**Au nanoparticles supported over  $\text{Co}_3\text{O}_4$  lead to a highly active and stable catalyst for  $\text{N}_2\text{O}$  decomposition even in the presence of excess oxygen and steam.**

Nitrous oxide ( $\text{N}_2\text{O}$ ) has been identified as a strong greenhouse effect gas with a global warming potential per molecule *ca.* 300 times that of carbon dioxide and as a contributor to the destruction of ozone in the stratosphere.<sup>1,2</sup> The emission of  $\text{N}_2\text{O}$  comes from both natural sources and human contributions, such as the production of adipic acid and nitric acid. The direct catalytic decomposition of  $\text{N}_2\text{O}$  into  $\text{N}_2$  and  $\text{O}_2$  is an attractive end-of-pipe solution to reduce  $\text{N}_2\text{O}$  emission, but few of the catalysts proposed in the literature show a good activity and stability for  $\text{N}_2\text{O}$  decomposition in the presence of excess oxygen and steam.<sup>2,3</sup> Gold was recognized as a poor catalyst,<sup>4</sup> however, when Au nanoparticles are highly dispersed on some metal oxides and hydroxides such as  $\text{TiO}_2$ ,  $\alpha\text{-Fe}_2\text{O}_3$ ,  $\text{Co}_3\text{O}_4$ ,  $\text{NiO}$  and  $\text{Mg}(\text{OH})_2$ , they exhibited activity for CO oxidation even at a temperature as low as  $-70^\circ\text{C}$ .<sup>5,6</sup> Such unusually high activity of gold strongly interacting with the support has later been confirmed by many research groups.<sup>7–10</sup> Kalback and Sliepcevich studied  $\text{N}_2\text{O}$  decomposition over an Au catalyst above 720 K in the absence of oxygen and steam.<sup>11</sup> In this study, nanoparticles of Au supported on  $\text{Co}_3\text{O}_4$  catalysts were shown to be very active and stable in direct  $\text{N}_2\text{O}$  decomposition even in the presence of excess oxygen and steam.

The catalysts were prepared by a co-precipitation method. Adding dropwise an aqueous solution of  $\text{Na}_2\text{CO}_3$  (10 wt%) to an mixed aqueous solution containing desired amounts of cobalt nitrate and  $\text{HAuCl}_4 \cdot 4\text{H}_2\text{O}$  at  $60^\circ\text{C}$  until the pH of the solution reached 8, and stirring for 3 h, led to the resultant precipitate which was washed until there were no chloride ions in the filtrate. The catalyst was then dried at  $80^\circ\text{C}$  overnight followed by calcination at  $550^\circ\text{C}$  in air for 5 h. The samples were characterized by XPS, XRD, TEM, AAS and  $\text{N}_2$  adsorption/desorption. The catalytic reaction was carried out in a standard fixed-bed flow reactor by passing a gaseous mixture of  $\text{N}_2\text{O}$  (1200 ppm),  $\text{O}_2$  (10 v/v%) and  $\text{H}_2\text{O}$  (5 v/v%) in a He flow at a total flow rate  $100\text{ ml min}^{-1}$  over 300 mg catalyst (total pressure: 1 atm; space velocity:  $20\,000\text{ h}^{-1}$ ). The products were monitored by two on-line gas chromatographs (PE autosystem XL) equipped with Molecular sieve 5A and Porapak Q columns, respectively.

The characterization results of the different catalysts and the conversion of  $\text{N}_2\text{O}$  to  $\text{N}_2$  over different Au loading catalysts at  $250^\circ\text{C}$  are shown in Table 1. These showed that the Au particle size increased with an increase of Au loading and the BET surface area was slightly decreased. The catalytic activity of  $\text{N}_2\text{O}$  decomposition reaches the highest level at a loading of 1.1 wt% Au, then decreases to constant level with increasing of Au loading. The reason for the decrease of the activity with increasing of the Au loading was that the gold nanoparticles were sintered to larger particles at higher loadings, as verified by the characterization results of TEM. The differences in activity of the different Au loading samples can be related to the Au particle size. A comparison of the Au particle size and TOF suggested a correlation (Table 1): the TOF increases with decreasing average Au particle size, 1–5 nm Au particles show much higher activity than larger particles. Compared to the

results of Fe-ZSM-5 catalyst at similar reaction conditions,<sup>9</sup> the TOF of Au/ $\text{Co}_3\text{O}_4$  at low Au loading is higher, which indicates that such catalysts were more active than Fe-ZSM-5 for the direct  $\text{N}_2\text{O}$  decomposition reaction.<sup>12</sup> Fig. 1 shows  $\text{N}_2\text{O}$  conversions in different reaction systems (over  $\text{Co}_3\text{O}_4$  and 1.1 wt% Au/ $\text{Co}_3\text{O}_4$  catalysts), respectively. Pure  $\text{Co}_3\text{O}_4$  was active for the  $\text{N}_2\text{O}$  decomposition at  $250\text{--}400^\circ\text{C}$ , which is consistent with results of the literature,<sup>13</sup> however, the presence of excess  $\text{O}_2$  and steam severely inhibited the reaction, and the  $\text{N}_2\text{O}$  conversion curve shifted to higher temperature. The presence of Au nanoparticles significantly promoted the catalytic activity and stability, causing the  $\text{N}_2\text{O}$  conversion curve to shift  $100^\circ\text{C}$  to lower temperature, which indicated that gold strongly interacted with the  $\text{Co}_3\text{O}_4$  support to form active gold species. The active gold species are highly dispersed on cobalt oxide to lead to the enhanced activity. Addition of  $\text{O}_2$  to the feed gases scarcely affected the activity of 1.1 wt% Au/ $\text{Co}_3\text{O}_4$ . Apparently, molecular oxygen does not dissociate over 1.1 wt% Au/ $\text{Co}_3\text{O}_4$  and does not compete with  $\text{N}_2\text{O}$  for active sites. Water inhibited the reaction mainly at low temperatures. An  $\text{H}_2\text{O}$ -TPD study

**Table 1** Data of the used catalysts

Catalyst	Au (wt%)	BET area/ $\text{m}^2\text{ g}^{-1}$	$d^a/\text{nm}$	$10^{-4}\text{TOF}^b/$ $\text{s}^{-1}$	Conv. of $\text{N}_2\text{O}$ (%)

**Fig. 1**  $\text{N}_2\text{O}$  conversion to  $\text{N}_2$  in different feed compositions: ( $\diamond, \blacklozenge$ ) 1200 ppm  $\text{N}_2\text{O}$ , ( $\triangle, \blacktriangle$ ) 1200 ppm  $\text{N}_2\text{O}$  + 10%  $\text{O}_2$ , ( $\circ, \bullet$ ) 1200 ppm  $\text{N}_2\text{O}$  + 5%  $\text{H}_2\text{O}$  ( $\square, \blacksquare$ ) 1200 ppm  $\text{N}_2\text{O}$  + 10%  $\text{O}_2$  + 5%  $\text{H}_2\text{O}$  over 1.1 wt% Au/ $\text{Co}_3\text{O}_4$  and  $\text{Co}_3\text{O}_4$  catalysts, respectively.

**Fig. 2** Conversion of N<sub>2</sub>O and CH<sub>4</sub> at different temperature over 1.1 wt% Au/Co<sub>3</sub>O<sub>4</sub> catalyst: (△) N<sub>2</sub>O, (○) CH<sub>4</sub>. Reaction conditions: 1200 ppm N<sub>2</sub>O, 300 ppm CH<sub>4</sub>, He as balance gas.

revealed there are desorption peaks of H<sub>2</sub>O at 210 and 430 °C. This suggested that the water was adsorbed on the active sites at low temperature so suppressing the decomposition of N<sub>2</sub>O. As the temperature increased, water was desorbed from the surface, and the activity for the N<sub>2</sub>O decomposition was recovered. Moreover, 1.1 wt% Au/Co<sub>3</sub>O<sub>4</sub> catalyst was highly stable in the presence of excess oxygen and steam, which was confirmed by the fact that the catalytic activity of N<sub>2</sub>O decomposition scarcely varied in the presence of excess O<sub>2</sub> and water vapor after reaction for 40 h.

The presence of reductant can significantly lower the conversion temperature of N<sub>2</sub>O over many catalysts.<sup>14–17</sup> In this study, we also studied the selective catalytic reduction (SCR) of N<sub>2</sub>O with CH<sub>4</sub> as reductant over 1.1 wt% Au/Co<sub>3</sub>O<sub>4</sub> catalyst. Addition of 300 ppm CH<sub>4</sub> to the feed gases scarcely affected the conversion of N<sub>2</sub>O as shown in Fig. 2, when N<sub>2</sub>O has completely converted to N<sub>2</sub> and O<sub>2</sub>, CH<sub>4</sub> was scarcely consumed and started to be converted to CO<sub>2</sub> and H<sub>2</sub>O only above 300 °C. This showed that the N<sub>2</sub>O decomposition mechanism over Au/Co<sub>3</sub>O<sub>4</sub> catalyst might be different from that over Fe-ZSM-5 which can form a special oxygen species (α-O) intermediate by N<sub>2</sub>O decomposition to oxidize methane at lower temperature.<sup>18</sup> Table 2 shows the temperature at 50 and 90% N<sub>2</sub>O conversion and apparent activation energies of N<sub>2</sub>O decomposition for various reaction systems over 1.1 wt% Au/Co<sub>3</sub>O<sub>4</sub> and Co<sub>3</sub>O<sub>4</sub> catalysts, respectively. The apparent activation energies of N<sub>2</sub>O decomposition scarcely depended on the presence of O<sub>2</sub> and CH<sub>4</sub> for the 1.1 wt% Au/Co<sub>3</sub>O<sub>4</sub> catalyst. Compared to the apparent activation energies for different reaction systems the 1.1 wt% Au/Co<sub>3</sub>O<sub>4</sub> catalyst is more active and stable than Co<sub>3</sub>O<sub>4</sub>.

The present results have demonstrated that the catalytic decomposition of N<sub>2</sub>O in the presence of excess O<sub>2</sub> and steam

**Table 2** T<sub>50</sub> and T<sub>90</sub> of the N<sub>2</sub>O decomposition and apparent activation energies for various reaction systems

Catalyst	Composition of feed gas	T <sub>50</sub> /°C	T <sub>90</sub> /°C	Apparent activation energy/kJmol <sup>-1</sup>
1.1 wt% Au/Co <sub>3</sub> O <sub>4</sub>	N <sub>2</sub> O	223	265	48
