Received (in Liverpool, UK) 28th October 1999, Accepted 21st December 1999

S₂O₄-Crown annelated derivatives of 9,10-bis(1,3-dithiol-2-ylidene)-9,10-dihydroanthracene function as efficient ligands in the voltammetric and spectroscopic recognition of Na⁺ and Ag⁺.

Redox-active ligand systems are important in the field of electrochemically-controlled uptake and release of guest metal cations.¹ For large shifts of the redox potential to be observed upon metal binding the antennae [e.g. crown ether unit(s)] should be situated close to the redox-responsive centre (*i.e.* the transducer), thereby enhancing the intramolecular electrostatic (through-space) effect which modulates the redox signal. Typical molecular² redox species for this purpose are ferrocene,³ metal coordinated dithiolate⁴ and diimine,⁵ and tetra-thiafulvalene (TTF) derivatives,⁶ *e.g.* **1**^{6a,b} and **2**.^{6d} For these systems cation binding induces a positive shift of the one-electron oxidation potential E_1^{ox} .

Derivatives of 9,10-bis(1,3-dithiol-2-ylidene)-9,10-dihydroanthracene are versatile building blocks in supramolecular and materials chemistry.⁷ The special feature of this system is a *two-electron* oxidation wave [neutral \rightarrow dication, E_1^{ox} *ca.* +0.35 V \ddagger (in MeCN, *vs.* Ag/AgCl) which is electrochemically quasi-reversible and chemically reversible].⁸ Herein we report the first crown-annelated derivatives **5** and **8**.

Reaction of anthraquinone **3** with the new reagent **4**⁹ under standard conditions^{8,10} gave a mixture of the bis- and mono-crown annelated derivatives **5** and **6**, respectively (Scheme 1). \S

Scheme 1 i, **4**, LDA, THF, -78°C , 3 h, then addition of **3**, then -78 to 20°C .

\ddagger Present address: Medicinal Chemistry Research, Novo Nordisk A/S, Novo Nordisk Park, 2760 Møløv, Denmark.

Scheme 2 i, **4**, LDA, THF, -78°C , 3 h, then addition of **7**, then -78 to 20°C .

The latter was characterised by X-ray diffraction. \P Reaction of **4** with **7**^{8a} gave the bis(1,3-dithiole) system **8** (Scheme 2).

An X-ray crystallographic study \P of **8**·CH₂Cl₂ showed a motif of saddle-shaped molecules (Fig. 1) engulfing each other's dimethyldithiole ends. The anthracenediylidene moiety is folded along the C(9)···C(10) vector, the two benzene rings forming a dihedral angle of 39° (*cf.* 21° in **6**). The dithiole rings are folded along the S(1)···S(2) and S(3)···S(4) vectors by 15.5 and 8.7° , and the S(1)C(16)C(17)S(2) and S(3)C(19)C(20)S(4) planes form an acute dihedral angle of 81° .

The cation binding properties of **5** were assessed by ¹H NMR titration studies in CDCl₃ at 50°C (at 20°C a precipitate formed on addition of metal salts). In the presence of Na⁺ and Ag⁺ the resonances due to the $-\text{SCH}_2\text{CH}_2\text{O}-$ protons of the crown [(SCH₂) δ 3.05; (OCH₂) δ 3.66] shifted downfield by *ca.* 0.07 ppm in the presence of 10 equiv. of Na⁺ and Ag⁺, while the anthracenediylidene resonances were unaffected, confirming that cation binding occurs at the crown site. Li⁺ and K⁺ cations had essentially no effect on the ¹H NMR spectrum. UV–VIS absorption spectra for **5** in MeCN in the presence of both Na⁺ and Ag⁺ (as the perchlorate salts) resulted in a specific change in the spectra. No isosbestic points were observed, indicating that, most probably, both 1:1 and 1:2 complexes [*i.e.* 5M^+ and $5(\text{M}^+)_2$] form simultaneously, and the absorption spectra of these species are different. Such behaviour is known for other bis(crown) chromoionophores.¹¹ Fig. 2 shows the changes in the spectrum of **5** upon complexation with Ag⁺. The stability constants for the formation of 5M^+ and $5(\text{M}^+)_2$ were estimated to be $\log K_1$ *ca.* 3.4 and $\log K_2$ *ca.* 5.5, respectively.

Cyclic voltammetry (CV) and square wave voltammetry (SQV) showed that **5** and **8** display a two-electron oxidation

Fig. 1 Molecular structure of **8**·CH₂Cl₂ (50% displacement ellipsoids).

Fig. 2 Absorption spectra of **5** (2×10^{-5} M) in MeCN (1 cm cell) containing AgClO_4 at concentrations of (a) 0, (b) 0.5, (c) 8.0 and (d) 30 mM. Inset: absorption at 445 nm as a function of Ag salt concentration fitted with eqn. (1), where A_0 , A_1 and A are the absorbances of the free ligand L and

$$A = A_0 + \frac{K_1 M_0 (A_1 - A_0)}{1 + K_1 M_0 + K_2 M_0^2} + \frac{K_2 M_0^2 (A_2 - A_0)}{1 + K_1 M_0 + K_2 M_0^2} \quad (1)$$

complexes LM^+ and $\text{L}(\text{M}^+)_2$, respectively; K_1 and K_2 are equilibrium constants for complex formation.

wave: $E_{1^{\text{ox}}} + 0.405$ V (**5**) and $E_{1^{\text{ox}}} + 0.345$ V (**8**). A second reversible one-electron wave, ascribed to oxidation of the anthracene system^{8b,c} (i.e. radical trication formation) was seen at $E_{2^{\text{ox}}} 1.62$ V for both compounds [CV data were recorded vs. Ag/AgCl , $\text{Bu}_4\text{N}^+\text{ClO}_4^-$ (0.1 M), MeCN, 20 °C, 100 mV s^{-1}]. The progressive addition of aliquots of metal triflate salts resulted in a positive shift of $E_{1^{\text{ox}}}$ (and a similar positive shift of the coupled reductive peak on the cathodic scan), while $E_{2^{\text{ox}}}$ remained unchanged, thereby acting as an internal reference. This is consistent with expulsion of the metal cation from the ionophore prior to the second oxidation wave. The maximum positive shifts ($\Delta E_{1^{\text{ox}}}$) are as follows: Li^+ (15–20 mV), Na^+ (100 mV), K^+ (15–20 mV) and Ag^+ (115 mV). The values of $\Delta E_{1^{\text{ox}}}$ are essentially the same for the mono- and bis-crown systems **8** and **5**, respectively, whereas in the TTF series, e.g. **1**, a larger shift is observed for bis-crowns. This is likely to be a consequence of intramolecular steric interactions between the crown rings of **5**, and/or sandwich complexation between two crowns, favoured by the rigid saddle conformation. A comparison with related S_2O_4 -crowned TTF systems⁶ shows two important advantages of systems **5** and **8**: (i) the positive shifts for Na^+ and Ag^+ are significantly larger, and (ii) the system is significantly more sensitive, with saturation being achieved with < 10 equiv. of cation (Fig. 3) (cf. 200 equiv. for **16a**).

Fig. 3 Shift of $E_{1^{\text{ox}}}$ in the CV of **5** with added equivalents of AgOTf (▲) and KOTf (●). Data were obtained in 0.2 M Bu_4NBF_4 , MeCN, Pt disk electrode, 50 mV s^{-1} , Ag/AgCl reference electrode, referenced vs. decamethylferrocene.

We suggest that these results are a consequence of the unique combination of structural and redox properties of the 9,10-bis(1,3-dithiol-2-ylidene)-9,10-dihydroanthracene transducer unit: (i) the saddle-shape folding of the anthracenediylidene system places the crown ring(s) of **5** and **8** in close proximity to the redox-responsive moiety, and there is a marked conformational change upon oxidation,^{7a} and (ii) the $E_{1^{\text{ox}}}$ redox process which is monitored is a two-electron oxidation (cf. the one-electron wave of TTF, ferrocene etc.) thereby enhancing the electrostatic repulsion by the bound metal cation(s) leading to an increase in $\Delta E_{1^{\text{ox}}}$.

In summary, using ligands **5** and **8** we have exploited for the first time the chromophoric and redox properties of the

9,10-bis(1,3-dithiol-2-ylidene)-9,10-dihydroanthracene system to provide efficient and controllable cation recognition within appended crown ether units. To enhance further these effects we suggest that redox species which undergo a multi-electron wave (e.g. certain dendrimers)¹² should be targets for future transducers in redox-controlled molecular recognition.

We acknowledge funding for this work from EPSRC, Office of Naval Research, Grant #: N00014-94-1-0592 (S. A. A.) and DOE Grant #: DE-FG07-98ER62708 (S. A. A.), and thank Dr A. J. Moore for helpful discussions.
