**Summary** The crystal structure of  $[\text{Cd}(\text{C}_3\text{H}_4\text{N}_2)_6]\text{CO}_3 \cdot 5\text{H}_2\text{O}$  has been determined and the complex has been shown to be identical with that previously reported as  $[\text{Cd}(\text{C}_3\text{H}_4\text{N}_2)_6(\text{OH})(\text{NO}_3) \cdot 4\text{H}_2\text{O}$ .

WHEN aqueous solutions of cadmium(II) chloride and imidazole in a molar ratio of 1:10 are mixed and allowed to

† Verified by N and  $\text{CO}_3^{2-}$  analyses.

evaporate, two types of crystal are obtained, one type with and one type without chloride. The crystals that do not contain chloride are isomorphous with  $[\text{Co}(\text{C}_3\text{H}_4\text{N}_2)_6]\text{CO}_3 \cdot 5\text{H}_2\text{O}$ ,<sup>1</sup> which indicated a molecular formula of  $[\text{Cd}(\text{C}_3\text{H}_4\text{N}_2)_6]\text{CO}_3 \cdot 5\text{H}_2\text{O}$ .†

Recently, a structure supposed to be  $[\text{Cd}(\text{C}_3\text{H}_4\text{N}_2)_6(\text{OH})(\text{NO}_3) \cdot 4\text{H}_2\text{O}$  has been described by Mighell and

Santoro.<sup>2</sup> Its cell parameters show a remarkable resemblance to those of  $[\text{Cd}(\text{C}_3\text{H}_4\text{N}_2)_6]\text{CO}_3 \cdot 5\text{H}_2\text{O}$ .

*Crystal Data:*  $a = 9.0426(5)$ ,  $c = 21.720(5)\text{\AA}$ ,  $U = 1538.07\text{\AA}^3$ ,  $Z = 2$ ,  $D_c = 1.45\text{ g cm}^{-3}$ ,  $D_m = 1.46\text{ g cm}^{-3}$ , space group  $P6_3/m$ .

The atomic parameters are almost the same. The fact that we obtained crystals free from chloride in a medium containing chloride, and the resemblance between the crystal data for the two complexes led us to believe that the reported structure of  $\text{Cd}(\text{C}_3\text{H}_4\text{N}_2)_6(\text{OH})(\text{NO}_3) \cdot 4\text{H}_2\text{O}$  is wrong. Mighell and Santoro reported that the N–O bond lengths (1.286 Å) were longer than expected (1.24 Å). They claimed that this increase arose from hydrogen bonding to water molecules. A distance of 1.286 Å is in fact normal for C–O bond lengths. We have found a C–O bond length of 1.285 Å in the carbonate ion. Thus we believe that the two compounds are identical and contain carbonate and not nitrate.

The  $\text{Co}^{\text{II}}$  compound was obtained from the preparation

described by Strandberg and Lundberg<sup>1</sup> and also from the reaction of  $\text{CoCl}_2$  with imidazole as described for the cadmium analogue. The carbonate ions in these cases can come only from dissolved  $\text{CO}_2$ . This means that the solubility products are very low for these compounds.

The intensities from the crystals of  $[\text{Cd}(\text{C}_3\text{H}_4\text{N}_2)_6]\text{CO}_3 \cdot 5\text{H}_2\text{O}$  were collected and measured by using an automatic linear diffractometer, PAILRED, and Mo- $K_\alpha$  radiation. Correction for Lorentz and polarisation factors was carried out in the usual way,<sup>3</sup> and correction for absorption was also made. Least-squares refinements are in progress using anisotropic temperature factors for all atoms. The conventional  $R$ -value is 0.050; the satisfactory refinement supports the formulation,  $[\text{Cd}(\text{C}_3\text{H}_4\text{N}_2)_6]\text{CO}_3 \cdot 5\text{H}_2\text{O}$ . Our aim is to locate the positions of the hydrogen atoms, especially those in the carbonate–water layers, since there are indications that the carbonate ions are hydrated.
