

## Hydrosulfination of Alkynes: Synthesis of Vinyl Sulfinato Complexes of Ruthenium(II)

Anthony F. Hill

Department of Chemistry, Imperial College of Science, Technology and Medicine, South Kensington, London, UK SW7 2AY, E-mail: a.hill@ic.ac.uk

The reaction of  $[\text{RuClH}(\text{CO})(\text{PPh}_3)_3]$  with alkynes ( $\text{R}^1\text{C}\equiv\text{CR}^2$ ) and  $\text{SO}_2$  provides the vinylsulfinato-*S,O* complexes  $[\text{Ru}(\eta^2\text{-SO}_2\text{CR}^1=\text{CHR}^2)\text{Cl}(\text{CO})(\text{PPh}_3)_2]$  in a process reminiscent of hydroformylation.

The insertion of sulfur dioxide into transition metal  $\sigma$ -alkyl and  $\sigma$ -aryl bonds has been extensively studied and is now one of the best understood reactions in organotransition metal chemistry.<sup>1</sup> Surprisingly, however, very few useful applications of this reaction have been developed in dramatic contrast to carbonyl insertion. A potentially close analogy between CO and  $\text{SO}_2$  in catalytic processes has been illustrated very recently in the palladium catalysed hydrosulfination of olefins<sup>2</sup> and an early report of the palladium chloride mediated condensation of ethene and  $\text{SO}_2$  to  $\text{EtSO}_2\text{CH}_2\text{CH}=\text{CHMe}$  almost certainly also involves related processes.<sup>3</sup> This report describes one such situation, namely the hydrosulfination of alkynes which may be viewed as a model process for the sulfur dioxide analogue of alkyne hydroformylation.

Treating a suspension of  $[\text{RuClH}(\text{CO})(\text{PPh}_3)_3]$  with a range of alkynes,  $\text{R}^1\text{C}\equiv\text{CR}^2$  (Scheme 1), in the presence of sulfur dioxide leads to the pale yellow or colourless vinyl sulfinato complexes  $[\text{Ru}(\text{SO}_2\text{CHR}^1=\text{CHR}^2)\text{Cl}(\text{CO})(\text{PPh}_3)_2]$  in spectroscopically† quantitative yield and isolated yields of 63–89% depending on the alkyne employed. The coordination of the sulfinato group to the 15 electron ruthenium centre in these and the related toluene sulfinates  $[\text{M}(\text{SO}_2\text{C}_6\text{H}_4\text{Me-4})\text{Cl}(\text{CO})(\text{PPh}_3)_2]$  ( $\text{M} = \text{Ru}, \text{Os}$ )<sup>5</sup> remains, in the absence of crystallographic data, a matter for conjecture; however, infrared data for the  $\text{RuSO}_2$  group are consistent with neither monodentate S nor O coordination. It therefore appears most likely that a weak or hemilabile dative interaction of one sulfoxide of an *S*-sulfinato operates (Scheme 1). This is supported by the rapid reaction with  $\pi$ -acid ligands to provide the complexes  $[\text{Ru}(\text{OSOCR}^1=\text{CHR}^2)\text{Cl}(\text{CO})(\text{L}')(\text{PPh}_3)_2]$  ( $\text{L}' = \text{CO}, \text{CNBu}^t, \text{CNC}_6\text{H}_3\text{Me}_2\text{-2,6}$ ), accompanied by an apparent rearrangement of the sulfinato to the monodentate *O*-bound coordination mode

as indicated by IR data and supported by precedent for the related toluene sulfinato complex.<sup>5</sup> In the absence of such ligands, the dihapto-*S,O* complexes are stable towards linkage isomerism.

Our view of the mechanism is based on the following observations: (i) The complex  $[\text{RuClH}(\text{CO})(\text{PPh}_3)_3]$  reacts reversibly with  $\text{SO}_2$  to provide  $[\text{RuClH}(\text{CO})(\text{SO}_2)(\text{PPh}_3)_3]$ . (ii) Reaction of  $[\text{RuClH}(\text{CO})(\text{PPh}_3)_3]$  with alkynes provides  $[\text{Ru}(\sigma\text{-vinyl})\text{Cl}(\text{CO})(\text{PPh}_3)_2]$ .<sup>4</sup> (iii) Reaction of the related  $\sigma$ -aryl complex  $[\text{Ru}(\text{C}_6\text{H}_4\text{Me})\text{Cl}(\text{CO})(\text{PPh}_3)_2]$  with  $\text{SO}_2$  provides the sulfinato  $[\text{Ru}(\text{SO}_2\text{C}_6\text{H}_4\text{Me})\text{Cl}(\text{CO})(\text{PPh}_3)_2]$ .<sup>5</sup> (iv) The  $\sigma$ -vinyl complexes  $[\text{Ru}(\text{R}^1\text{CH}=\text{CHR}^2)\text{Cl}(\text{CO})(\text{PPh}_3)_2]$  may be prepared separately and converted to the corresponding sulfinates on treatment with  $\text{SO}_2$ . (v) The sulfinato of the preformed  $\sigma$ -vinyl complexes is essentially instantaneous at room temperature; however, the temperature required for alkyne insertion varies according to the nature of the alkyne. (vi) In the reaction of  $[\text{Os}(\text{C}_6\text{H}_4\text{Me-4})\text{Cl}(\text{CO})(\text{PPh}_3)_2]$  with  $\text{SO}_2$ , the insertion reaction was retarded by high concentrations of  $\text{SO}_2$  (*e.g.* as a solvent) and this is due to the competitive though reversible formation of an isolable  $\text{SO}_2$  adduct with this ligand *trans* to the  $\sigma$ -aryl group and therefore unavailable for an intramolecular migratory insertion. In the case of the ruthenium analogue, the product of such a reaction could not be isolated due to the increased reaction rates, and such a compound may also reversibly divert the reaction sequence for the alkyne hydrosulfination process described here. These points lead us to the mechanism depicted in Scheme 1.

I wish to thank Johnson Matthey Ltd for the generous loan of ruthenium salts.
