*Summary* Geometrical data for  $IF_5$  and  $BrF_5$  have been deduced from a combination of electron diffraction measurements and rotational constants measured by microwave spectroscopy.

RECENT microwave studies by Bradley, Brier, and Whittle<sup>1,2</sup> have yielded rotational constants for  $^{79}\text{BrF}_5$ ,  $^{81}\text{BrF}_5$ , and  $^{1}\text{F}_5$ , and have demonstrated that these molecules have  $C_{4v}$ symmetry in the gas phase. The spectroscopic data alone are not sufficient to determine the molecular structures, but the rotational constants taken together with electron diffraction results enable the structures to be evaluated with reasonable confidence. Electron diffraction data were collected photographically on the Balzers KDG2 instrument at the University of Manchester Institute of Science and Technology, and processed at Cambridge using published procedures.<sup>3</sup> The electron diffraction data for  $\text{BrF}_5$ were obtained in this study. Hewitt, Robiette, and Sheldrick<sup>4</sup> obtained the data for  $IF_5$  which have been further refined since the rotational constant became available.

Three geometrical parameters are necessary to define a  $C_{4v}$  model for  $XF_{5}$  with four equatorial (eq) and one axial

(ax) fluorine atoms. These were chosen as  $r(XF)$ <sub>mean</sub>, the weighted mean XF bond length;  $\Delta(XF)$ , the difference between the two types of bond length  $[\Delta = r(XF)_{eq}$  $r(XF)_{ax}$ ; and the angle  $F_{ax}-X-F_{eq}$ . The parameters refined were those of the average structure,<sup>5</sup> in which distances are described as  $r_{\alpha}$ :  $r_{\alpha}$  distances were interconverted with the observed electron diffraction distances  $r_a$ by means of previously calculated perpendicular amplitude corrections.<sup>6</sup> Geometrical parameters obtained from refinements on electron diffraction data alone are listed in the Table, together with rotational constants (designated  $B_{\alpha}$ ) calculated from these structures, and for comparison the observed rotational constants *B,* in the vibrational ground states.  $B_0$  is in general almost always greater than  $B_{\alpha}$ <sup>7</sup> The harmonic force fields for  $BrF_5$  and  $IF_5$  are poorly determined<sup>8</sup> at the present time and therefore the differences  $(B_0 - B_{\alpha})$  cannot be calculated with any precision. It is likely however, that the values of  $(B_0 - B_\alpha)$  lie in the range *0-5* **MHz.** 

For BrF<sub>5</sub> the calculated values of  $B_{\alpha}$  are 4.5 MHz less than the corresponding values of  $B_0$ . The calculated iso-<br>topic shift  $[B({}^nB\text{Fr}_5) - B({}^{81}\text{BrF}_5)$ , designated  $\delta$  in the Table], which should be almost the same for  $B_{\alpha}$  as for  $B_{0}$ ,

agrees within experimental error with the observed shift in  $B_0$ . If  $r(BrF)$ <sub>mean</sub> and  $\Delta(BrF)$  are calculated directly from the two measured  $B_0$  constants, assuming the electron diffraction angle as the third geometrical parameter, the results obtained are  $r(BrF)_{\text{mean}} = 1.754 \text{ A}, \Delta(BrF) =$ 0.079 Å (this approximates to a mixed  $r_s/r_0$  structure). This agreement is very satisfactory. For  $IF_5$ , the most conspicuous feature of the results is that  $\Delta(\mathrm{IF})$  is poorly determined from the electron diffraction data alone. Unfortunately  $B_{\alpha}$  is such a sensitive function of  $r(\text{IF})_{\text{mean}}$ and  $\Delta$ (IF)-a fact reflected in the high standard deviation of  $B_{\alpha}$  in the Table-that the observed rotational constant is of little use in fixing  $\Delta(\text{IF})$  more accurately. If  $r(\text{IF})_{\text{mean}}$ and  $\angle$ F<sub>ax</sub>-I-F<sub>eq</sub> are taken to be 1.861 Å and 81.9°, then  $\Delta$ (IF) would have to be 0.046 or 0.029 Å to yield  $B_{\alpha}$  values of 2727.55 MHz or 2722.55 MHz *(i.e.* assuming  $B_0 - B_{\alpha} =$ **0** or 5 MHz, respectively). The estimated standard deviation of  $0.005 \text{ Å}$  in  $r(\text{IF})_{\text{mean}}$ , however, implies a standard *deviation of 0.05 Å* in these estimates of  $\Delta$ (IF). The various gas-phase estimates of  $\Delta(\text{IF})$  are therefore consistent though not at all precise; work is in progress to

combine the two types of data in the most suitable way. For both molecules agreement with crystallographic determinations is good; these parameters<sup>9,10</sup> are also given in the Table. In particular,  $\overline{\Delta}(\text{IF})$  from the librationallycorrected X-ray bond lengths is  $0.030 \pm 0.012$ , which lends further confidence to the gas-phase values.

 $BrF<sub>5</sub>$  and  $IF<sub>5</sub>$  are often used as illustrations of the valenceshell electron pair repulsion theory, $11$  in which distortions from idealised octahedral co-ordination with angles **of 90"**  at the central atom are ascribed to the effect of the lone pair of electrons. In this connection it is interesting that while IF<sub>5</sub> has the greater angular distortion ( $\angle$ F<sub>ax</sub>-I-F<sub>eq</sub> 81.9°,  $\angle$ F<sub>ax</sub>-Br-F<sub>eq</sub> 84.8°), the lengthening of the equatorial bonds is apparently substantially greater in  $\text{BrF}_{5}$ .

We thank Prof. D. W. J. Cruickshank and Dr. B. Beagley for the use of the electron diffraction apparatus and Mr. R. W. Mather for his technical assistance. We also thank the S.R.C. for a Research Studentship for one of us (R.H.B.).
