An antivitamin  $B_6$ , 4'-methoxypyridoxine (1) was isolated from the seed of <u>Ginkgo biloba</u> L. (Ginkgoaceae). The albumen of the seed of <u>G. biloba</u> L., which is called "Gin-nan or Ginkyo", is used as a crude drug in China and as food in Japan. However, in Japan, there have been about 70 reports of "Gin-nan sitotoxism."

In this paper, we report that the substance responsible for this sitotoxism is 4'-methoxypyridoxine (1), which is known to have antivitamin  ${\bf B}_6$  activities. This compound (1) is reported for the first time from natural products.

KEYWORDS — <u>Ginkgo biloba</u> L.; Ginkgoaceae; antivitamin B<sub>6</sub>; 4'-methoxypyridoxine; Gin-nan sitotoxism; convulsive agent; acute toxicity; guinea pig

"Gin-nan" is the seed of <u>Ginkgo biloba</u> L. (maidenhair tree, Ginkgoaceae), and its albumen is used as a crude drug in China and as food in Japan. "Gin-nan sitotoxism" (cardinal symptom: convulsions) has sometimes occurred during food shortages in Japan (1930-1960). Mainly infants contracted this sitotoxism (lethality: about 27%). Several investigations have been undertaken to elucidate the cause of the sitotoxism, <sup>2,3)</sup> but the cause of it remained unknown. This paper describes our finding that 4'-methoxypyridoxine (1), antivitamin  $B_6$ , isolated from <u>G</u>. <u>biloba</u> is the substance that causes "Gin-nan sitotoxism."

The albumen of Ginkgo seeds was dried at 40°C for 7 days and then ground. The powder was treated as reported before. The outline of the procedure is shown in Chart 1. The toxicity was evaluated by orally administered acute toxicity tests using guinea pigs (250-400 g) of either sex. Test samples were dissolved or suspended in water in appropriate concentrations. Signs of toxicity were paralysis of legs, opisthotonus, tonic convulsions, and auditory hyperalgesia. These symptoms occurred within 30-40 minutes after administration of the toxic fractions.

The isolation procedure afforded compound (1) [ca. 0.01% yield, dry weight], which induced the characteristic convulsions in guinea pigs at an oral dose of 11 mg/kg.

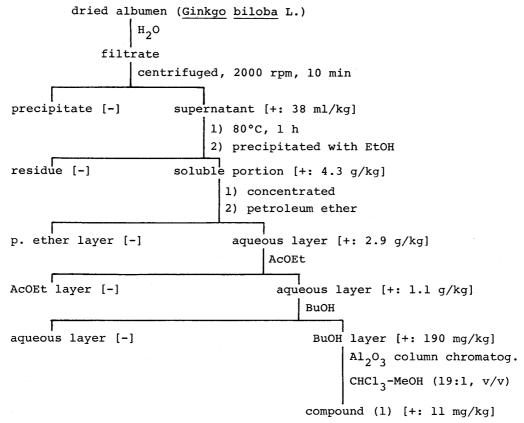

Chart 1

[+: ml, g, or mg/kg] indicates toxic fraction and dose.

(Typical symptoms for this sitotoxism occurred with this dose.)

[-] indicates nontoxic fraction.

(In this fraction, no typical symptoms occurred when administration dose was more than that of corresponding toxic fraction.)

Compound (1) was found by high resolution mass spectrum to have the molecular formula  $C_9H_{13}NO_3$  [183 (M<sup>+</sup>,  $C_9H_{13}NO_3$ , Calcd: 183.0891. Found: 183.0890)]. Compound (1) showed positive reactions with ferric chloride solution, and with Fast Blue B Salt (diazonium reagent) indicating that it has a hydroxypyridine without substitution groups at the para position.  $^1H$ - and  $^{13}C$ -NMR spectra  $^4$ ) showed the presence of an aromatic methyl group [2.42(3H, s,  $C_2$ -CH $_3$ ) and 18.4(q,  $C_2$ -CH $_3$ )], a methoxy group [3.44(3H, s,  $C_4$ -OCH $_3$ ) and 58.8(q,  $C_4$ -OCH $_3$ )], two methylene groups (-CH $_2$ O-) [4.63 and 4.76(each 2H, each s,  $C_4$ - and  $C_5$ -CH $_2$ O-) and 60.4, 67.9(each t,  $C_5$ - and  $C_4$ -CH $_2$ O-)], an aromatic proton [7.90(1H, s,  $C_6$ -H)], and a tetrasubstituted pyridine ring [130.8(d,  $C_6$ ), 131.3(s,  $C_5$ ), 135.2(s,  $C_4$ ), 147.6(s,  $C_2$ ), and 152.4(s,  $C_3$ )].

As compound (1) coupled with 2,6-dichloroquinonechloroimide (Gibbs reagent) even in the presence of borate,<sup>5)</sup> it was a 4'-substituted (i.e. 4'-methoxy) pyridoxine. The mixed melting point with authentic 4'-methoxypyridoxine hydrochloride (mp 181°C)<sup>6)</sup> was 179-180°C. Compound (1) was identified as 4'-methoxypyridoxine (2-methyl-3-hydroxy-4-methoxymethyl-5-hydroxymethyl pyridine) by these analyses.

4'-methoxypyridoxine (1):  $R^1=CH_3$ ,  $R^2=H$  pyridoxine (vitamin  $B_6$ ):  $R^1=R^2=H$ 

4'-Methoxypyridoxine is known to have antivitamin  $B_6$  activities and to be a synthetic potent convulsive agent in a variety of animals and in man. However, pyridoxine (vitamin  $B_6$ ) prevents the convulsions, or promptly stops them. Therefore, pyridoxine may prevent the symptoms of "Gin-nan sitotoxism," because these symptoms are derived from the effect of vitamin  $B_6$  deficiency induced with compound (1). The lack of vitamin  $B_6$  during food shortage times also may be one of the causes of "Gin-nan sitotoxism." Compound (1) (i.e. 4'-methoxypyridoxine) was found for the first time from natural products.

ACKNOWLEDGEMENT The authors wish to thank Professor Jun-ichi Ushijima, The College of Dairying, Ebetsu, for the acute toxicity tests. Thanks are also due Mr. K. Watanabe, Miss T. Nishida, and Dr. M. Ishikura for mass spectrometric analyses, and Mrs. A. Watanabe and Dr. K. Oda for NMR studies.
