Concepts, Methods, Starting Materials

This book is addressed to the advanced student of chemistry and to research chemists. It attempts to convey knowledge about concepts, methods, starting materials and some target molecules, which are thought to be important to modern organic synthesis. Also, the application of this knowledge to retrosynthetic analysis and the design of synthesis plans is described. Important concepts are summarized at the beginning of each chapter. They include the synthon approach, systematic evaluation of the arrangement of functionality, strategies to achieve regio- and stereoselectivity in carbon-carbon bond formation and functional group conversions, strategies to enforce thermodynamically unlikely reactions and retrosynthetic analysis. Criteria for the selection of methods were generality, simplicity and didactic usefulness. Generality implies that the method has been applied in complex syntheses, simplicity means that the method is not too time consuming, and didactic usefulness points to principles of selectivity control which the authors want to demonstrate.

A list of commercial starting materials tells the chemist working in organic synthesis what industry is able to do for him and a selection of more complex procedures shows what he may aim for.
