

Total syntheses of (+)-castanospermine and (+)-6-epicastanospermine

Sung Ho Kang*† and Joon Seop Kim

Department of Chemistry, Korea Advanced Institute of Science and Technology, Taejeon 305-701, Korea

A divergent synthetic route to (+)-castanospermine **1** and (+)-6-epicastanospermine **2** has been developed *via* phenylselenoamidation of trichloroacetimidate derived from allylic alcohol **7**, and dihydroxylations of *trans*-olefins **14** and **18** to dispose the three contiguous asymmetric centers, one amino group and two hydroxy groups.

The naturally occurring hydroxylated indolizidine alkaloids such as (–)-swainsonine, (+)-castanospermine **1** and (+)-6-epicastanospermine **2** continue to enjoy considerable attention from synthetic and medicinal chemists due to their pronounced biological activities. Their inhibition of enzymatic glycosidic hydrolysis is closely related with the potential chemotherapeutic utility for the treatment of diabetes,¹ cancer,² viral diseases³ and AIDS.⁴ Their intriguing molecular structures and promising medicinal value led us to explore their efficient synthetic routes. Here we describe total syntheses⁵ of (+)-castanospermine **1** and (+)-6-epicastanospermine **2**, which have been isolated from *Castanospermum australe*⁶ and *Alexa leiopetalata*.⁷

Based on our retrosynthetic analysis toward **1** and **2**, a crucial synthetic step was a stereoselective dihydroxylation of *trans*-olefin **3** (Scheme 1). While the effect of the allylic amino group in **3** on the stereochemical outcome was in question,⁸ its allylic alkoxy group was properly disposed for the desired α -dihydroxylation according to Kishi's empirical rule.⁹ Another key step was to produce a *syn*-amino alcohol as a prospective precursor to **3** *via* intramolecular phenylselenoamidation of trichloroacetimidate derived from *cis*-olefinic allylic alcohol **4**.¹⁰

(*S*)-Butane-1,2,4-triol reacted with *p*-anisaldehyde in the presence of PPTS in benzene using a Dean–Stark trap to give a 7.5–8 : 1 mixture of 6- and 5-membered benzylidenes (Scheme 2). After Swern oxidation¹¹ of the inseparable mixture, the resulting aldehydes were olefinated with phosphonium salt **5** prepared from (*S*)-butane-1,2,4-triol¹² to afford a 19 : 1 mixture of *cis*-olefin **6**, $[\alpha]_{\text{D}}^{28} + 110.8$ (*c* 1.5, CHCl₃), and the corresponding *trans*-olefin in 69% combined overall yield, along with 7% of the isomeric olefins generated from the 5-membered benzylidenes. Hydrolysis of **6** with PPTS in MeOH at 0 °C removed its *p*-methoxybenzylidene group chemoselectively to provide diol **4**, $[\alpha]_{\text{D}}^{27} + 9.9$ (*c* 1.3, CHCl₃), in 86% yield. The primary hydroxy group of **4** was regioselectively silylated with TBDPSCl in the presence of imidazole at –60 °C to furnish silyl ether **7**, $[\alpha]_{\text{D}}^{22} - 2.6$ (*c* 2.2, CHCl₃), in 92% yield. For the unprecedented phenylselenoamidation, **7** was treated with

Scheme 1

Cl₃CCN in the presence of DBU in MeCN at 0 °C, and subsequently cyclized using phenylselenenyl chloride in the presence of methyl 2,2,2-trichloroacetimidate and Et₃N in MeCN at –20 °C to produce an inseparable 15 : 1 mixture of *trans*-oxazoline **8** and the isomeric *cis*-oxazoline in 63% combined yield. In this cyclization, the addition of methyl 2,2,2-trichloroacetimidate was essential to suppress the formation of the corresponding trichloroacetate from trichloroacetimidate. Subjection of the mixture to PPTS in aqueous MeOH induced partial hydrolysis of the oxazoline groups to give hydroxy trichloroacetamides, of which the desired *syn*-stereoisomer, $[\alpha]_{\text{D}}^{22} - 6.8$ (*c* 2.0, CHCl₃), was readily separated in 87% yield from the *anti*-stereoisomer. Oxidative elimination of the *syn*-stereoisomer with H₂O₂ in THF afforded *trans*-olefin **9**, $[\alpha]_{\text{D}}^{24} + 15.8$ (*c* 3.7, CHCl₃), in 84% yield contaminated with less than 3% of *cis*-isomer.

The next event was a stereoselective dihydroxylation of the introduced *trans*-olefinic double bond. In order to attain better stereoselectivity, **9** was variously functionalized by changing the protecting groups and the molecular structural shapes. It was found that the most promising outcomes could be obtained with benzyloxycarbonyl (*Z*)-protected pyrrolidine derivatives. Accordingly, **9** was desilylated in 92% yield and then the resultant alcohol **10**, $[\alpha]_{\text{D}}^{21} + 34.9$ (*c* 0.7, CHCl₃), was cyclized under Mitsunobu conditions¹³ using diisopropyl azodicarboxylate (DIAD) and PPh₃ in THF at 0 °C to provide pyrrolidine **11**, $[\alpha]_{\text{D}}^{24} + 58.6$ (*c* 1.0, CHCl₃), in 88% yield. Treatment of **11** with BnONa in THF resulted in the formation of *Z*-protected pyrrolidine **12**, $[\alpha]_{\text{D}}^{26} + 54.9$ (*c* 1.1, CHCl₃), in 90% yield. After removal of the acetonide group under acidic conditions, the obtained triol **13**, $[\alpha]_{\text{D}}^{25} + 17.0$ (*c* 3.0, MeOH), was regioselectively sulfonated with 2,4,6-triisopropylbenzenesulfonyl chloride (TIPBSCl) in pyridine to furnish monosulfonate **14**, $[\alpha]_{\text{D}}^{25} + 18.9$ (*c* 1.2, CHCl₃), in 83% overall yield based on 15% of the recovered **13**. Dihydroxylation of **14** with a catalytic amount of OsO₄ in the presence of NMO in aqueous acetone¹⁴ at 0 °C produced the requisite tetraol **15**, $[\alpha]_{\text{D}}^{23} + 9.2$ (*c* 1.1, CHCl₃), in 88% yield along with less than 8% of **17**, which was undoubtedly formed by the spontaneous intramolecular etherification of the isomeric tetraol **16**. Subjection of **15** to hydrogenolysis followed by *in situ* cyclization in the presence of Et₃N gave (+)-6-epicastanospermine **2**, $[\alpha]_{\text{D}}^{23} + 2.8$ (*c* 0.6, MeOH), in 66% yield.¹⁵

For the synthesis of (+)-castanospermine, **12** was converted into silyl ether **18**, $[\alpha]_{\text{D}}^{25} - 12.6$ (*c* 1.7, CHCl₃), in 88% overall yield by protection of the secondary hydroxy group with MeOCH₂Cl (MOMCl), hydrolysis of the acetonide group and monosilylation of the primary hydroxy group with TBDPSCl in sequence (Scheme 3). Osmylation of **18** gave triol **19**, $[\alpha]_{\text{D}}^{24} - 4.9$ (*c* 0.7, CHCl₃), in 91% yield along with 6% of the isomeric β -dihydroxylated triol. When **19** was exposed to acetone in the presence of TsOH, the desired dioxolane **20**, $[\alpha]_{\text{D}}^{23} - 7.1$ (*c* 1.5, CHCl₃), was prepared in 92% yield by ketalization of the two *syn*-hydroxy groups, accompanied by 2% of the regioisomeric dioxolane. In order to secure the correct stereochemistry at 6-position of (+)-castanospermine, the remaining hydroxy group of **20** was inverted by mesylation followed by desilylation to afford epoxide **21**, $[\alpha]_{\text{D}}^{21} - 19.7$ (*c* 1.2, CHCl₃), in 87% overall yield. Removal of the *Z* group in **21**

Scheme 2 Reagents and conditions: i, *p*-anisaldehyde, PPTS, PhH, Dean-Stark trap; ii, (COCl)₂, DMSO, Et₃N, then **5**, BuⁿLi, HMPA, THF, -78 to 0 °C; iii, PPTS, MeOH, 0 °C; iv, TBDPSCl, imidazole, DMF, CH₂Cl₂, -60 °C; v, Cl₃CCN, DBU, MeCN, 0 °C, then PhSeCl, MeOC(=NH)CCl₃, Et₃N, MeCN, -20 to -15 °C; vi, PPTS, H₂O, MeOH, 20 °C; vii, 30% H₂O₂, THF, 0 to 20 °C; viii, Bu₄NF, THF, -5 to 0 °C, then aq. NaH₂PO₄; ix, DIAD, Ph₃P, THF, 0 °C; x, NaOBn, THF, 20 °C; xi, TsOH, MeOH, 20 °C; xii, TIPBSCl, pyridine, 20 °C; xiii, OsO₄, NMO, acetone, 0 °C; xiv, H₂, 10% Pd/C, MeOH, 20 °C, then Et₃N, reflux

was anticipated to induce 6-*endo* cyclization rather than 5-*exo* cyclization due to the *anti* arrangement of the dioxolane ring. Indeed heating **21** under catalytic transfer hydrogenation conditions¹⁶ provided only indolizidine **22**, [α]_D²² +39.5 (*c* 0.8, CHCl₃), in 76% yield. Finally methanolysis of **22** with methanolic HCl furnished (+)-castanospermine **1**, mp 205–207 °C (decomp.), [α]_D²² +79.7 (*c* 1.0, MeOH), in 96% yield.¹⁵

In summary, we have accomplished total syntheses of (+)-castanospermine **1** and (+)-6-epicastanospermine **2**, which culminated in the stereoselective phenylselenoamidation of trichloroacetimidate (from **7**) and the asymmetric dihydroxylation of **14** and **18** to establish the four contiguous chiral centers.

This work was supported by the Korea Advanced Institute of Science and Technology and the Organic Chemistry Research Center sponsored by the Korea Science and Engineering Foundation. Dedicated to Professor Yoshito Kishi on the occasion of his 60th birthday.

Scheme 3 Reagents and conditions: i, MOMCl, Et₃N, CH₂Cl₂, reflux; ii, TsOH, MeOH, 20 °C; iii, TBDPSCl, imidazole, DMF, CH₂Cl₂, -60 °C; iv, OsO₄, NMO, H₂O, acetone, 0 °C; v, TsOH, acetone, 20 °C; vi, MsCl, DMAP, Et₃N, CH₂Cl₂, 20 °C; vii, Bu₄NF, THF, 20 °C, then 5 M NaOH; viii, 5% Pd/C, cyclohexene, EtOH, reflux; ix, conc. HCl, MeOH, reflux, then Dowex 50WX8-100 ion-exchange resin
