Exposure of tertiary thioamides to (*E*)-1-hexenyl(phenyl)- $\lambda^3$ -iodane results in vinylic  $S_N2$  reaction to give the inverted (*Z*)-*S*-vinylthioimidonium salts, which under alkaline hydrolysis ( $\text{Na}_2\text{CO}_3$  or  $\text{K}_2\text{CO}_3$ ) selectively afford amides, while (*Z*)-*S*-vinyl thioesters are obtained in high yields *via* the hydrolysis under acidic conditions (HCl).

(*E*)-Alkenyl(phenyl)- $\lambda^3$ -iodanes **1** undergo vinylic  $S_N2$  reactions under mild conditions because of the very high leaving group ability of phenyl- $\lambda^3$ -iodanyl groups.<sup>1</sup> The reaction affords (*Z*)-vinylic compounds with exclusive inversion of configuration.<sup>2,3</sup> Nucleophiles that undergo vinylic  $S_N2$  reaction with (*E*)-alkenyl(phenyl)- $\lambda^3$ -iodanes **1** include halides,<sup>2</sup> dialkyl sulfides and selenides,<sup>3a</sup> phosphoroselenoates,<sup>4a</sup> dithiocarbamates,<sup>4b</sup> and carboxylic acids.<sup>5</sup> Formamides and acetamides with rather low nucleophilicity also act as good nucleophiles toward  $\lambda^3$ -iodanes **1**, and afford (*Z*)-vinyl formates and (*Z*)-vinyl acetates, respectively, in a highly stereoselective manner.<sup>6</sup> Use of thioamides as nucleophiles, however, affords (*Z*)-enethiols stereoselectively, instead of (*Z*)-*S*-vinyl thiocarboxylates:<sup>7</sup> for instance, reaction of (*E*)-1-decenyloxy(phenyl)- $\lambda^3$ -iodane **1b** with thioacetamide in dichloromethane at room temperature results in formation of (*Z*)-1-mercaptodec-1-ene in 82% yield with exclusive inversion of configuration. This reaction involves the intervention of the highly labile (*Z*)-*S*-vinylthioimidonium salt, produced through nucleophilic attack by the sulfur atom of thioacetamide on (*E*)-1-decenyloxy- $\lambda^3$ -iodane **1b** from the side opposite the hyperleaving group  $\text{PhI}(\text{BF}_4)$  stereoselectively. Subsequent hydrolysis of the (*Z*)-*S*-vinylthioimidonium salt affords the retained (*Z*)-enethiol. The fact that, in the reaction with thioamides, (*E*)-alkenyl(phenyl)- $\lambda^3$ -iodane **1b** selectively captures the sulfur atom by forming (*Z*)-enethiols suggested to us that the  $\lambda^3$ -iodane **1** could function as an agent for the conversion of thioamides to amides. We report herein on vinylic  $S_N2$ -based conversion of thioamides into amides, in which (*E*)-alkenyl(phenyl)- $\lambda^3$ -iodanes **1** act as efficient sulfur atom acceptor agents.

Diverse synthetic methods are available for the conversion of thioamides into amides.<sup>8</sup> These include oxidative conversion using hydrogen peroxide, *m*-chloroperbenzoic acid, diaryl telluroxide, manganese dioxide and (diacetoxyiodo)benzene, as well as hydrolytic conversion catalyzed by soft metal ions such as  $\text{Cu}(\text{I})$ ,  $\text{Ag}(\text{I})$  and  $\text{Hg}(\text{II})$ . Alkylation of thioamides followed by alkaline hydrolysis is an effective alternative for conversion into amides.

Exposure of tertiary thioamides to (*E*)-1-hexenyl(phenyl)- $\lambda^3$ -iodane **1a**, prepared from (*E*)-1-hexenylboronic acid by the  $\text{BF}_3$ -catalyzed reaction with (diacetoxyiodo)benzene *via* boron- $\lambda^3$ -iodane exchange in 82% yield,<sup>9</sup> results in vinylic  $S_N2$  reaction to give the inverted (*Z*)-*S*-vinylthioimidonium salts **2** stereoselectively in >90% yields (Scheme 1). For instance, reaction of  $\lambda^3$ -iodane **1a** with *N,N*-dimethylcyclohexanecarbothioamide in dichloromethane at 50 °C for 17 h gave (*Z*)-*S*-vinylthioimidonium tetrafluoroborate **2a** (98%) as a colorless oil.† A small vicinal coupling constant ( $J = 8.9$  Hz) between the vinylic protons in  $^1\text{H}$  NMR indicates a *cis* structure. The reaction is exclusively stereoselective to the limits of  $^1\text{H}$  NMR detection with inversion of olefin geometry. As shown in Table

1, a variety of *N,N*-dimethyl and *N*-methyl-*N*-phenyl tertiary thioamides as well as cyclic *N*-methylpyrrolidine-2-thione afford *S*-vinylthioimidonium salts **2** in high yields.

The imidonium salts **2** are labile and highly susceptible to hydrolysis with moisture (Scheme 2); exposure of **2a** to  $\text{THF-H}_2\text{O}$  (10:1) at room temperature for 4 h results in the hydrolysis to give a mixture of the amide **3a** ( $\text{R}^1 = c\text{-C}_6\text{H}_{11}$ ,  $\text{R}^2 = \text{Me}$ , 71%) (probably with liberation of (*Z*)-1-mercapto-1-hexene) and (*Z*)-*S*-vinyl thiocarboxylate **4a** ( $\text{R} = \text{Bu}^n$ ,  $\text{R}^1 = c\text{-C}_6\text{H}_{11}$ , 29%). Use of alkali metal carbonates ( $\text{M}_2\text{CO}_3$ ;  $\text{M} = \text{Na}, \text{K}, \text{Rb}, \text{Cs}$ ) as an additive not only accelerates the hydrolysis but also increases the selectivity for amide formation (Table 2); thus,  $\text{Na}_2\text{CO}_3$  or  $\text{K}_2\text{CO}_3$  in THF gave a high yield of the amide **3a** (>90%) within 20 min at room temperature (Table 2, entries 2 and 3), along with the formation of (*Z*)-*S*-vinyl thiocarboxylate **4a** in less than 8% yield. Formation of thioamide (14–17%) was observed when the hydrolysis was carried out in the presence of

<sup>a</sup> Unless otherwise noted, reactions were carried in THF at room temperature under nitrogen. <sup>b</sup> Yields were determined by <sup>1</sup>H NMR. Isolated yields are shown in parenthesis. <sup>c</sup> In THF–H<sub>2</sub>O (2:1). <sup>d</sup> Thioamides were obtained in 14–20% yields. <sup>e</sup> Reaction temperature: 0 °C. <sup>f</sup> In THF–H<sub>2</sub>O (4:1).

Rb<sub>2</sub>CO<sub>3</sub> or Cs<sub>2</sub>CO<sub>3</sub>. Use of AgOAc in THF–H<sub>2</sub>O (2:1) is an effective alternative and afforded **3a** in 87% yield (Table 2, entry 6). Hydrolysis of the cyclic imidonium salt **2i** with K<sub>2</sub>CO<sub>3</sub> gave an 81% yield of *N*-methyl-2-pyrrolidinone **3i**. The alkaline hydrolysis of the imidonium salts **2d–f** with aromatic R<sup>1</sup> group proceeds slowly and takes a longer reaction time than that of **2a–c** with aliphatic R<sup>1</sup> groups.

In marked contrast, hydrolysis of the imidonium salts **2** under acidic conditions is slow and selectively gives rise to (*Z*)-*S*-vinyl thiocarboxylates **4**: thus, treatment of **2a** with 10% aqueous HCl solution at room temperature for 11 h afforded the thiocarboxylate **4a** as a colorless oil in 81% yield, along with the formation of the amide **3a** (14%).<sup>10</sup> Under similar conditions, the imidonium salts **2c**, **2g** and **2h** gave the (*Z*)-*S*-vinyl thiocarboxylates **4c** (R = Bu<sup>n</sup>, R<sup>1</sup> = *c*-C<sub>5</sub>H<sub>9</sub>), **4g** (R = R<sup>1</sup> = Bu<sup>n</sup>) and **4h** (R = Bu<sup>n</sup>, R<sup>1</sup> = Ph) in 81, 72 and 83% yields, respectively. Acidic hydrolysis accompanies the isomerization of the double bond geometry to a discernible extent by <sup>1</sup>H NMR: less than 5% for **4c** and **4g**, and 10% for **4h**.

Hydrolysis of the imidonium salts **2** under basic conditions probably involves the tetrahedral uncharged **5** and charged intermediates **6** (Scheme 3). Decomposition of **6** is a product determining step and selectively produces the amide **3** through C–S bond cleavage with liberation of (*Z*)-enethiol, because of the greater leaving ability of a vinylthio group than that of an amino group. Formation of (*Z*)-enethiol **7** was confirmed by the hydrolysis (5% Na<sub>2</sub>CO<sub>3</sub>/THF/rt/25 min) of **2j** (R = *n*-C<sub>8</sub>H<sub>17</sub>, R<sup>1</sup> = *c*-C<sub>6</sub>H<sub>11</sub>, R<sup>2</sup> = Me), which afforded a mixture of (*Z*)-enethiol **7** (R = *n*-C<sub>8</sub>H<sub>17</sub>, 14%) and its dimer, (*Z*)-1-decenyl 1-mercapto-

**Scheme 3**

decyl sulfide<sup>7</sup> (72%), along with the formation of amide **3a** (81%) and thioester **4a** (6%). The extent of C–S bond cleavage decreases when the reaction was carried out under acidic conditions. Under acidic conditions, protonation to the tetrahedral intermediate **5** with formation of the conjugate acids would play an important role and the (*Z*)-*S*-vinyl thiocarboxylate **4** is produced selectively through protonation at the more basic nitrogen atom. Amide formation *via* *S*-protonation of **5** will be a disfavoured process.

In the alkali metal carbonate-accelerated hydrolysis of **2**, changing the metal cation from Li to Na, K, Rb and Cs increases the selectivity for formation of the amide **3** over the thioester **4** (Table 1, entries 1–5). The results probably reflect differences in ionicity in the metal–oxygen bond, which increase in the order Li<sub>2</sub>CO<sub>3</sub> < Na<sub>2</sub>CO<sub>3</sub> < K<sub>2</sub>CO<sub>3</sub> < Rb<sub>2</sub>CO<sub>3</sub> < Cs<sub>2</sub>CO<sub>3</sub>.<sup>11</sup> An increased ionicity will result in a decrease in the rate of *N*-protonation of **5** leading to the formation of the thioester **4**.

In conclusion, a vinylic S<sub>N</sub>2-based strategy provides a method for conversion of thioamides to amides, in which (*E*)-alkenyl(phenyl)-λ<sup>3</sup>-iodanes serve as efficient sulfur atom acceptors. The basic hydrolysis of (*Z*)-*S*-vinylthioimidonium salts **2** involves selective C–S bond cleavage of charged tetrahedral intermediates **6**, whereas the acidic hydrolysis involves selective C–N bond cleavage of the conjugate acids of **5**.

## Notes and references

† *Typical experimental procedure* for synthesis of (*Z*)-*S*-vinylthioimidonium tetrafluoroborates **2** (Table 1, entry 1): to a stirred solution of λ<sup>3</sup>-iodane **1a** (0.27 mmol) in dichloromethane (5 mL) was added *N,N*-dimethylcyclohexanecarbothioamide (0.29 mmol) at room temperature under nitrogen and the mixture was warmed at 50 °C for 17 h. After cooling, the mixture was concentrated *in vacuo*. Purification of the crude product by repeated decantation with dichloromethane–hexane gave (*Z*)-*S*-vinylthioimidonium tetrafluoroborate **2a** (98%) as a colorless oil: δ<sub>H</sub> (300 MHz, CDCl<sub>3</sub>, /Hz) 0.93 (t, *J* 7.1, 3H), 1.2–1.8 (m, 10H), 1.90–2.05 (m, 4H), 2.31 (q, *J* 6.8, 2H), 3.09 (tt, *J* 11.6 and 3.2, 1H), 3.68 (s, 3H), 3.78 (s, 3H), 6.33 (br d, *J* 8.9, 1H), 6.38 (dt, *J* 8.9 and 6.8, 1H); ν<sub>max</sub>(neat)/cm<sup>-1</sup> 2931, 2859, 1607, 1453, 1150–1000; HRMS (FAB): calc. for C<sub>15</sub>H<sub>28</sub>NS [(M – BF<sub>4</sub>)<sup>+</sup>], *m/z* 254.1942, found 254.1962.
