Cyclopentadien-5-ols, the major products resulting from decomposition of some ferrocenium cations by molecular oxygen, are regio- and stereo-selectively trapped by 4-phenyl-1,2,4-triazoline-3,5-dione.

In oxygenated organic solvents, ferrocenium cations are unstable¹ and can easily be used for generating substituted cyclopentadienes in the presence of very reactive dienophiles. The strong dienophilic character of cyclic α -carbonyl azo compounds is well known.²⁻⁶ These are generally prepared by chemical oxidation of the corresponding hydrazino compounds using lead(IV) acetate^{7,8} or *tert*-butyl hypochlorite.^{9–11} We report herein the co-oxidation of ferrocenes and a triazolidinedione (urazole) in a flow cell fitted with a graphite felt porous anode.¹² Electrolyses were performed in acidified MeCN (2% H_2SO_4); solid sodium carbonate and oxygen were added to the solution of triazolinedione and ferrocenium cations at the outlet of the cell. Decomposition of ferrocenium cations proceeded via unexpected cyclopentadien-5-ols as major products which were trapped in situ with 4-phenyl-1,2,4-triazoline-3,5-dione (Scheme 1). To the best of our knowledge, this reaction has never been reported before. Theoretical calculations show that the three cyclopentadienol isomers should be very unstable.¹³ Previously, cyclopentadienol has only been postulated as an intermediate during a thermal retro-Diels-Alder reaction.14

Decomposition of ferrocenium cation 1a in the presence of triazolinedione 2 was complete after 1 h and gave a mixture of 3a and 4a. The yield of 3a increased as the molar ratio triazolinedione:ferrocenium cation increased, whereas the yield of 4a was practically unchanged (Table 1). The ¹H and ¹³C NMR spectra of 3a show a regio- and stereo-selective addition. X-Ray analyses show that 3a results from an *exo* addition

(Fig. 1) and **4a** from an *endo* addition. Compound **4a** is identical to the Diels–Alder adduct prepared by a different method using **2** and freshly distillated cyclopentadiene.⁸

1,1'-Dialkylated ferrocenium cations 1b and 1d decomposed more slowly than 1a and gave, after reaction with 2, compounds 3b and 3d respectively. The ¹H and ¹³C NMR spectra of 3b and 3d and the X-ray analysis of 3b (Fig. 2) indicate a regioselective *exo*-addition like that for 3a. After decomposition of monoalkylated ferrocenium cation 1c and reaction with 2, a mixture of 3a and 3d was isolated. Compounds 3a and 3d were separated by column chromatography. Adduct 4a was not detected.

The rate of decomposition of acetylferrocenium 1e and 1,1'-diacetylferrocenium 1f was much faster. Thus 1f gave a mixture of unidentified products and 1e gave 3a in poor yield (12%).

Table 1 Composition of mixtures from decomposition of ferroceniumcations 1 in the presence of 4-phenyl-1,2,4-triazoline-3,5-dione

Substrates (molar ratio)	Products (% yield ^a)
1a + 2 (1:1)	3a (46) + 4a (12)
1a + 2(1:2)	3a (69) + 4a (14)
1a + 2(1:3)	3a $(80) + 4a$ (15)
1b + 2(1:2)	3b (41)
1c + 2(1:2)	3a(24) + 3d(45)
1d + 2(1:2)	3d (52)
1e + 2(1:2)	3a (12)
1f + 2(1:2)	

^a Calculated from initial ferrocene.

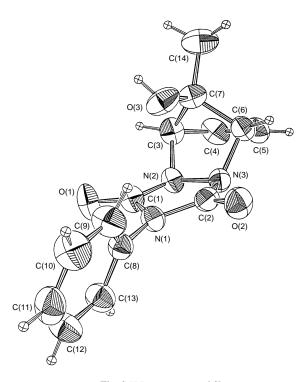

Fig. 2 X-Ray structure of 3b

Decomposition of ferrocenium cation is probably initiated *via* radical coupling with molecular oxygen as previously suggested.¹ After rearrangement and chemical evolution, cleavage of the iron and the formed cyclopentadienol ligand takes place, whereas only limited decomplexation of the second ligand (in case of **1a**) leads to free cyclopentadiene. To support this hypothesis, we note that the oxygen decomposition of ferrocenium cations in MeCN gave a brown precipitate characterised as an iron salt; elemental analyses of this salt showed the presence of one cyclopentadienyl ligand.¹⁵
