Trifluoromethanesulfonic Acid-Promoted Reaction of Hexahydro-1,3,5-triazines. Introduction of a Secondary Aminomethyl Grouping into Carboxylates at the α-Position through Ketene Silyl Acetals

KIYOSHI IKEDA, KAZUO ACHIWA,* and MINORU SEKIYA

Shizuoka College of Pharmacy, Oshika 2-2-1, Shizuoka 422, Japan

(Received September 24, 1985)

Introduction of the secondary aminomethyl grouping RNHCH₂ into carboxylates at the α -position has been achieved by reaction of hexahydro-1,3,5-triazines with ketene silyl acetals in the presence of a catalytic amount of trifluoromethanesulfonic acid.

Keywords—N-alkylaminomethylation; 1,3,5-trialkylhexahydro-1,3,5-triazine; ketene silyl acetal; trifluoromethanesulfonic acid; catalysis; β -lactam

Methods for synthesizing β -aminocarboxylates are of particular interest in connection with naturally occurring nocardicin A, sulfazecin, and related monobactam antibiotics. The reactivities¹⁾ of 1,3,5-trialkylhexahydro-1,3,5-triazines (1) as N-alkylmethylenimine synthons²⁾ were shown by us to permit the N-alkylacetamidomethylation of electron-rich carbons by using 1 with acetyl chloride in the absence or in the presence of titanium tetrachloride. One of these papers reported the synthesis of N-alkyl-N-ureido- β -aminocarboxylates by the titanium tetrachloride-aided reaction of N-(chloromethyl)carbamate, derived from 1, with ketene silyl acetals (2).

As communicated later, the *in situ* N-alkylaminomethylation of carboxylates at the α -position was found³⁾ to be readily achievable by the reaction of 1 with 2 in the presence of a catalytic amount of trifluoromethanesulfonic acid (3c). This reaction constitutes an important means for the introduction of the secondary aminomethyl grouping RNHCH₂ into carboxylates at the α -position, since no existing method can do this in a satisfactory way.

The previously known methods⁴⁾ have been limited to the introduction of the tertiary aminomethyl grouping $R'RNCH_2$ into carbonyl compounds at the α -position. We now wish to describe the details of our work.

Preliminary experiments included examination of the relative efficiencies of various trifluoromethanesulfonate catalysts such as Me₃SiOSO₂CF₃ (3a), n-Bu₂BOSO₂CF₃ (3b), and HOSO₂CF₃ (3c). The reaction of ketene silyl acetal (2a), derived from methyl isovalerate, with one-third molar equivalent of 1,3,5-tribenzylhexahydro-1,3,5-triazine was carried out in dichloromethane at room temperature for 3 h using 0.05 molar equivalent of the catalyst. Under uniform conditions 3a, 3b, and 3c gave methyl 2,2-dimethyl-3-(benzylamino)propionate in nearly the same yield (83—85%). The mechanistic rationale for the reaction is illustrated in

1580 Vol. 34 (1986)

Chart 1. It is considered that 3a may be the true catalyst which initiates formation of the N-silylated methyleniminium salt by reaction with 1, and this intermediate attacks 2 as an electrophile to give N-silylated N-alkyl- β -aminocarboxylate with the stimultaneous generation of 3a. In the reaction with 3b or 3c, a catalytic amount may initially be converted into 3a by reacting with 2, and thus enter the catalytic cycle.

Chart 1

With 3a as a catalyst, the reaction was extended to a number of derivatives of 1 and 2, and the results are summarized in Table I. As can be seen, secondary aminomethylation of carboxylates at the α -position generally proceeds at room temperature in fair yield. N-(α -Methoxycarbonyl)benzyl-substituted β -aminocarboxylate (entry 8), which may be converted into a β -lactam structurally related to nocardicin A, was produced in considerable yield. The reaction of tetracyclic hexahydro-1,3,5-triazine is exemplified by the use of the trimer of 1-pyrroline; an alicyclic β -aminocarboxylate was formed but in rather low yield. This is probably because there exists an equilibrium (Chart 2) of the intermediary iminium salt which thermodynamically favors the less reactive enamine form.

Chart 2

Identification of the products was done on the basis of their spectral data (Table II). The infrared (IR) spectrum showed characteristic bands of a secondary amino group at 3312—3395 cm⁻¹ and a carbonyl group at 1716—1740 cm⁻¹. The ¹H-nuclear magnetic resonance (NMR) spectrum showed the signal of a methylene proton (>N-CH₂-) at 2.06—3.19 ppm. In addition, the ¹³C-NMR spectrum showed the signal of a carbonyl carbon (singlet) at 176.3—

a) Triazine, ketene silyl acetal=1:3 (molar proportion); CF_3SO_3H , 5 mol%; solvent, CH_2Cl_2 . b) Based on the product isolated. r.t., room temperature.

177.9 ppm. In the 1H -NMR spectrum of **4h**, the methylene proton (>N-CH₂-) signals appeared at 2.55 and 2.64 ppm (AB-quartet, J=12 Hz).

Thus, the reaction provides an efficient method for direct introduction of the secondary aminomethyl grouping $RNHCH_2$ into a carboxylate at the α -position by simple procedures and in good yield.

Experimental

All melting and boiling points are uncorrected. IR spectra were recorded on a JASCO A-202 spectrometer. ¹H-

a) KBr. b) Bulb-to-bulb distillation.

NMR spectra (90 MHz) and 13 C-NMR spectra (22.5 MHz) were taken on a JEOL JNM-90Q NMR spectrometer in CDCl₃ with tetramethylsilane (TMS) as an internal standard, and the chemical shifts are given in δ values.

Preparation of 1,3,5-Trialkylhexahydro-1,3,5-triazines (1a—g)—The following 1,3,5-trialkylhexahydro-1,3,5-triazines were prepared according to the methods described in the literature; their boiling and melting points are as follows: **1a**, bp 125—126 °C/25 mmHg (lit.,¹⁾ bp 87 °C/0.6 mmHg); **1b**, mp 50—51 °C (lit.,¹⁾ mp 46—48 °C); **1c**, bp 82—92 °C/20 mmHg (lit.,¹⁾ bp 53 °C/0.3 mmHg); **1d**, bp 88 °C/0.4 mmHg (lit.,¹⁾ bp 92 °C/0.4 mmHg); **1e**, mp 135—139 °C (lit.,⁵⁾ mp 140—141 °C); **1f**, mp 167—168 °C (lit.,⁶⁾ mp 148—155 °C); **1g**, bp 92—98 °C (lit.,⁷⁾ bp 81—97 °C).

Preparation of Ketene Silyl Acetals (2a—c)—The ketene trimethylsilyl acetals were prepared from the corresponding carboxylic esters by the previously reported procedure⁸); their boiling points are as follows: **2a**, bp 76—77 °C/65 mmHg (lit.,⁸) bp 35 °C/15 mmHg); **2b**, bp 68—69 °C/65 mmHg (lit.,⁸) bp 70 °C/3 mmHg); **2c**, bp 98—99 °C/0.4 mmHg (lit.,⁸) bp 63 °C/0.001 mmHg).

N-Alkylaminomethylation (Table I)—General Procedure: Compound 3c (0.3 mmol) was added as a catalyst to a stirred solution of 2 mmol of 1,3,5-trialkylhexahydro-1,3,5-triazine (1a—g) and 6 mmol of ketene silyl acetal (2a—c) in 10 ml of dry CH₂Cl₂, under cooling. After being stirred for the requisite time at room temperature, the reaction mixture was washed with 10% aqueous KHCO₃ solution. The separated organic layer was dried over anhydrous MgSO₄. Removal of the solvent gave an oily residue, which was fractionally distilled under reduced pressure to give the product (4a—i). Yields, and physical and analytical data for the products are listed in Tables I and II, respectively.

Acknowledgment The authors are indebted to Dr. K. Narita and the staff of the Analysis Center of this college for microanalysis. This work was supported in part by a Grant-in-Aid for Scientific Research (No. 59570900) from the Ministry of Education, Science and Culture of Japan.
