Summary The reaction of 5,10,15,20-tetraphenylporphinatoiron(II) [(TPP)Fe^{II}] with carbon tetrachloride in the presence of an excess of reducing agent leads to a complex having properties consistent with the carbene, :CCl₂, bound to Fe^{II}; this is believed to be the first example of a carbene complex of a metalloporphyrin.

IRON(II) complexes,¹ particularly iron(II) porphyrins² and haemoproteins,³ are known to react with halogenated compounds with carbon-halogen bond cleavage. Involvement of complexes with a metal-carbon bond has been postulated in some of these reactions. Although we reported⁴ that the reaction between deutero-porphyriniron(II) and CCl₄ gives such a complex which is stable in this particular case, we did not discuss the nature of the chloromethyl residue bound to Fe^{II}. Data have also been reported recently supporting the formation of carbene complexes of iron(II) cytochrome P450 on reduction of various polyhalogenated compounds.⁵

We now report the isolation of the product of reaction of 5,10,15,20-tetraphenylporphinatoiron(II) [(TPP)Fe^{II}] with CCl₄, under reducing conditions, which has properties corresponding to the carbene complex [(TPP)Fe^{II}(CCl₂)].

Addition of deoxygenated CCl_4 to a benzene solution of $[(TPP)Fe^{II}]$ results in the disappearance of the bands due

to the latter in the visible spectrum and the appearance of new bands due to [(TPP)Fe^{III}Cl] and a new species (I). The new compound (I) [λ_{max} 408 (ϵ 2 × 10⁵), 525 (ϵ 15 × 10³), and 550 (sh) nm in benzene] is also obtained when [(TPP)Fe^{III}Cl] is reduced with an excess of a reducing agent, *e.g.* dithionite (C₆H₆-H₂O or CH₂Cl₂-H₂O, two-phase system), H₂-Pd (H₂O saturated C₆H₆), or iron powder (*NN*-dimethylformamide or CH₂Cl₂-MeOH), in the presence of CCl₄; its complete formation requires 1 mol. equiv. of CCl₄. A spectrophotometric titration⁶ shows that the stoicheiometric reaction performed with the system dithionite-C₆H₆-H₂O involves the liberation of two chloride ions in addition to the chloride ligand of the starting Fe^{III} complex.

In a preparative experiment, a CH_2Cl_2 -MeOH (9:1) solution of [(TPP)Fe^{III}Cl] (0.25 mmol) and CCl₄ (0.5 mmol) was stirred under argon in the presence of an excess of iron powder for 1 h. Filtration, evaporation of the solvents, washing of a CHCl₃ solution of the residue with water, recrystallisation from CHCl₃-MeOH, and heating at 100 °C at 10⁻² mmHg for 10 h gave (I) as a purple-red solid (90% yield) whose elemental analysis (C, H, Cl, Fe, N) agrees with the formula $C_{45}H_{28}Cl_2FeN_4$ of [(TPP)Fe(CCl₂)]. The mass spectrum (70 eV, 220 °C) of (I) exhibits the molecular ion at m/e 750 (for ³⁵Cl); this peak disappears at higher

temperatures with the simultaneous appearance of peaks characteristic of tetrachloroethylene, the dimerisation product of the carbene, : CCl₂.

The preparation of (I) involving an excess of reducing agent, the similarity of its optical spectrum to that of $[(TPP)Fe^{{\scriptscriptstyle\rm II}}(CO)],$ and its oxidation to the $Fe^{{\scriptscriptstyle\rm III}}$ state by oxygen (half-life in aerated benzene, 4 h) suggest that it is an Fe¹¹ complex. This is confirmed by its ¹H n.m.r. spectrum [δ (CDCl₃, SiMe₄) 7.71 (m, *m*- and *p*-phenyl H), 8.12 (m, o-phenyl H), and 8.77 (s, pyrrole H)] which does not display paramagnetic shift or broadening and which is similar to that of [(TPP)Fe^{II}(pyridine)₂]. The ¹³C n.m.r. spectrum of (I) exhibits, in addition to the signals due to the carbon atoms of the porphyrin ring, δ (CDCl₃, SiMe₄) 146, 141.6, 133.4, 132.3, 127.6, 126.6, and 122 p.p.m., a sharp peak at 224.7 p.p.m. which can actually be observed when (I) is prepared from ¹³CCl₄. The ¹H and ¹³C n.m.r. data are indicative of an axial symmetry and give a chemical shift of the carbon atom derived from CCl_4 which is in the range of those of carbenes bound to transition metals,7 similar to that of ¹³CO bound to Fe¹¹ porphyrins or haemoproteins,⁸ but very different from that of the ethoxycarbonylmethylene carbon atom (25.7 p.p.m.) inserted into the Ni-N bond of [(TPP)Ni¹¹].⁹ This strongly suggests that the CCl₂ residue is axially bound to the iron atom. Accordingly, complex (I) readily binds one pyridine molecule with a high affinity to give a new complex [formation constant $K = 3500 \,\mathrm{l}\,\mathrm{mol}^{-1}$ at 20 °C; λ_{max} 423 (ϵ

 2.4×10^{5}), 504 (ϵ 9.6 $\times 10^{3}$), and 544 (12×10^{3}) nm in The latter is slowly transformed into the known benzene]. [(TPP)Fe^{II}(pyridine)₂]¹⁰ only by further addition of a large excess of pyridine.

All our data are in agreement with a pentaco-ordinated [(TPP)Fe^{II}] complex with a : CCl₂ ligand, which is believed to be the first isolated carbene complex of an iron porphyrin as well as the first dihalogenated carbene complex of a transition metal, and is believed to form as shown in the Scheme.

$$\begin{split} [(\text{TPP})\text{Fe}^{\text{II}}] + \text{CCl}_4 \rightarrow [(\text{TPP})\text{Fe}^{\text{II}}\text{Cl} \\ &+ \cdot \text{CCl}_3] \xrightarrow{+2e^-} [(\text{TPP})\text{Fe}^{\text{II}}\text{CCl}_2] \end{split}$$

However, one cannot completely exclude a hexaco-ordinated carbyne type¹¹ structure [(TPP)Fe(Cl)(CCl)] and further investigations, including X-ray analysis, are in progress.

Other polyhalogenated compounds such as CBr₄, CCl₃Br, CCl₃F, CCl₃CN, CCl₃CO₂Et, and CF₂Br₂ react similarly with [(TPP)Fe¹¹].

We thank Professor V. Ullrich for his contribution to the initiation of this work and Dr. J. Y. Lallemand for his contribution to the n.m.r. work.
