**Summary** Triorganotin hydride reduction of methyl 6 $\beta$ -isothiocyanatopenicillanate is accompanied by intramolecular radical capture and cleavage of the sulphur-C(2) bond to give thiazolines (9) and (10); a similar mechanism is proposed for the formation of thiazoline (3), a minor product of tri-n-butyltin hydride reduction of benzyl 6 $\alpha$ -(1-hydroxy-1-methylethyl)-6 $\beta$ -isocyanopenicillanate (1; R<sup>2</sup> = Me<sub>2</sub>COH).

RECENTLY the tri-n-butyltin hydride reduction of 6 $\alpha$ -alkyl-6 $\beta$ -isocyanopenicillanates (1) was shown to be a useful stereoselective synthesis of 6 $\beta$ -alkylpenicillanates (2).<sup>1</sup> A minor side-product was formed in some of these reductions, and was isolated in 15% yield from the reduction of benzyl 6 $\alpha$ -(1-hydroxy-1-methylethyl)-6 $\beta$ -isocyanopenicillanate (1; R<sup>2</sup> = Me<sub>2</sub>COH), being identified as thiazoline (3). We here report that reduction of methyl 6 $\beta$ -isothiocyanatopenicillanate (8) with tin hydride reagents proceeds with predominant sulphur-C(2) bond cleavage to give rearranged thiazolines as the only isolable products.<sup>2</sup>

Thus, treatment of methyl 6 $\beta$ -isothiocyanatopenicillanate (8)<sup>3</sup> with either tri-n-butyl- or triphenyl-tin hydride in

(1) R<sup>1</sup> = CN-, R<sup>2</sup> = alkyl

(2) R<sup>1</sup> = alkyl, R<sup>2</sup> = H

(3) R<sup>1</sup> = R<sup>2</sup> = H

(4) R<sup>1</sup> = H, R<sup>2</sup> = D

(5) R<sup>1</sup> = SnBu<sub>3</sub><sup>n</sup>, R<sup>2</sup> = H

(6) R<sup>1</sup> = D, R<sup>2</sup> = H

(7) R<sup>1</sup> = D, R<sup>2</sup> = D

refluxing benzene, in the presence of a trace of azobisisobutyronitrile, led to the formation of thiazolines (9) and (10). These products were difficult to purify, repeated chromatography on silica causing loss of the tin moiety giving dithiourethane (11)† which was isolated in 30% overall yield. A more efficient cleavage of the tin moiety was achieved by treatment with tetra-n-butylammonium

† Satisfactory spectroscopic data were obtained for all new compounds. In addition thiazolines (11), (12), and (13) were characterized using accurate mass data.

fluoride<sup>4</sup> in dioxan (25 °C, 12 h). Use of this procedure, for example, in the case of the triphenylstannylthiothiazoline (10), led to the isolation of the dithiourethane (11) in 68% yield after silica chromatography. Alternatively, treatment of the triphenylstannylthiothiazoline (10) with methyl

iodide<sup>5</sup> in benzene (25 °C, 5 days), followed by aqueous potassium fluoride (to remove tin residues), led to the isolation of the crystalline methylthiothiazoline (12), m.p. 84–86 °C,  $[\alpha]_D -229^\circ$  (CHCl<sub>3</sub>), in 48% yield after silica chromatography. The structure of (12) was established by spectroscopic methods, e.g.  $\nu_{max}$  1760, 1730, and 1560 cm<sup>-1</sup>,  $\delta$  (CDCl<sub>3</sub>) 0.95 and 1.3 (each 3H, d, *J* 6.5 Hz, CHMe<sub>2</sub>), 2.1–2.4 (1H, m, CHMe<sub>2</sub>), 2.60 (3H, s, SCH<sub>3</sub>), 3.75 (3H, s, CO<sub>2</sub>CH<sub>3</sub>), 4.15 (1H, d, *J* 8.8 Hz, CHCO<sub>2</sub>Me), and 5.9 and 6.04 (each 1H, d, *J* 4.1 Hz, NCH and CHS). Finally, treatment of thiazoline (9) with bromine (1 mol)<sup>5</sup> led to the formation of disulphide (13), 59% isolated after silica chromatography.

The formation of thiazolines (9) and (10) is reminiscent of the formation of thiazolines (15) on attempted AgNO<sub>3</sub>-catalysed hydrolysis of the 6 $\alpha$ -fluoro-6 $\beta$ -iminochlorides (14).<sup>6</sup> However a radical process must be involved in our case. Perhaps addition of the trialkyltin radical to the isothiocyanato-group to give adduct (16) is followed by intramolecular capture and cleavage of the sulphur-C(2) bond to give the tertiary radical (17). Transfer of a hydrogen atom to this radical from the tin hydride reagent would then complete the cycle. This radical-induced sulphur-C(2) cleavage is analogous to the reverse of a proposed mechanism for the formation of the thiazolidine ring in penicillin biosynthesis.<sup>7</sup>

A similar mechanism seems to be involved in the formation of the thiazoline side products observed in the 6 $\beta$ -

isocyanopenicillanate reductions.<sup>1</sup> Use of Bu<sub>3</sub>SnD to reduce the 6 $\alpha$ -(1-hydroxy-1-methylethyl)-6 $\beta$ -isocyanopenicillanate (1; R<sup>2</sup> = Me<sub>2</sub>COH) gave the thiazoline (4) labelled at the valine  $\beta$ -position only, consistent with this proposal. Moreover, examination of the reduction of isonitrile (1; R<sup>2</sup> = Me<sub>2</sub>COH) by Bu<sub>3</sub>SnH suggests that the immediate rearrangement product is the unstable tri-*n*-butyltin thiazoline intermediate (5) since the imino-proton (R<sup>1</sup>) is not observable by <sup>1</sup>H n.m.r. spectroscopy. This intermediate thiazoline (5) rapidly loses the tin moiety on silica chromatography (or more slowly over a period of weeks in chloroform solution) to provide thiazoline (3). If the intermediate (5) is decomposed by treatment with D<sub>2</sub>O-acetone in the presence of silica, deuteriated thiazoline (6) is obtained together with a small amount of the non-deuteriated product, (6):(3) = 4:1. Moreover reduction of isonitrile (1; R<sup>2</sup> = Me<sub>2</sub>COH) with Bu<sub>3</sub>SnD, followed by decomposition of the intermediate tri-*n*-alkylstannylthiazoline in D<sub>2</sub>O-acetone-silica, led to an analogous mixture comprising the dideuteriothiazoline (7), and the monodeuteriothiazoline (4), again in a ratio of 4:1, respectively.

We thank the S.R.C. for a CASE award (to N. D. T.) and Beecham Pharmaceuticals for generous support.
