Summary The preparation, n.m.r. data, and molecular structure of the neutral compound, $\mathrm{Rh}\left[\mathrm{P}(\mathrm{OMe})_{3}\right]_{2} \mathrm{BPh}_{4}$, in which the $\mathrm{BPh}_{4}$ group is bonded to the rhodium atom through an arene ring, are reported.

We report the first example of a complex in which the $\mathrm{BPh}_{4}$ group is directly bonded to a transition metal atom. The addition of $\mathrm{NaBPh}_{4}$ to $\left[\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{RhCl}_{2}\right.$ and an excess of $\mathrm{P}(\mathrm{OMe})_{3}$ in methanol gave an ionic derivative which was

Figure 1. Molecular geometry of $\operatorname{Rh}\left[\mathrm{P}(\mathrm{OMe})_{3}\right]_{2} \mathrm{BPh}_{4}$.
characterised as the five-co-ordinate $\mathrm{Rh}^{\mathrm{I}}$ complex, $\{\mathrm{Rh}[\mathrm{P}$ $\left.\left.(\mathrm{OMe})_{3}\right]_{5}\right\} \mathrm{BPh}_{4}$. This ionic compound decomposed in air to give a neutral complex ( $\Lambda=0.3 \mathrm{ohms}^{-1} \mathrm{~cm}^{2}{ }^{2} \mathrm{~mole}^{-1}$, $\mathrm{Me}_{2} \mathrm{CO}$ ) which was formulated as $\mathrm{Rh}\left[\mathrm{P}(\mathrm{OMe})_{3}\right]_{2} \mathrm{BPh}_{4}$ (n.m.r., analytical, and molecular weight data).

The deep yellow crystals of $\mathrm{Rh}\left[\mathrm{P}(\mathrm{OMe})_{3}\right]_{2} \mathrm{BPh}_{4}$ are
monoclinic; $a=15.57, \quad b=11.52, \quad c=19.73 \AA, \quad \beta=$ $120.68^{\circ}, D_{\mathrm{m}}=1.39, D_{\mathrm{c}}=1.40 \mathrm{~g} . \mathrm{cm} .^{-3}$ for $Z=4$, space group $P 2_{1} / c$; Hilger and Watts diffractometer ( $\mathrm{Mo}-K_{\alpha}$ radiation): the 1984 most intense reflections used in the initial structure determination. Patterson and Fourier syntheses followed by nine cycles of full-matrix leastsquares refinement ${ }^{1}$ gave the present structure: $R 0.073$, anisotropic thermal motion for the rhodium, phosphorus, and oxygen atoms.

Figure 2. Molecular configuration including deviations ( $\dot{\AA}$ ) of atoms from the mean plane of the six ring (A) carbon atoms.

The average estimated standard deviations of the bond lengths (Figures 1 and 2) $\mathrm{Rh}-\mathrm{P}, \mathrm{Rh}-\mathrm{C}$, and $\mathrm{C}-\mathrm{C}$ are 0.01 , 0.02 , and $0.03 \AA$, respectively. The rhodium atom is situated symmetrically with respect to one of the phenyl rings of the $\mathrm{BPh}_{4}$ group and at a distance of $1.86 \AA$ from the mean plane of this ring (A). This [cf. $1.72 \AA$ for the metal-ring distance $\left.\left(\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Cr}(\mathrm{CO})_{3}\right]^{2}$ clearly shows the rhodium atom to be directly bonded to the phenyl ring (A). The plane defined by the atoms $R h, P(1)$, and $P(2)$ makes an
angle of $91^{\circ}$ with the mean plane of the bonded phenyl ring, with the two phosphorus atoms equidistant from the latter. The plane through $R h, P(1)$, and $P(2)$ intersects the phenyl ring (A) in an asymmetric manner (Figure 2). The $\mathrm{P}(2) \mathrm{RhP}(1)$ valency angle is $90 \pm 1^{\circ}$.
The $\mathrm{C}-\mathrm{C}$ bond distances in the phenyl ring (A) range from 1.39 to $1.44 \AA$ but deviations from the mean are not significant. The non-bonded rings are planar, having r.m.s. deviations of $0.01-0.02 \AA$. By contrast, the atoms of the bonded ring (A) show a r.m.s. deviation of $0.04 \AA$ with individual displacements consistent with a boat configuration. The dihedral angles between the best plane through $\mathrm{C}(2) \mathrm{C}(3) \mathrm{C}(5) \mathrm{C}(6)$ and the $\mathrm{C}(1) \mathrm{C}(2) \mathrm{C}(6)$ and $\mathrm{C}(3) \mathrm{C}(4) \mathrm{C}(5)$ planes are $6^{\circ}$. The four distances, $\mathrm{Rh}-\mathrm{C}(2), \mathrm{Rh}-\mathrm{C}(3)$, $\mathrm{Rh}-\mathrm{C}(5)$, and $\mathrm{Rh}-\mathrm{C}(6)$, are similar to within their e.s.d.'s and average $2.31 \AA$, whilst the other two, $\mathrm{Rh}-\mathrm{C}(1)(2 \cdot 41 \AA)$ and $\mathrm{Rh}-\mathrm{C}(4)(2 \cdot 40 \AA)$, are significantly longer. This
distortion of the bonded phenyl ring (A) might be a consequence of packing forces but may also result from a slight localisation of the bonding M.O's of the ring (A) on the carbon atoms $2,3,5$, and 6 .

The n.m.r. assignments [ $\tau 3.5(\mathrm{~d}, 2-\mathrm{H}$ and $6-\mathrm{H}, J 6.5 \mathrm{~Hz})$, $4 \cdot 16(\mathrm{t}, 3-\mathrm{H}$ and $5-\mathrm{H}, J 6.5 \mathrm{~Hz}), 3 \cdot 19$ (poorly resolved t , $4-\mathrm{H}), 2.89(\mathrm{~m}$, non-bonded $\mathrm{Ar} H)$, and $6.73\left(\mathrm{t}, \mathrm{P}-\mathrm{O}-\mathrm{CH}_{3}\right.$, $J_{\mathrm{PH}} 6.2 \mathrm{~Hz}$ )] are in accord with previous studies which have shown that the proton resonances of an arene ring bonded to a metal atom occur at $\tau 1$ to 2 to high field of those of the free arene ligand. ${ }^{3}$ The pattern of the last resonance (a broad central component and two sharp outer peaks) is attributed to a "virtual coupling" effect."

The complexes, $\mathrm{Rh}\left[\mathrm{P}(\mathrm{OR})_{3}\right]_{2} \mathrm{BPh}_{4}\left(\mathrm{R}=\mathrm{Pr}^{\mathrm{I}}, \mathrm{Bu}^{\mathrm{n}}, \mathrm{Bu}^{\mathrm{i}}\right)$ have alsn been synthesised by a similar method.
