Hydrogen peroxide in high yields can be generated with high efficiency at mild conditions (25 °C and atmospheric pressure) with the formation of only environment-friendly by-products (N<sub>2</sub> and H<sub>2</sub>O) by a reduction of O<sub>2</sub> by hydrazine from its hydrate/salt with its complete conversion in a short reaction period ( $\leq 0.5$  h) using an easily separable supported Pd catalyst (Pd/Al<sub>2</sub>O<sub>3</sub>, Pd/Ga<sub>2</sub>O<sub>3</sub> or Pd/C) in an acidic aqueous medium in the presence of bromide anions; the presence of both acid (protons) and bromide anions is essential for the selective reduction of O<sub>2</sub> by hydrazine to H<sub>2</sub>O<sub>2</sub> and in their absence, the reaction leads only to the formation of water.

Hydrogen peroxide is an environmentally clean oxidizing agent; the by-product of its use is only water (which is environmentally benign). Because of the increasing environmental concerns, the use of H<sub>2</sub>O<sub>2</sub> in a number of organic oxidation processes (*e.g.* epoxidation of olefins, hydroxylation of aromatics/olefins, oxidation of benzylic –CH<sub>2</sub>OH to –CHO or –COOH, *etc.*) for the synthesis of fine/speciality chemicals is widely increasing.<sup>1–3</sup> At present, H<sub>2</sub>O<sub>2</sub> is produced commercially mainly by the autoxidation of hydroanthraquinone in a complex organic solvent, involving cyclic oxidation–hydrogenation steps.<sup>4</sup> This process however, is cost effective only on a large scale (>20 000 tpa). The transport, storage and handling of bulk H<sub>2</sub>O<sub>2</sub> are also quite hazardous. Hence, the use of *in-situ* generated H<sub>2</sub>O<sub>2</sub> for organic oxidation reactions is not only of scientific interest but also of great practical importance. A few studies have been reported on the use of *in-situ* generated H<sub>2</sub>O<sub>2</sub> in liquid-phase organic oxidation reactions.<sup>3,5–7</sup>

The conventional method for *in-situ* H<sub>2</sub>O<sub>2</sub> generation is based on the autoxidation of hydroanthraquinones by O<sub>2</sub> (hydroanthraquinone + O<sub>2</sub> → H<sub>2</sub>O<sub>2</sub> + anthraquinone).<sup>3</sup> However, the use of the autoxidation is limited because of the complex organic solvent system used to keep both the hydroquinone and quinone in their dissolved form. Moreover, the separation of the solvent, quinone and hydroquinone from the products of organic oxidation reaction is problematic. Direct oxidation of H<sub>2</sub> by O<sub>2</sub> using Pd catalyst is highly hazardous<sup>8</sup> and hence its use for the *in-situ* H<sub>2</sub>O<sub>2</sub> generation for organic oxidation reactions is dangerous. Sheriff and coworkers<sup>9,10</sup> used Mn(II)/4,5-dihydroxybenzene-1,3-disulfonate as a homogeneous catalyst<sup>9</sup> and Mn(II)-exchanged montmorillonite clay as a heterogeneous catalyst<sup>10</sup> for the reduction of dioxygen by hydroxylamine to H<sub>2</sub>O<sub>2</sub> with high turnover numbers (>10<sup>4</sup>). Recently, they have reported the use of Mn(III) and Mn(IV) complexes as homogeneous catalysts for the O<sub>2</sub>-to-H<sub>2</sub>O<sub>2</sub>

reduction by hydroxylamine, using acetonitrile–water mixture as the reaction medium.<sup>11</sup> Because of separation problem, the use of homogeneous catalyst and/or organic solvent in the reaction is problematic. It is, therefore, of both scientific and practical interest to develop a new route for the *in-situ* H<sub>2</sub>O<sub>2</sub> generation, which requires no organic solvent, produces only environment-friendly and easily separable by-product(s) and provides H<sub>2</sub>O<sub>2</sub> with high yield under mild conditions, preferably using an easily separable heterogeneous catalyst. We have accomplished this difficult task. We report here our new route for the *in-situ* H<sub>2</sub>O<sub>2</sub> generation from the selective reduction of O<sub>2</sub> by hydrazine (N<sub>2</sub>H<sub>4</sub>) from its hydrate/salt in an acidic aqueous medium, using Pd/C or Pd/Al<sub>2</sub>O<sub>3</sub> (or Ga<sub>2</sub>O<sub>3</sub>) catalyst, in the presence of Br<sup>–</sup> in the medium or in the catalyst. The presence of both the mineral acid (protons) and Br<sup>–</sup> is a requirement for the selective oxidation of hydrazine to H<sub>2</sub>O<sub>2</sub>. In this method, the by-products formed are only N<sub>2</sub> and water, which are environmentally benign and pose no problem for their separation. Also, a complete conversion of hydrazine with high H<sub>2</sub>O<sub>2</sub> yield can be accomplished in a short reaction period ( $\leq 30$  min) at room temperature (25 °C) and atmospheric pressure.

Results (Tables 1–4) clearly show the formation of H<sub>2</sub>O<sub>2</sub> with high rate in the reduction of O<sub>2</sub> by hydrazine from its sulfate or hydrate (N<sub>2</sub>H<sub>4</sub> + 2 O<sub>2</sub> → 2 H<sub>2</sub>O<sub>2</sub> + N<sub>2</sub>) over the supported Pd catalysts<sup>12</sup> in an aqueous acidic medium in the presence of bromide anions in the medium or in the catalyst at 25 °C and atmospheric pressure. However, since the H<sub>2</sub>O<sub>2</sub> formed per mole of N<sub>2</sub>H<sub>4</sub> converted is less than 2.0, the non-selective conversion of N<sub>2</sub>H<sub>4</sub> to water (N<sub>2</sub>H<sub>4</sub> + O<sub>2</sub> → 2 H<sub>2</sub>O + N<sub>2</sub>) also occurs simultaneously, depending upon the reaction conditions. The procedure for carrying out the oxidation reaction is given elsewhere.<sup>13</sup> No decomposition of N<sub>2</sub>H<sub>4</sub> to N<sub>2</sub> and H<sub>2</sub> over the catalysts was observed at the reaction conditions employed for the reaction.

**Table 1** H<sub>2</sub>O<sub>2</sub> formed in the reduction of O<sub>2</sub> by hydrazine sulfate (at 25 °C) over Pd/Al<sub>2</sub>O<sub>3</sub> in water as the reaction medium in the presence or absence of halide (reaction period = 0.5 h)

<sup>a</sup> mol/mol of N<sub>2</sub>H<sub>4</sub> converted. <sup>b</sup> Conversion of N<sub>2</sub>H<sub>4</sub> was 10%. <sup>c</sup> Conversion of N<sub>2</sub>H<sub>4</sub> was 12%; in all the other cases it was 100%.

Results (Table 1) reveal that in the absence of any halide or in the presence of KF or KCl in the medium, the hydrazine from the hydrazine sulfate is completely converted to water (N<sub>2</sub>H<sub>4</sub> + O<sub>2</sub> → 2 H<sub>2</sub>O + N<sub>2</sub>), without formation of any H<sub>2</sub>O<sub>2</sub>. The addition of KI to the medium also leads to similar results except that the hydrazine conversion is drastically reduced from 100 to 10% due to poisoning of the catalyst. However, in the presence of KBr in the medium at the same (0.94 mmol dm<sup>-3</sup>) or at higher concentration,

the H<sub>2</sub>O<sub>2</sub> formed per mol of hydrazine was drastically increased from zero to 1.17 and 1.22, respectively, and also the hydrazine conversion was 100%. Influence of cations (H<sup>+</sup>, Na<sup>+</sup>, K<sup>+</sup> or NH<sub>4</sub><sup>+</sup>) on the reaction as compared to that of the halide anions was found to be negligibly small.

The results, when the halogens (F, Cl, Br or I) are incorporated in the Pd/Al<sub>2</sub>O<sub>3</sub> and Pd/Ga<sub>2</sub>O<sub>3</sub> catalysts (Table 2), are quite similar to those observed for the halides in the reaction medium (Table 1). The results for the Pd/Al<sub>2</sub>O<sub>3</sub> catalyst (Table 2) show that the addition of acid (H<sub>3</sub>PO<sub>4</sub>) in the medium causes an appreciable increase in the H<sub>2</sub>O<sub>2</sub> yield (from 61.5 to 68.0%). It may be noted that the reaction medium containing the hydrazine salts is acidic (pH < 2) because of the release of associated acid molecules (H<sub>2</sub>SO<sub>4</sub> or HCl) from the hydrazine salts after their dissolution in water.

When hydrazine hydrate was used instead of the hydrazine salts, in the absence of acid in the medium no H<sub>2</sub>O<sub>2</sub> formation in the hydrazine oxidation is observed even though in the presence of bromide anions. In the absence of either bromide anions or mineral acid or both, the oxidation of hydrazine hydrate leads only to the formation of N<sub>2</sub> and water (Tables 3 and 4). With increasing the acid/hydrazine mole ratio, the H<sub>2</sub>O<sub>2</sub> yield (or H<sub>2</sub>O<sub>2</sub> formed per mol of hydrazine consumed) is increased appreciably. Among the mineral acids, the most preferable for the selective reduction of O<sub>2</sub> to H<sub>2</sub>O<sub>2</sub> is sulfuric acid.

**Table 4** H<sub>2</sub>O<sub>2</sub> formed in the reduction of O<sub>2</sub> by hydrazine monohydrate over halogenated Pd/Al<sub>2</sub>O<sub>3</sub> (halogen loading = 1.0 wt%) in aqueous reaction medium in the presence or absence of mineral acid (at 25 °C) (reaction period = 0.5 h)

<sup>a</sup> Reaction period = 1.0 h. <sup>b</sup> mol/mol of N<sub>2</sub>H<sub>4</sub> converted.

From the above results, it can be concluded that the reduction of O<sub>2</sub> by hydrazine (from hydrazine salt or hydrate) leads to H<sub>2</sub>O<sub>2</sub> formation with high yields only in the presence of Br<sup>-</sup> anions and protons (mineral acid). In their absence or in the presence of other halides and acid, only water (without even traces of H<sub>2</sub>O<sub>2</sub>) is formed in the reaction.

The hydrazine oxidation is not economically feasible for the large-scale production of H<sub>2</sub>O<sub>2</sub> as a commodity chemical. However, although hydrazine is toxic and carcinogenic, since the reaction is fast and completed in a short period (<30 min), even at room temperature and atmospheric pressure, leaving no traces of unconverted hydrazine, it has high potential for providing an efficient route for the *in-situ* generation of H<sub>2</sub>O<sub>2</sub>. It is environment-friendly, involving no objectionable by-products or organic solvent, unlike the hydroanthraquinone-to-H<sub>2</sub>O<sub>2</sub> oxidation.

- 12 The Pd (5%)/Al<sub>2</sub>O<sub>3</sub> and Pd (5%)/C catalysts in their reduced form were obtained from Lancaster (UK). The Ga<sub>2</sub>O<sub>3</sub> (Aldrich) supported Pd (2.5%) catalyst was prepared by impregnating the support with palladium acetate from its acetonitrile solution, drying and calcining at 500 °C for 3 h and then reducing by ammoniacal hydrazine. The halogenation of the Pd catalysts was done by impregnating the catalyst with ammonium halide from its aqueous solution, drying and calcining in a flow of oxygen-free N<sub>2</sub> at 400 °C for 1 h.
- 13 The catalytic reduction of O<sub>2</sub> by hydrazine to H<sub>2</sub>O<sub>2</sub> over the Pd catalysts was carried out in a magnetically stirred jacketed glass reactor (capacity: 100 cm<sup>3</sup>) by passing continuously pure O<sub>2</sub> (99.5%) through an aqueous reaction medium in the presence or absence of different halide anions and/or mineral acids at the following reaction conditions: volume of reaction medium = 50 cm<sup>3</sup>, amount of catalyst = 0.1 g, hydrazine salt or hydrazine hydrate = 2.3 mmol, O<sub>2</sub> flow rate = 10 cm<sup>3</sup> min<sup>-1</sup>, temperature = 25 °C and pressure = atmospheric (0.95 atm). The initial concentration of hydrazine or its salt and catalyst was 46 mmol dm<sup>-3</sup> and 2.0 g dm<sup>-3</sup>, respectively. The temperature of the reaction was controlled by passing continuously thermostated water maintained at desired temperature through the reactor jacket. The H<sub>2</sub>O<sub>2</sub> from the reaction mixture (after separating the catalyst from the reaction mixture by filtration) was determined by iodometric titration and also by decomposing the H<sub>2</sub>O<sub>2</sub> by MnO<sub>2</sub> and measuring the O<sub>2</sub> evolved quantitatively, according to the H<sub>2</sub>O<sub>2</sub> decomposition reaction (H<sub>2</sub>O<sub>2</sub> → H<sub>2</sub>O + 0.5 O<sub>2</sub>); both the methods gave the same results. The unconverted hydrazine (if any) was determined by its titration against potassium iodate in a mixture of aqueous acidic (HCl) and CHCl<sub>3</sub> medium. The reactor effluent gas was analysed by gas chromatography. Only N<sub>2</sub> and O<sub>2</sub> are found in the gaseous products, indicating the formation of N<sub>2</sub> as the only other main product in both the selective and non-selective oxidation of hydrazine.
