Treatment of H_3AlNMe_3 with 1,3,5-trimethylhexahydro-1,3,5-triazine (tmtz) yields trigonal bipyramidal, monomeric $[\text{H}_3\text{Al}(\text{tmtz})_2]$, **1**, or polymeric $[\text{H}_3\text{Al}(\text{tmtz})]_\infty$, **2**, which undergo N-CH₂ cleavage at ca. 123 °C; nitrogen-atoms in **1** and **2** are in apical positions, as also established for polymeric $[\text{H}_3\text{Al}(\text{N,N,N',N'}$ -tetramethylpropylenediamine)]_∞, in accordance with *ab initio* molecular orbital calculations on the model system $\text{H}_3\text{Al}(\text{NH}_3)_2$.

Tertiary amine aluminium hydride adducts are versatile reagents in synthesis,¹ and as precursors for delivering aluminium metal to surfaces.²⁻⁵ Recently we established that the ubiquitous trimethylamine adduct, H_3AlNMe_3 , and some other unidentate amine adducts, are dimeric in the solid, possessing unsymmetrical hydride bridges,⁶ in contrast with monomeric H_3AlNMe_3 in the gas phase.⁷ The availability of more than one tertiary amine centre can result in (i) five-coordinate species, e.g. $\text{H}_3\text{Al}(\text{NMe}_3)_2$,⁸ polymeric $\text{H}_3\text{Al}(\text{tmeda})^9$ (tmeda = *N,N,N',N'*-tetramethylethylene-

diamine) (based on incomplete X-ray structure determinations), and dimeric $\text{H}_3\text{Al}(\text{tmeda})$ (vapour phase),¹⁰ and (ii) ionic species for higher polydentate tertiary amines, $[\text{H}_2\text{Al}(\text{N,N,N',N'',N''}$ -pentamethyldiethylenetriamine)]⁺[AlH₄]⁻, and *trans*- $[\text{H}_2\text{Al}(\text{N,N',N'',N''}$ -tetramethylcyclam)]⁺[AlH₄]⁻.¹¹

1,3,5-Trimethylhexahydro-1,3,5-triazine (tmtz) is potentially a tridentate tertiary amine, but because of steric strain in any derived four-membered chelate rings oligomeric species are more likely, in which the metal forms a polymeric network

Fig. 1 Projections of (a) $[\text{H}_3\text{Al}(\text{tmtz})_2]$, **1**, (b) $[\text{H}_3\text{Al}(\text{tmtz})]_\infty$, **2**, and (c) $[\text{H}_3\text{Al}(\text{tmpda})]_\infty$, **3**, with 20% thermal ellipsoids for non-hydrogen atoms and arbitrary radii for hydrogen atoms shown, hydrides for **3** excepted. Selected bond distances (Å) and angles ($^\circ$): **1** Al(1)–N(1, 3) 2.188(4), 2.187(4), Al(1)–H(1a, b) 1.64(4), 1.70(6), N(1)–Al(1)–N(3) 177.4(2); N(1)–Al(1)–H(1a, b) 90(1), 91(2), N(3)–Al(1)–H(1a, b) 89(1), 92(2), H(1a)–Al(1)–H(1b) 120(1), H(1a)–Al(1)–H(1a') 120(2). **2** Al(1)–N(1, 3) 2.231(5), 2.198(6), Al(1)–H(1a, b, c) 1.61, 1.51, 1.48; N(1)–Al(1)–N(3) 174.9(2), N(1, 3)–H(1a, b, c) 84–93. **3** Al(1)–N(1, 2) 2.217(4), 2.200(4), Al(1)–H(1, 2, 3) 1.61(4), 1.47(4), 1.62(5); N(1)–Al(1)–H(1, 2, 3) 88(2), 93(2), 87(2), N(2)–Al(1)–H(1, 2, 3) 92, 94, 95, N(1)–Al(1)–N(2) 177.9(1), H(1)–Al(1)–H(2, 3) 114(2), 124(3), H(2)–Al(1)–H(3) 122(3).

Scheme 1

with the metal centres connected to two different tmtz units, as for the related ligand hexamethylenetetramine.¹² We report that tmtz forms neutral rather than ionic species, monomeric, $[\text{H}_3\text{Al}(\text{tmtz})_2]$, **1**, and polymeric, $[\text{H}_3\text{Al}(\text{tmtz})]_\infty$, **2**, and that the 1:1 adduct of aluminium hydride with *N,N,N',N'*-tetramethylpropylenediamine (tmpda), *viz.* $[\text{H}_3\text{Al}(\text{tmpda})]_\infty$, **3**, is also polymeric in the solid, although it is dimeric in benzene.¹³ Connectivity has been established using X-ray diffraction data and the resulting refinements represent the first complete structure determinations of five-coordinate aluminium hydride species. We also report a high level theoretical study on the model compound, $\text{H}_3\text{Al}(\text{NH}_3)_2$.

Synthesis of **1**, **2** and **3**,¹³ involved treating H_3AlNMe_3 with the corresponding amine in the appropriate ratio, Scheme 1.† No further uptake of aluminium hydride from H_3AlNMe_3 is evident on the formation of **2** despite the availability of a nitrogen lone pair on each tmtz moiety (see below). Compound **1** decomposes thermally to **2** then undergoes N–CH₂ cleavage at *ca.* 123 °C yielding on hydrolysis NMe_3 and $\text{CH}_2(\text{NMe}_2)_2$, and some tmtz. The aluminium hydride adduct of $\text{CH}_2(\text{NMe}_2)_2$ also undergoes N–CH₂ cleavage but at ambient temperature.¹⁴ All other aluminium hydride tertiary

† **Compound 1**: a solution of 1,3,5-trimethylhexahydro-1,3,5-triazine (0.40 ml, 0.37 g, 2.84 mmol) in OEt_2 (10 ml) was added over 15 min to a slurry of 1,3,5-trimethylhexahydro-1,3,5-triazinealane (0.45 g, 2.84 mmol) in OEt_2 (20 ml) at 0 °C. Upon warming to room temperature the suspension dissolved and the resulting solution was stirred for 30 min after which solvent was removed *in vacuo* leaving a white solid. Recrystallisation from OEt_2 (5 ml) yielded colourless prisms (0.71 g, 86% yield). M.p. 93–94 °C; satisfactory C, H and N analyses were obtained for compounds **1** and **2**; ^1H NMR (250 MHz, C_6D_6 , 25 °C): δ 2.16 (s, 18H, NMe) 3.16 (br, 12H, NCH_2) 3.49 (br, 3H, AlH); ^{13}C NMR (62.8 MHz, C_6D_6 , 25 °C): δ 39.6 (NMe) 75.8 (NCH_2); ^{27}Al NMR (78.18 MHz, C_6D_6 , 25 °C): δ 102.6 (br); IR: ν/cm^{-1} 1717 (br, AlH).

Compound 2: a solution of 1,3,5-trimethylhexahydro-1,3,5-triazine (0.84 ml, 0.77 g, 5.98 mmol) in OEt_2 (10 ml) was added over 30 min to a stirred solution of H_3AlNMe_3 (0.54 g, 6.07 mmol) in OEt_2 (30 ml) at 0 °C. The resulting suspension was stirred at room temperature for 1 h after which solvent was removed *in vacuo* leaving a white solid. Recrystallisation from OEt_2 (100 ml) yielded colourless rods (0.72 g, 61% yield). M.p. 109–112 °C (decomp. > 123 °C); ^1H NMR (250 MHz, C_6D_6 , 25 °C): δ 1.10 (t, 3H, Me) 2.06 (s, 9H, NMe) 3.09 (br, 6H, NCH_2) 3.27 (qt, 2H, OCH_2) 3.93 (br, 3H, AlH); ^{13}C NMR (62.8 MHz, C_6D_6 , 25 °C): δ 14.6 (Me) 39.5 (NMe) 65.3 (OCH_2) 75.3 (NCH_2); IR: ν/cm^{-1} 1718 (br, AlH).

amine adducts,^{6,10,11} including **3** and those based on tmeda and *N,N,N',N'*-tetramethylbutylenediamine (tmbda),¹⁵ decompose to free amine, metal and hydrogen, at typically >100 °C.

Results of the X-ray structure determinations of **1–3**† are presented in Fig. 1. Molecules in **1** have *m*-crystallographic symmetry whereas in **2** two tmtz ligands have *m*-crystallographic symmetry, and in **3** the asymmetric unit is AlH₃ and one diamine. In all three structures, and also in polymeric H₃Al(tmbda),¹⁵ the metal centres are trigonal planar with the nitrogens in apical positions and Al–N distances (mean), **1**, 2.188, **2**, 2.217, **3**, 2.208 Å. These distances are significantly longer than in monomeric mono-tertiary amine aluminium hydride derivatives, 2.063(8) for H₃AlNMe₃ (gas phase),⁷ and 2.088(2) and 2.082(4) Å for weakly associated [(H₃AIL)₂], L = benzylidimethylamine and 1-methyltetrahydropyridine,⁶ reflecting greater solvation at the metal centres. The earlier defined Al–N distances in H₃Al(NMe₃)₂⁸ and H₃Al(tmeda)⁹ are similar, at 2.18(1) and 2.21 Å, respectively. In **2** the one dimensional polymeric strand results in a congested metal free N-centre, thus accounting for the lack of additional uptake of aluminium hydride. Five-coordinate adducts of aluminium hydride have also been structurally authenticated for phosphine and mixed phosphine–amine aluminium hydride adducts.¹⁶

Collectively, structural information on bis(amine) aluminium hydride adducts clearly establish the preference for the AlH₃ entity to be planar even if a chelate ring is likely to be relatively unstrained as would be the case in monomeric adducts of tmpda. *Ab initio* molecular orbital calculations§

were carried out on H₃Al(NH₃)₂ at the Hartree Fock (HF) level of theory using a double-zeta (DZ) then double-zeta plus polarisation (DZP), both with an effective core potential (ECP) for Al.¹⁷ HF/DZP-ECP calculations converged with *D*_{3h} symmetry, Al–N 2.220, Al–H 1.611 Å, N–Al–H 90.0° (N–H 1.005 Å, Al–N–H 110.9°) which is close to the structures of **1–3**. Starting with geometries for the isomeric *C*_{2v} and *C*_s trigonal bipyramidal structures for H₃Al(NH₃)₂ resulted in fragmentation to H₃AlNH₃ and NH₃ which collectively are only 10.74 kcal mol⁻¹ (1 cal = 4.184 J) less stable than H₃Al(NH₃)₂. This is consistent with equilibrium between H₃Al(NMe₃)₂ and H₃AlNMe₃–NMe₃,¹⁸ and overall represents an energy inequality: *C*_{2v} and *C*_s H₃Al(NH₃)₂ < H₃AlNH₃–NH₃ < *D*_{3h} H₃Al(NH₃)₂.

We thank the Australian Research Council for a Grant and a Fellowship (G. A. K.), and the Department of Industry, Technology and Commerce (Australia) for support of this work. We also thank Karl Byriel for collection of some diffraction data.

† Crystal structure determinations (*T* = 296 K; Enraf-Nonius CAD4 diffractometer, crystals mounted in capillaries): compound **1**, C₁₂H₃₃AlN₆, *M* = 288.4, monoclinic, space group *I*2*m*, *a* = 10.906(8), *b* = 12.784(5), *c* = 13.58(1) Å, β = 99.99(4)°, *U* = 1865 Å³, *F*(000) = 640; *Z* = 4, *D*_c = 1.034 g cm⁻³, Mo–Kα λ = 0.71069 Å, μ(Mo–Kα) = 1.14 cm⁻¹, specimen 0.25 × 0.30 × 0.30 mm, 1714 unique reflections, 1043 with *I* > 2.5σ(*I*) used in the refinement, 2θ_{max} = 50°. Compound **2**, C₆H₁₈AlN₃·(OEt₂)_{0.5}, *M* = 196.3, orthorhombic, space group *Pmnn*, *a* = 11.569(1), *b* = 12.606(1), *c* = 15.532(2) Å, *U* = 2265 Å³, *F*(000) = 768; *Z* = 8, *D*_c = 1.15 g cm⁻³, Mo–Kα λ = 0.71069 Å, μ(Mo–Kα) = 1.47 cm⁻¹, specimen 0.15 × 0.25 × 0.40 mm, 2102 unique reflections, 1272 with *I* > 2.5σ(*I*) used in the refinement, 2θ_{max} = 50°. Compound **3**, C₇H₂₁AlN₂, *M* = 160.2, orthorhombic, space group *Pbca*, *a* = 12.265(1), *b* = 12.499(2), *c* = 14.272(1) Å, *U* = 2188 Å³, *F*(000) = 720; *Z* = 8, *D*_c = 0.98 g cm⁻³, Cu–Kα λ = 1.5418 Å, μ(Cu–Kα) = 11.7 cm⁻¹, specimen 0.20 × 0.25 × 0.35 mm, 1236 unique reflections, 1030 with *I* > 3σ(*I*) used in the refinement, 2θ_{max} = 110°.

The structures were solved by direct methods and refined by full-matrix least-squares refinement using SHELX and XTAL programmes. Hydrogen atoms attached to Al were located and refined in *x*, *y*, *z*, *U*_{iso}, **1**, or *x*, *y*, *z*, **2** and **3**; hydrogens attached to carbon were included as invariants. Unit weights were used and the final residuals were *R* = 0.053, 0.077, 0.058, *R'* = 0.053, 0.077, 0.062, **1**, **2** and **3**, respectively. Atomic coordinates, bond lengths and angles, and thermal parameters have been deposited at the Cambridge Crystallographic Data Centre. See Notice to Authors, Issue No. 1.

§ Calculation used the Hondo/7 package¹⁹ on the Convex platform. To investigate the effects of polarization on the Al–N bonds the DZ basis sets were augmented with *d*-functions (DZP) on Al and N (exponents of *d*-functions were 0.3 and 0.8, respectively). A comparison with earlier work on H₃AlNH₃⁶ shows that the Al–N bond length increases by only 0.017 Å, when the ECP approximation is implemented, and therefore, the ECP approximation represents a good compromise between economy and accuracy for this study.
