Received (in Cambridge, UK) 23rd December 2002, Accepted 14th February 2003
First published as an Advance Article on the web 11th March 2003

In the solid state, $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}\right]$ forms a three-dimensional network with each $\mathrm{Cu}^{\mathrm{I}}$ ion being surrounded by three other $\mathrm{Cu}^{\mathrm{I}}$ centres in a trigonal-planar fashion $[\mathrm{Cu} \cdots \mathrm{Cu}=2.979$ (1) $\AA$; cubic space group $\left.I 2_{1} 3\right]$, whereas in $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{2}\right] \mathrm{Br}$ the cations establish infinite linear $(\mathbf{C u} \cdots \mathrm{Cu})_{\infty}$ chains spanning the crystal lattice $[\mathrm{Cu} \cdots \mathrm{Cu}=2.931(1) \mathrm{A}$; monoclinic space group $C 2 / c]$.

Two-coordinate linear complexes $\left[\mathrm{AuL}_{2}\right]$ of $\operatorname{gold}(\mathrm{I})$ tend to aggregate in the solid state in such a manner that the $\mathrm{Au}-\mathrm{Au}$ contacts approximate to those distances found in the bulk metal. ${ }^{1,2}$ The term "aurophilicity" has been coined for this phenomenon, which is to be attributed to relativistic effects and hybridisation of 5 d and 6 s orbitals on the gold centres. ${ }^{3}$ The question whether similar bonding interactions exist for the lighter elements (e.g. copper) is still heavily under debate. The problem is aggravated by the fact that most of the few structurally characterized copper complexes ${ }^{3-7}$ featuring short $\mathrm{Cu}^{\mathrm{I}}-\mathrm{Cu}^{1}$ contacts either possess bridging ligands (e.g. tris[1,5ditolylpentaazadienidocopper(I)] ${ }^{8}$ ) or are made up between monomeric units of different charge (e.g. $\left[\mathrm{CuL}_{2}\right]^{+}\left[\mathrm{CuL}^{\prime}{ }_{2}\right]^{-9,10}$ ). In many of these cases, aggregation may thus be merely ligandenforced ${ }^{11}$ or due to ion pairing, and it is difficult to decide whether weak $\mathrm{d}^{10}-\mathrm{d}^{10}$ closed shell interactions do play a significant additional role. However, two examples of compounds have been published recently providing evidence for attractive $\mathrm{Cu}^{\mathrm{L}}-\mathrm{Cu}^{\mathrm{I}}$ interactions between uncharged trinuclear complexes ${ }^{12}$ and even between negatively charged cuprate molecules ${ }^{13}$ in the absence of any bridging ligation. Similar conclusions can be drawn from theoretical studies on model dimers of the type $\left[\mathrm{H}_{3} \mathrm{CCuX}\right]_{2}\left(\mathrm{X}=e . g . \mathrm{NH}_{3}, \mathrm{CO}, \mathrm{CNLi}\right)^{14}$ and $\left[\mathrm{H}_{3} \mathrm{NCuCl}\right]_{2} .{ }^{15}$ We present in this paper the X-ray crystal structure determinations of the textbook compounds $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}\right] 1$ and $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{2}\right] \mathrm{Br} 2$ as a contribution to the current discussion (Scheme 1).

Single crystals of $\mathbf{1}$ and $\mathbf{2}$ have been grown from the reaction mixtures of the appropriate copper(II) halide with two equivs. of lithium bis(trimethylsilyl)amide and 1,4-naphthohydroquinone (Scheme 1 ) $\dagger$ As byproducts, 1,4-naphthoquinone and 1,4-bis(trimethylsiloxy)naphthalene could be isolated and identified using IR and NMR spectroscopy. It may thus be concluded that 1,4-naphthohydroquinone not only acts as a proton source, but is also involved in the reduction of the $\mathrm{Cu}($ (I) $)$ centres. The reaction of copper(II) chloride with lithium bis(trimethylsilyl)-

\end{aligned}
$$

Scheme 1 Synthesis of 1 and 2
amide in the absence of 1,4-naphthohydroquinone is known to give the copper(I) amide $\left[\mathrm{CuN}\left(\mathrm{SiMe}_{3}\right)_{2}\right] \cdot{ }^{16} \mathrm{It}$ is thus uncertain whether 1,4-naphthohydroquinone is the only reducing agent in our case. However, we found no evidence for the formation of hydrazine derivatives or other products likely to be generated via amine radical species.
The crystals of $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}\right] \mathbf{1}$ are chiral (cubic space group $I 2_{1} 3$ ) with the three heavy atoms lying on a crystallographic three-fold axis (Fig. 1) $\ddagger$ The copper-nitrogen and copperchlorine bond lengths possess values of 1.894(3) $\AA$ and 2.105 (1) $\AA$, respectively. Each copper atom is surrounded by three other [ $\left.\mathrm{Cu}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}\right]$ moieties which leads to a trigonal-bipyramidal coordination sphere (Fig. 1). Given the high symmetry of the crystal lattice, all three $\mathrm{Cu} \cdots \mathrm{Cu}$ distances are necessarily equal $[\mathrm{Cu} \cdots \mathrm{Cu}$ contacts between next neighbours $=2.979(1) \AA$; copper metal: $2.56 \AA^{4}$ ]. All in all, an infinite three-dimensional network of $\mathrm{Cu}^{1}$ ions featuring comparatively short $\mathrm{Cu} \cdots \mathrm{Cu}$ contacts is established in the solid state. In each trigonalbipyramidal fragment three $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}\right]$ molecules are grouped around the central unit in a propeller-like arrangement with their chloride ligands placed on the same side of the $\mathrm{Cu}_{4}$ plane as the central ammine group [Cl-Cu $\cdots \mathrm{Cu} \mathrm{\# 1}=87.5(1)^{\circ}$; $\left.\mathrm{Cl}-\mathrm{Cu} \cdots \mathrm{Cu} \mathrm{\# 1-Cl} \mathrm{\# 1}=109.4(1)^{\circ}\right]$. The three equatorial $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}\right]$ units are linked via $\mathrm{N}-\mathrm{H} \cdots \mathrm{Cl}$ hydrogen bonds [ $\mathrm{N}-$ $\left.\mathrm{H}=0.89(4) \AA, \mathrm{H} \cdots \mathrm{Cl}=2.66(4) \AA ; \mathrm{N}-\mathrm{H} \cdots \mathrm{Cl}=167(3)^{\circ}\right]$.
$\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{2}\right] \mathrm{Br} 2$ crystallizes in the monoclinic space group $C 2 / c$ (Fig. 2) $\ddagger$ The $\mathrm{Cu}-\mathrm{N}$ bond lengths of 1.898(3) $\AA$ in the linear cation $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}$are identical to those found in the corresponding monoammine complex $\mathbf{1}[\mathrm{Cu}-\mathrm{N}=1.894(3) \AA$ A .

Fig. 1 Crystal structure of compound 1; thermal ellipsoids shown at the 50\% probability level. Selected bond lengths [ $\AA$ ], atom-atom distances [ $\AA \AA$ ], angles [ ${ }^{\circ}$ ] and torsion angles [ ${ }^{\circ}$ ]: $\mathrm{Cu}-\mathrm{N}=1.894(3), \mathrm{Cu}-\mathrm{Cl}=2.105(1)$, $\mathrm{Cu} \cdots \mathrm{Cu} \mathrm{\# 1}=2.979(1) ; \mathrm{N}-\mathrm{Cu}-\mathrm{Cl}=180.0, \mathrm{~N}-\mathrm{Cu} \cdots \mathrm{Cu} 1=92.6(1), \mathrm{Cl}-$ $\mathrm{Cu} \cdots \mathrm{Cu} \mathrm{\# 1}=87.5(1), \mathrm{Cu} \mathrm{\# 1} \cdots \mathrm{Cu} \cdots \mathrm{Cu} \mathrm{\#} 2=119.8(1), \mathrm{N}-\mathrm{Cu} \cdots \mathrm{Cu} \mathrm{\# 1}-\mathrm{N} \# 1$ $=109.4(1), \mathrm{Cl}-\mathrm{Cu} \cdots \mathrm{Cu} \# 1-\mathrm{Cl} \# 1=109.4(1), \mathrm{N}-\mathrm{Cu} \cdots \mathrm{Cu} \mathrm{\# 1}-\mathrm{Cl} \# 1=$ $-70.6(1), \quad \mathrm{Cu} \# 2 \cdots \mathrm{Cu} \cdots \mathrm{Cu} \mathrm{\# 1} \cdots \mathrm{Cu} \mathrm{\# 4}=109.4(1), \quad \mathrm{Cu} \# 3 \cdots \mathrm{Cu}-$ $\cdots \mathrm{Cu} \mathrm{\# 1} 1 \cdots \mathrm{Cu} \mathrm{\# 4}=-61.8(1), \mathrm{Cu} \mathrm{\#} 2 \cdots \mathrm{Cu} \cdots \mathrm{Cu} \mathrm{\# 1} \cdots \mathrm{Cu} \mathrm{\# 5}=-79.4(1)$; Hydrogen bonds: $\mathrm{N}-\mathrm{H}=0.89(4), \mathrm{H} \cdots \mathrm{Cl}=2.66(4) ; \mathrm{N}-\mathrm{H} \cdots \mathrm{Cl}=167(3)$. Symmetry transformations used to generate equivalent atoms: $x,-y,-z-$ $1 / 2 ;-x,-y-1 / 2, z ;-x-1 / 2, y,-z$.

In contrast to $\mathbf{1}$, which establishes a $\mathrm{Cu}-\mathrm{Cl}$ bond, the bromide counterion of 2 does not coordinate to the copper centre [shortest distance $\mathrm{Cu} \cdots \mathrm{Br}=3.446(1) \AA$ ]. Similar to 1 , comparatively short $\mathrm{Cu} \cdots \mathrm{Cu}$ contacts are also observed between the cationic $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}$fragments of $2[\mathrm{Cu} \cdots \mathrm{Cu}=$ 2.931(1) $\AA$ ], even though this arrangement suffers from electrostatic repulsion (note: for the ligand-unsupported anionic dimer $[t \mathrm{BuCuCN}]_{2}{ }^{2-}$, a $\mathrm{Cu} \cdots \mathrm{Cu}$ distance of 2.713(1) $\AA$ has been reported. ${ }^{13}$ The fact that this value is $0.218 \AA$ smaller than the one observed in $\mathbf{2}$ indicates a rather shallow potential energy surface related to the $\mathrm{Cu} \cdots \mathrm{Cu}$ stretching mode). Each $\mathrm{Cu}^{\mathrm{I}}$ ion of $\mathbf{2}$ is surrounded by two nitrogen atoms and two other $\mathrm{Cu}^{1}$ centres in a planar fashion. This coordination sphere results in infinite linear $(\mathrm{Cu} \cdots \mathrm{Cu})_{\infty}$ chains spanning the crystal lattice. Adjacent $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}$moieties adopt a staggered rather than an eclipsed conformation relative to each other [torsion angle N $\left.\mathrm{Cu} \cdots \mathrm{Cu} \# 1-\mathrm{N} \# 1=68.2(4)^{\circ}\right]$. Each bromide ion is connected to six different ammonia molecules via hydrogen bonds. While the crystal structure of $\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right] \mathrm{Br}$ is yet unknown, the corresponding gold complex has been investigated by X-ray diffraction. ${ }^{17}$ Here, the asymmetric unit contains two crystallographically independent $C_{s}$-symmetric $\left[\mathrm{Au}\left(\mathrm{NH}_{3}\right)_{2}\right] \mathrm{Br}$ molecules forming a dimer consisting of mutually orthogonal linear $\left[\mathrm{Au}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}$cations $[\mathrm{Au} \cdots \mathrm{Au}=3.414(1) \AA]$. DFT calculations will soon be published to provide information on the nature of the $\mathrm{Cu} \cdots \mathrm{Cu}$ interactions in $\mathbf{1}$ and 2 in the solid state.
M.W. is grateful to the "Deutsche Forschungsgemeinschaft" (DFG) for financial support. G.M. wishes to thank the "Fonds der Chemischen Industrie" (FCI) and the "Bundesministerium für Bildung und Forschung" (BMBF) for a Ph. D. grant.

## Notes and references

$\dagger$ Synthesis of $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}\right]$ 1: A solution of $\mathrm{LiN}\left(\mathrm{SiMe}_{3}\right)_{2}(0.33 \mathrm{~g}, 2.00$ $\mathrm{mmol})$ in THF ( 2 mL ) was added dropwise with stirring at $-78{ }^{\circ} \mathrm{C}$ to a slurry of $\mathrm{CuCl}_{2}(0.13 \mathrm{~g}, 1.00 \mathrm{mmol})$ in THF $(10 \mathrm{~mL})$, whereupon a deep blue solution formed. After the solution had been stirred at $-78{ }^{\circ} \mathrm{C}$ for 1 h , 1,4-naphthohydroquinone ( $0.32 \mathrm{~g}, 2.00 \mathrm{mmol}$ ) in THF $(15 \mathrm{~mL})$ was added slowly. The resulting mixture was allowed to warm to ambient temperature and stored for 1 d to give colourless blocks of 1 . Yield: $0.04 \mathrm{~g}(35 \%)$. Synthesis of $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{2}\right] \mathrm{Br} \mathbf{2}$ : $\mathbf{2}$ was synthesized similar to $\mathbf{1}$ from $\mathrm{CuBr}_{2}$ $(0.22 \mathrm{~g}, 1.00 \mathrm{mmol}), \mathrm{LiN}\left(\mathrm{SiMe}_{3}\right)_{2}(0.33 \mathrm{~g}, 2.00 \mathrm{mmol})$ and 1,4-naphthohydroquinone ( $0.32 \mathrm{~g}, 2.00 \mathrm{mmol}$ ) in THF. The product crystallized as colourless needles. The reaction was repeated ten times with yields ranging between $25-45 \%$.
$\ddagger$ Crystal data of $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}\right]$ 1: $\mathrm{H}_{3} \mathrm{ClCuN}, M=116.02 \mathrm{~g} \mathrm{~mol}^{-1}$, cubic, $a=b=c=8.4135(8) \AA, V=595.57(10) \AA^{3}, T=146(2) \mathrm{K}$, space group $I 2_{1} 3, Z=8, \mu\left(\mathrm{Mo}-\mathrm{K}_{\alpha}\right)=7.898 \mathrm{~mm}^{-1}, 6829$ reflections measured, 505 unique ( $R_{\mathrm{int}}=0.072$ ) which were used in all calculations. The final $w R\left(F^{2}\right)$ was 0.042 (all data), min./max. residual electron density $-0.36 / 0.46$ e $\AA^{-3}$. The H atom position was taken from a difference Fourier synthesis. It was refined with an individual isotropic displacement parameter. The direction of the chiral axis was determined by the value of the Flack $x$ parameter: $x=$ -0.03 (2). 11 Stalke et al. mentioned that in some cases two $\mathrm{Cu}^{\mathrm{I}}$ centres tend to approach each other even against the sterical strain of chelating ligands and that metallophilicity should thus neither be expected nor ruled out merely on the basis of ligand features. The geometry of the $\mathrm{L}-\mathrm{Cu}-\mathrm{L}$ moiety orthogonal to the $\mathrm{Cu} \cdots \mathrm{Cu}$ interaction (i.e. the deviation from linearity) is also a very important feature (cf.
