ($CDCl_3$) δ: 7.85 (d, *J* = 8 Hz, 2H, Ar), 7.69 (d, *J* = 8 Hz, 2H, Ar), 7.55 (s, 2H, Ar), 7.46 (ov dd, *J* = 8 Hz, 2H, Ar), 7.33 (ov dd, *J* = 8 Hz, 2H, Ar), 7.20 (br d, *J* = 8 Hz, 2H, Ar), 6.78 (d, *J* = 8 Hz, 2H, Ar), 1.33 (s, 24H, BO_2(CH_3)$_4$). ^{13}C NMR δ: 161.2, 151.4, 141.8, 131.2, 130.7, 130 (br, C-B), 128.8 (2C), 128.7, 127.7, 124.3, 124.1, 121.2, 83.9, 25.0. ^{11}B NMR δ: 30 (br).

(1,4-Bis[3-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)-phenyl]-2,3-dimethyl-1,4-diaza-1,3-butadiene)dichloropalladium(II) (2a)

To a stirred CH_2Cl_2 solution (10 mL) of [$PdCl_2$(coe)]$_2$ (0.10 g, 0.17 mmol), **1a** (0.18 g, 0.37 mmol) in CH_2Cl_2 (5 mL) was added dropwise. The reaction was allowed to proceed for 18 h, at which point the solvent was removed under vacuum to afford an orange solid, which was then triturated with Et_2O (3 × 10 mL). Yield: 0.19 g (84%); mp 200–202°C (decomp.). IR (Nujol) (cm^{-1}): 2943, 2904, 2870, 1603, 1462, 1427, 1358, 1311, 1269, 1140, 1076, 964, 858, 704. ^{1}H NMR ($CDCl_3$) δ: 7.76 (br d, *J* = 8 Hz, 2H, Ar), 7.54 (br ov m, 2H, Ar), 7.38 (br ov m, 4H, Ar), 2.13 (br s, 6H, N=C(CH_3)), 1.34 (s, 24H, BO_2(CH_3)$_4$). ^{13}C NMR δ: 179.6, 145.0, 134.4, 129.8 (br, C-B), 128.9, 128.3, 126.1, 84.2, 25.1, 21.2. ^{11}B NMR δ: 31 (br). Anal. calcd. for $PdCl_2C_{28}H_{38}N_2B_2O_4$: C 50.51, H 5.77, N 4.21; found: C 49.94, H 5.87, N 4.16.

(1,4-Bis[3-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)-phenyl]-2,3-diphenyl-1,4-diaza-1,3-butadiene)dichloropalladium(II) (2b)

A CH_2Cl_2 solution (5 mL) of **1b** (0.12 g, 0.20 mmol) was added dropwise to a stirred solution of [$PdCl_2$(coe)]$_2$ (0.05 g, 0.09 mmol) in CH_2Cl_2 (10 mL). The reaction was allowed to proceed for 6 h, at which point the solvent was removed under vacuum to afford an orange solid. The solid was triturated with Et_2O (3 × 10 mL). Yield: 0.11 g (77%); mp 214–216°C (decomp.). IR (Nujol) (cm^{-1}): 2937, 2868, 1601, 1462, 1423, 1377, 1358, 1319, 1271, 1142, 1074, 999, 852, 723, 700, 561. ^{1}H NMR ($CDCl_3$) δ: 7.52 (br d, *J* = 8 Hz, 4H, Ar), 7.38 (br d, *J* = 8 Hz, 2H, Ar), 7.08–6.92 (br ov m, 12H, Ar), 1.29 (s, 24H, BO_2(CH_3)$_4$). ^{13}C NMR δ: 178.6, 145.4, 134.0, 132.2, 130.3, 130 (br, C-B), 129.9, 128.7, 127.9, 127.6, 127.3, 84.0, 25.0. ^{11}B NMR δ: 31 (br). Anal. calcd. for $PdCl_2C_{38}H_{42}N_2B_2O_4$: C 57.78, H 5.37, N 3.55; found: C 56.94, H 5.31, N 3.49.

(1,4-Bis[3-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)-phenyl]-2,3-acenaphthene-1,4-diaza-1,3-butadiene)dichloropalladium(II) (2c)

A CH_2Cl_2 solution (5 mL) of **1c** (0.11 g, 0.19 mmol) was added dropwise to a stirred solution of [$PdCl_2$(coe)]$_2$ (0.05 g, 0.09 mmol) in CH_2Cl_2 (10 mL). The reaction was allowed to proceed for 6 h, whereupon removal of the solvent under vacuum afforded an orange solid, which was triturated with Et_2O (3 × 5 mL). Yield: 0.11 g (80%); mp 338°C (decomp.). IR (Nujol) (cm^{-1}): 2967, 2945, 2894, 2871, 2847, 1599, 1579, 1461, 1376, 1359, 1141, 971, 735, 701. ^{1}H NMR

A CH_2Cl_2 solution (5 mL) of **1c** (0.16 g, 0.27 mmol) was added dropwise to a stirred solution of $[PtCl_2(coe)]_2$ (0.10 g, 0.13 mmol) in CH_2Cl_2 (10 mL). The reaction was allowed to proceed for 4 h, at which point the solvent was removed under vacuum. The resultant oily solid was triturated with Et_2O (3 × 10 mL) to afford a red solid. Yield: 0.17 g (77%); mp 350°C (decomp.). IR (Nujol) (cm^{-1}): 2924, 2855, 1600, 1420, 1358, 1303, 1210, 1145, 967, 856, 777, 703. ^1H NMR ($CDCl_3$) δ: 8.24 (d, *J* = 8 Hz, 2H, Ar), 7.96 (d, *J* = 8 Hz, 2H, Ar), 7.88 (br s, 2H, Ar), 7.67–7.57 (ov m, 4H, Ar), 7.40 (ov dd, *J* = 8 Hz, 2H, Ar), 6.89 (br d, *J* = 8 Hz, 2H, Ar), 1.33 (s, 24H, $BO_2(CH_3)_4$). ^{13}C NMR δ: 175.6, 147.2, 144.5, 135.6, 132.2, 131.0, 130 (br, *C*-B), 129.7, 129.1, 128.8, 126.3, 126.1, 124.5, 84.2, 25.0. ^{11}B NMR δ: 30 (br). Anal. calcd. for $PtCl_2C_{36}H_{38}N_2B_2O_4$: C 50.84, H 4.51, N 3.29; found: C 50.44, H 4.69, N 3.40.

Nuclease digest studies

Binding of the platinum complexes to DNA was investigated using enzymatic degradation of the DNA to nucleosides. Nucleosides were detected using reverse-phase HPLC. The sequence of the model 20-mer DNA strand used in this study (eq. [1]) has two predominant cisplatin-binding-sites: TGGT on one strand and AGGA on the complementary strand. Both the single and the double DNA strands were incubated with each platinum complex, in a 1:3 DNA:Pt molar ratio, for 24 h, in the dark. Samples (2.0 nmol of single-stranded and 1.0 nmol of double-stranded DNA) were digested in series with DNAse I (Amersham Biosciences) (36 U, 4 h), nuclease P1 (Sigma) (10 U, 18 h), and alkaline phosphatase (Promega) (20 U, 4 h), at 37°C, to convert the DNA strand into mononucleosides. The samples were heated to 90°C for 2 min, centrifuged at 10 000 g for 30 s, and then the protein pellet was discarded. The nucleoside composition in each sample was analyzed at 254 nm on a C_{18} column, using a Pro-Star RP-HPLC (Varian). The isocratic solvent system used was Et_3NH–OAc (93%, 20 mM, pH 6.5) and CH_3CN (7%, 1 mL min^{-1}). The areas under the nucleoside peaks were integrated and the G:C ratio analyzed and compared with ANOVA, followed by post-hoc multiple comparisons with Bonferonni's adjustment.

Results and discussion

Diimines

Protection of the boronic acid groups in commercially available 3-aminophenylboronic acid (3-$H_2NC_6H_4B(OH)_2$), by transesterification with pinacol ($HOCMe_2CMe_2OH$) to prevent unwanted formation of anhydrides (25), gave quantitative formation of aminoboronate ester 3-$H_2NC_6H_4$Bpin (3-APBpin (pin = $O_2C_2Me_4$)) (12). Unfortunately, the addition of 3-APBpin to glyoxal gave complex product distributions, as evidenced by ^1H NMR spectroscopy, and isolation of the corresponding boron-containing diazabutadiene proved unsuccessful. This result is not surprising as previous studies have shown that glyoxal reacts with electron-deficient amines, such as 3-nitroaniline, to give high yields of 1,2-dihydroxy-1,2-diamino compounds (26). Conversely, we found that reactions of 3-APBpin proceeded smoothly with substituted α-diketones, 2,3-butanedione, benzil, and acenaphthenequinone, to give the corresponding boron-containing α-diimines (**1a**–**1c**) in moderate yields (Fig. 1). All diazabutadienes were characterized by multinuclear NMR spectroscopy. A peak at ca. δ 30 ppm in the ^{11}B NMR spectra is indicative of a three-coordinate boron atom, which suggests that no appreciable intermolecular interaction

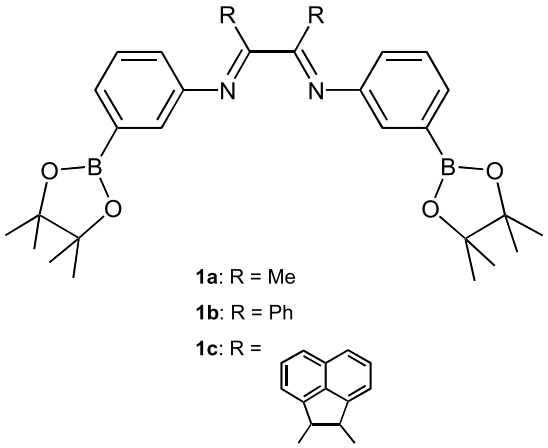
Fig. 1. α-Diimines derived from 3-APBpin.



occurs with the basic imine functionality in solution (27). Although one boron resonance is observed for **1b**, it is interesting to note that two separate peaks are observed for the Bpin methyl groups in the ^{1}H NMR spectra, presumably arising from the perpendicular phenyl groups in the backbone. It is plausible that restricted rotation about the B–C bond causes this loss of symmetry.

Palladium complexes

To examine the potential of these electron withdrawing diimines to act as ligands, we have prepared palladium complexes **2a**–**2c** by the addition of **1a**–**1c** to organic-soluble $[PdCl_2(coe)]_2$ (28, Fig. 2). Indeed, complexes **2a**–**2c** were prepared in high yield and characterized using a number of physical methods, including multinuclear NMR spectroscopy. The boron atom appears to maintain its three-coordinate geometry in solution, as evidenced by a peak at 30 ppm in the ^{11}B NMR spectra. Coincidentally, only one peak is observed for the Bpin methyl groups in the ^{1}H NMR spectra for **2b**.

Electrophilic 1,4-diazabutadiene palladium complexes have found extensive application as catalysts in the polymerization of alkynes (29) and alkenes (14, 30–34). Unfortunately, attempts to catalyze the polymerization of ethylene using complexes **2a**–**2c** proved unsuccessful. Although the addition of electron-withdrawing boronate ester groups should enhance polymerization activities, previous studies have shown that palladium diimine complexes also require bulky substituents in the ortho- position of the *N*-aryl group to be effective catalysts. Indeed, complexes lacking this steric requirement are known to give oligomerization products (14). It appears that the boronate ester groups in **2a**–**2c** are too far removed from the metal center to provide the steric requirement needed for polymerization. Future studies will, therefore, concentrate on designing analogous diimine catalysts derived from 2-APBpin (35).

Platinum complexes

Cisplatin (*cis*-$PtCl_2(NH_3)_2$) is one of the most effective chemotherapeutic agents currently used for the treatment of ovarian, bladder, and testicular cancer (36–44). The drug has to be administered intravenously, however, and has dose-limiting side effects such as severe renal toxicity, neurotoxicity, and emesis, arising, in part, from the low solubility of cisplatin in water. These problems, along with the fact that cancer cells treated with cisplatin acquire resistance to the drug, have resulted in considerable research focussed on the development of a more effective platinum drug that can be administered orally and with reduced side effects. Cisplatin acts by making intra- and interstrand cross-links with DNA, which result in a halt of replication and lead to programmed cell death. Structural analogues of cisplatin, however, react with DNA in a way similar to the parent drug and therefore cause similar biological effects (36). In fact, to be considered for clinical evaluation, a new platinum drug should have an activity different from that of cisplatin and thereby eliminate multi-factorial drug resistance. Therefore, it is highly unlikely that future platinum drug candidates will adhere to the classical structure-activity relationships for cisplatin analogues. Toward this objective, we have prepared platinum complexes (**3a**–**3c**) containing α-diimines by addition to $[PtCl_2(coe)]_2$ (45, Fig. 2). The use of bidentate ligands prevents trans labilization and undesired displacement of the ligands by sulfur and nitrogen donors in biomolecules, interactions that are believed to be responsible for the adverse side effects associated with cisplatin (42).

Interactions of platinum complexes with DNA

As the efficacy of platinum-based anticancer drugs is believed to arise from the coordination of the metal to DNA (43), we decided to examine the binding potential of plati-

Fig. 3. The G:C ratio from the nuclease digests of single-stranded 20-mer DNA. Values are mean ±95%CI (n = 10). Complex **4c** is not significantly different from the non-platinum control at $p > 0.05$.

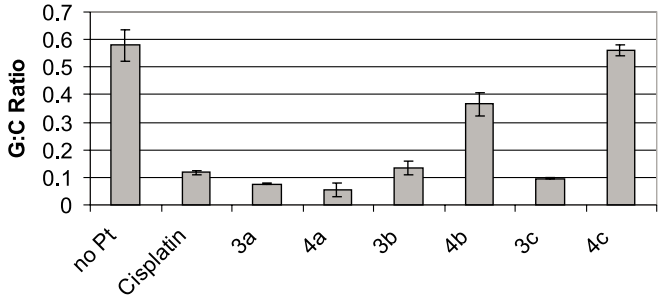

Fig. 4. The G:C ratio from the nuclease digests of double-stranded 20-mer DNA. Values are mean ±95%CI (n = 10). Complexes **3b**, **4b**, and **4c** are not significantly different from the non-platinum control at $p > 0.05$.

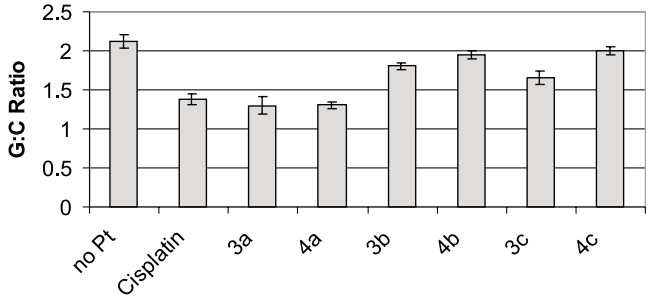

num complexes **3a**–**3c** using a 20-bp strand (46). This DNA model contains one preferential binding site (a TGGT motif) in the single strand and a second binding site (AGGA) on the complementary strand. The degree of platinated DNA can be quantified by enzymatically degrading the DNA strand and separating the mononucleosides and Pt-containing dinucleotides using reverse-phase HPLC (47–49). Platinum binding will result in the formation of *cis*-[Pt(diimine){d(GpG)}], and the amount of free guanosine can, therefore, be negatively correlated to the degree of platinated DNA. Cytosine can be used as an internal standard because its concentration is not affected by platinated DNA (50–52).

As expected, the nuclease digest results showed that treatment with cisplatin significantly decreased the G:C ratio (compared to the unplatinated control) in both single-stranded (Fig. 3) and double-stranded DNA (Fig. 4), and confirmed that cisplatin binds well to both types of DNA. The binding affinity for single-stranded DNA was also found to decrease as the size of the backbone of the non-boron diimine compounds (**4a**–**4c**, 14) increased. This result was also evident in the double-stranded samples. It is possible that the larger, more sterically-hindered backbones of **4b** and **4c** do not fit into the binding site and are therefore excluded from the major groove of double-stranded DNA. Remarkably, the boron-containing compounds (**3a**–**3c**) bound to single-stranded DNA as well as, or better than, the non-boron controls, and exhibited binding capabilities not significantly different from those of cisplatin. Binding among the boron complexes could not be correlated with the size of the backbone. These results suggest that the boronate ester may indeed contribute to the increased affinity of these compounds to bind to single-stranded DNA. Compound **3b** showed significant binding to single-, but not to double-stranded DNA; presumably, the flexibility of the DNA single-strand was sufficient to allow access to the binding site, but the complex could not fit into the major groove of the helix in the double-stranded DNA. This binding difference may provide higher selectivity in rapidly dividing cancer cells, where the DNA is replicated at a higher rate, and, as a result, is more often in the single-stranded form. Achieving significant binding to single-, but not to double-stranded DNA, might provide a solution to the problems associated with current platinum therapies. Future work in this area will examine the cytotoxicities of compounds **3a**–**3c**, and relate these findings to binding studies in an effort to design more potent and less toxic platinum complexes for the treatment of cancer.

Conclusion

α-Diimines, derived from the condensation of substituted α-diketones and aminoboronate ester 3-$H_2NC_6H_4$Bpin (pin = $O_2C_2Me_4$), have been prepared in moderate yield and used as ligands for palladium and platinum. The platinum complexes have been studied for their ability to bind to DNA. The boron-containing complexes bound to single-stranded DNA as well as, or better than, the non-boron containing controls, and showed binding not significantly different from that of cisplatin.

Attempt to approach the role of phenolic phenylpropenol structures in the photoyellowing of softwood mechanical pulps

Brigitte Ruffin, Stéphane Grelier, Aziz Nourmamode, and Alain Castellan

Abstract: Three biphenyl (**I**, **II**, **III**) compounds and a benzylarylether (**IV**) compound were synthesized to detect and quantify the presence of phenolic phenylpropenols in unbleached, peroxide-bleached, or sodium borohydride-reduced mechanical softwood pulps. The methodology used is based on a gas chromatography – mass spectrometry search of the prepared compounds in the residue obtained after ethylation, thioacidolysis, and desulfurization of the pulps. Detection of biphenyl **I** ($\approx 4 \times 10^{-6}$ mol g^{-1}) in unbleached and $NaBH_4$-reduced pulps is indicative of the presence of phenolic coniferaldehyde units in these pulps. Traces of biphenyl **II**, found in the peroxide-bleached pulp, probably came from ferulic acid units formed by oxidation of coniferaldehyde by H_2O_2. No biphenyl ether **III** or benzylaryl ether **IV** were detected in the three pulps. This result indicates that phenolic phenylpropenol units are not present in softwood mechanical pulps and do not contribute to the fast part of their photoyellowing.

Key words: mechanical pulp, photoyellowing, phenol, coniferyl alcohol, biphenyl.

Résumé : Trois biphenyls (**I**, **II**, **III**) et un éther benzylaryle (**IV**) ont été synthétisés afin de détecter et quantifier la présence de structures phénylpropénol dans des pâtes mécaniques de bois tendre non-blanchie, blanchie avec du peroxyde d'hydrogène ou réduite avec du borohydrure de sodium. La méthodologie utilisée est basée sur une recherche, par chromatographie – spectrométrie de masse, des composés préparés dans le résidu obtenu après éthylation, thioacidolyse et désulfuration des pâtes. La détection du biphényl **I** ($\approx 4 \times 10^{-6}$ mol g^{-1}) dans la pâte non-blanchie et dans celle réduite par $NaBH_4$ indique la présence de motifs coniféraldéhyde phénolique dans ces pâtes. Les traces du biphényl **II**, trouvées dans la pâte blanchie avec H_2O_2, proviennent vraisemblablement de structures acide férulique formées par oxydation par H_2O_2 d'unités coniféraldéhyde. L'absence de détection du biphényl **III** ou de l'éther benzylaryle dans les trois pâtes indique que les unités phénylpropénol phénolique ne sont pas présentes dans les pâtes mécaniques de bois tendre et ne contribue pas à la phase rapide de leur photojaunissement.

Mots clés : pâte à papier, lignine, photojaunissement, phénols, alcool conifférylique.

Introduction

High-yield pulps are obtained by the mechanical refining of wood. This defibration of lignocellulosic material might induce some chemical modification and new chemical structures might be formed. Phenylcoumaran and β-1 units are turned into stilbenes (1–3), β-*O*-4 entities are converted into *para*-hydroxybenzaldehydes (4), and coniferyl alcohols create α,β-unsaturated groups (5). Acidic treatment generates stilbenes (6) and phenylcoumarones, which are very sensitive to UV light (7, 8).

Comparison of the fluorescence emission between stone-ground wood pulp and native wood (*abies* (fir)) (9) leads to the conclusion that pulp and wood behave similarly. Reduction of the material with sodium borohydride enhanced the fluorescence due to coniferyl alcohol and biphenyl units. It was observed that when paper and wood were subject to photobleaching of the fluorescent chromophores, the materials exhibited a photochromic effect (10). The borohydride-reduced woods performed differently in the photobleaching experiment from their paper counterpart. These subtle differences were attributed to stilbene chromophores formed by mechanochemistry present in paper and not in the wood (10). Nevertheless, studies on the effect of mechanical refining on the formation of photoactive chromophores in black spruce chips casts doubt on this effect (11).

When lignin-rich pulps are bleached with alkaline hydrogen peroxide, β-1 units are transformed into stilbenes (12), and α-carbonyl phenols and coniferaldehydes are converted into methoxyhydroquinones (13, 14). All these chromophores are considered to have a key role in the photoyellowing of bleached lignin-rich pulps (15). Lee and Sumimoto (16) considered that *para*-hydroxybenzoquinone derivatives, including stilbene-, biphenyl-, or diphenylether-conjugated structures, were the major ones responsible for color reversion of pulps. However, recent studies on light-induced brightness loss of pulps, which were targeted on the role of stilbene phenols formed from β-1 units (17) and stilbenes (including hydroquinone moieties formed from β-5 units (18)), indicate a minor role of these structural elements.

According to model studies (8, 19), phenolic coniferyl alcohol units were found to be very light-sensitive and might

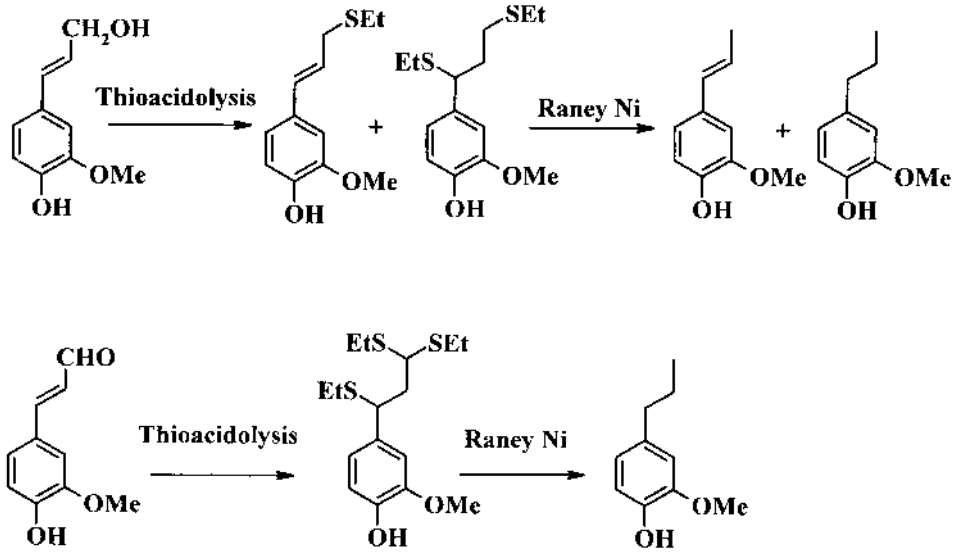
Fig. 1. Compounds obtained by thioacidolysis followed by desulfurization (Raney nickel) of coniferyl alcohol and coniferaldehyde (22, 24).



participate in the photoyellowing of bleached high-yield pulps. In our continuous effort to determine structures at the origin of the fast photoyellowing of lignocellulosic materials (17 to 18, 20 to 21), we present in this paper an attempt to detect, in pulp, the phenolic phenylpropenol moiety included in biphenyl or diarylether structures. The methodology used was thioacidolysis, followed by desulfurization with Raney nickel, GC–MS analysis, and comparison of the data with those from authentic samples synthesized for the purpose.

Results and discussion

General

During irradiation of thermomechanical pulps, Pan et al. (22) observed the formation of coniferyl aldehydes and the disappearance of coniferyl alcohols. Moreover, fluorescence studies on milled wood lignin (MWL) have revealed a great reactivity of coniferyl alcohol structures under irradiation (23); in particular, they are turned into coniferyl aldehydes and other structures that emit at 500 nm. It was observed that coniferyl aldehydes deactivate the emission at 400 nm caused by biphenyl structures. Based on this observation, we decided to attempt to detect and quantify phenolic phenylpropenols in high yield pulps and follow their evolution under UV–vis irradiation.

A widespread method for analysis and quantitative determination of lignin units is thioacidolysis; this method is a depolymerization of lignin by ethanethiol in the presence of $BF_3{\cdot}Et_2O$, followed by gas chromatography separation and mass spectrometry analysis of the products (24). For analysis of lignin-condensed structures by thioacidolysis, a desulfurization step with Raney nickel is necessary, because condensed structures are too heavy to be analyzed by GC. However, reductive treatment leads to the formation of a propyl chain for both coniferyl alcohol and coniferyl aldehyde (Fig. 1) (24).

To differentiate phenolic coniferyl alcohol elements from non-phenolic coniferyl alcohol units, the pulp was ethylated. In this study, we looked for coniferyl alcohol structures included in the lignin macrostructure as biphenyl elements, such as structures **A** and **B**, and diarylether units, such as structure **C** (Fig. 2). Biphenyl structures were found to exist in high proportion in lignin in the form of dibenzodioxocin (25).

By thioacidolysis followed by desulfurization, structure **A** should lead to compounds **I–III** (Fig. 2). The same treatment applied on structure **B** should give compounds **I** and **III**. The syntheses of the biphenyl model compounds **I–III** and the diarylether model **IV** (representative of structure **C**) (Fig. 2) were completed. Compound **V**, isomer of **III**, was not considered because it is not formed from structure **B**, and unit **A** is accounted for by dimers **I–III**. The investigation was made on three pulps: unbleached mechanical softwood pulp (MSP) (mainly from spruce), hydrogen peroxide bleached MSP, and sodium borohydride reduced MSP (vide infra).

Synthesis of compounds

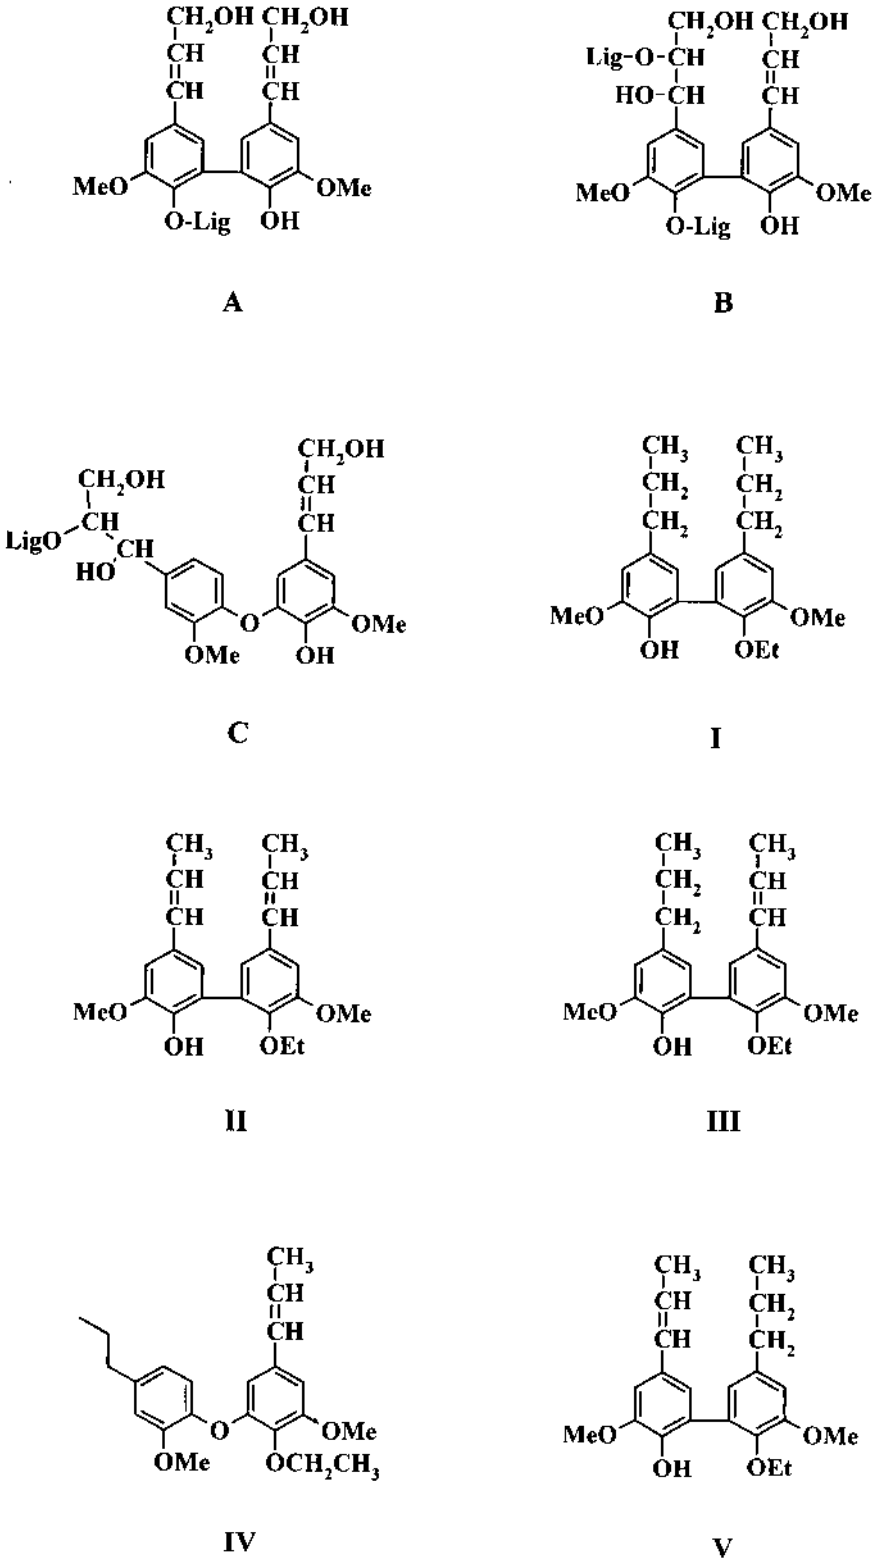
Synthesis of compound **I** is described in Fig. 3. The key step in this synthesis is the monoprotection of one of the two phenoxyl groups of the biphenyl. Eugenol is converted into the dehydrodimer by oxidative coupling with potassium ferricyanide. The compound obtained is then hydrogenated and monoethylated by treatment with diethylsulfate with sodium hydroxide, thanks to the different acidity between the two phenolic groups (26).

Compound **II** could not be obtained by isomerization of the corresponding isomer at high temperature (unlike isoeugenol, which is obtained from eugenol by treatment with sodium hydroxide in diethylene glycol (27)). Other attempts with different solvents (DMSO, THF) or bases (*t*-BuOK) were conducted without success. Compound **II** was prepared according to the route described in Fig. 4. GC–MS analysis of compound **II** revealed the presence of four propene chain isomers in the relative ratio 36:30:19:15. According to their relative stability, the highest and lowest figures could be assigned to *E*,*E* and *Z*,*Z* isomers.

Compound **III** was synthesized according to the scheme described in Fig. 5. The key step for this synthesis is the Kharasch reaction between a Grignard reagent and an aryl halide (28, 29).

© 2002 NRC Canada

Fig. 2. Phenolic phenylpropenol units present in softwood pulp and structures resulting from thioacidolysis and desulfurization treatments.



Compound **IV** was obtained by the reaction sequence described in Fig. 6. The yield (3.5%) is very low because the main product formed by this procedure was compound **2**. The latter is formed by oxidative coupling of compound **10** in the presence of Cu^{2+} (30).

Analysis of the pulps

To characterize only phenolic coniferyl alcohol structures, the pulp was treated with diethylsulfate in alkaline medium — this is a very efficient reaction to etherify phenols. Then the pulps were thioacidolysed and desulfurized. GC–MS

Fig. 3. Synthetic scheme of compound **I**.

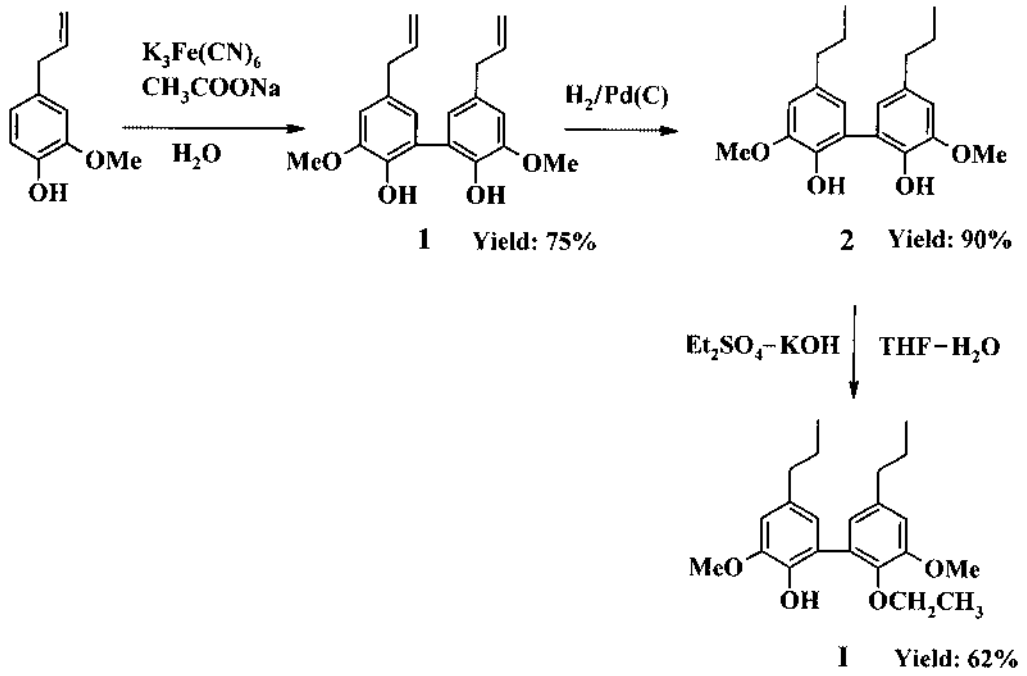

Fig. 4. Synthetic scheme of compound **II**.

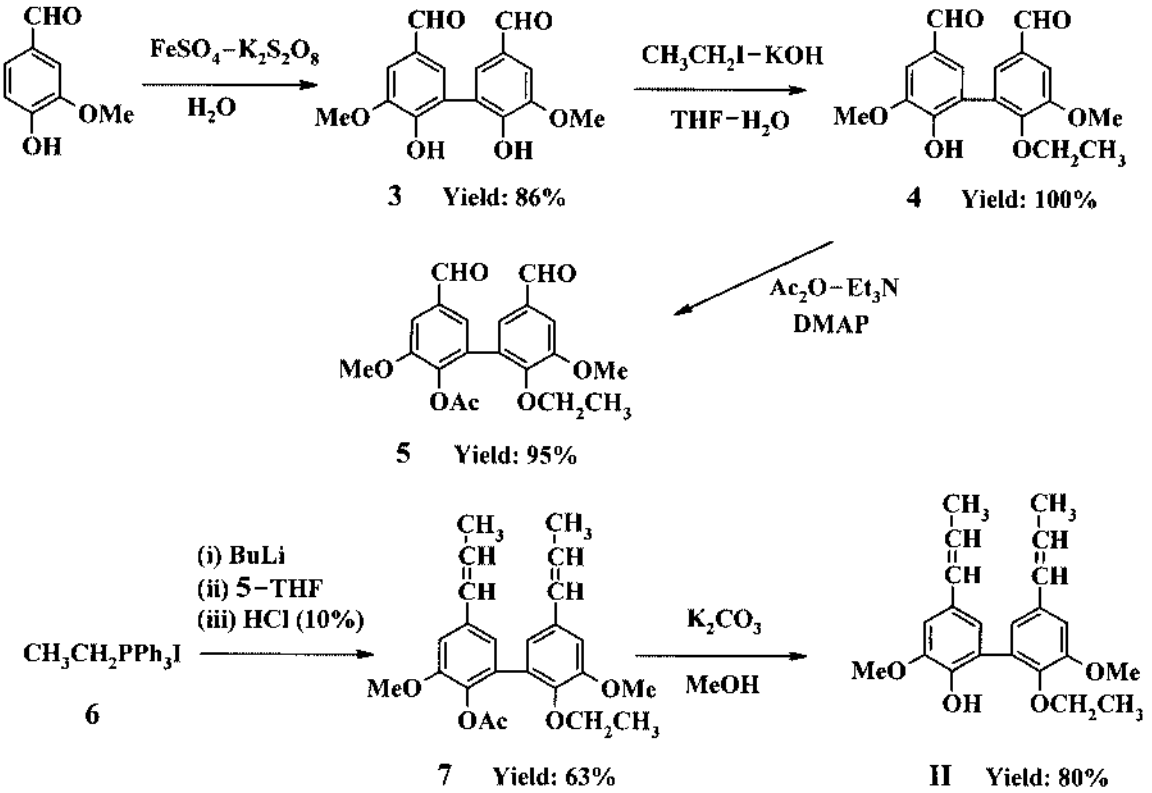

analyses are reported in Table 1 for unbleached and H_2O_2- and $NaBH_4$-treated pulps.

Among the four studied compounds, only compound **I** was found in unbleached and reduced pulps, in minute quantity ($\approx 4 \times 10^{-6}$ mol g^{-1}), which represents an order of magnitude higher than that found for stilbene phenols in peroxide bleached pulps (17). In peroxide bleached pulp, compound **I** was not detected. It is likely that compound **I** is not formed from phenylpropenol units but from phenylpropenal ones, these structures being degraded by hydrogen peroxide.

© 2002 NRC Canada

Fig. 5. Synthetic scheme of compound **III**.

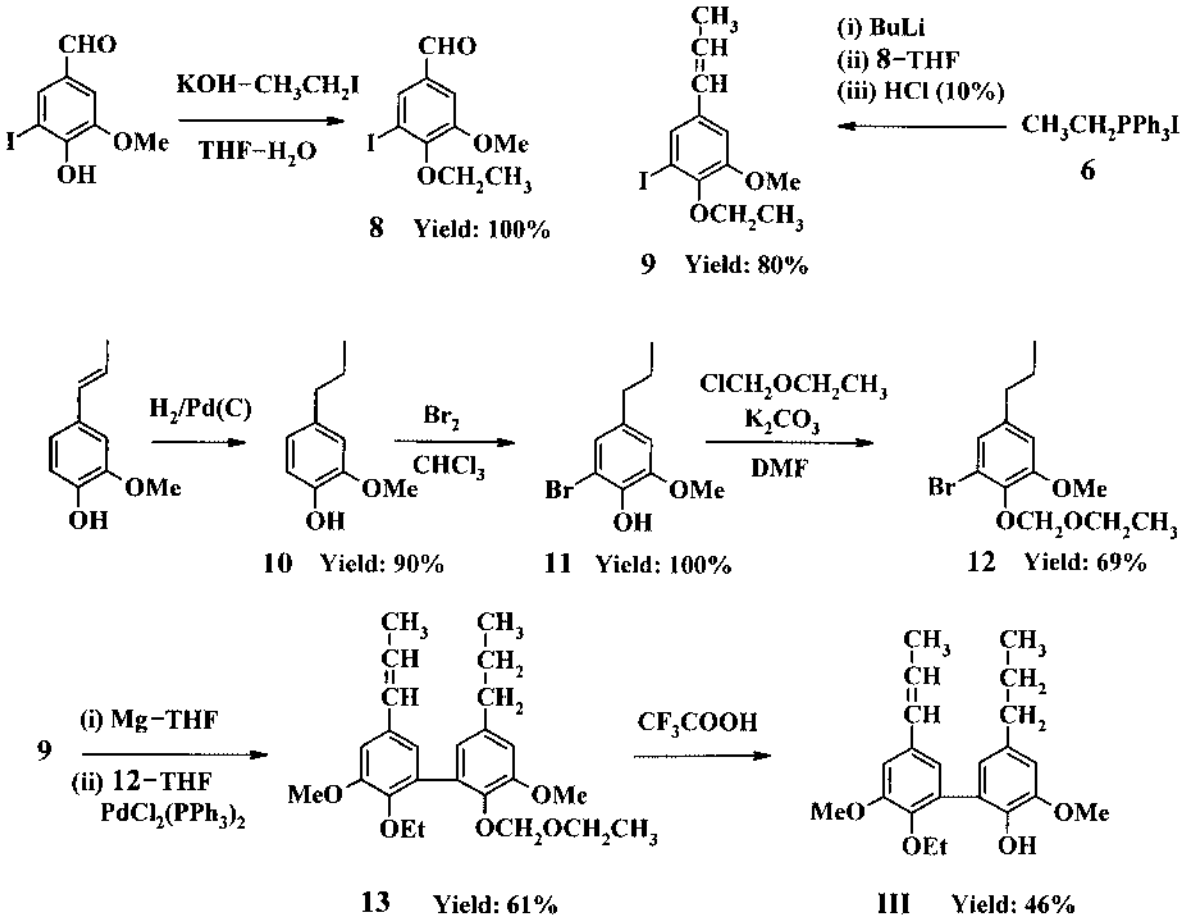

Fig. 6. Synthetic scheme of compound **IV**.

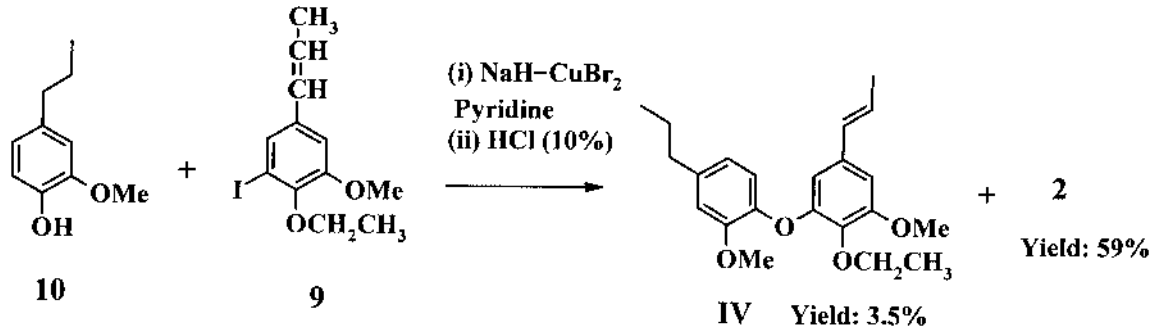

Traces of compound **II** were detected only for peroxide treated pulp in the form of two isomers, *E,E* and *Z,E* or *E,Z*. These isomers might be formed from cinnamic acid structures generated by the action of hydrogen peroxide on coniferaldehyde units. The lack of detection of compounds **III** and **IV** would indicate a very low content of phenolic coniferyl alcohol units or an inefficient ethylation of phenols, which is improbable considering the detection of compound **I** and the large excess of diethylsulfate used to treat pulps.

The lack of detection of compounds **III** and **IV** indicates that phenolic phenylpropenol units are not present in large amounts in bleached softwood mechanical pulps and therefore do not contribute to their fast photoyellowing.

Experimental

General

Melting points were measured with a Mettler FP62 heating block. NMR spectra were recorded on a Bruker DPX200 (^{1}H, ^{13}C) spectrometer (reference Me_4Si, solvent $CDCl_3$). The IR and UV absorption spectra were performed on PerkinElmer Paragon 1000 PC and Hitachi U-3300 spectrometers, respectively. Mass spectra were obtained using a VG Micromass Autospec Q instrument incorporating an electron ionization source (70 eV).

The usual chemicals were obtained from Aldrich, and they were used without further purification. The synthesized compounds were purified by column chromatography on

silica gel 60 (70−200 mesh) using the appropriate eluents. The solid products were crystallized after chromatography.

Analysis of the compounds was performed by gas chromatography (GC) with a flame ionization detector (Shimadzu GC 14A equipped with a CR4A Chromatopac data analyzer) or GC (Hewlett-Packard 5890 chromatograph) interfaced with a mass spectrometer (VG Micromass Autospec Q). The GC analyses were made using capillary columns (J and W Scientific) (30 m × 0.25 mm; film thickness, 0.25 μm; stationary phase DB-5MS). The injector port temperature was set at 280°C and the detector port temperature at 300°C (Shimadzu GC 14A). The transfer line between the GC apparatus and the mass spectrometer source was fixed at 220°C. The oven temperature program (GC) started at 180°C (1 min), then rose between 180 and 300°C with a gradient of 4°C min^{-1}, and finally was set to 300°C (30 min).

Chemical treatment of pulp

Bleaching of pulp with hydrogen peroxide

Mechanical pulp, mainly from spruce (0.5 g), kindly given by Dr. Petit-Conil (Centre Technique du Papier, Grenoble, France), was treated with hydrogen peroxide (30%, 0.5 mL) and sodium hydroxide (10 mg in 50 mL of water) in a plastic bag. After being heated at 50°C for 4 h, the pulp was washed with distilled water, diluted hydrochloric acid (5%), and water to bring the pH near 5. The pulp was filtered and keep at 4°C before etherification with diethylsulfate.

Reduction of pulp with $NaBH_4$

Mechanical pulp mainly from spruce (0.5 g) was reacted with sodium borohydride (0.5 g in 20 mL of water). After being stirred at room temperature for 2 days, the pulp was washed with hydrochloric acid (5%) and water to bring the pH near 5. The pulp was filtered and kept at 4°C before etherification with diethylsulfate.

Ethylation of pulps

The defiberized pulps (3 g) in suspension in water (100 mL) were treated under magnetic stirring and a nitrogen atmosphere with 5 mL of 10% sodium hydroxide solution. The mixtures were heated at 40°C for 15 min and then diethylsulfate (2 mL) was added. The stirring was continued for 1 h and then the alternating addition of sodium hydroxide and diethylsulfate was repeated. This cycle was repeated once more. Then the pulp was successively washed with dilute hydrochloric acid (5%) and distilled water (to pH ≈ 5), and filtered. The pulp was first dried in an oven at 40°C and then over P_2O_5 under vacuum before thioacidolysis treatment.

Thioacidolysis and Raney nickel treatment of pulps

Thioacidolysis and desulfurization experiments were performed according to a procedure described by Lapierre et al. (24, 31). Pulp (50 mg), treated with 10 mL of thioacidolysis solution (10 mL EtSH + 2.4 mL $BF_3{\cdot}Et_2O$ + 80 mL dioxan), was heated at 100°C for 4 h under magnetic stirring. After hydrolysis with diluted $NaHCO_3$ solution until pH 3 to 4, the reaction mixture was extracted with dichloromethane. To the dichloromethane solution, docosane was added as an internal standard for quantitative measurements. The organic phase was washed with water, dried over magnesium sulfate, and evaporated under vacuum. The solid residue was dissolved in 0.5 mL of dichloromethane and reacted with 2 mL of aqueous Raney nickel solution (50%) in 10 mL of methanol for 4 h at 80°C. After cooling, the resulting mixture was hydrolyzed with hydrochloric acid (10%) and extracted with dichloromethane. The organic phase, after washing with water, was dried over magnesium sulfate and evaporated to 0.5 mL. The organic phase was silylated with BSTFA (50 μL) in the presence of pyridine (10 μL) at room temperature for 30 min.

Syntheses

Synthesis of compound I

*5,5′-Diallyl-2,2′-dihydroxy-3,3′-dimethoxybiphenyl (dihydrodiisoeugenol) (**1**)*

A solution of eugenol (5.0 g, 30.5 mmol) and sodium acetate (9.0 g, 110.0 mmol) in water (200 mL) was treated, dropwise, with a solution of potassium ferricyanide (20.0 g, 60.8 mmol) in water (200 mL). After being stirred at room temperature for 3 h, the reaction mixture was filtered and the solid product was purified by crystallization in CH_2Cl_2 – petroleum ether (PET), affording the expected biphenyl **1** as beige crystals (3.8 g), yield 75%; mp 107°C (lit. (32) value mp +106°C). ^{1}H NMR ($CDCl_3$) δ: 3.40 (d, 4H, CH_2), 3.84 (s, 6H, OCH_3), 5.17 (d, 4H, $=CH_2$), 6.0 (m, 4H, CH), 6.9–7.0 (m, 4H, ArH). ^{13}C NMR ($CDCl_3$) δ: 40.0 (CH_2), 56.1 (OCH_3), 110.7 (CH Ar), 115.7 ($=CH_2$), 123.1 (CH Ar), 124.3 (C Ar), 131.9 (C Ar), 137.7 (=CH), 140.9 (C Ar), 147.2 (C Ar).

*2,2′-Dihydroxy-3,3′-dimethoxy-5,5′-di-*n*-propylbiphenyl (**2**)*

Hydrogenation of compound **1** (2.0 g, 6.1 mmol) in methanol (75 mL) containing 0.2 g of carbon palladium (10%) was accomplished by treating the mixture under hydrogen pressure (180 bar) for 24 h at room temperature. The mixture, after filtration, afforded a beige solid (1.8 g, 90%); mp 152°C (lit. (33) value mp +152°C). IR (KBr) (cm^{-1}): 850, 1050, 1145, 1230, 1260, 1375, 1425, 2920, 2945, 3300. ^{1}H NMR ($CDCl_3$) δ: 0.95 (t, 6H, CH_3), 1.63 (m, 4H, CH_2), 2.55 (t, 4H, CH_2), 3.91 (s, 6H, OCH_3), 6.03 (s, 2H, OH), 6.7

(m, 4H, ArH). ^{13}C NMR ($CDCl_3$) δ: 13.9 (CH_3), 24.8 (CH_2), 37.9 (CH_2), 56.1 (OCH_3), 110.6 (CH Ar), 122.9 (CH Ar), 124.4 (C Ar), 134.7 (C Ar), 140.5 (C Ar), 147.1 (C Ar).

2-Hydroxy-2′-ethoxy-3,3′-dimethoxy-5,5′-di-n-*propylbiphenyl (**I**)*

A solution of compound **2** (600 mg, 1.82 mmol) in THF (50 mL) was treated with a solution of potassium hydroxide (102 mg, 1.82 mmol) and diethylsulfate (0.5 mL, 4.0 mmol). After being stirred at 70°C for 12 h, the solution was reacted with a solution of hydrochloric acid (10%). The aqueous layer was extracted with CH_2Cl_2. The combined organic layers were washed with water, dried over $MgSO_4$, filtered, and concentrated. The product was purified by chromatography on silica gel (eluent Et_2O–PET, 60:40) affording the expected compound **I** (400 mg, 62%) as a pale yellow oil. IR (NaCl) (cm^{-1}): 840, 1050, 1140, 1230, 1460, 1580, 2870, 2930, 2960. ^{1}H NMR ($CDCl_3$) δ: 0.84 (t, 3H, CH_3), 0.86 (t, 3H, CH_3), 1.02 (t, 3H, CH_3), 1.55 (m, 4H, 2×CH_2), 2.46 (t, 2H, CH_2), 2.48 (t, 2H, CH_2) 3.74 (q, 2H, OCH_2), 3.78 (s, 3H, OCH_3), 3.80 (s, 3H, OCH_3), 6.6–6.7 (m, 4H, ArH), 6.72 (s, 1H, OH). ^{13}C NMR ($CDCl_3$) δ: 13.8 (CH_3), 14.0 (CH_3), 15.3 (CH_3), 24.6 (CH_2), 24.8 (CH_2), 37.8 (CH_2), 38.0 (CH_2), 55.9 (OCH_3), 56.1 (OCH_3), 69.9 (OCH_2), 111.2 (CH Ar), 111.7 (CH Ar), 122.9 (CH Ar), 123.4 (CH Ar), 128.2 (C Ar), 132.6 (C Ar), 134.3 (C Ar), 139.2 (C Ar), 141.2 (C Ar), 142.4 (C Ar), 148.5 (C Ar), 152.6 (C Ar). MS (TMS derivative): 430 ($[M]^+$,100%), 401 (10%), 387 (14%), 357 (9%), 73 (31%).

Synthesis of compound II

*4,4′-Diformyl-2,2′-dihydroxy-3,3′-dimethoxybiphenyl (**3**)*

Vanillin (5.0 g, 33 mmol) in hot water (200 mL) was treated by ferrous sulfate (200 mg, 0.7 mmol) and potassium persulfate (5.0 g, 20 mmol) at 100°C for 2 h. The resulting product was filtered and dried in an oven, affording the expected compound **3** (4.3 g, 86%); mp 304°C (lit. (34) value mp +305°C). IR (KBr) (cm^{-1}): 750, 850, 1050, 1150, 1260, 1420, 1460, 1590, 1680, 3260. ^{1}H NMR (DMSO) δ: 3.98 (s, 6H, OCH_3), 7.4 (s, 4H, ArH), 9.85 (s, 2H, CHO). ^{13}C NMR (DMSO) δ: 56.0 (OCH_3), 109.0 (CH Ar), 124.5 (CH Ar), 127.9 (C Ar), 128.2 (C Ar), 148.1 (C Ar), 150.3 (C Ar), 191.1 (CHO).

*2-Ethoxy-4,4′-diformyl-2′-hydroxy-3,3′-dimethoxybiphenyl (**4**)*

Dehydrodivanillin **3** (3.0 g, 9.9 mmol) in THF (100 mL) was treated with a solution of potassium hydroxide (0.6 g, 10.0 mmol) in water (10 mL) and iodoethane (3.2 g, 20.5 mmol). After being refluxed for 6 h, the mixture was reacted with a solution of hydrochloric acid (10%). The aqueous layer was extracted with CH_2Cl_2. The combined organic layers were washed with water, dried over $MgSO_4$, filtered, and concentrated, affording the expected compound **4** (3.3 g, 100%) as a pale yellow solid; mp 195°C. IR (KBr) (cm^{-1}): 740, 890, 1040, 1150, 1180, 1260, 1420, 1580, 1700, 3250. ^{1}H NMR ($CDCl_3$) δ: 1.11 (t, 3H, CH_3), 3.98 (s, 3H, OCH_3), 4.01 (q, 2H, OCH_2), 4.06 (s, 3H, OCH_3), 6.59 (s, 1H, OH), 7.4–7.5 (m, 4H, ArH), 9.86 (s, 1H, CHO), 9.92 (s, 1H, CHO).

*2-Ethoxy-4,4′-diformyl-2′-acetoxy-3,3′-dimethoxybiphenyl (**5**)*

A solution of **4** (3.3 g, 9.9 mmol) in CH_2Cl_2 (50 mL) was treated with triethylamine (5 mL, 36.1 mmol), acetic anhydride (1.4 mL, 12.6 mmol), and traces of 4-dimethylaminopyridine (DMAP). After being refluxed for 20 h, the mixture was reacted with water. The aqueous layer was extracted with CH_2Cl_2. The combined organic layers were washed with water, dried over $MgSO_4$, filtered, and concentrated, affording the expected compound **5** (3.5 g), yield 95%, as a pale yellow solid; mp 127°C. IR (KBr) (cm^{-1}): 740, 890, 1040, 1130, 1180, 1270, 1380, 1576, 1700, 1765. ^{1}H NMR ($CDCl_3$) δ: 1.08 (t, 3H, CH_3), 2.10 (s, 3H, OAc), 3.92 (q, 2H, OCH_2), 3.94 (s, 3H, OCH_3), 3.95 (s, 3H, OCH_3), 7.2–7.5 (m, 4H, ArH), 9.87 (s, 1H, CHO), 9.95 (s, 1H, CHO).

*Ethyltriphenylphosphonium iodide (**6**)*

A solution of iodoethane (3.0 g, 19.1 mmol) in toluene (50 mL) was treated with triphenylphosphine (6.0 g, 23.0 mmol) at 80°C for 3 h. The resulting white product was filtered and dried, affording the expected salt **6** (6.8 g), yield 84%; mp 168°C (lit. (35) value mp +168 to 169°C).

*2-Ethoxy-4,4′-diformyl-2′-acetoxy-3,3′-dipropenylbiphenyl (**7**)*

An *n*-butyl lithium solution in *n*-hexane (2.5 mol L^{-1}, 5.2 mmol) was added to a solution of the phosphonium salt **6** (2.1 g, 5 mmol) in anhyd THF (30 mL) under an N_2 atmosphere and the mixture was stirred at –70°C for 15 min. The resulting red solution was treated with a solution of aldehyde **5** (0.9 g, 2.4 mmol) in anhyd THF (20 mL). After being stirred at room temperature for 2 h, the mixture was reacted with a solution of hydrochloric acid (10%). The aqueous layer was extracted with CH_2Cl_2. The combined organic layers were washed with water, dried over $MgSO_4$, filtered, and concentrated. The product was purified by chromatography on silica gel (eluent CH_2Cl_2) affording the expected compound **7** (0.6 g, 63%) as a yellow solid; mp 127°C. IR (KBr) (cm^{-1}): 760, 790, 960, 1050, 1140, 1460, 1580, 1700, 1770, 2950. ^{1}H NMR ($CDCl_3$) δ: 1.1 (t, 3H, CH_3), 1.6 (2d, 6H, CH_3), 2.0 (s, 3H, OAc), 3.9 (m, 8H, 2 × OCH_3 and OCH_2), 5.5–6.0 (m, 4H, CH=CH), 6.8 (m, 4H, ArH). ^{13}C NMR ($CDCl_3$) δ: 15.4 (CH_3), 20.4 (Ac), 56.0 (OCH_3), 56.3 (OCH_3), 69.6 (OCH_2), 109.7 (CH Ar), 110.1 (CH Ar), 127.1 (CH Ar), 127.4 (CH Ar), 130.7 (C Ar), 132,0 (C Ar), 132.5 (C Ar), 134.3 (C Ar), 190.8 (CHO), 191.0 (CHO).

*2-Ethoxy-4,4′-diformyl-2′-hydroxy-3,3′-dipropenylbiphenyl (**II**)*

A solution of **7** (600 g, 1.52 mmol) in methanol (50 mL) was treated with potassium carbonate (250 mg, 1.81 mmol). After being stirred at room temperature for 4 h, the mixture was reacted with a solution of hydrochloric acid (10%). The aqueous layer was extracted with CH_2Cl_2. The combined organic layers were washed with water, dried over $MgSO_4$, filtered, and concentrated. The product was purified by chromatography on silica gel (eluent CH_2Cl_2–Et_2O, 98:2) affording the expected compound **II** (450 mg, 80%) as a pale yellow oil; mp 127°C. ^{1}H NMR ($CDCl_3$) δ: 1.1 (t, 3H, CH_3), 1.8 (d, 3H, CH_3), 1.9 (d, 3H, CH_3), 3.9 (m, 8H, 2 × OCH_3 and OCH_2), 5.6–7.0 (m, 8H, ArH, and CH=CH). Four stereoisomers displaying the same mass spectrum were identified by GC–MS (retention time: 18.8 (30%), 19.7 (36%),

© 2002 NRC Canada

20.0 (15%), and 21.0 min (19%)). MS (TMS derivative): 426 ([M]$^+$, 100%), 383 (12%), 73 (35%).

Synthesis of compound III

*4-Ethoxy-5-iodo-3-methoxybenzaldehyde (**8**)*

5-Iodovanillin (3.0 g, 10.8 mmol) in THF (75 mL) was treated with a solution of potassium hydroxide (1.0 g, 17.8 mmol) in water (10 mL) and iodoethane (4.0 g, 25.6 mmol). After being refluxed for 6 h, the mixture was reacted with water. The aqueous layer was extracted with CH_2Cl_2. The combined organic layers were washed with a solution of hydrochloric acid (10%), dried over $MgSO_4$, filtered, and concentrated, affording the expected compound **8** (3.3 g, 100%) as white crystals; mp 42°C. IR (KBr) (cm^{-1}): 590, 670, 790, 1040, 1150, 1270, 1390, 1460, 1560, 1580, 1690, 2970. ^{1}H NMR ($CDCl_3$) δ: 1.25 (t, 3H, CH_3), 3.83 (s, 3H, OCH_3), 4.05 (q, 2H, OCH_2), 7.23 (d, 1H, ArH), 7.77 (d, 1H, ArH), 9.81 (s, 1H, CHO). ^{13}C NMR ($CDCl_3$) δ: 15.7 (CH_3), 56.2 (OCH_2), 69.5 (OCH_3), 110.0 (CH Ar), 118.3 (C-I), 128.6 (CH Ar), 132.8 (C Ar), 151.0 (C Ar), 154.2 (C Ar), 169.9 (CHO).

*2-Ethoxy-1-iodo-3-methoxy-5-propenylbenzene (**9**)*

An *n*-butyl lithium solution in *n*-hexane (2.5 mol L^{-1}, 10.0 mmol) was added to a solution of the phosphonium salt **6** (4.2 g, 10.0 mmol) in anhyd THF (50 mL) under N_2 atmosphere and the mixture was stirred at –70°C for 15 min. The resulting red solution was treated with a solution of aldehyde **8** (3.0 g, 9.8 mmol) in anhyd THF (40 mL). After being stirred at room temperature for 2 h, the mixture was reacted with a solution of hydrochloric acid (10%). The aqueous layer was extracted with CH_2Cl_2. The combined organic layers were washed with water, dried over $MgSO_4$, filtered, and concentrated. The product was purified by chromatography on silica gel (eluent CH_2Cl_2) affording the expected compound **9** (2.5 g), yield 80%, as a pale yellow solid; mp 33°C. IR (KBr) (cm^{-1}): 780, 870, 960, 1050, 1140, 1230, 1250, 1510, 2950. ^{1}H NMR ($CDCl_3$) δ: 1.44 (t, 3H, CH_2-CH_3), 1.87 (2 × dd, 3H, CH-CH_3), 3.85 (s, 3H, OCH_3), 4.04 (q, 2H, OCH_2), 6.0–6.4 (m, 2H, CH=CH), 6.79 (d, 1H, ArH, J = 1.72 Hz), 6.81 (d, 1H, ArH, J = 1.72 Hz). ^{13}C NMR ($CDCl_3$) δ: 14.8 (CH_3), 18.4 (CH-CH_3), 55.8 (OCH_2), 64.3 (OCH_3), 108.8 (CH Ar), 112.7 (CH=), 118.7 (C-I), 123.7 (CH), 130.6 (CH), 131.1 (C Ar), 148.2 (C Ar), 149.5 (C Ar).

*2-Methoxy-4-*n*-propylphenol (**10**)*

Hydrogenation of eugenol (3.0 g, 18.3 mmol) in methanol (75 mL) containing 0.3 g of carbon palladium (10%) was accomplished by treating the mixture under hydrogen pressure (80 bar) for 24 h at 40°C. The mixture, after filtration, afforded compound **10** (2.7 g, 90%) as a green oil. IR (NaCl) (cm^{-1}): 795, 820, 1030, 1120, 1150, 1270, 1430, 1460, 1500, 1600, 2870, 2930, 2960, 3500. ^{1}H NMR ($CDCl_3$) δ: 0.7 (t, 3H, CH_3), 2.25 (t, 2H, CH_2), 2.85 (t, 2H, CH_2), 3.45 (s, 3H, OCH_3), 5.3 (s, 1H, OH), 6.2–6.7 (m, 3H, ArH).

*2-Bromo-6-methoxy-4-*n*-propylphenol (**11**)*

A solution of bromine (0.7 mL, 13.6 mmol) in $CHCl_3$ (60 mL) was added dropwise to a solution of **10** (2.0 g, 12.0 mmol) in $CHCl_3$ (100 mL) at 0°C. Once the addition was completed, the mixture was stirred at room temperature for 2 h. The solvent was removed and compound **11** (3.0 g, 100%) was obtained as a beige solid; mp 83°C (lit. (36) value mp +82.5 to 83.5°C). IR (KBr) (cm^{-1}): 820, 860, 960, 1040, 1150, 1200, 1270, 1500, 1590, 2870, 2930, 2950, 3420. ^{1}H NMR ($CDCl_3$) δ: 0.96 (t, 3H, CH_3), 1.60 (q, 2H, CH_2), 2.60 (t, 2H, CH_2), 3.85 (s, 3H, OCH_3), 6.66 (s, 1H, ArH), 7.08 (s, 1H, ArH). ^{13}C NMR ($CDCl_3$) δ: 13.8 (CH_3), 23.5 (CH_2), 37.9 (CH_2), 56.1 (OCH_3), 112.2 (CH Ar), 114.6 (C-Br), 118.4 (CH Ar), 133.3 (C Ar), 144.3 (C Ar), 145.9 (C Ar).

*1-Bromo-2-ethoxymethoxy-3-methoxy-5-propylbenzene (**12**)*

A solution of **11** (2.9 g, 11.8 mmol) in DMF (120 mL) was treated with potassium carbonate (9.0 g, 65.2 mmol) and chloromethylethylether (3.4 mL, 36.6 mmol). After being stirred at 80°C for 18 h, the mixture was reacted with a solution of hydrochloric acid (10%). The aqueous layer was extracted with CH_2Cl_2. The combined organic layers were washed with water, dried over $MgSO_4$, filtered, and concentrated. The product was purified by chromatography on silica gel (eluent CH_2Cl_2) affording the expected compound **12** (2.5 g, 69%) as a green oil. IR (NaCl) (cm^{-1}): 850, 950, 1160, 1250, 1460, 1500, 2870, 2930, 2960. ^{1}H NMR ($CDCl_3$) δ: 0.92 (t, 3H, CH_3), 1.15 (t, 3H, CH_3), 1.8 (m, 2H, CH_2), 2.8 (m, 2H, CH_2), 3.78 (q, 2H, OCH_2), 3.85 (s, 3H, OCH_3) 5.24 (s, 2H, OCH_2O), 6.8–7.0 (m, 2H, ArH).

*2′-Ethoxy-2-ethoxymethoxy-3,3′-dimethoxy-5′-propenyl-5-propylbiphenyl (**13**)*

Magnesium (0.2 g, 5.0 mmol) and two crystals of iodine in anhyd THF (5 mL) under an N_2 atmosphere were treated with a solution of **9** (1.0 g, 3.1 mmol) in anhyd THF (30 mL). After being stirred at 70°C for 6 h, the mixture was transferred dropwise into a second flask charged with palladium (II) bis-(triphenylphosphine) dichloride (0.2 mg, 0.28 mmol), compound **12** (0.95 g, 3.1 mmol), and 20 mL of anhyd THF. After being stirred at 70°C for 8 h, the mixture was reacted with a solution of hydrochloric acid (10%). The aqueous layer was extracted with CH_2Cl_2. The combined organic layers were washed with water, dried over $MgSO_4$, filtered, and concentrated. The product was purified by chromatography on silica gel (eluent CH_2Cl_2), affording the expected compound **13** (800 mg, 61%) as an orange oil. ^{1}H NMR ($CDCl_3$) δ: 0.94 (t, 3H, CH_3), 1.12 (t, 3H, CH_3), 1.35 (m, 3H, CH_3), 1.47 (m, 2H, CH_2), 1.72 (2d, 3H, CH_3-CH=), 3.79 (t, 2H, OCH_2), 3.87 (s, 3H, OCH_3), 3.89 (s, 3H, OCH_3), 4.15 (s, 2H, OCH_2), 5.22 (s, 2H, OCH_2O), 5.8–6.2 (m, 2H, CH=CH), 6.4–6.8 (m, 4H, ArH).

*2′-Ethoxy-2-hydroxy-3,3′-dimethoxy-5′-propenyl-5-propylbiphenyl (**III**)*

A solution of **13** (500 mg, 1.2 mmol) in CH_2Cl_2 (30 mL) was treated with trifluoroacetic acid (0.09 mL, 1.2 mmol). After being stirred at room temperature for 4 h, the mixture was reacted with water. The aqueous layer was extracted with CH_2Cl_2. The combined organic layers were washed with water, dried over $MgSO_4$, filtered, and concentrated to afford the expected compound **III** (*Z* isomer, 200 mg, 46%) as a yellow oil. IR (NaCl) (cm^{-1}): 960, 1050, 1230, 1250, 1500, 2950, 3600. ^{1}H NMR ($CDCl_3$) δ: 0.92 (t, 3H, CH_3), 1.35 (m, 3H, CH_3), 1.49 (m, 2H, CH_2), 1.75 (2d 3H, CH_3-CH=), 2.64 (m, 2H, CH_2), 3.88 (s, 3H, OCH_3), 3.91 (s, 3H, OCH_3), 4.21 (s, 2H, OCH_2O), 5.8–6.2, m, CH=CH), 6.4–6.8

© 2002 NRC Canada

(m, 4H, ArH). ^{13}C NMR ($CDCl_3$) δ: 13.8 (CH_3), 14.5 (CH_3), 17.7 (CH_3), 24.2 (CH_2), 37.5 (CH_2), 55.2 (OCH_3), 56.6 (OCH_3), 64.8 (OCH_2), 112.1 (CH), 117.0 (CH), 120.0 (CH), 121.5 (CH), 124.1 (CH), 126.8 (CH), 128.3 (C Ar), 130.5 (C Ar), 130.8 (C Ar), 131.4 (C Ar), 144.3 (C Ar), 145.9 (C Ar), 147.2 (C Ar), 149.1 (C Ar). MS (TMS derivative): 428 ([M]$^+$,100%), 399 (10%), 385 (15%), 73 (32%).

*2-Ethoxy-3,2′-dimethoxy-5-propenyl-4′-propyldiarylether (**IV**)*

A solution of **10** (560 mg, 3.4 mmol) in pyridine (15 mL) was treated with sodium hydride (90 mg, 3.7 mmol) and copper bromide (490 mg, 3.4 mmol). Then compound **9** (550 mg, 1.7 mmol) was added. After being stirred at 125°C for 18 h, the mixture was reacted with a solution of hydrochloric acid (10%). The aqueous layer was extracted with CH_2Cl_2. The combined organic layers were washed with water, dried over $MgSO_4$, filtered, and concentrated. The products were purified by chromatography on silica gel (eluent CH_2Cl_2) affording **2** (360 mg, 59%) as white crystals; mp 152°C (lit. (33) value mp +152°C), and compound **IV** (20 mg, 3.5%) as a pale oil. IR (NaCl) (cm^{-1}): 790, 1040, 1210, 1260, 1420, 1460, 1500, 1590, 2870, 2930, 2960. ^{1}H NMR ($CDCl_3$) δ: 0.95 (t, 3H, CH_3), 1.27 (t, 3H, CH_3), 1.62, 1.80, 2.56, 3.80, 3.82 (s, 3H, OCH_3), 3.86 (s, 3H, OCH_3), 4.10 (q, 2H, OCH_2), 6.0 to 6.8 (m, 8H, ArH, and CH=CH). ^{13}C NMR ($CDCl_3$) δ: 13.8 (CH_3), 15.4 (CH_3), 18.2 (CH_3), 24.7 (CH_2), 29.7 (CH_2), 37.8 (OCH_2), 55.8 (OCH_3), 55.9 (OCH_3), 104.3 (CH Ar), 109.0 (CH Ar), 112.9 (CH Ar), 119.2 (CH Ar), 120.6 (CH Ar), 125.1 (CH Ar), 130.5 (CH Ar), 133.3 (C Ar), 138.6 (C Ar), 139.5 (C Ar), 143.7 (C Ar), 148.1 (C Ar), 150.3 (C Ar), 153.9 (C Ar). MS: 356 ([M]$^+$,100%), 327 (20%), 296 (34%), 150 (31%).

Conclusion

Three biphenyl dimers (**I**–**III**) and one benzylaryl ether (**IV**) were synthesized to show the presence and the importance of phenolic coniferyl alcohol structures in the photoyellowing of high-yield pulps. The dimer **I**, incorporating two propyl chains, was detected in unbleached and sodium borohydride-reduced high-yield pulps in small amounts (≈4 × 10^{-6} mol g^{-1}). It is probably formed by thioacidolysis and Raney nickel treatments from phenolic biphenyl bearing coniferyl aldehyde moieties. Biphenyl **II**, which includes two propenyl chains, was detected in small amounts in peroxide bleached high-yield pulps, in the form of two stereoisomers. Biphenyl **II** probably comes from a ferulic-acid-type structure obtained from an oxidized propenal chain. No arylether **IV** or biphenyl **III** compounds were detected. This result probably indicates that phenolic phenylpropenol units are not present in softwood mechanical pulps, so they do not contribute to the photoyellowing process. A similar conclusion was obtained by us, on the involvement of stilbene phenol leucochromophores (17), and recently confirmed by Johansson et al. (37). After this study and others, the molecular origins of the fast photoyellowing of high-yield pulps remains to be established.

Electrochemical oxidation of 6-propionyl-2-(*N*,*N*-dimethylamino)naphthalene (prodan) in acetonitrile on Pt electrodes: Reversible dimerization of prodan radical cations

Marcela Beatriz Moressi, María Alicia Zón, and Héctor Fernández

Abstract: The electrooxidation of 6-propionyl-2-(*N*,*N*-dimethylamino)naphthalene (prodan) has been investigated for the first time. It has been performed on both conventional size platinum electrodes and platinum ultramicroelectrodes in acetonitrile by cyclic voltammetry with convolution analysis and controlled-potential electrolysis. The voltammetric responses at room temperature are similar to those corresponding to a kinetically controlled anodic electron-transfer process. Cyclic voltammetry measurements were also carried out at different concentrations of prodan and at different temperatures. Chemical transformation of the radical monocation formed after the electrochemical oxidation of prodan, as deduced from reverse controlled potential bulk electrolysis and cyclic voltammetry measurements, gives evidence for the reversible dimerization of prodan radical cations. Both diagnostic criteria and digital simulation confirm that radical–radical coupling is the reversible chemical reaction coupled to the initial electron transfer step, to give the corresponding dimeric dication. The kinetic and thermodynamic parameters for the first electron transfer reaction and the dimerization process were estimated from digital simulation at 293 K. Values of 8.0×10^6 M^{-1} and 3.2×10^5 M^{-1} s^{-1} were determined for the dimerization reaction equilibrium constant and the dimer formation rate constant, respectively. The diffusion coefficient of prodan was determined from both limiting currents from convoluted cyclic voltammograms as well as limiting currents on ultramicroelectrodes. For such cases where the electron number exchanged in the electrode process is unknown, a method derived from the combination of data previously indicated is also proposed to obtain the diffusion coefficient of the electroactive species.

Key words: prodan, cyclic voltammetry, reaction mechanism, reversible dimerization, electron transfer reactions, radical cation.

Résumé : On a étudié l'électrooxydation du 6-propionyl-2-(*N*,*N*-diméthylamino)naphtalène (prodan). Ces études ont été réalisées sur des électrodes de platine de taille conventionnelle ainsi que sur des ultramicroélectrodes de platine, dans l'acétonitrile, en faisant appel à la voltampérométrie cyclique avec analyse de convolution et un potentiel d'électrolyse contrôlé. Les réponses voltampérométriques à la température ambiante sont semblables à celles d'un processus de transfert d'électron anodique sous contrôle cinétique. On a aussi effectué des mesures de voltampérométrie cyclique à diverses concentrations de prodan et à diverses températures. Des mesures de voltampérométrie cyclique et d'électrolyse globale inverse sous potentiel contrôlé suggèrent que la transformation chimique du monocation radicalaire qui se forme après l'oxydation électrochimique du prodan conduit à une dimérisation réversible des cations radicaux du prodan. Des critères diagnostiques et une simulation digitale permettent de confirmer que le couplage radical–radical est la réaction chimique réversible couplée à l'étape initiale de transfert d'électron et qu'elle conduit au dication dimère correspondant. Les paramètres cinétiques et thermodynamiques pour la réaction de transfert du premier électron et pour le processus de dimérisation ont été évalués à partir de la simulation digitale à 293 K. On a déterminé des valeurs de $8{,}0 \times 10^6$ M^{-1} et $3{,}2 \times 10^5$ M^{-1} s^{-1} respectivement pour la constante d'équilibre de la réaction de dimérisation et pour la constante de vitesse de formation du dimère. On a déterminé le coefficient de diffusion du prodan à partir des courants limites tant des voltampérogrammes cycliques convulés que des courants limites sur les ultramicroélectrodes. Pour obtenir le coefficient de diffusion des espèces électroactives dans les cas où on ne connaît pas le nombre d'électrons qui sont échangés au cours du processus à l'électrode, on propose aussi une méthode suggérée antérieurement et dérivée de la combinaison de données.

Mots clés : prodan, voltampérométrie cyclique, mécanisme réactionnel, dimérisation réversible, réactions de transfert d'électron, cation radical.

Introduction

6-Propionyl-2-(*N*,*N*-dimethylamino)naphthalene (prodan) was introduced by Weber et al. (1) as a sensitive fluorescent probe for the electrostatic character of its environment. It has both an electron donor and an electron acceptor substituent in its molecular structure (see Fig. 1).

Prodan has a ground-state dipole moment between 2 and 2.5 D. Due to its large excited-state dipole moment (18–20 D), the maximum emission energy of prodan is highly dependent upon solvent polarity and its ability to hydrogen bond with protic solvents. The extension of its preferential solvation in binary solvent mixtures, where one component is capable of hydrogen bonding, was studied by fluorescence spectroscopy (2).

Prodan has been used in protein and more recently in lipid research (3–5). When this molecule is incorporated to membranes, its fluorescence spectra are sensitive to the physical state of the surrounding phospholipids. It is mainly located at the membrane surface (3), although FT-IR measurements indicate some degree of penetration into the interior lipid bilayer (6). Excited-state relaxation of prodan is sensitive to the nature of the linkage (ester or ether) between the phospholipid hydrocarbon tails and the glycerol backbone (7).

AM1 semiempirical calculations performed on the ground state of prodan predicted that this molecule has a planar conformation (8), in agreement with the X-ray crystal structure data. These theoretical calculations also allowed for estimations of the rotational barriers (0.03 kcal mol^{-1} for the propionyl and 0.33 kcal mol^{-1} for the amino group) and of the heat of formation (ΔE_f = 6.74 kcal mol^{-1}) (8).

As far as we know, no electrochemical study has been performed on this substrate. In this work, we discuss the results from the electrochemical oxidation of prodan in 0.1 M $NaClO_4$ + acetonitrile (ACN) on conventional-size platinum-disk electrodes (CSE) as well as platinum-disk ultramicroelectrodes (UME) by using cyclic voltammetry (CV) and controlled-potential bulk electrolysis.

Experimental

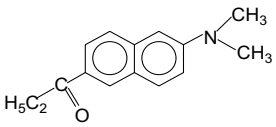
Reagents

Prodan was obtained from Molecular Probes and used as received. ACN (Sintorgan, HPLC grade) was dried over molecular sieves (3 Å) for 48 h prior to use and then used without further purification. $NaClO_4$ (Koch Light A.R.) was purified as previously reported (9). Stock solutions of prodan were prepared in ACN. Working solutions were prepared daily by adding aliquots of stock solutions to the 0.1 M $NaClO_4$ + ACN reaction medium, and protected from light. Prodan concentration was in the 0.05–6 × 10^{-3} M range. Sigma Chemical Co supplied analytical grade ferrocene.

Apparatus and experimental measurements

Cyclic voltammetry and large-scale electrolysis were performed with an EG&G Princenton Applied Research (PAR) potenciostat–galvanostat Model 273, equipped with Model PAR270 electrochemical-analysis software. The scan rate (v) was in the range of 0.010–100 V s^{-1}. Universal Programmer PARC model 175 was used with PAR 273 for high-sweep-rate experiments, and voltammograms were recorded in a Tektronic 7633 storaged oscilloscope.

Fig. 1. Chemical structure of 6-propionyl-2-(*N*,*N*-dimethylamino)naphthalene (prodan).



Electrochemical measurements were performed in a two-compartment Pyrex cell (10). Working electrodes were a Pt disk CSE or inlaid Pt disk UME. Pt UME were constructed in our laboratory as previously described (11). Before each measurement, the working electrodes were pretreated as reported elsewhere (11, 12). The electrochemical area of Pt CSE (A = 0.126 cm^2) as well as the Pt UME radii were calculated as previously reported (11, 12). The UME radii were in the range from 5 to 30 μm. The counter electrode was a platinum foil of large area (approx 2 cm^2). The reference electrode was an aqueous saturated calomel electrode (SCE) fitted with a fine-glass Luggin capillary containing a bridge solution identical to that of the sample being measured. Bulk-electrolysis cell and the corresponding electrodes were of the type described elsewhere (13). Positive-feedback techniques were employed in all experiments to compensate for solution resistance. All solutions were purged with solvent-saturated pure nitrogen. For most of the experiments, the working temperature was 293 ± 0.1 K, although it was changed in the 293–318 K range for some experiments to get more information about of the electrode-reaction mechanism. Fitting of experimental voltammograms was carried out through the BAS DigiSim® software, although simulations on UME were performed through POLAR 4.1 software (14). Calculations for chemical structures of probable reaction products were made through HyperChem® software.

Results and discussion

Cyclic voltammetry at CSE
