Thermal decomposition of the 2*H*-azaphosphirene tungsten complex 1 in benzonitrile and in the presence of dimethylcyanamide yields the 2*H*-1,3,2-diazaphosphole tungsten complex 4, containing a novel five-membered heterocyclic ligand; the overall reaction may be described as a 1,3-dipolar cycloaddition of an *in situ* generated nitrilium phosphane ylide complex to benzonitrile.

Nitrilium ylides, like nitrile oxides,¹ sulfides² and nitrileimines,¹,³ are versatile building blocks in heterocyclic chemistry. Very recently, we obtained the first evidence of a nitrilium phosphane ylide complex as a reactive intermediate in the thermolysis of 2*H*-azaphosphirene tungsten complexes in the presence of dimethylacetylenedicarboxylate (DMAD) in toluene.⁴ The formation of the 2*H*-1,2-azaphosphole tungsten complexes, which were obtained as by-products, was explained as a 1,3-dipolar cycloaddition of a nitrilium phosphane ylide complex to the trapping reagent.⁴

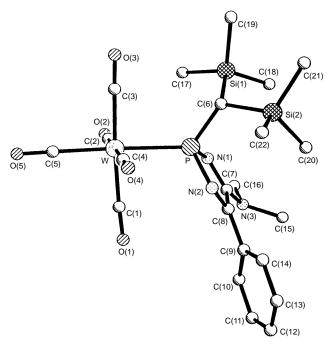

We now report the first synthesis of a 2*H*-1,3,2-diazaphosphole tungsten complex **4**, which has been obtained in good yield by thermal decomposition of the 2*H*-azaphosphirene tungsten complex **1** in benzonitrile and in the presence of 2 equiv. of dimethylcyanamide. Under these reaction conditions the 1,3-dipolar cycloaddition is stereoselective and the exclusive formation of this regionsomer was observed.

This reaction is interpreted as a further example of a 1,3-dipolar cycloaddition of the transiently formed nitrilium phosphane ylide tungsten complex **2b** to benzonitrile (Scheme 1, pathway (c)]. Pathways (a) and (b) seem less plausible, especially, if taken into account that under these reaction conditions the formation of the diphenyl-substituted 2*H*-1,3,2-diazaphosphole tungsten complex **3** was not observed [pathway (a)].

The composition of 2*H*-1,3,2-diazaphosphole tungsten complex **4** is confirmed by elemental analysis and mass spectrometry;† the structural formulation is based on the characteristic

$$(OC)_{5}W \xrightarrow{CH(SiMe_{3})_{2}} (OC)_{5}W \xrightarrow{CH(SiMe_{3})_{2}} (OC)$$

**Scheme 1** Reagents and conditions: 1 mmol **1** was treated with 2 mmol dimethylcyanamide in benzonitrile at 75 °C for 1.5 h. Work-up by column chromatography at low temperature afforded **4** in good yield (67%, mp 90 °C).

 $\label{eq:fig. 1} \begin{array}{l} \textbf{Fig. 1} \ Molecular \ structure \ of \ complex \ \textbf{4} \ in \ the \ crystal. \ Radii \ are \ arbitrary. \\ \textbf{Selected bond lengths (Å) and angles (°): P-W 2.479(11), P-N(1) 1.705(3), P-N(2) 1.705(3), N(1)-C(7) 1.291(5), N(2)-C(8) 1.284(5), C(7)-C(8) 1.488(5); N(1)-P-N(2) 96.3(2), P-N(1)-C(7) 108.2(3), N(1)-C(7)-C(8) 114.0(3), N(2)-C(8)-C(7) 113.4(4), P-N(2)-C(8) 107.8(3). \end{array}$ 

NMR spectral data† in solution and was confirmed for the solid state by a X-ray crystal structure analysis.‡ In comparison to related 2H-1,2-azaphosphole tungsten complexes,⁴ the 2H-1,3,2-diazaphosphole tungsten complex 4 displays a low-field shifted resonance signal of the phosphorus nucleus at  $\delta$  149.8 (cf.  $\delta$  102–105⁴) and a markedly increased phosphorus tungsten coupling constant of 257.1 Hz (cf.  $^{1}J_{WP}$  236–238 Hz⁴). The phosphorus–carbon coupling constants of the quaternary ring carbon atoms are 2–10 Hz, which are characteristically small for both five-membered heterocycles.

Remarkable features of the molecular structure of **4** and 2*H*-1,2-azaphosphole complexes<sup>4</sup> are the planar five-membered ring system and the localised double bonds; the latter being in contrast to the situation of aromatic heterocycles like 2*H*-1,2,3-diazaphospholes<sup>5,6</sup> and 2*H*-1,2,3-triazoles.<sup>7</sup> The coordination sphere of phosphorus is distorted tetrahedral and the phosphorus–tungsten bond length is 2.479(11) Å.

We are currently investigating the synthetic potential of nitrilium phosphane ylide complexes in 1,3-dipolar cycloaddition reactions.
