

Reactions of Nitrosylpenta-ammineruthenium(II) with Hydroxylamine, Hydrazine, and Ammonia

By F. BOTTOMLEY* and JANICE R. CRAWFORD

(Department of Chemistry, University of New Brunswick, Fredericton, New Brunswick, Canada)

Summary Nitrosylpenta-ammineruthenium(II) reacts with hydroxylamine, hydrazine, or ammonia to form (dinitrogen oxide)penta-ammineruthenium(II) and in the last two cases, dinitrogenpenta-ammineruthenium(II).

REACTIONS of nitrosylruthenium(II) complexes have attracted attention recently.¹⁻³ We report the reactions of hydroxylamine, hydrazine, and ammonia with nitrosylpenta-ammineruthenium(II).

$[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{NO}]\text{X}_3$ (X = Cl, I) reacted rapidly with hydroxylamine at room temperature to form $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{N}_2\text{O}]\text{X}_2$.[†] The diamagnetic products have similar properties to those reported for $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{N}_2\text{O}]\text{BF}_4$.⁴ The gas evolved on oxidizing the iodide salt with cerium(IV) was shown to be N_2O by mass spectrometry, and on heating this salt *in vacuo* N_2O , N_2 , and H_2O were evolved. The i.r. spectra showed a very strong band at 1175 cm^{-1} (I⁻ salt) or 1150 cm^{-1} (Cl⁻) (the ν_1 band of N_2O) and a weak band at

2250 cm^{-1} (I⁻) or 2240 cm^{-1} (Cl⁻) (the ν_3 band of N_2O). Similar shifts in the position of i.r. bands with the counter-anion have been reported for $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{N}_2]\text{X}_2$.⁵ The iodide salt is very much more stable than the chloride or, as reported, the tetrafluoroborate.⁴

$[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{NO}]\text{Cl}_3$ and excess of hydrazine hydrate at room temperature rapidly yielded $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{N}_2]\text{X}_2$ (X = Cl, I), unlike $[\text{Ru}^{\text{II}}(\text{das})_2\text{ClNO}]\text{Cl}_2$ which gave $[\text{Ru}^{\text{II}}(\text{das})_2(\text{N}_3)\text{Cl}]^{\ddagger}$ (das = *o*-phenylenebisdimethylarsine). At -23°C immediate (10 s) addition of NH_4Cl , KBr, or KI yielded a mixture of $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{N}_2\text{O}]\text{X}_2$ and $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{N}_2]\text{X}_2$ (X = Cl, Br, I).[‡] The diamagnetic mixed salt showed a band at 2105 cm^{-1} (Cl⁻ salt), 2118 cm^{-1} (Br⁻), or 2129 cm^{-1} (I⁻), assigned to $\nu_{\text{N-N}}$,⁵ in addition to the bands due to N_2O described above (Br⁻ salt, ν_1 bands of N_2O , 1160 cm^{-1} and the ν_3 band of N_2O , 2260 cm^{-1}). No band assignable to co-ordinated NO was observed. The mixture evolved N_2O , N_2 , and H_2O but no NO_2 on heating *in vacuo*.

[†] Satisfactory elemental analyses were obtained for these salts.

[‡] Elemental analyses are consistent with this formulation.

The same mixed salt was obtained at temperatures down to -40°C .

With a longer reaction time (*ca.* 3 min) at -23°C a brick red (Cl^-) or purple (I^-) salt was precipitated, which turned pale yellow when set aside. The i.r. spectra of the salts showed bands at 2020 cm^{-1} in addition to those described above. The electronic absorption spectrum showed a band at 460 nm ($\epsilon > 1000$) which decreased with time. These properties indicated the presence of $[\text{Ru}^{\text{III}}(\text{NH}_3)_5\text{N}_3]\text{X}_2$.⁵

The major product of the reaction of $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{NO}]\text{X}_3$ ($\text{X} = \text{Cl}, \text{I}$) with ammonia was $[\text{Ru}^{\text{II}}(\text{NH}_3)_4(\text{OH})\text{NO}]\text{X}_2$.⁶ However, partial conversion into $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{N}_2\text{O}]\text{I}_2$ or $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{N}_2]\text{I}_2$ or a mixture of these also occurred, depending on the conditions. $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{NO}]\text{X}_3$ was not converted into $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{NO}_2]\text{X}$ by either ammonia or sodium hydroxide, in contrast to $[\text{Ru}^{\text{II}}(\text{bipy})_2(\text{NO})\text{X}]^{2+}$.³

The formation of $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{N}_2\text{O}]^{2+}$ from $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{NO}]^{3+}$ and any of the three reactants is presumed to take

place *via* nucleophilic attack of hydroxylamine, hydrazine or ammonia at the nitrosyl-N atom in a manner analogous to that for carbonyl complexes.⁷ $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{N}_2\text{O}]^{2+}$ is known² to decompose in solution to $[\text{Ru}^{\text{III}}(\text{NH}_3)_5\text{OH}]^{2+}$, which is reduced by hydrazine under the conditions described here.⁸ It seems likely that this reaction is the predominant source of $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{N}_2]^{2+}$ in the reaction of $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{NO}]^{3+}$ with hydrazine. $[\text{Ru}^{\text{III}}(\text{NH}_3)_5\text{N}_3]^{2+}$ may be formed by further nucleophilic attack of N_2H_4 on $[\text{Ru}^{\text{II}}(\text{NH}_3)_5\text{N}_2\text{O}]^{2+}$, followed by oxidation,⁹ and this is under investigation.

We thank Dr. R. D. Feltham for helpful discussions, the National Research Council of Canada and the University of New Brunswick for financial support, and Johnson, Matthey and Mallory for a loan of ruthenium.
