

## Regio- and Stereo-selectivity in the Hydrogenation of Aryl Phosphines by Niobium Aryloxy Compounds

Mark C. Potyen and Ian P. Rothwell\*

Department of Chemistry, 1393 Brown Building, Purdue University, West Lafayette, IN 47907-1393, USA

The sequential hydrogenation of the three aryl rings in  $\text{PPh}_3$  by the catalyst system  $[\text{Nb}(\text{OC}_6\text{HPh}_{4-2,3,5,6})_3\text{Cl}_2]/3\text{Bu}^n\text{Li}$  occurs with relative rates of 39:28:1; NMR analysis of the  $\text{PPhCy}_2$  obtained from  $[\text{P}(\text{C}_6\text{D}_5)_3/\text{H}_2]$  and  $[\text{P}(\text{C}_6\text{H}_5)_3/\text{D}_2]$  shows a predominately all *cis* hydrogenation of both aryl rings has occurred.

The recently demonstrated ability of niobium aryloxy compounds to carry out the hydrogenation of aryl phosphines raises many mechanistic problems.<sup>1,2</sup> Two key questions concern substrate selectivity and the stereochemistry of the reaction. Aspects of both of these questions are addressed here.

Although originally demonstrated using the catalyst precursor  $[\text{Nb}(\text{OC}_6\text{H}_3\text{Ph}_2-2,6)_2(\text{CH}_2\text{C}_6\text{H}_4-4\text{Me})_3]$  ( $\text{OC}_6\text{H}_3\text{Ph}_2-2,6 = 2,6$ -diphenylphenoxide)<sup>1</sup> the hydrogenation of aryl phosphines can also be achieved in the presence of chloroaryloxides  $[\text{Nb}(\text{OAr})_2\text{Cl}_3]$  and  $[\text{Nb}(\text{OAr})_3\text{Cl}_2]$  ( $\text{OAr} =$  various 2,6-disubstituted phenoxides)<sup>3</sup> activated with varying ratios of  $\text{Bu}^n\text{Li}$ .<sup>†</sup> Monitoring ( $^{31}\text{P}$  NMR of aliquots<sup>‡</sup>) the hydrogenation of  $\text{PPh}_3$  by the mixture  $[\text{Nb}(\text{OC}_6\text{H}_3\text{Pr}^i-2,6)_2\text{Cl}_3]/4\text{Bu}^n\text{Li}$  ( $\text{OC}_6\text{H}_3\text{Pr}^i-2,6 = 2,6$ -diisopropylphenoxide) over time (Fig. 1) shows that the third phenyl ring is hydrogenated at a much slower rate than the first two. The reaction profile can be fit using a consecutive first order kinetic model which yields the relative rates of hydrogenation of  $\text{PPh}_3$ ,  $\text{PPh}_2\text{Cy}$  and  $\text{PPhCy}_2$  (Fig. 1). The reaction profile at 60 °C is insensitive to the ratio of catalyst/substrate. In contrast, using bis(diphenylphosphino)methane (dppm) as substrate with the catalyst system  $[\text{Nb}(\text{OC}_6\text{H}_3\text{Pr}^i-$

$2,6)_3\text{Cl}_2]/3\text{Bu}^n\text{Li}$  shows a completely different reaction profile (not yet modelled) in which the final product (dcpm) is generated with only small amounts of intermediates being built up (Fig. 2). This profile is possibly indicative of multiple arene rings being hydrogenated while the substrate is attached to a single catalyst site.

The catalyst mixture  $[\text{NbOC}_6\text{HPh}_{4-2,3,5,6})_3\text{Cl}_2]/3\text{Bu}^n\text{Li}$  containing 2,3,5,6-tetraphenylphenoxide ancillary ligation generates a reaction profile for  $\text{PPh}_3$  in which the intermediate  $\text{PPhCy}_2$  builds up dramatically (Fig. 3). This system can be used to synthetically prepare and purify  $\text{PPhCy}_2$  whose  $^1\text{H}$  NMR spectrum (assigned by a combination of COSY and HETCOR experiments) shows all eleven, non-equivalent cyclohexyl ring protons (Fig. 4). The samples of  $\text{PPhCy}_2$  obtained by reacting  $\text{P}(\text{C}_6\text{H}_5)_3$  with  $\text{D}_2$  and  $\text{P}(\text{C}_6\text{D}_5)_3$  with  $\text{H}_2$  give  $^1\text{H}$  NMR spectra consistent with a predominantly all *cis* hydrogenation of the two phenyl rings (Fig. 4). Mass spectrometric studies show that these samples are  $[\text{H}_2]$  and  $[\text{H}_{15}]$  respectively, *i.e.* negligible H/D  $[\text{H}_2]$  scrambling occurs during hydrogenation.

The hydrogenation of  $\text{MePPh}_2$  by  $[\text{Nb}(\text{OC}_6\text{HPh}_{4-2,3,5,6})_3\text{Cl}_2]/3\text{Bu}^n\text{Li}$  proceeds *via* intermediate  $\text{MePPhCy}$  with

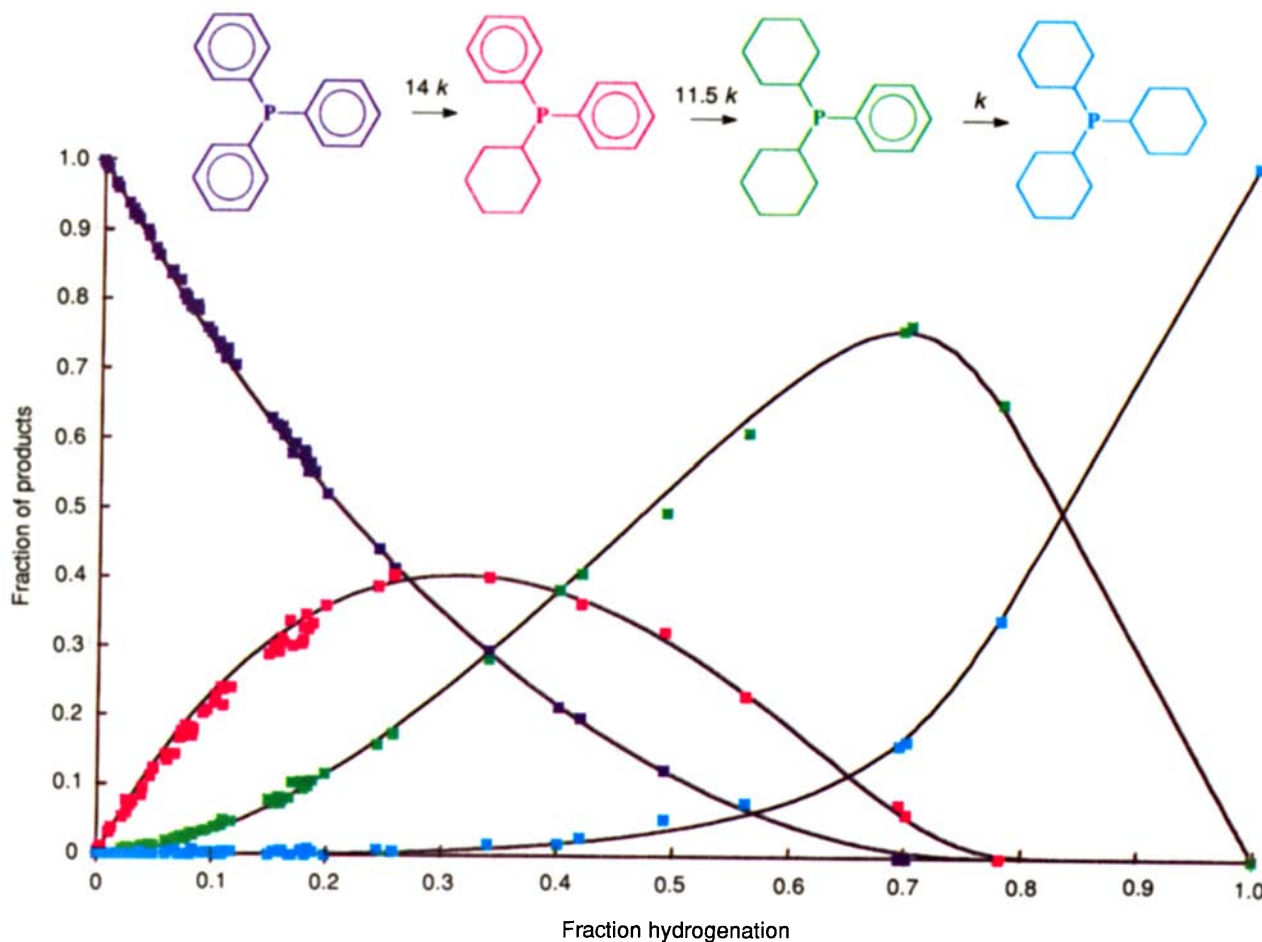

Fig. 1 Reaction profile (fraction of products vs. the fraction hydrogenation) for the hydrogenation of  $\text{PPh}_3$  by the mixture  $[\text{Nb}(\text{OC}_6\text{H}_3\text{Pr}^i-2,6)_2\text{Cl}_3]/4\text{Bu}^n\text{Li}$  ( $\text{OC}_6\text{H}_3\text{Pr}^i-2,6 = 2,6$ -diisopropylphenoxide). The solid black lines represent the reaction profile predicted by the kinetic model shown.

Fig. 2 Reaction profile (fraction of products vs. the fraction hydrogenation) for the hydrogenation of dppm by the mixture  $[\text{Nb}(\text{OC}_6\text{H}_3\text{Pr}^i\text{-2,6})_3\text{Cl}_2]/3\text{Bu}^n\text{Li}$  ( $\text{OC}_6\text{H}_3\text{Pr}^i\text{-2,6} = 2,6\text{-diisopropylphenoxide}$ ). The solid coloured lines do not represent a kinetic model but simply show the trends.

Fig. 3 Reaction profile (fraction of products vs. the fraction hydrogenation) for the hydrogenation of  $\text{PPh}_3$  by the mixture  $[\text{Nb}(\text{OC}_6\text{HPh}_4\text{-2,3,5,6})_3\text{Cl}_2]/3\text{Bu}^n\text{Li}$  ( $\text{OC}_6\text{HPh}_4\text{-2,3,5,6} = 2,3,5,6\text{-tetraphenylphenoxide}$ ). The solid black lines represent the reaction profile predicted by the kinetic model shown.

**Fig. 4**  $^1\text{H}$  NMR spectra of the aliphatic region (500 MHz,  $\text{C}_6\text{D}_6$ , 30 °C) for  $\text{P}(\text{C}_6\text{H}_5)(\text{C}_6\text{H}_{11})_2$ ,  $\text{P}(\text{C}_6\text{H}_5)(\text{C}_6\text{H}_5\text{D}_6)_2$  and  $\text{P}(\text{C}_6\text{D}_5)(\text{C}_6\text{D}_5\text{H}_6)_2$  obtained using the mixture  $[\text{Nb}(\text{OC}_6\text{HPh}_4-2,3,5,6)_3\text{Cl}_2]/3\text{Bu}^n\text{Li}$  ( $\text{OC}_6\text{HPh}_4-2,3,5,6 = 2,3,5,6$ -tetraphenylphenoxide) to carry out the reactions  $[\text{P}(\text{C}_6\text{H}_5)_3/\text{H}_2]$ ,  $[\text{P}(\text{C}_6\text{H}_5)_3/\text{D}_2]$  and  $[\text{P}(\text{C}_6\text{D}_5)_3/\text{H}_2]$

a reaction profile modelled by a 2 : 1 ratio of rate constants, *i.e.*  $\text{MePPH}_2$  is hydrogenated twice as fast as  $\text{MePPHcY}$ . The bulkier  $\text{Pr}^i\text{PPH}_2$ , however, generates the chiral intermediate  $\text{Pr}^i\text{PPHcY}$  in > 80% isolable yield (rate constant ratio of *ca.* 28 : 1).  $^1\text{H}$  NMR of the  $\text{Pr}^i\text{PPH}(\text{C}_6\text{H}_5\text{D}_6)$  obtained by reacting  $\text{Pr}^i\text{PPH}_2$  with  $\text{D}_2$  again shows a predominantly all *cis* arene hydrogenation has occurred (Fig. 5).

We thank the Department of Energy for support of this research.

### Footnotes

† In a typical procedure, a 300 ml stainless steel high pressure reactor fitted with a glass liner was charged in a dry box with  $[\text{Nb}(\text{OC}_6\text{H}_3\text{Pr}_2-2,6)_2\text{Cl}_3]$  (0.26 g, 0.47 mmol) and  $\text{PPh}_3$  (2.5 g, 9.5 mmol) in benzene (17 ml). After the addition of  $\text{Bu}^n\text{Li}$  in hexane (3.0 ml of 0.5 mol  $\text{l}^{-1}$ , 1.5 mmol), the reactor was pressurized with  $\text{H}_2$  (1200 psi initial pressure) and heated at 60 °C for varying amounts of time.
