Reaction of the cluster  $[\text{Os}_3(\text{CO})_{10}(\text{MeCN})_2]$  with formylferrocene gives the oxidative addition product  $[\text{Os}_3\text{H}(\mu\text{-FcCO})(\text{CO})_{10}]$  (Fc = ferrocenyl) (structurally characterised by X-ray crystallography), which has been shown by cyclic voltammetry and i.r. spectroelectrochemistry to undergo a reversible one-electron oxidation at iron and an irreversible two-electron reduction at the osmium cluster.

Benzaldehyde reacts with  $[\text{Os}_3(\text{CO})_{12}]$  (**1**) or  $[\text{Os}_3(\text{CO})_{10}(\text{MeCN})_2]$  (**2**) to give the benzoyl cluster  $[\text{Os}_3\text{H}(\mu\text{-PhCO})(\text{CO})_{10}]$ <sup>1,2</sup> which undergoes a double decarbonylation in refluxing nonane (150 °C) to give the benzyne (*ortho*-phenylene) cluster  $[\text{Os}_3\text{H}_2(\mu_3\text{-C}_6\text{H}_4)(\text{CO})_9]$ , which may also be formed by direct reaction of benzene with (**1**).<sup>3</sup> We have unsuccessfully attempted to copy this chemistry as a route to

the analogous ferrocene cluster  $[\text{Os}_3\text{H}_2(\mu_3\text{-C}_5\text{H}_3\text{FeC}_5\text{H}_5)(\text{CO})_9]$ . Direct reactions of ferrocene with  $[\text{Os}_3(\text{CO})_{12}]$  or  $[\text{Os}_3(\text{CO})_{10}(\text{MeCN})_2]$  require very high temperatures and give no tractable products; however, cluster (**2**) [or (**1**), less effectively and at higher temperatures] reacts with formylferrocene (FcCHO) in refluxing cyclohexane (45 min) to give the acyl oxidative addition product  $[\text{Os}_3\text{H}$

**Figure 1.** Molecular structure of  $[\text{Os}_3\text{H}(\text{FeCO})(\text{CO})_{10}]$  (**3**). H-atoms were not located but the hydride ligand probably lies close to the intersection of the  $\text{Os}(3)\text{--C}(6)$  and  $\text{Os}(1)\text{--C}(1)$  directions. Bond lengths:  $\text{Os}(1)\text{--Os}(2)$  2.879(4),  $\text{Os}(2)\text{--Os}(3)$  2.843(4),  $\text{Os}(1)\text{--Os}(3)$  2.888(4),  $\text{Os}(1)\text{--C}(11)$  2.072(11),  $\text{Os}(3)\text{--O}(11)$  2.093(9),  $\text{C}(11)\text{--O}(11)$  1.273(11),  $\text{C}(11)\text{--C}(12)$  1.478(14) Å. Bond angles:  $\text{Os}(3)\text{--O}(11)\text{--C}(11)$  109.9(7),  $\text{Os}(1)\text{--C}(11)\text{--O}(11)$  115.8(8),  $\text{Os}(1)\text{--C}(11)\text{--C}(12)$  131.6(7),  $\text{C}(12)\text{--C}(11)\text{--O}(11)$  112.5(9)°.

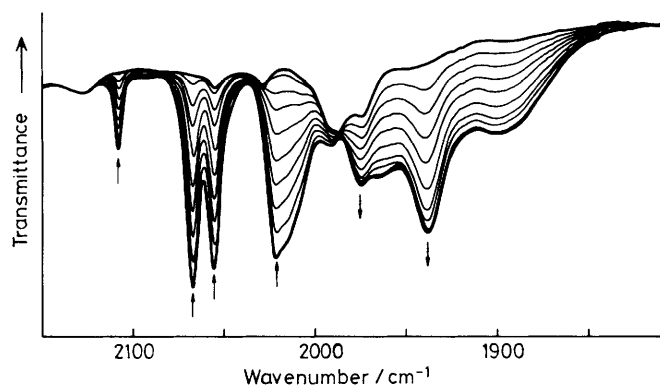

$(\text{FcCO})(\text{CO})_{10}$  (**3**) as red crystals (68% yield) after t.l.c. on silica. The i.r. and n.m.r. spectral data for (**3**),<sup>†</sup> when compared with those of the corresponding benzoyl complex,<sup>1,2</sup> indicate that these complexes have related structures. To confirm this we have determined the single crystal X-ray structure of (**3**) (Figure 1).<sup>‡</sup> The ferrocenyl (Fc) group is linked to the  $\text{Os}_3\text{H}(\text{CO})_{10}$  group through the carbonyl  $\text{C}(11)\text{O}(11)$ . The  $\text{FcCO}$  ligand relates directly to other  $\mu$ -acyl ligands such as phenacyl ( $\text{PhCH}_2\text{CO}$ ).<sup>2</sup> The strongest contact between the acyl and the metal atoms is through  $\text{C}(11)$ , and the bond *trans* to it [ $\text{Os}(1)\text{--C}(2)$  1.955(13) Å] is much longer than the bond *trans* to  $\text{O}(11)$  [ $\text{Os}(3)\text{--C}(5)$  1.883(14) Å].

<sup>†</sup> Selected spectroscopic data for cluster (**3**): parent molecular ion (EI mass spectrum):  $\nu(\text{CO})$  ( $\text{CH}_2\text{Cl}_2$ ) ( $\text{cm}^{-1}$ ) 2107(m), 2067(s), 2055(s), 2021(s), 2017(sh), 2008(sh), 1991(m), 1974(m);  $^1\text{H}$  n.m.r. ( $\text{CDCl}_3$ ),  $\delta$  4.72 (m, 1H,  $\text{C}_5\text{H}_4$ ), 4.65 (m, 1H,  $\text{C}_5\text{H}_4$ ), 4.62 (m, 2H,  $\text{C}_5\text{H}_4$ ), 4.16 (s,  $\text{C}_5\text{H}_5$ ), -13.75 (s, OsH). For cluster (**4**):  $\nu(\text{CO})$  ( $\text{C}_6\text{H}_{12}$ ) ( $\text{cm}^{-1}$ ) 2095(m), 2050(s), 2016(s), 2010(m), 2004(w), 1998(m), 1978(w), 1968(m), 1930(m);  $^1\text{H}$  n.m.r. ( $\text{CDCl}_3$ )  $\delta$  4.82 (m, 2H,  $\text{C}_5\text{H}_4$ ), 4.80 (m, 1H,  $\text{C}_5\text{H}_4$ ), 4.59 (m, 1H,  $\text{C}_5\text{H}_4$ ), 4.20 (s,  $\text{C}_5\text{H}_5$ ), 3.01 (s, Me), -12.34 (s, OsH). For cluster (**5**):  $\nu(\text{CO})$  ( $\text{CH}_2\text{Cl}_2$ ) ( $\text{cm}^{-1}$ ) 2113(m), 2075(s), 2062(s), 2032(s), 2018(s), 2007(m), 2000(sh), 1985(w).

<sup>‡</sup> Crystal data for (**3**):  $\text{C}_{21}\text{H}_{10}\text{FeO}_{11}\text{Os}_3$ ,  $M = 1064.75$ , monoclinic, space group  $P2_1/a$ ,  $a = 14.102(6)$ ,  $b = 12.492(4)$ ,  $c = 14.264(6)$  Å,  $\beta = 99.47(3)^\circ$ ,  $U = 2478(2)$  Å<sup>3</sup>,  $Z = 4$ ,  $F(000) = 1912$ ,  $\text{Mo-K}\alpha$  radiation (graphite monochromated),  $\lambda = 0.71069$  Å,  $\mu(\text{Mo-K}\alpha) = 159.9$   $\text{cm}^{-1}$ ,  $D_c = 2.854$   $\text{g cm}^{-3}$ , 4351 independent reflections, absorption corrected, 3190 with  $I > 3.0\sigma(I)$  used, heavy-atom methods (SHELXS-84),  $R = 0.029$ ,  $R_w = 0.030$ . Non-hydrogen atoms refined anisotropically, hydrogen atoms not included in the model, 325 parameters refined. Atomic co-ordinates, bond lengths and angles, and thermal parameters have been deposited at the Cambridge Crystallographic Data Centre. See Notice to Authors, Issue No. 1.

**Figure 2.** (a) Time-resolved i.r. spectra (interval 10 s) and (b) corresponding difference spectra, of a solution of (**3**) in  $\text{CH}_2\text{Cl}_2$  on changing the applied potential from 0.00 to +1.00 V. The arrows indicate the directions of intensity changes on oxidation of (**3**) to (**5**).

**Figure 3.** Time-resolved i.r. spectra (interval 10 s) of a solution of (**3**) in  $\text{CH}_2\text{Cl}_2$  during a two-electron reduction initiated by changing the applied potential from 0.00 to -2.00 V. The arrows indicate the directions of intensity changes on reduction.

In spite of the structural and spectroscopic similarity between the clusters  $[\text{Os}_3\text{H}(\text{RCO})(\text{CO})_{10}]$  ( $\text{R} = \text{Ph}$ ,  $\text{PhCH}_2$ , or  $\text{Fc}$ ), the  $\text{PhCO}$  complex readily decarbonylates to  $[\text{Os}_3\text{H}_2(\text{C}_6\text{H}_4)(\text{CO})_9]$  at 150 °C, whereas the  $\text{FcCO}$  complex is remarkably stable even in refluxing decane (173 °C) and does not decarbonylate on u.v. irradiation. However, it does react with an excess of  $\text{Me}_3\text{NO}\cdot 2\text{H}_2\text{O}$  to give  $[\text{Os}_3\text{H}(\text{FcCO})(\text{CO})_9(\text{NMe}_3)]$  (**4**) in moderate yield.<sup>†</sup> Even though this compound contains weakly co-ordinated  $\text{NMe}_3$ , there is no observable tendency for Fc transfer from carbon to osmium,

and on being heated (4) decomposes to (3). It is possible that the ferrocene cluster is stable but that a large kinetic barrier to Fc migration prevents its formation by this route.

Interested in the transmission of electronic effects through complexes,<sup>4</sup> in this case through the linking carbonyl C(11)O(11), we have examined the electrochemistry and spectroelectrochemistry of cluster (3). Cyclic voltammetry (c.v.) studies show that this cluster in dichloromethane solution undergoes reversible one-electron oxidation at +0.80 V, § close to the oxidation potential for formylferrocene (+0.78 V). Since the benzoyl analogue [Os<sub>3</sub>H(PhCO)(CO)<sub>10</sub>] shows only an irreversible oxidation at +1.36 V, we can be sure that the oxidation of (3) is at the Fc group [to give the ferrocenium cation (5)] and not at the triosmium centre. Figure 2 shows time-resolved i.r. spectra of (3) (and difference spectra) during its oxidation to (5) in an i.r. spectroelectrochemical cell<sup>5</sup> initiated by switching the applied potential from 0.00 to +1.00 V, *i.e.* about 0.20 V beyond the oxidation potential. The spectra of (3) and its oxidised form (5) are very similar in shape showing that there is no substantial structural difference between the two compounds. The  $\nu(\text{CO})$  wavenumbers are 6–8 cm<sup>-1</sup> higher for (5) than for (3) so that, although it is primarily the ferrocene moiety that is oxidised, there is estimated to be a positive charge of *ca.* 0.15 on the triosmium component of cation (5) relative to that on (3); this is based on an expected wavenumber change of +45 to +50 cm<sup>-1</sup> on introducing a full positive charge.<sup>6</sup> The spectral changes in Figure 2 are totally reversible on returning the potential to 0.00 V.

An irreversible two-electron reduction of (3) in dichloromethane occurs at -1.63 V with an associated re-oxidation at

-0.46 V. Time-resolved i.r. spectroelectrochemical results (Figure 2) show that the reduction is cluster based with a build-up of negative charge at the osmium atoms and that on re-oxidation there is about 80% recovery of compound (3). The reduced species has not been fully characterised, but its generation probably involves either loss of CO, the process being substantially reversed on re-oxidation, or a structure change involving Os–Os bond cleavage, or possibly conversion of the acyl into a monodentate ligand. We have looked unsuccessfully for spectral changes at lower wavenumbers which might have characterised this structural change.

This work exemplifies the potential of spectroelectrochemistry in direct characterisation of oxidation and reduction products.

We are grateful to Professor W. R. Cullen for suggesting that ferrocene complexes might possibly be synthesised in this way, and to the S.E.R.C. for support of the crystallographic and spectroelectrochemical studies and for a studentship (to N. I. P.) and a fellowship (to R. C. S. McQ.).
