New 1,10-phenanthroline ligands have been synthesized with C<sub>6</sub>F<sub>5</sub>- or 2,4,6-(CF<sub>3</sub>)<sub>3</sub>C<sub>6</sub>H<sub>2</sub>- groups in the 2- and 9-positions; a cationic copper(I) complex of the latter catalyses nitrene transfer to the C–H bonds of electron-rich arenes.

The efficient and selective functionalisation of carbon–hydrogen bonds represents an ongoing challenge in inorganic and organic chemistry.<sup>1</sup> We are interested in low-coordinate late transition metal complexes as catalysts for atom- and group-transfer reactions of this type. Ligands such as 2,9-diphenyl-1,10-phenanthroline,<sup>2</sup> and its 2,9-dimesityl analogue,<sup>3</sup> project considerable steric bulk about the metal, but expose C–H bonds to the metal center. We report herein the synthesis of two new 1,10-phenanthroline ligands, substituted in the 2- and 9-positions with heavily fluorinated aryl groups<sup>4</sup> to avoid oxidative ligand modification.<sup>5</sup> Copper(I) complexes of both phenanthrolines have been prepared and structurally characterized; the more sterically demanding ligand gives rise to a reactive precatalyst for the transfer of a nitrene group from iminodianes to the C–H bonds of electron-rich arenes.<sup>6</sup>

The new phenanthrolines were prepared by cross-coupling reactions, using Pd(OAc)<sub>2</sub> precatalyst and the 2-(dicyclohexylphosphino)biphenyl ligand developed by Buchwald and coworkers<sup>7</sup> (Scheme 1). The reaction of 2,9-dichloro-1,10-phenanthroline<sup>8</sup> with C<sub>6</sub>F<sub>5</sub>ZnBr<sup>9</sup> affords 2,9-bis(pentafluorophenyl)-1,10-phenanthroline (**1**) in good yield. The Negishi coupling has been used previously to prepare a variety of 2,9-diaryl-1,10-phenanthrolines.<sup>10</sup> The reaction of 2,9-diiodo-1,10-phenanthroline<sup>11</sup> with 2,4,6-(CF<sub>3</sub>)<sub>3</sub>C<sub>6</sub>H<sub>2</sub>Cu,<sup>12</sup> prepared *in situ* by lithiation of 2,4,6-(CF<sub>3</sub>)<sub>3</sub>C<sub>6</sub>H<sub>3</sub> followed by addition of CuI, affords 2,9-bis-[2',4',6'-tris(trifluoromethyl)phenyl]-1,10-phenanthroline (**2**).

Reaction of **1** with CuI in CH<sub>2</sub>Cl<sub>2</sub> at ambient temperature (Scheme 2) results in the formation of a homoleptic complex [(1)<sub>2</sub>Cu]<sup>+</sup>, crystallised as its SbF<sub>6</sub><sup>−</sup> salt **3**.† The X-ray crystal structure of **3** (Fig. 1)‡ shows bond lengths and bite angles similar to those in copper(I) complexes of 2,9-diphenyl-1,10-phenanthroline;<sup>2</sup> however, one phenanthroline is canted, permitting a π-stacking interaction with a pentafluorophenyl group; the distance between rings is 3.343(5) Å.

Ligand **2** presents considerably greater steric demand than **1**, and reacts with CuI in CH<sub>2</sub>Cl<sub>2</sub> to afford trigonal 2-CuI. The iodide ligand is readily abstracted by AgSbF<sub>6</sub>, and the product after drying

is the solvent-free [2-Cu]<sup>+</sup> SbF<sub>6</sub><sup>−</sup> (**4**), characterised by NMR and elemental analysis.§ This complex has resisted efforts at crystallisation; however, exposure of a concentrated CH<sub>2</sub>Cl<sub>2</sub> solution of **4** to a small concentration of benzene vapor results in crystallisation of the η<sup>2</sup>-benzene adduct **4'** (Fig. 2).‡ Like other copper(I)–benzene adducts,<sup>13</sup> **4'** shows no substantial lengthening of the coordinated C–C bond.

Solutions of complex **4**, on addition of the reagent (*p*-toluenesulfonylimino)phenyliodane (PhINTs),<sup>14</sup> form a reactive green intermediate, with liberation of free iodobenzene. We have as yet been unable to preclude extensive decomposition during the isolation of this intermediate, possibly a cationic (sulfonylimido)-copper(III) complex. Instead, we have investigated its activity in the transfer of tosyl nitrene to arene C–H bonds.

The reaction of PhINTs with anisole<sup>15</sup> (17 equiv) in PhCF<sub>3</sub> solution, catalysed by **4** (0.5 mol%), resulted in the rapid

Scheme 2 Synthesis of copper(I) complexes **3** and **4**.

dissolution of the iminoiodinane, with the formation of *o*- and *p*-sulfonamidation products, TsNH<sub>2</sub>, and poorly soluble oligomers that were removed during NMR and GC-MS sample preparation. The substrate 1,3-dimethoxybenzene was chosen next, to sidestep temporarily the issue of *o/p* selectivity, and to examine whether the desired reaction would occur more readily with this doubly activated nucleus, minimizing the subsequent side-reactions (Scheme 3).<sup>¶</sup> Indeed, the reaction of PhINTs with this substrate (20 equiv in PhCF<sub>3</sub> at ambient temperature), catalysed by **4** (1.8 mol%) led to the formation of *p*-tosyl-1,3-dimethoxyaniline in an isolated yield of 63% based on iminoiodinane.

A change in stoichiometry resulted in a notably different outcome. With arene as the limiting reagent, the major product was the *N,N*-diarylsulfonamide. Only a trace of monoarylsulfonamide was observed; the other products appear to be sulfonated oligo-arylamines. This seemingly paradoxical result suggests that the initially formed *N*-arylsulfonamide can be activated under the reaction conditions to generate a nitrogen-based electrophile.

In conclusion, we have prepared new 1,10-phenanthroline ligands substituted with heavily fluorinated aryl rings to confer steric bulk while resisting oxidation. With the C<sub>6</sub>F<sub>5</sub>-substituent, the ligand is small enough to form a homoleptic copper(I) complex, whereas the larger 2,4,6-(CF<sub>3</sub>)<sub>3</sub>C<sub>6</sub>H<sub>2</sub>-substituted ligand supports the formation of a reactive copper(I) cation. This complex catalyses nitrene transfer to the C–H bonds of an electron-rich arene, leading to either of two major products depending on the reaction stoichiometry. Near-future goals include the elucidation of relevant reaction mechanisms, and the development of more versatile arene functionalization reactions.

We thank Mr Gergely Sirokman for improvements to the initial preparation of **1**, and Prof. Daniel G. Nocera for helpful discussions. CWH gratefully acknowledges a Lester Wolfe predoctoral fellowship. We thank the MIT Department of Chemistry for startup funding, and the NSF (Awards CHE-9808061 and DBI-9729592) for support of our NMR facilities.

**Fig. 2** Representation of **4**, shown as 50% ellipsoids. For clarity, the SbF<sub>6</sub><sup>−</sup> ion, solvent, and hydrogen atoms have been omitted, and only one molecule in the asymmetric unit is shown. A more extensive structure, showing  $\pi$ -stacking interactions among the cations, is available in the ESI.<sup>†</sup> Selected interatomic distances (Å) and bond angles (°): Cu(1)–N(1) 2.108(4), Cu(1)–N(2) 2.026(4), Cu(1)–C(31) 2.232(5), Cu(1)–C(32) 2.113(5), C(31)–C(32) 1.397(9); N(1)–Cu(1)–N(2) 82.71(15), N(1)–Cu(1)–C(31) 127.1(2), N(1)–Cu(1)–C(32) 117.2(2).

<sup>§</sup> *Synthesis and characterization data for 4*: Reactions were carried out at ambient temperature, in dried solvents under inert atmosphere. CuI (1.05 mmol) and **2** (0.696 mmol) were stirred overnight in CH<sub>2</sub>Cl<sub>2</sub> (7 mL). Filtration of the mixture and concentration *in vacuo* afforded 2-CuI as a red powder in 80% yield. The reaction of 2-CuI (0.210 mmol) with AgSbF<sub>6</sub> (0.216 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (5 mL) for 5 min, followed by filtration and concentration *in vacuo*, afforded **4** as a yellow powder in 87% yield. <sup>1</sup>H NMR (300 MHz, acetone-*d*<sub>6</sub>):  $\delta$  9.20 (d, *J* = 8.4 Hz, 2H), 8.63 (s, 4H), 8.57 (s, 2H), 8.50 (d, *J* = 8.4 Hz, 2H). <sup>19</sup>F NMR (282 MHz, acetone-*d*<sub>6</sub>):  $\delta$  −57.14 (s, 12 F), −62.90 (s, 6F). Anal. calcd for C<sub>30</sub>H<sub>10</sub>N<sub>2</sub>F<sub>24</sub>CuSb: C, 34.66; H, 0.97; N, 2.69. Found: C, 34.46; H, 1.00; N, 2.65%.

<sup>¶</sup> *General procedure for sulfonamidations*: Reactions were carried out at ambient temperature, in dried solvent under inert atmosphere. PhINTs and activated 3 Å molecular sieves were suspended, and catalytic amounts of **4** dissolved, in PhCF<sub>3</sub>. 1,3-Dimethoxybenzene was added *via* syringe. Upon completion of the reactions, the mixtures were concentrated *in vacuo* and the organic products isolated by column chromatography on silica gel.
