## **Relative Solvent Transport of Ion Constituents in Aqueous Organic Solvents**

By DAVID FEAKINS,\* ROBERT O'NEILL, W. EARLE WAGHORNE, and ANTHONY J. I. WARD *(Department of Chemistry, University College, Belfield, Dublin* **4)** 

*Summary* In dilute solutions of the organic component the alkali-metal, chloride, and hydrogen ions mostly transport water with respect to raffinose, dioxan, dimethyl sulphoxide, and allyl alcohol, but transport glycine with respect to water.

 $RECENTLY<sup>1</sup>$  we showed how the relative solvent transport of individual ions in a binary solvent mixture could be determined unambiguously. For a **(1** : **1)** electrolyte at infinite dilution in an aqueous mixture, a transport experiment<sup>2</sup> gives the Washburn number,  $w_{\rm w}^{\rm o}$ , of water W with respect to the co-solvent S [equation (1)]. Erdey-Grúz<br>  $w_{\rm w}^{\circ} = (n_{\rm w}^{\circ})_+ t_+^{\circ} - (n_{\rm w}^{\circ})_- t_-^{\circ}$  (1)

$$
w_{\mathbf{w}}^{\circ} = (n_{\mathbf{w}}^{\circ})_{+} t_{+}^{\circ} - (n_{\mathbf{w}}^{\circ})_{-} t_{-}^{\circ}
$$
 (1)

proposed that diffusion experiments<sup>3</sup> could give  $\sum n_{\rm w}^{\rm o}$  [equation **(Z)].** 

$$
\sum n_{\rm w}^{\rm o} = (n_{\rm w}^{\rm o})_+ + (n_{\rm w}^{\rm o})_- \tag{2}
$$

The numbers of moles of water transported per mole of ions with respect to the co-solvent  $(n_{\pi})_+$  and  $(n_{\pi})_-$  then follow from equations **(1)** and **(2).** 

We have now carried out a substantial programme of measurements of  $\Sigma_{n_x}$  using a diffusion cell based on Stokes's<sup>4</sup> design, and analysis by interferometry, and measurements of  $w^{\circ}_{\bullet}$ .

When we began our own programme of diffusion measurements it became clear that Erdey-Grúz et al.<sup>3</sup> had not properly corrected their results for the effect of dissolved

electrolyte on the solvent activities, and had thereby seriously overestimated the transport of the non-aqueous component. Thus, as well as a selection of the new data for ionic  $n_{\rm w}^{\rm o}$ , the Table shows the corrected data for the system previously reported,<sup>1</sup> 10%  $(w/w)$  allyl alcohol.

The values shown for the raffinose system were obtained using Miller's<sup>5</sup> measurements of diffusion and Longsworth's<sup>6</sup> measurements of transport.

Preferential solvation in these systems is predominantly by water (positive  $n_w$ ). A striking exception is the glycinewater system, which is also interesting because the large negative  $n_{\rm w}^{\rm o}$  resolve to very small  $w_{\rm w}^{\rm o}$  for the alkali-metal chlorides  $(0-0.2 \text{ mol } F^{-1})$ . These results must be related to the zwitterionic and amphoteric character of glycine.

The corrected values for the allyl alcohol system are now all positive, not negative as stated previously. Now,  $n_{\text{w}}^{\text{o}}$ will be given by equation (3), where  $\overline{N}$  is the total number  $n_{\overline{n}}^{\circ} = N(l - \lambda)/(l + 1)$  (3)

$$
n_{\rm w}^{\rm o}=N(l-\lambda)/(l+1)\qquad \qquad (3)
$$

of molecules of water and organic solvent transported by the ion and  $\lambda$  and *l* respectively are the ratios of number of moles of W to the number of moles of S in the mixture and in the transported solvent respectively.

Where there is strong preferential solvation by water,  $n_{\pi}^{\circ}$  closely approaches  $N$ ; it has been suggested<sup>7</sup> that this happens in the raffinose-water system. Now that  $n_{\rm w}^{\rm o}$  is experimentally accessible, a minimum value of *N* can be found for any ion; it will be the highest value of  $n_{\pi}^{\circ}$  found

TABLE. Number of moles of water transported with respect to the organic component at infinite dilution,  $n_{\rm w}^{\rm o}$ .<sup>8</sup>

|       | Raffinose<br>$0.75\%$ | Dioxan<br>$5\%$ | Allyl alcohol<br>10% | Me <sub>2</sub> SO<br>5% | Glycine<br>$2.5\%$ |
|-------|-----------------------|-----------------|----------------------|--------------------------|--------------------|
| $Li+$ | 15                    | 9.5             | 4·1                  | 0.8                      | $-7.3$             |
| $Na+$ | 10                    | 8.3             | 4.6                  | 4.3                      | $-5.0$             |
| $K^+$ | 5.5                   | 4.8             | 2.8                  | $2-1$                    | $-3.5$             |
| $Rb+$ |                       | 1.5             |                      | $3-1$                    |                    |
| $Cs+$ |                       | $1-3$           |                      | 1.8                      | $-3.3$             |
| $H^+$ | $1-5$                 | ----            |                      | $-0.9$                   |                    |
| $Cl-$ |                       | 1.7             | $0-0$                | $-0.9$                   | $-3.6$             |

<sup>a</sup> Composition as weight % organic component. Accuracy: raffinose  $\pm$  2; others better than  $\pm$  1; relative accuracy in a given system rather better.

concentrations. For the present, therefore, N cannot be ible thermodynamics involved, and have confirmed the less than the  $n_{\omega}^{\circ}$  values in the raffinose-water system. possibility of obtaining ionic  $n_{\omega}^{\circ}$ . They

ideas' about shear occurring at the ionic surface for the Extrapolation of our results gives  $n_x^2 = 12 \pm 2$ . larger alkali-metal and halide ions must be revised.

The smaller  $n_{\pi}^{\circ}$  values in the remaining systems therefore indicate varying degrees of competition by the co-solvent for the solvation of the ion;  $n_x^{\circ}$  for Li<sup>+</sup> shows this particularly well. *(Received,* **19th** *July* **1979;** *Corn.* **782.)** 

in all measurements with various co-solvents at high water Recently Chemla and M'Halla<sup>8</sup> have analysed the irrevers-Its than the *n*<sub>v</sub> values in the raffinose-water system. possibility of obtaining ionic *n*<sub>v</sub>. They have obtained a Although these are perhaps the least accurate of any in value of  $\sum n_x^{\circ} = 14$  for Na<sup>+</sup>Cl<sup>-</sup> at infin Although these are perhaps the least accurate of any in value of  $\sum n_x^0 = 14$  for Na+Cl<sup>-</sup> at infinite dilution of dioxant the Table it is still clear that they are large and that earlier from a rather different type of d from a rather different type of diffusion experiment.
