**Summary** The reaction of  $\text{SiF}_4$  with solid silicon or silicon carbide at  $1200^\circ\text{--}1850^\circ$  forms gaseous species which, on condensation with  $\text{BF}_3$  at  $-196^\circ$ , yield  $\text{SiF}_3\text{BF}_2$  in addition to known silicon boron fluorides.

WE report the synthesis and characterization of difluoro(trifluorosilyl)borane, the simplest and previously the most elusive of the silicon boron fluorides.<sup>1-3</sup>

Silicon tetrafluoride was passed at the rate of  $1.4\text{ mmol min}^{-1}$  downward through a column of granular silicon or silicon carbide contained in a graphite tube heated inductively to  $1200^\circ\text{--}1850^\circ$ . The gases emerged from the bottom of the tube into a high vacuum ( $<10^{-4}$  Torr) and were immediately condensed on the liquid nitrogen cooled walls of the vacuum chamber. Boron trifluoride was condensed on the walls simultaneously at the rate of  $3.0\text{ mmol min}^{-1}$ . After 30 min, unchanged reactants and volatile products were pumped off the walls and fractionated.

The most volatile product was shown to be difluoro(trifluorosilyl)borane by its n.m.r. spectrum [ $^{19}\text{F}$  ( $\text{CCl}_3\text{F}$ )  $\delta$  40.9 and 128.0 p.p.m.,  $^{11}\text{B}$  ( $\text{BF}_3\text{OEt}_2$ )  $\delta$  -28.0 p.p.m.], its i.r. spectrum (bands with rotational structure centred at 1375, 1265, 987, and  $867\text{ cm}^{-1}$ ), its mass spectrum ( $m/e$  114-117,  $\text{SiBF}_4^+$ ), and from its vapour density and chemical analysis.

The gaseous compound (b.p.  $-19^\circ$ , m.p.  $-59^\circ$ ) was stable at  $25^\circ$  in the absence of air. About  $1.5\text{ mmols}$  were formed from each run.

The other products of the reaction were identified as the known compounds  $\text{SiF}_3\text{SiF}_2\text{BF}_2$  and  $\text{SiF}_3(\text{SiF}_2)_2\text{BF}_2$ , with a small amount of  $\text{Si}_2\text{F}_6$ . These compounds have been made by reacting  $\text{SiF}_2$  with  $\text{BF}_3$  at  $-196^\circ$  but no  $\text{SiF}_3\text{BF}_2$  was then formed.<sup>1,3</sup>

Our results suggest that the reaction of  $\text{SiF}_4$  with silicon or silicon carbide at  $1200^\circ\text{--}1850^\circ$  yields a short-lived species in addition to longer-lived ground state  $\text{SiF}_2$  previously reported.<sup>3,4</sup> The former is responsible for the formation of  $\text{SiF}_3\text{BF}_2$  from  $\text{BF}_3$  in this work. Conditions used in earlier work would have allowed decay of a short-lived species before condensation with  $\text{BF}_3$ . Replacement of the inductively heated graphite tube with a resistance heated quartz tube containing silicon, did not affect the production of  $\text{SiF}_3\text{BF}_2$ . The mol ratio of the products  $\text{SiF}_3\text{BF}_2$ : [ $\text{SiF}_3\text{SiF}_2\text{BF}_2$  +  $\text{SiF}_3(\text{SiF}_2)_2\text{BF}_2$ ] varied from 1:3 using silicon heated to  $1250^\circ$ , to 2:1 using silicon carbide heated to  $1850^\circ$ . It seems likely that the short-lived species is an electronically excited form of  $\text{SiF}_2$ .

One of us (D.L.S.) thanks Owens-Illinois for a fellowship.
