## *cis*-Activation by the Nitrate-ligand in Amminechromium(III) Ions

By GIOVANNI GUASTALLA and THOMAS W. SWADDLE\*

(Department of Chemistry, The University of Calgary, Calgary, Alberta, Canada T2N 1N4)

**Summary** Nitrate-ligands in Cr<sup>III</sup> amines strongly accelerate the aquation of NH<sub>3</sub> ligands in the *cis*-positions.

We have found, by use of cation-exchange chromatography and specific NH<sub>4</sub><sup>+</sup> and NO<sub>3</sub><sup>-</sup> ion electrodes, that the spontaneous thermal aquation of Cr(NH<sub>3</sub>)<sub>5</sub>NO<sub>3</sub><sup>2+</sup> ion in 0.1M-NH<sub>4</sub>ClO<sub>4</sub> (pH 6) at 25° yields 100 ± 5% of NO<sub>3</sub><sup>-</sup> as expected, but only 34% of Cr(NH<sub>3</sub>)<sub>5</sub>OH<sub>2</sub><sup>2+</sup>; the other products are NH<sub>4</sub><sup>+</sup> (100 ± 10%), *cis*-Cr(NH<sub>3</sub>)<sub>4</sub>(OH)OH<sub>2</sub><sup>2+</sup> (35%) (but none of the *trans*-isomer), and a mixture of *fac*- and *mer*-Cr(NH<sub>3</sub>)<sub>3</sub>(OH)<sub>2</sub>OH<sub>2</sub><sup>+</sup>.

The spectrum (260–700 nm) of the Cr(NH<sub>3</sub>)<sub>5</sub>NO<sub>3</sub><sup>2+</sup> solution changed during aquation in accordance with the formation of these products; isosbestic points were precisely maintained, and the rate of change of optical absorbance at 275, 400, and 560 nm showed that the rate of disappearance of Cr(NH<sub>3</sub>)<sub>5</sub>NO<sub>3</sub><sup>2+</sup> was accurately first-order in [Cr(NH<sub>3</sub>)<sub>5</sub>NO<sub>3</sub><sup>2+</sup>], with rate coefficient  $k(\text{NO}_3) = (2.4 \pm 0.1) \times 10^{-3} \text{ s}^{-1}$ . The rates of formation of free NO<sub>3</sub><sup>-</sup> and NH<sub>4</sub><sup>+</sup> ions yielded this same rate coefficient, within the experimental uncertainty. The pH remained constant at *ca.* 6 because acidic aquo-ligands were being introduced concomitantly with NH<sub>3</sub> release.

The complexes Cr(NH<sub>3</sub>)<sub>5</sub>OH<sub>2</sub><sup>2+</sup> and *cis*-Cr(NH<sub>3</sub>)<sub>4</sub>(OH)-OH<sub>2</sub><sup>2+</sup> were found not to aquate significantly in 0.1M-perchlorate media (pH 6) at 25° over a period greater than 10 half-lives of the Cr(NH<sub>3</sub>)<sub>5</sub>NO<sub>3</sub><sup>2+</sup> aquation (and were not significantly affected by our ion-exchange procedure), while the aquations of Cr(NH<sub>3</sub>)<sub>5</sub>Br<sup>2+</sup> and Cr(NH<sub>3</sub>)<sub>5</sub>I<sup>2+</sup> yield *exclusively* Cr(NH<sub>3</sub>)<sub>5</sub>OH<sub>2</sub><sup>2+</sup> and halide ion under comparable conditions over even longer periods.<sup>1,2</sup> Thus, the observed characteristics of the aquation of Cr(NH<sub>3</sub>)<sub>5</sub>NO<sub>3</sub><sup>2+</sup> constitute clear evidence for a strong activation of ligands *cis* to a nitrate-ligand in Cr<sup>III</sup> complexes. The aquations of Cr(NH<sub>3</sub>)<sub>5</sub>F<sup>2+</sup> and Cr(NH<sub>3</sub>)<sub>5</sub>Cl<sup>2+</sup> do involve some ammonia

release,<sup>3</sup> but this is because the rates of replacement of F and Cl by H<sub>2</sub>O are comparable with the rate of ammonia aquation of, *e.g.*, Cr(NH<sub>3</sub>)<sub>6</sub><sup>3+</sup> to Cr(NH<sub>3</sub>)<sub>5</sub>OH<sub>2</sub><sup>3+</sup> ( $k = 8 \times 10^{-5} \text{ s}^{-1}$  at 75° in 0.5 M-HClO<sub>4</sub> for all six ammine ligands)<sup>4</sup> and not because of activation by F or Cl.

These observations are consistent with the following Scheme, in which  $k_1 = 0.8 \times 10^{-3} \text{ s}^{-1}$ ,  $k_2 = 1.6 \times 10^{-3} \text{ s}^{-1}$ , and  $k_3, k_4$ , and  $k_5$  are assumed to be high (with  $k_3/k_4$  *ca.* 1:1); this assumption is consistent with the observation<sup>5</sup> that a pathway with inverse [H<sup>+</sup>] dependence is detectable in the aquation of Cr(H<sub>2</sub>O)<sub>5</sub>NO<sub>3</sub><sup>2+</sup> even in the pH range 0–1.

SCHEME

At pH 6, the equilibrium  $K$  will lie almost entirely toward the presumably labile ion *cis*-Cr(NH<sub>3</sub>)<sub>4</sub>(OH)NO<sub>3</sub><sup>+</sup> ( $\text{p}K_a$  estimated to be *ca.* 5–6), and the rate of aquation of Cr(NH<sub>3</sub>)<sub>5</sub>NO<sub>3</sub><sup>2+</sup> will be controlled by  $k_1$  and  $k_2$  alone and is therefore cleanly first-order. However, in 0.1M-HClO<sub>4</sub>, *cis*-Cr(NH<sub>3</sub>)<sub>4</sub>(OH)NO<sub>3</sub><sup>+</sup> formation will be greatly suppressed, and the slow step  $k_2$  should be followed by the further *slow*

aquation of  $cis\text{-Cr}(\text{NH}_3)_4(\text{OH}_2)\text{NO}_3^{2+}$  to  $cis\text{-Cr}(\text{NH}_3)_4(\text{OH}_2)_2^{3+}$  and  $\text{Cr}(\text{NH}_3)_3(\text{NO}_3)(\text{OH}_2)_2^{2+}$ , if  $cis$ -activation by the nitrate-ligand is again operative; the last-named species should in turn slowly yield  $\text{Cr}(\text{NH}_3)_3(\text{OH}_2)_3^{3+}$  isomers. Indeed, we observed that the products of the aquation at pH 1 were essentially the same as at pH 6, but isobestic points were *not* maintained, and the spectrophotometric reaction rate was slower overall and *not* first-order, being instead indicative of a series of at least two consecutive slow reactions operating concurrently with the process  $k_1$ , exactly as the above Scheme requires. Our results confirm and explain Monacelli's observations<sup>6</sup> that the spectrophotometric rate of disappearance of  $\text{Cr}(\text{NH}_3)_5\text{NO}_3^{2+}$  is depressed by increasing  $[\text{H}^+]$  and deviates considerably from first-order in  $[\text{Cr}(\text{NH}_3)_5\text{NO}_3^{2+}]$  at high acidities.

We believe that simple substitutions at  $\text{Cr}^{\text{III}}$  centres occur by associative ( $I_a$  or  $S_N2$ ) mechanisms,<sup>1</sup> and therefore suggest that the stereospecific expulsion of  $cis$ -ligands by

the nitrate-group in  $\text{Cr}^{\text{III}}$  complexes may occur *via* an associative ring-closure process leading to a transiently bidentate nitrate-complex. This could operate equally well with other potentially bidentate ligands such as sulphate, sulphite, carbonate, nitrite, or carboxylate. Thus, we have an explanation for numerous apparent anomalies in  $\text{Cr}^{\text{III}}$  co-ordination chemistry, such as labilization by the nitrito-ligand<sup>7</sup> and by carboxylate.<sup>8</sup> Similarly, the marked acceleration of the rate of decomposition of  $\text{Cr}^{\text{III}}$  amines in aqueous nitrate,<sup>9,10</sup> sulphate<sup>9</sup> and sulphite<sup>4</sup> media *vis-à-vis* perchlorate or halide solutions<sup>4,9</sup> can be understood in terms of the formation of small amounts of the oxyanion-complexes (perchlorate excepted, being a poor complexing agent); significantly, attempts to isolate salts of  $\text{Cr}(\text{NH}_3)_5\text{-SO}_4^+$  have so far failed.<sup>4</sup>
