Iridium(II) octaethylporphyrin dimer, $[\text{Ir}(\text{OEP})]_2$, has been prepared by photolysis of $(\text{OEP})\text{IrCH}_3$ in C_6D_6 solvent, and found to undergo alkene insertion and oxidative addition of alkyl C-H bonds.

Iridium(II) octaethylporphyrin dimer, $[\text{Ir}(\text{OEP})]_2$ (**1**), is the exclusive metalloporphyrin product that results from photolysis (λ 350 nm) of $(\text{OEP})\text{IrCH}_3$ ¹ in C_6D_6 solvent (reaction 1).[†] Photohomolytic cleavage of the Ir-CH₃ bond² is shown to be an important pathway by the observed trapping of methyl radicals by C_6D_6 solvent to form $\text{CH}_3\text{C}_6\text{D}_5$ and CH_3D (Figure 1).³ The ¹H n.m.r. and electronic spectra for compound (**1**) are analogous to the spectra previously reported for $[\text{Rh}(\text{OEP})]_2$,⁴ and are uniquely characteristic of metal-metal bonded octaethylporphyrin dimers (Figures 1 and 2).⁵

There is only one previous report of a compound that contains an unsupported Ir^I-Ir^{II} bond,⁶ and reactions involving the metal-metal bond have not been reported. Several of the key organometallic reactions of $[\text{Ir}(\text{OEP})]_2$ have been evaluated, including oxidative addition of H₂ and alkyl C-H bonds, and alkene insertion (reactions 2-6).^{7†} The organometallic products from reactions (3) and (4) were separated from reaction mixtures by t.l.c. (silica), and characterized by ¹H n.m.r., i.r., and mass spectroscopy. $(\text{OEP})\text{Ir}(\text{H})$ produced

in reactions (4) and (5) reacts with excess of aldehyde to form α -hydroxyalkyl complexes $(\text{OEP})\text{IrCH}(\text{OH})\text{R}$ (R = H, CH₃).[§] $(\text{OEP})\text{IrCH}_2\text{CH}(\text{OEt})\text{Ir}(\text{OEP})$ was characterized by the exceptionally high field proton chemical shifts and a pattern of proton coupling constants consistent with an approximate *trans* arrangement of $(\text{OEP})\text{Ir}$ units; see structure (A): ¹H n.m.r. (C_6D_6) δ - 1.14 (3H, t, ³J_{HH} 6.6 Hz,

[§] *Spectroscopic data:* $(\text{OEP})\text{IrCH}_2\text{Ph}$: ¹H n.m.r. (C_6D_6) δ 9.75 (4H, s, porphyrin -CH=), 6.23 (1H, t, Ph *p*-H), 5.68 (2H, t, Ph *m*-H), 3.87 (16H, q, CH₂Me), 2.94 (2H, d, Ph *o*-H), 1.87 (24H, t, CH₂Me), and -4.25 (2H, s, CH₂Ph); *m/z* 816/814 (*M*⁺).

$(\text{OEP})\text{IrCH}_2\text{C}(\text{:O})\text{H}$: ¹H n.m.r. (C_6D_6) δ 10.07 (4H, s, porphyrin -CH=), 3.93 (16H, m, CH₂Me), 3.79 [1H, t, C(:O)H], 1.88 (24H, t, CH₂Me), and -4.68 (2H, d, ³J_{HH} 4.4 Hz, CH₂CHO); ν_{CO} (KBr) 1693 cm⁻¹.

$(\text{OEP})\text{IrCH}(\text{OH})\text{Me}$: ¹H n.m.r. (C_6D_6) δ 9.93 (4H, s, porphyrin -CH=), 3.94 (16H, m, CH₂Me), 1.87 (24H, t, CH₂Me), -3.25 [1H, p, ³J_{HH} 5.3 Hz, CH(OH)Me], -4.16 [3H, d, CH(OH)Me], and -4.73 (1H, d, OH).

$(\text{OEP})\text{IrCH}_2\text{OH}$: ¹H n.m.r. (C_6D_6) δ 9.94 (4H, s, porphyrin -CH=), 3.92 (16H, m, CH₂Me), 1.88 (24H, t, CH₂Me), -2.95 (2H, d, ³J_{HH} 7.3 Hz, CH₂OH), and -5.30 (1H, t, CH₂OH); ¹³CH₂OH compound: CH₂OH becomes dd, ¹J_{CH} 157.3, ³J_{HH} 7.3 Hz, and OH m, ²J_{CH} 5.2 Hz.

$(\text{OEP})\text{IrCH}_2\text{CH}(\text{OEt})\text{Ir}(\text{OEP})$: ¹H n.m.r. (C_6D_6) δ 9.20 and 8.99 (total 8H, s, porphyrin -CH=), 3.92 and 3.73 (total 32H, overlapping m, CH₂Me), and 1.72 (48H, t, CH₂Me): see text for bridging CH₂CH(OEt).

[†] In a typical photoreaction, a solution composed of $(\text{OEP})\text{IrCH}_3$ (2 mg) and C_6D_6 (0.3 ml) was sealed *in vacuo* in a Pyrex container, and irradiated for 180 h in a Rayonet Photochemical Reactor equipped with RPR-3500 Å lamps. The quantum yield for this process was determined to be 0.018 ± 0.005 ($310 \leq \lambda \leq 410$ nm).

[‡] Reactions were performed at 25°C in C_6D_6 solvent with a slight excess of reagent, unless otherwise stated.

Figure 1. ^1H N.m.r. spectrum of $[\text{Ir}(\text{OEP})_2]_2$ formed *in situ* by photolysis of $(\text{OEP})\text{IrCH}_3$ in C_6D_6 .

OCH_2Me), -10.92 (1H, d, $J_{1,3}$ 9.45 Hz, H^1), -10.11 (1H, t, H^3), and -8.63 (1H, d, $J_{2,3}$ 10.5 Hz, H^2); $J_{1,2} \leq 1.5$ Hz. §

Figure 2. Electronic spectra in C_6H_6 for a 5.1×10^{-5} M solution of $[\text{Ir}(\text{OEP})_2]_2$ (—) formed *in situ* by photolysis of a 1.02×10^{-4} M solution of $(\text{OEP})\text{IrCH}_3$ (---), with λ_{max} values (and ϵ values in parentheses).

Reactions (2)—(6), which are analogous to previously reported reactions of $[\text{Rh}(\text{OEP})_2]_2$,^{4,7,8} probably proceed through the intermediacy of the metallo-radical, $(\text{OEP})\text{Ir}^\cdot$, formed by homolytic dissociation of the $\text{Ir}^{\text{II}}-\text{Ir}^{\text{II}}$ bond. Selective reaction with methyl C—H bonds in toluene is compatible with a metallo-radical mechanism in analogy with the reactions of organic radicals with toluene.⁹

Reaction of (1) with acetaldehyde selectively produces the

β -formyl complex, (OEP)IrCH₂C(O)H, which corresponds to the net activation of the stronger methyl C–H bond ($D_{C-H} \approx 95$ kcal/mol; 1 kcal = 4.184 kJ) in preference to the weaker aldehydic C–H bond ($D_{C-H} \approx 86$ kcal/mol).¹⁰ Several examples of ketone alkyl α -CH bond reactivity with transition metals are known,^{11–13} but aldehydes have invariably reacted with metallo species at the aldehydic C–H bond.^{13,14} We believe that this unusual example of C–H bond reactivity occurs through a kinetic pathway which utilizes the enol form of acetaldehyde [CH₂=CH(OH)]. Addition of (1) to CH₂=CH(OH), by the metallo-radical mechanism proposed by Halpern for [Rh(OEP)]₂,⁷ would produce an intermediate bridging complex, (OEP)IrCH₂CH(OH)Ir(OEP), and subsequently eliminate (OEP)IrH (reaction 7). Plausibility for the

intermediate addition product is established by reaction (6) in which the bridging complex, (OEP)IrCH₂CH(OEt)Ir(OEP), is stabilized by substituting an ethoxy group for the hydroxy unit.

Current studies of this system are focused on more detailed kinetic–mechanistic studies of reactions (2)–(6).
