

## Tris(pyrazolyl)hydroboratozinc Alkyl Derivatives: Direct Comparison of the Reactivity of Zn–C and Mg–C Bonds

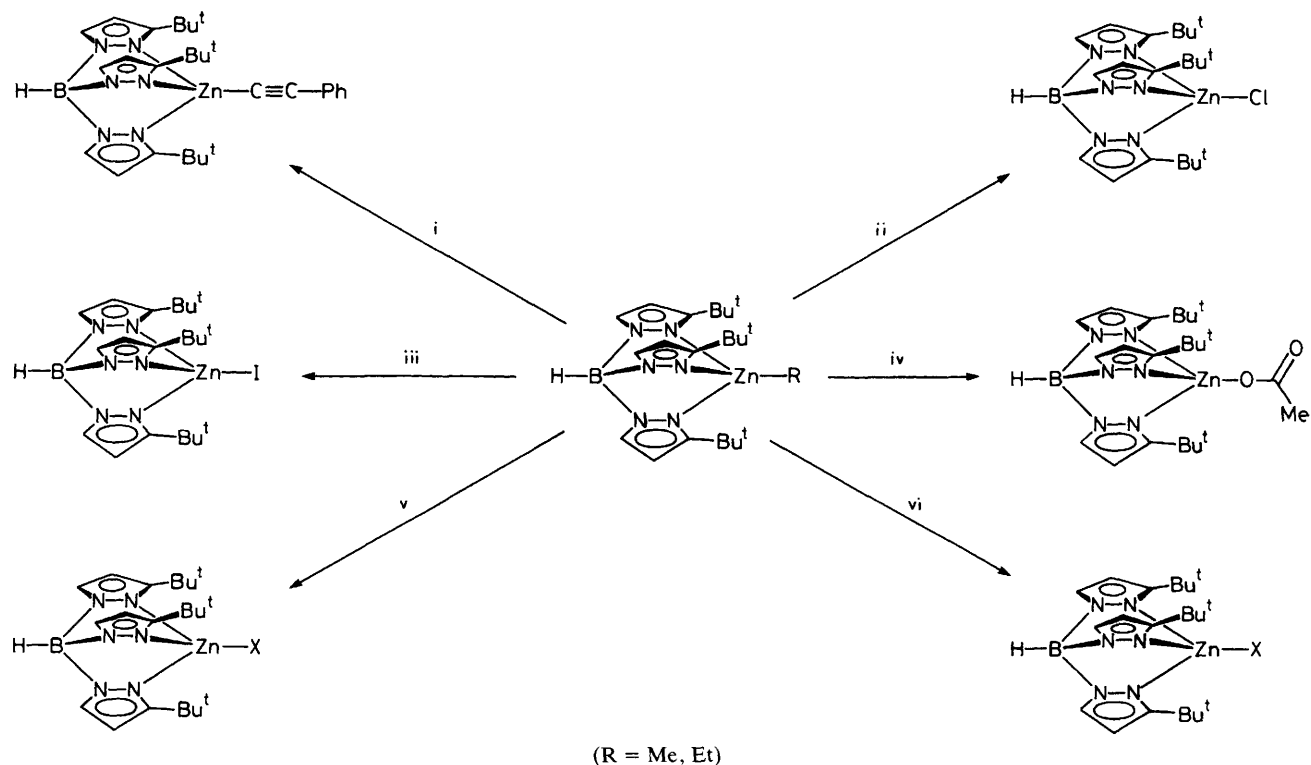

Ian B. Gorrell, Adrian Looney, and Gerard Parkin\*

Department of Chemistry, Columbia University, New York, New York 10027, U.S.A.

The monoalkyl zinc derivatives  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{ZnR}$  ( $3\text{-Bu}^t\text{pz} = 3\text{-C}_3\text{N}_2\text{Bu}^t\text{H}_2$ ;  $\text{R} = \text{Me}, \text{Et}$ ) have been prepared by metathesis of  $\text{R}_2\text{Zn}$  with  $\text{Ti}[\text{HB}(3\text{-Bu}^t\text{pz})_3]$ , and their reactivity compared with that of the isostructural magnesium alkyl derivatives.

Organozinc and organomagnesium derivatives are invaluable reagents in organic synthesis.<sup>1</sup> More recently,  $\text{R}_2\text{M}$  ( $\text{M} = \text{Mg}, \text{Zn}$ ) derivatives have been used successfully for the asymmetric alkylation of aldehydes in the presence of chiral amino alcohols.<sup>2</sup> In order to be able to control the selectivity and reactivity of such organic transformations by the use of

different organomagnesium or organozinc derivatives, it is essential to understand the detailed nature of the reactivity of the  $\text{M}-\text{C}$  bonds in such complexes. Previous studies have demonstrated that magnesium alkyl derivatives are often more reactive than the corresponding zinc derivatives.<sup>3</sup> However, in order to make quantitative comparisons between

**Scheme 1.** Reagents: i,  $\text{PhCCH}$ ,  $-\text{RH}$ ; ii,  $\text{HCl}$ ,  $-\text{RH}$ ; iii,  $\text{RI}$  ( $\text{R} = \text{Me}, \text{PhCH}_2$ ); iv,  $\text{MeCO}_2\text{H}$ ,  $-\text{RH}$ ; v,  $\text{Me}_3\text{SiX}/\text{H}_2\text{O}$  ( $\text{X} = \text{I}, \text{Br}, \text{Cl}, \text{CN}, \text{N}_3, \text{NCS}$ ),  $-\text{RH}$ ; vi,  $\text{X}_2$  ( $\text{X}_2 = \text{Cl}_2, \text{Br}_2, \text{I}_2$ ),  $-\text{RX}$ .

magnesium and zinc alkyl derivatives, and thus determine the intrinsic reactivity of Mg–C vs. Zn–C bonds, it is important to examine isostructural alkyl derivatives. Thus, comparisons between  $R_2Zn$ , a molecular species containing two-co-ordinate zinc, and  $(R_2Mg)_n$ , a polymeric solid, would not be expected to give a true indication of the relative intrinsic reactivities of the Zn–C and Mg–C bonds. Similarly, comparisons between the RMX (M = Mg, Zn) derivatives would not be straightforward as a result of the complex nature of these species in solution. We have recently described the syntheses and reactivity of the magnesium alkyl derivatives  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{MgR}$  (3-Bu<sup>t</sup>pz = 3-C<sub>3</sub>N<sub>2</sub>Bu<sup>t</sup>H<sub>2</sub>; R = Me, Et), in which the tris(pyrazolyl)hydroborato ligand provides a well-defined environment about the magnesium centre.<sup>4</sup> Here we describe the syntheses and reactivity of the monoalkyl zinc derivatives  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{ZnR}$  (R = Me, Et) so that direct comparisons between the reactivity of the Zn–C and Mg–C bonds may be made.

The zinc alkyl complexes  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{ZnR}^\dagger$  are readily prepared by metathesis of  $R_2Zn$  with  $\text{Ti}[\text{HB}(3\text{-Bu}^t\text{pz})_3]$  (equation 1, where THF = tetrahydrofuran).

The molecular structure of  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{ZnMe}$  has been determined by single-crystal X-ray diffraction studies (Figure 1), which confirm both the monomeric nature of the complex and the  $\eta^3$ -co-ordination mode of the  $[\eta^3\text{-tris}(\text{pyr-}$

**Figure 1.** ORTEP diagram of  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{ZnMe}$ . For clarity, thermal ellipsoids are shown at 20% probability. Selected bond distances (Å) and angles (°): Zn–C(1) 1.890(10), Zn–N(12) 2.121(9), Zn–N(22) 2.117(6), N(11)–N(12) 1.374(13), N(21)–N(22) 1.368(8), B–N(11) 1.530(17), B–N(21) 1.555(10); N(12)–Zn–N(22) 90.5(2), N(22)–Zn–N(22') 90.1(3), N(11)–B–N(21) 109.8(7), N(21)–B–N(21') 108.5(9), C(1)–Zn–N(12) 123.8(4), C(1)–Zn–N(22) 125.6(2).

azolyl)hydroborato] ligand.‡ The Zn–C bond length [1.890(10) Å] is noticeably shorter than the Mg–C bond length [2.118(11) Å] in the isostructural derivative,  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{MgMe}$ .<sup>4</sup> For comparison, the Zn–C bond length [1.957(5) Å] in the diethyl derivative, (18-crown-6) $\text{ZnEt}_2$  is also shorter than the Mg–C bond length [2.104(2) Å] in the related complex, (18-crown-6) $\text{MgEt}_2$ .<sup>5</sup>

The complexes  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{ZnR}$  represent the first examples of zinc alkyl derivatives stabilized by a  $[\eta^3\text{-tris}(\text{pyrazolyl})\text{hydroborato}]$  ligand. The stabilizing influence of the  $[\eta^3\text{-tris}(\text{pyrazolyl})\text{hydroborato}]$  ligand upon the Zn–C bond is clearly indicated the remarkable stability of  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{ZnR}$  (R = Me, Et) towards oxygen, both in the solid state and in solution over a period of days.

The reactivity of  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{ZnR}$  is illustrated in Scheme 1.§ The Zn–C bond is readily cleaved by protic reagents to eliminate RH. Thus, the reactions of  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{ZnR}$  with hydrogen chloride, acetic acid and phenylacetylene give  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{ZnCl}$ ,†  $[\eta^3\text{-HB}(3\text{-}$

‡ *Crystal data for  $[\eta^3\text{-HB}(3\text{-Bu}^t\text{pz})_3]\text{ZnMe}$ :* C<sub>22</sub>H<sub>37</sub>N<sub>6</sub>BZn, *M* = 461.77, orthorhombic, space group *Pnma* (No. 62), *a* = 16.341(4), *b* = 15.932(6), *c* = 9.775(4) Å, *U* = 2545(2) Å<sup>3</sup>, *Z* = 4, *D<sub>c</sub>* = 1.2 g cm<sup>–3</sup>, *F*(000) = 984 electrons, μ(Mo-*K*<sub>α</sub>) = 10.1 cm<sup>–1</sup>, *T* = 295 K, crystal dimensions 0.30 mm × 0.36 mm × 0.42 mm. Intensity data were collected on a Nicolet R3m diffractometer using monochromated Mo-*K*<sub>α</sub> X-radiation (λ = 0.71073 Å) and were corrected for Lorentz, polarization, and absorption effects. A total of 3498 unique reflections were collected in the range 3 < 2θ < 58°, of which 953 with *F<sub>o</sub>* > 6σ(*F<sub>o</sub>*) were used in the structure determination. The structure was solved using Patterson and standard difference map techniques. Most of the hydrogen atoms were located in the difference map after all the non-hydrogen atoms were located and refined anisotropically, but hydrogens on carbon were allowed to refine in calculated positions [*d*<sub>C–H</sub> = 0.96 Å; *U*<sub>iso</sub>(H) = 1.2*U*<sub>iso</sub>(C)]. Block-diagonal least-squares refinement converged to *R* = 5.47 (*R<sub>w</sub>* = 4.20), with the maximum shift-to-σ ratio of 0.028 for the last cycle. The final difference map showed no significant features, with the highest final peak 0.6 e Å<sup>–3</sup> near Zn. Atomic co-ordinates, bond lengths and angles, and thermal parameters have been deposited at the Cambridge Crystallographic Data Centre. See Notice to Authors, Issue No. 1.

§ Reactions were most conveniently monitored by <sup>1</sup>H NMR spectroscopy.

$\text{Bu}^t\text{pz}_3\text{Zn}(\eta^1\text{-O}_2\text{CMe})$ ,<sup>†</sup> and  $[\eta^3\text{-HB(3-Bu}^t\text{pz)}_3\text{ZnCCPh}]$ ,<sup>†</sup> respectively. Similarly, halogens cleave the Zn–C bond to eliminate RX and give the halide,  $[\eta^3\text{-HB(3-Bu}^t\text{pz)}_3\text{ZnX}]$  (X = Cl, Br, I).<sup>†</sup> The reactions of  $[\eta^3\text{-HB(3-Bu}^t\text{pz)}_3\text{ZnR}]$  with HX (X = Br, Cl, I, CN, N<sub>3</sub>, NCS), generated *in situ* by the prior treatment of Me<sub>3</sub>SiX with H<sub>2</sub>O, provide convenient synthetic procedures for the formation of  $[\eta^3\text{-HB(3-Bu}^t\text{pz)}_3\text{ZnX}]$ .<sup>6</sup>

The rates of the reactions of  $[\eta^3\text{-HB(3-Bu}^t\text{pz)}_3\text{ZnR}]$  are significantly slower than the corresponding reactions of the magnesium derivatives.<sup>4</sup> For example, whereas both  $[\eta^3\text{-HB(3-Bu}^t\text{pz)}_3\text{ZnEt}]$  and  $[\eta^3\text{-HB(3-Bu}^t\text{pz)}_3\text{MgEt}]$  react with PhCH<sub>2</sub>I to give  $[\eta^3\text{-HB(3-Bu}^t\text{pz)}_3\text{MI}]$  (M = Zn, Mg), the half-lives under similar conditions at 100 °C are  $2.3 \times 10^3$  and 0.23 h, respectively, a factor of four orders of magnitude difference in reactivity.<sup>¶</sup> Similarly, whereas  $[\eta^3\text{-HB(3-Bu}^t\text{pz)}_3\text{MgMe}]$  undergoes insertion of CO<sub>2</sub> into the Mg–C bond at room temperature, no reaction is observed between  $[\eta^3\text{-HB(3-Bu}^t\text{pz)}_3\text{ZnMe}]$  and CO<sub>2</sub> at 140 °C, although the expected product,  $[\eta^3\text{-HB(3-Bu}^t\text{pz)}_3\text{Zn}(\eta^1\text{-O}_2\text{CMe})]$ , has been isolated by the reaction of  $[\eta^3\text{-HB(3-Bu}^t\text{pz)}_3\text{ZnR}]$  with MeCO<sub>2</sub>H.

In conclusion, we have demonstrated that co-ordination of the  $[\eta^3\text{-tris(pyrazolyl)hydroborato}]$  ligands to zinc alkyl derivatives results in the formation of 4-co-ordinate monoalkyl complexes that are isostructural with the analogous magnesium derivatives. Comparison of the reactivity of the Zn–C and Mg–C bonds in these complexes provides good evidence

<sup>¶</sup> These preliminary kinetic studies are only intended to give an indication of the relative reactivity under similar conditions and the complete rate-law has not yet been determined.

for the intrinsic higher reactivity of the Mg–C vs. the Zn–C bonds.

We thank the Donors of the Petroleum Research Fund, administered by the ACS, for partial support of this research.
