Regio- and stereoselective hydrostannation of allenes using dibutyliodotin hydride (Bu₂SnIH) and successive coupling with aromatic halides \dagger

Naoki Hayashi,^a Kazunao Kusano,^a Shingo Sekizawa,^a Ikuya Shibata,^{*b} Makoto Yasuda^a and Akio Baba^{*a}

Received (in Cambridge, UK) 23rd August 2007, Accepted 5th September 2007 First published as an Advance Article on the web 14th September 2007 DOI: 10.1039/b712998j

Regio- and stereoselective hydrostannation of allenes by using di-*n*-butyliodotin hydride (Bu₂SnIH) was accomplished to give α , β -disubstituted vinyltins, which induced the synthesis of multi-substituted alkenes in a one-pot procedure.

Vinyltin compounds are very useful reagents whose tin moieties can be transformed to various organic groups through the Kosugi–Migita–Stille coupling.¹ One of the most powerful synthetic methods for synthesis of vinyltins is hydrostannation of C–C triple bonds. Regioselective hydrostannation, however, is generally limited to terminal alkynes, in which the stannation occurred at the terminal carbon to give β -substituted vinyltins.² Few methods are available for synthesis of internal tin substituted adducts (α -substituted vinyltins), even when only monosubstituted vinyltins are obtained.³ The effective synthesis of multi-substituted vinyltins remains to be a challenge.

However, hydrostannation of allenes,⁴ with a regioselectivity strongly dependent on the conditions employed, has rarely been reported (Scheme 1). In the hydrostannation of *n*-octylallene (1a), Pd-catalysis promotes the stannation of the terminal carbon to give allyltin 4a', and Lewis acid B(C₆F₅)₃ selectively produces an α -substituted terminal vinyltin 3a'.⁵ Only a radical reaction could produce an α , β -disubstituted vinyltin 2a', although a poor selectivity of 2a' was obtained.⁶ As illustrated in Scheme 1, it is

accepted that no methods are available for the regio- and stereoselective addition of a tin moiety to the center carbon of allenes to give **2**. Here we wish to report the highly regio- and stereoselective radical hydrostannation of allenes which was accomplished by using di-*n*-butyliodotin hydride (Bu₂SnIH)⁷ to give α,β -disubstituted vinyltins **2**. Furthermore, one-pot synthesis of multi-substituted alkenes was established by coupling of the resulting vinyltins without isolation.

First, hydrostannation of monosubstituted allenes was examined by using Bu₂SnIH generated *in situ* by the redistribution between Bu₂SnI₂ and Bu₂SnH₂.⁸ The reaction of *n*-octylallene (**1a**) took place without any promoters to give vinyltin **2a** in 65% yield (Table 1, entry 1). This reaction plausibly proceeds in a radical manner because a radical scavenger, galvinoxyl, completely suppressed the reaction (entry 2). In contrast to tributyltin hydride, a predominant addition of a tin moiety to the allene center carbon took place in all runs to produce the α , β -disubstituted vinyltins **2** along with a small amount of **3**, and no formation of an allylic tin

^{*a*} THF 1 mL, allene 1 mmol, Bu₂SnIH 1 mmol. ^{*b*} Galvinoxyl (0.1 mmol) was added.

^bResearch Center for Environmental Preservation, Osaka University, 2-4 Yamadaoka, Suita, Osaka, 565-0871, Japan.

4 was observed. In the reaction of 1a, using Bu₂SnClH instead of Bu₂SnIH resulted in a mixture of 2 (65%), 3 (17%) and 4 (11%). Although the hydrostannations of *n*- and *sec*-alkyl substituted allenes 1a and 1b furnished *E*- and *Z*-isomers of vinyltins 2a and 2b in poor stereoselectivities (entries 1 and 3), the selectivity was improved by introducing tertiary alkyl substituents to predominantly give *E*-alkenes (entries 4 and 5). It was surprising that the tertiary substituents also depressed the formation of vinyltin 3, in particular the dimethylphenylmethyl moiety was decreased to only a 2% yield (entry 5). In contrast, allenes having oxygen substituents provided vinyltins 2e and 2f with opposite *Z*-stereochemistry (entries 6 and 7).

Scheme 2 shows the hydrostannation of disubstituted allenes. Cyclic vinyltin 2g was obtained in 90% yield as a sole product from internal allene 1g (eqn. (1)). 1,1-Disubstituted allene 1h, having an oxygen substituent, gave trisubstituted vinyltin 2h with perfect *Z*-stereochemistry (eqn. (2)).

It has been reported that small amounts of the Bu₂ISn[•] radical is generated through the redistribution between Bu₂SnI₂ and Bu₂SnH₂, and so no radical initiator such as Et₃B is required.⁸ As shown in Scheme 3, the generated tin radical is added to an allene carbon center to form a stable allyl radical, then a bulky Bu₂SnIH reacts with the less-hindered terminal carbon to produce the desired vinyltin 2, along with regeneration of the Bu₂ISn[•] radical. However, the clear difference between having Bu₃SnH and having Bu₂SnIH in the attack position of a tin radical is yet to be explained. The E-stereoselectivity depends on steric repulsion between an alkyl substituent and the tin moiety in the formation of an allyl radical (Scheme 3, top). On the other hand, in the case of allenes with oxygen substituents, coordination with the acidic iodotin center helps form the Z-isomers, 2e and 2f (Scheme 3, bottom). Thus, the iodine-substituted tin moiety plays a very important role, having characteristics that are both sterically hindering and electron-withdrawing.

In the next stage, our group attempted to achieve a subsequent coupling reaction of the products **2** without isolation. The conventional catalyst for Kosugi–Migita–Stille coupling has not

Scheme 2 Hydrostannation of disubstituted allenes. *Reagents*: THF (1 mL), allene (1 mmol), Bu₂SnIH (1 mmol).

Scheme 3 Regio- and stereoselective hydrostannation.

been feasible for use with halogenated organotin nucleophiles because of the deactivating nature of the halogen. If completed, however, this one-pot coupling would present a convenient method for synthesis of multi-substituted alkenes. Kosugi's group recently achieved this type of coupling between chlorinated aryltins and aryl halides.⁹ Fortunately, our group was able to apply this catalysis on iodinated vinyltin 2 to produce various multi-substituted alkenes as shown in Scheme 4. Regio- and stereoselectivities of all products appeared to depend on the hydrostannation step. Thus E- and Z-alkenes, 5c and 5f, were obtained with high regio- and stereoselectivities (eqn (3) and (4)).‡ Internal allene 1g gave trisubstituted alkene 5g in moderate yield (eqn (5)). Tetrasubstituted alkenes, 5h-5j, were also obtained from the reaction of allenes 1h, 1i, 1j (eqn (6)-(8)). It is worth noting that alkenes bearing four different substituents, 5h and 5j, were produced with high stereoselectivities derived from chelation between the tin moiety and oxygen (eqn (6) and (8)). The stereochemistry obtained in 5j suggests that the chelation is larger from the hydroxy moiety than it is that from the methoxy moiety.

In summary, highly regio- and stereoselective hydrostannation of allenes was accomplished by using dibutyliodotin hydride (Bu_2SnIH). This system could also be applied to a subsequent coupling reaction to give multi-substituted alkenes in a one-pot procedure.

Scheme 4 Hydrostannation and one-pot coupling reactions. *Reagents*: THF (1 mL), allene (1 mmol), Bu₂SnIH (1 mmol), PhI (1 mmol), Pd cat. (0.01 mmol), TBAF (1 M solution in THF, 3.0 mmol). "Et₃B (0.1 mmol) was added at the hydrostannation step; PPh₃ (0.04 mmol) was added at the coupling step. ^bBu₂SnIH (1.2 mmol) was used; Et₃B (0.1 mmol) was added at the hydrostannation step; PPh₃ (0.04 mmol) was added at the coupling step. ^cPPh₃ (0.07 mmol) was added at the coupling step. ^dPhI (1.2 mmol) was used.

This research has been supported by JSPS Research Fellowships for Young Scientists, and by the Grant-in-Aid for Scientific Research on Priority Areas (459 and 460) from Ministry of Education, Culture, Sports, Science and Technology, Japan, and by the Sumitomo Foundation.

Notes and references

‡ Typical experimental procedure to synthesize multisubstituted alkenes: A 10 mL round-bottom flask was dried by flame under nitrogen atmosphere. After THF (1.0 mL) was added, Bu₂SnH₂ (0.117 g, 0.5 mmol) and Bu₂SnI₂ (0.243 g, 0.5 mmol) were added to generate Bu₂SnIH by the redistribution reaction. To the mixture was added allene **1f** (0.070 g, 1.0 mmol) and the resulting mixture was stirred at rt for 12 h until the IR absorption of Sn–H at 1855 cm⁻¹ disappeared. [In the case of applying initiator, 1 M Et₃B solution (0.1 mL) was added after the addition of allenes.] PhI (0.204 g, 1.0 mmol), Pd₂(dba)₃–CHCl₃ (0.010 g, 1 mol%) and 1 M Bu₄NF solution in THF (3.0 mL) were added and the mixture was stirred at 65 °C for 24 h. After the reaction, the resulting solution was filtrated using Celite. After concentration of the filtrate, yield of product **5f** was determined by ¹H NMR (81%). Further purification was performed by silica gel column chromatography eluting with hexane–AcOEt = 95 : 5 followed by distillation under reduced pressure (0.070 g, 48%).
