DOI: 10.1039/b602222g

Incorporation of diplatinum complex $\text{Pt}_2(\mu\text{-dppm})_2(\text{bpyC}\equiv\text{C})_4$ or $\text{Pt}_2(\mu\text{-dppm})_2(\text{phenC}\equiv\text{C})_4$ with $\text{Ln}(\text{hfac})_3(\text{H}_2\text{O})_2$ ($\text{Ln} = \text{Nd}, \text{Eu}, \text{Yb}$) gave a series of Pt_2Ln_2 and Pt_2Ln_4 bimetallic arrays, in which the excitation of $d(\text{Pt}) \rightarrow \pi^*(\text{R}-\text{C}\equiv\text{C})$ MLCT absorption induces sensitization of lanthanide luminescence through efficient $d \rightarrow f$ energy transfer from Pt^{II} alkynyl chromophores.

Because of the weak absorption of forbidden $f-f$ transitions, luminescence from lanthanides is usually sensitized by the excitation of strongly absorbing organic antenna chromophores.¹ More recently, attention has been focused on the use of d -block metal chromophores as sensitizers for near-infrared (NIR) emission from lanthanides.^{2,3} In order for the d -block chromophores to be connected to the lanthanide luminophores, the design of bifunctional bridging ligands with suitable bonding sites for d -block and f -block metals is critical to achieve NIR emitting sensitization from lanthanides through $d \rightarrow f$ energy transfer.^{2–12} The bridging ligands exploited to date include cyanide,^{3e,3f,7} oxalate,¹² tetrazine,^{3a–3d} and functionalized oligopyridine^{2,4–6,9–11} or porphyrin⁸ etc.

As bifunctional bridging ligands, acetylide-functionalized di-imines have been used widely in the design of multi-component transition metal complexes composed of discrete redox and/or photoactive sub-units.^{13,14} It is anticipated that they are ideal bridging ligands for the design of $d-f$ bimetallic arrays by introducing d -block chromophores and f -block luminophores bound to acetylide and bipyridine/phenanthroline, respectively. Furthermore, such heterometallic arrays would allow $d \rightarrow f$ energy transfer to occur from transition metal alkynyl chromophores to f -block luminophores, thus emitting NIR lanthanide luminescence by excitation of the charge-transfer absorption in the organometallic energy donors.

As shown in Scheme 1, reaction of ligand L_1 ¹⁵ with $\text{PtCl}_2(\text{dppm})$ in the presence of KF and CuI led to binuclear Pt^{II} alkynyl complex **1** being prepared *via* fluoride-catalyzed desilylation. Addition of excess $\text{Ln}(\text{hfac})_3(\text{H}_2\text{O})_2$ into CH_2Cl_2 solutions of **1**, following crystallization by layering with *n*-hexane, gave Pt_2Ln_2 complexes as yellow crystals. Formation of the Pt_2Ln_2 arrays instead of the desired Pt_2Ln_4 complexes is probably induced by steric effects as well as hydrogen bonding interactions between the

Scheme 1 Synthetic routes to the $\text{Pt}^{\text{II}}_2\text{Ln}^{\text{III}}_2$ and $\text{Pt}^{\text{II}}_2\text{Ln}^{\text{III}}_4$ complexes.

free bipyridyl N atom and the coordinated H_2O (*vide infra*). Compared to 2,2'-bipyridine, 1,10-phenanthroline is more rigid and has a stronger affinity for Ln^{III} ions. The 1,10-phenanthroline-containing ligand L_2 ¹⁵ was utilized to prepare binuclear Pt^{II} alkynyl complex **5**. Incorporating **5** with $\text{Ln}(\text{hfac})_3(\text{H}_2\text{O})_2$ indeed afforded the desired Pt_2Ln_4 complexes. The compounds were all characterized by microanalysis and spectroscopic measurements (ESI†). The structures of **2**, **3** and **7** were determined by X-ray crystallography.†

The Pt_2Ln_2 array is composed of $\text{Pt}_2(\mu\text{-dppm})_2(\text{bpyC}\equiv\text{C})_4$ units, incorporating $\text{Ln}(\text{hfac})_3$ components through 2,2'-bipyridyl chelating, which are stabilized by strong intramolecular hydrogen bonding interactions (Fig. 1a) between the coordinated H_2O and the free bipyridyl N atom, $\text{O}7 \cdots \text{N}3\text{A}$ being *ca.* 2.70 Å. The diplatinum unit $\text{Pt}_2(\mu\text{-dppm})_2(\text{bpyC}\equiv\text{C})_4$ displays a face-to-face conformation.^{16,17} The *trans*-oriented array $\text{C}\equiv\text{C}-\text{Pt}-\text{C}\equiv\text{C}$ deviates obviously from linearity, with the angles $\text{C}\equiv\text{C}-\text{Pt}$ and $\text{C}-\text{Pt}-\text{C}$ being 167.9(8)–172.3(6)° and *ca.* 167.7(2)°, respectively. The $\text{Pt}-\text{Pt}$ distances are *ca.* 3.25 Å, implying the presence of metal–metal contacts.^{16,17} The dihedral angles between the bonding and free bipyridyl are 65.3° for **2** and 67.4° for **3**. The Ln^{III} center is nine-coordinated with N_2O_7 donors to form a distorted capped square antiprism. The Pt^{II} center exhibits a square-planar geometry built from *trans*-oriented N_2P_2 donors. The intramolecular $\text{Pt} \cdots \text{Ln}$ separation through bridging L_1 is *ca.* 8.8 Å.

Pt_2Eu_4 compound **7** (Fig. 1b) is formed from the linkage of four $\text{Eu}(\text{hfac})_3$ with $\text{Pt}_2(\mu\text{-dppm})_2(\text{phenC}\equiv\text{C})_4$ through **1**,

10-phenanthroline chelation. The *trans*-situated array C≡C–Pt–C≡C is a little more linear than in the Pt₂Ln₂ complexes **2** and **3** with 2,2'-bipyridyl-5-acetylide. The Pt^{II} center exhibits an approximately square-planar geometry with *trans*-oriented C₂P₂ donors, whereas the Eu^{III} center is eight-coordinated with the N₂O₆ chromophore to form a distorted square-antiprism. The dihedral angle between the 1,10-phenanthrolines bound to Eu1 and Eu2 is 38.9°. The Pt–Pt distance (3.298(8) Å) is a little longer than those (3.246–3.251 Å) in Pt₂Ln₂ complexes **2** and **3**. The intramolecular Pt⋯Eu separation through bridging L₂ is *ca.* 10.2 Å.

The UV-vis spectra of diplatinum compounds **1** and **5** in CH₂Cl₂ display a dppm-centered absorption band at *ca.* 230–270 nm together with two low energy bands at 348 and 392 nm for **1**, and at 345 and 378 nm for **5**, most likely originating from metal-perturbed π → π*(C≡C) and d(Pt) → π*(R–C≡C) metal-to-ligand charge transfer (MLCT) transitions,¹⁷ respectively. Upon formation of the Pt₂Ln₂ or Pt₂Ln₄ assemblies, the two low energy bands show *ca.* 10–20 nm bathochromic shifts relative to those of the Pt₂ precursor compounds **1** or **5**. By addition of portions of Eu(hfac)₃(H₂O)₂ to a CH₂Cl₂ solution of **1**, the MLCT bands show a red shift from 348 and 392 nm to 366 and 405 nm, which is responsible for the color deepening during the reaction. The dependence of the absorbance at a selected wavelength on the amount of Eu(hfac)₃(H₂O)₂ added reveals a 1 : 2 ratio between the Pt₂ and Eu(hfac)₃ components in the produced Pt₂Eu₂ array. The calculated association constant for the binding of the Ln^{III} fragment to the bipyridyl sites is *ca.* 3 × 10⁷ for Pt₂Eu₂ complex **3**. Similarly, titration of a CH₂Cl₂ solution of **5** by addition of an increasing amount of Nd(hfac)₃(H₂O)₂ reveals a 1 : 4 ratio between the Pt₂ and Nd(hfac)₃ units in the produced Pt₂Nd₄ complex.

With excitation wavelength λ_{ex} > 340 nm, both solid and solution (CH₂Cl₂) samples of diplatinum compounds **1** and **5** luminesce in the range 530–650 nm⁻¹ at 298 K. With reference to the emission studies of [Pt₂(μ-dppm)₂(C≡CR)₄] (R = alkyl or aryl),¹⁷ their origin is ascribed tentatively to a d(Pt₂) → π*(R–C≡C) ³MMLCT (metal–metal-to-ligand charge transfer) transition in view of their microsecond range lifetimes at 298 K and their short intramolecular Pt–Pt contacts in the solid state. Additionally, CH₂Cl₂ solutions of **1** and **5** afford intense ligand-centered emission at 375–450 nm due to the intraligand transitions of L₁ or L₂.

Upon irradiation of the MLCT absorption of the diplatinum alkynyl moiety at λ_{ex} = 350–450 nm, all of the Pt₂Ln₂ and Pt₂Ln₄ complexes exhibit characteristic emissions for these lanthanide ions with lifetimes in the microsecond range in both the solid state and in CH₂Cl₂ solution at 298 K (Table 1). By contrast, MMLCT and ligand-centered emissions from diplatinum alkynyl chromophores disappeared entirely for all of the Pt–Ln complexes in both the solid state and in CH₂Cl₂ solution, indicating that the Pt-based luminescence is completely quenched because of a quite efficient and fast energy transfer occurring from the d-block chromophores to the f-block luminophores. As anticipated, three emission bands were observed for Pt^{II}–Nd^{III} complexes at *ca.* 865, 1060 and 1330 nm (⁴F_{3/2} → ⁴I_{9/2}, ⁴I_{11/2}, ⁴I_{13/2}), four for Pt^{II}–Eu^{III} complexes at *ca.* 595, 615, 650 and 695 nm (⁵D₀ → ⁷F₁, ⁷F₂, ⁷F₃, ⁷F₄), and one for Pt^{II}–Yb^{III} complexes at *ca.* 980 nm (²F_{5/2} → ²F_{7/2}) (Fig. 2). It has been suggested that the efficiency of d → f energy transfer is principally determined by the conjugacy of the bridging ligand and the distance between transition metal chromophores and lanthanide luminophores.^{1,3,5} Because of the short Pt–Ln distances (<10.5 Å) as well as favourable conjugacy in the bridging ligands L₁ or L₂, both Dexter and Förster energy transfer mechanisms are likely to be operative in the Pt–Ln bimetallic complexes.

In summary, an unprecedented synthetic route has been established to prepare a series of Pt^{II}–Ln^{III} bimetallic arrays using acetylide-functionalized bipyridines/phenanthrolines as bridging ligands. Sensitisation of lanthanide luminescence by the d(Pt₂) → π*(R–C≡C) ³MMLCT excited state is achieved through efficient d → f energy transfer from the Pt^{II} alkynyl antenna chromophore to the f-block energy acceptor. This synthetic strategy opens up a

5	566 (0.27)	535 (<0.1)	
6	1060 (0.49)	1060 (weak)	1.96
7	615 (25.2)	615 (33.6)	5.0
8	980 (12.7)	980 (12.9)	6.35

^a The excitation wavelength in the lifetime measurements is 397 nm.

^b The quantum yields of Nd^{III} and Yb^{III} complexes in the solid state are estimated by the equation Φ = τ_{obs}/τ₀, in which τ_{obs} is the observed emission lifetime and τ₀ is the radiative or 'natural' lifetime with τ₀ = 0.25 ms for Nd^{III} and 2 ms for Yb^{III}. ^c The quantum yields of Eu^{III} complexes in de-gassed CH₂Cl₂ are determined relative to that of Eu(terpy)₃(ClO₄)₃ (Φ = 0.013)¹⁸ in de-gassed CH₃CN.
