Novel Carboranyl C-Glycosides for the Treatment of Cancer by Boron Neutron Capture Therapy

Lutz F. Tietze,*^[a] Ulrich Griesbach,^[a] Ingrid Schuberth,^[a] Ulrich Bothe,^[a] Alberto Marra,^[b] and Alessandro Dondoni*^[b]

Abstract: The synthesis of the novel unprotected carboranyl C-glycosides 2 and 20-24 starting from ethynyl C-glycosides 1, 5-8, 10, and 13 is described. The new compounds are highly water-soluble and display only a very low cytotoxicity, which makes them promising candidates for use in boron neutron capture therapy for the treatment of cancer.

Keywords: alkynes \cdot antitumor agents \cdot boron neutron capture therapy \cdot carboranes \cdot drug research \cdot *C*-glycosides

Introduction

Boron neutron capture therapy (BNCT) is a binary system used for the treatment of cancer, which involves administration of a boron compound and subsequent irradiation with slow neutrons. It relies on the specific ability of the

isotope ¹⁰B to react with thermic neutrons to give an α particle and a ⁷Li³⁺ ion in a nuclear reaction. If boron is present in a tumor cell, irradiation with a beam of slow neutrons will cause destruction of the malign tissue.^[1] However, there are several problems associated with this approach, such as the need to introduce high levels of boron into the cancer cells. The stable *ortho*-carboranes^[2] are therefore used as the boron source, which allow the transport of ten boron atoms per molecule into the cancer cells. However, the poor solubility in water and distinct cytotoxicity of most of these compounds has limited their use in BNCT. In view of their excellent water solubilities, negligible toxicities, and high rates of uptake into cancer cells, we have focused our interest on carboranyl *O*glycosides such as maltoside **3** for use in BNCT.^[3] Mixed carboranediyl *O*-bisglycosides such as **4** show almost no

uptake into tumor cells due to their enhanced hydrophilicities. They may therefore be used for a selective delivery into malignant cells by employing glycohydrolases connected to monoclonal antibodies that bind to tumor-associated antigens. These glycohydrolases can transform the bisglycosides into lipophilic compounds.^[4]

нò

... B₁₀H₁₀

A possible disadvantage of *O*-glycosylated carboranes might be the enzymatic cleavage of such compounds by glycohydrolases. This problem would not arise with *C*glycosylated carboranes, although, to date, there has been only one example of a carborane unit connected to the anomeric carbon atom of a tetrahydropyran ring with the anomeric carbon atom still bearing a hydroxy group, as reported by Dahlhoff et al.^[5] Such *C*-linked compounds were obtained as anomeric mixtures by the addition of monolithio *meta*-carborane to trimethylsilyl-protected D-glucono-1,5-lactone or analogous 1,4-lactones.

Herein, we describe the stereoselective synthesis of novel *C*-glycosylated carboranes for use in BNCT by reaction of decaborane(14) with alkynyl *C*-glycosides, and their biological evaluation. We expected the biological and chemical properties of this new class of configurationally stable carboranyl *C*-glycosides to be as good as those of their *O*-glycosidic analogues. As already mentioned, the novel *C*-glycosides should not be affected by the action of any glycohydrolase.

Results and Discussion

The carboranyl-*C*-glycosides **2**, **20**–**24** were synthesized by a well-established procedure involving addition of the $B_{10}H_{12}$. 2 CH₃CN complex to the triple bond of the perbenzylated ethynyl *C*-glycosides **1**, **5**–**8**, **10**, and **13**, followed by hydrogenolytic cleavage of the benzyl protecting groups.

Synthesis of *C*-glycosyl acetylenes: The known perbenzylated ethynyl β -*C*-glycoside **1** was readily prepared^[6, 7] by a sequence of addition of cerium TMS-acetylide to the corresponding gluconolactone, deoxygenation with triethylsilane

and boron trifluoride etherate (Et₃SiH/BF₃ · Et₂O), and cleavage of the TMS group with sodium hydroxide.^[6, 7] The α linked derivatives 5-7 were also obtained as described previously,^[7] by C-glycosidation (ethynylation) of the corresponding sugar acetates using tributylstannyl(trimethylsilyl)ethyne (nBu₃SnC=CSiMe₃) in the presence of trimethylsilyl triflate (TMSOTf), followed by desilylation. The 1-propynyl C-glucoside 8 was synthesized in high yield (90%) in one step by methylation of the lithio derivative of **1** using methyl triflate as the alkylating agent.^[8] The stereointegrity of the β linkage at the pseudoanomeric center of 8, as in the precursor C-glycoside 1, was confirmed by 1 H NMR spectroscopy; the signal of the pseudoanomeric proton (4-H), observed at $\delta =$ 4.06 ppm, shows a coupling constant of $J_{4.5} = 9.5$ Hz, which is typical for a trans-diaxial arrangement. The bisglycosylated ethyne 10 was also prepared in good yield (52%) in a straightforward manner by addition of the lithio derivative of

Abstract in German: Die Synthese der neuartigen ungeschützten Carboranyl-C-Glycoside 2 und 20–24 ausgehend von Ethinyl-C-Glycosiden wie 1, 5–8, 10 und 13 wird beschrieben. Die neuen Verbindungen sind wasserlöslich und zeigen eine nur sehr geringe Cytotoxizität, was sie zu vielversprechenden Kandidaten für den Einsatz in der Bor-Neutroneneinfang-Tumortherapie macht.

Abstract in Italian: Viene descritta la sintesi di una nuova serie di carboranil C-glicosidi deprotetti 2 e 20-24 a partire dagli etinil C-glicosidi 1, 5-8, 10 e 13. I nuovi composti oltre ad essere molto solubili in acqua mostrano una bassa citossicità così che si presentano come promettenti candidati nella terapia del cancro basata sulla cattura di neutroni da parte del boro.

1 to the gluconolactone **9** and deoxygenation with Et₃SiH/ BF₃·Et₂O (Scheme 1). The β -linkage at the anomeric centers of the two glycoside residues was again confirmed by the vicinal coupling constant of the anomeric proton (9.2 Hz).

Scheme 1. Synthesis of 10. a) BuLi, THF, $-70\,^\circ\text{C}$, 1.5 h; b) Et_3SiH, BF_3 \cdot Et_2O, CH_3CN/CH_2Cl_2, $-10\,^\circ\text{C}$, 1 h.

The synthesis of the ethynyl *C*-gentiobioside **13** was more laborious because it involved the stereoselective formation of two *C*-glycosidic bonds, one in the assembly of the two sugar residues, and the other in installing the ethynyl group into the resulting *C*-disaccharide. The methyl *O*-glycoside **11** (Scheme 2) had already been prepared in one of our

Scheme 2. Synthesis of **13**. a) AcOH, H_2SO_4 , 100 °C, 75 min; PCC, CH₂Cl₂, RT, 1 h; c) TMS-ethyne, BuLi, CeCl₃, THF, -78 °C, 2 h; d) Et₃. SiH, BF₃ · Et₂O, CH₃CN/CH₂Cl₂, -10 °C, 1 h; e) aq. NaOH, CH₃OH/THF, RT, 1 h.

laboratories by Wittig coupling of a sugar aldehyde and a sugar phosphorane.^[9] Acid-catalyzed hydrolysis of the anomeric methoxy group in **11**, followed by oxidation of the corresponding hemiacetal with pyridinium chlorochromate (PCC) afforded the *C*-gentiobionolactone **12** in very good overall yield (82%). The ethynyl group was introduced by following the same reaction sequence as employed for the ethynylation of monosaccharides, that is addition of cerium TMS-acetylide, deoxygenation with Et₃SiH/BF₃ · Et₂O, and desilylation with NaOH. Compound **13** was obtained in 63% overall yield according to this three-step reaction sequence. The β -linkage at the anomeric center of **13** was confirmed by the vicinal coupling constant of J = 9.7 Hz for the signal at $\delta = 3.96$ ppm attributable to the pseudoanomeric proton (3-H).

Synthesis of carboranyl C-glycosides: To prepare the carboranyl C-glycosides, decaborane(14) $(B_{10}H_{14})$ was heated in acetonitrile under reflux for 1 h to give the $B_{10}H_{12} \cdot 2 CH_3 CN$ adduct,^[10] which was then treated with the ethynyl C-glycosides 1, 5–8, 10, and 13 in toluene to give the benzyl-protected carboranyl C-glycosides 14–19 in moderate to excellent

- 1297

yields depending on the substituents in the vicinity of the triple bond. Thus, starting from the β -ethynyl *C*-glucoside **1**, the yield of the corresponding carborane **14** was 92% (Scheme 3), whereas the *C*₂-symmetric carborane **19** was

Scheme 3. Synthesis of **2**. a) $B_{10}H_{14}$, CH₃CN, reflux 30–60 min; then **1** in toluene, reflux, 16–18 h, 92%; b) Pd(OH)₂/C, H₂ (2–3 bar), MeOH/ EtOAc, RT, 5–8 h, 81%.

obtained in only 13% yield from ethynyl bisglucoside **10** due to the steric demand of the two sugar moieties. Ethynyl *C*glycosides with terminal triple bonds such as **1**, **5**, **6**, and **13** gave consistently higher yields (64-92%) as compared to the acetylenes **8** and **10** with internal triple bonds (13-31%). Astoundingly, in the case of the acetyl amide **6**, protection of the acidic amide NH, as reported in our previous work,^[3e] was not necessary and the corresponding carborane **17** was obtained in 73% yield. In contrast, starting from azide **7**, no carborane was obtained, presumably due to the thermal instability of the azido group (Table 1).

Debenzylation was carried out by hydrogenation under elevated H₂ pressure (2-3 bar) in the presence of Pearlman's catalyst^[11] (Pd(OH)₂ on activated charcoal). The deprotected carboranyl *C*-glycosides **2**, **20–24** were obtained in good yields in every case (Table 1). The novel compounds **2**, **20–24** could not be purified by column chromatography due to partial degradation under the conditions employed. This decomposition also occurred on standing for several days in

Table 1. Structures and yields of the carboranyl *C*-glycosides and -bisglycosides. Reaction conditions for carborane formation and debenzylation were similar to those given in Scheme 3.

MeOH. Therefore, the crude products obtained by removal of the catalyst and evaporation of the solvents were merely washed with Et_2O to give satisfactory purities.

Structure determination of the carboranyl C-glycosides: The structures of the new compounds were determined by means of ¹H and ¹³C NMR spectroscopy (1 D and 2 D experiments) and mass spectrometry. As is typical for carboranes, a broad signal due to the ten protons attached to boron atoms is seen at $\delta = 0.5 - 4.0$ ppm in the ¹H NMR spectra. Furthermore, the IR spectra of the novel carboranes feature the typical strong B-H stretching signal at approximately 2590 cm^{-1} . The prepared boron compounds contain the natural isotopic distribution of boron. In the mass spectra of the new compounds, a broad assembly of peaks is therefore detected, together with the peak of highest intensity, which correlates to the most abundant ¹⁰B/¹¹B ratio. As proven by NMR experiments on the compounds obtained, upon addition of B₁₀H₁₄ to the triple bond of the ethynyl C-glycosides and subsequent deprotection, the configuration at the pseudoanomeric center is not affected. The β -linkage at the anomeric centers of the carboranyl C-glycosides 2, 14, 16, 18, 19, 21, 23, and 24 was also confirmed by the large values (9.0 - 10.0 Hz) of the vicinal coupling constant of the doublets attributable to the anomeric protons, as is typical for a trans-diaxial arrangement. In contrast, the α -linkage at the pseudoanometric centers of compounds 15, 17, 20, and 22 was indicated by the low J values (1.0-2.0 Hz) observed for the signals of the anomeric protons due to an equatorial-axial arrangement. The C-H of the carborane moiety of C-glycosides with monosubstituted carboranes gives rise to a characteristic broad singlet at around $\delta = 4.0$ in the ¹H NMR spectra. In the case of the C_2 symmetric bisglucosides 10, 19, and 24, with an internal triple bond or carborane moiety, two equivalent carbons give rise to just one signal in the ¹³C NMR spectra.

In vitro cytotoxicity tests: The cytotoxicities of the novel carboranyl *C*-glycosides **2** and **20**–**23** were determined using the MTT test.^[12] This test is based on the irreversible reduction of the yellow tetrazolium salt 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) into a dark blue, water-insoluble but alcohol-soluble formazane derivative by mitochondrial dehydrogenases of viable cells. MTT is taken up by viable cells and then reduced. The concentration of the resulting blue formazane derivative is measured with a photometer after cell lysis. The optical density of the blue formazane derivative is proportional to the fraction of the living, metabolically active cells.^[12]

In vitro studies with the new compounds were carried out on four different cell lines: on human bronchial carcinoma cells of line A 549,^[13] on murine melanoma cells of line B-16, on human pancreas carcinoma cells of line PancTu 1,^[14] and on colonrectal human adeno carcinoma cells of line LoVo.^[15]

The results of these in vitro studies are presented in Table 2 and Figure 1. The β - and α -carboranyl *C*-glucosides **2** and **20**, with ED₅₀ values in the range 227-482 μ M (*ED*₅₀ = drug concentration required for 50% effect on target cells), show only a low cytotoxicity. The ED₅₀ values for the methylcarborane **21** and acetamide **22** are slightly lower, falling in the

range >124–293 μ M. With ED_{50} values greater than 1.1 mM with all four cell lines, carboranyl *C*-gentiobiose **23** displays the lowest cytotoxicity among the carboranes investigated. In comparison, hydroxymethylcarboranes such as **25**, which we have investigated in our previous work,^[3] have a significantly higher toxicity. For example, an ED₅₀ value of 78 μ M was measured in the case of **25**^[3c, 16] (Table 2, Figure 1).

In conclusion, we have prepared several novel *C*-glycosidic carboranes by way of a short and convenient synthesis from the corresponding alkynes. As shown by an MTT cytotoxicity assay, this new class of compounds displays lower cytotoxicities and an increased water solubility compared to simple carborane derivatives such as hydroxymethylcarborane **25**. The biological properties of the carboranyl *C*-glycosides make them promising candidates for use in boron neutron capture therapy for the treatment of cancer.

1296 - 1302

Experimental Section

Synthesis of the C-glycosides: general: All moisture-sensitive reactions were performed under a nitrogen or argon atmosphere using oven-dried glassware. Anhydrous solvents were dried over standard drying agents^[17] and were freshly distilled prior to use. Commercially available powdered 4 Å molecular sieves (average particle size 5 mm) was used without further activation. Reactions were monitored by TLC on silica gel 60F254 with detection using sulfuric acid alone or in conjunction with vanillin. Flash column chromatography^[18] was performed on silica gel 60 (230-400 mesh). The sugar lactone 9^[19] was prepared by oxidation of the corresponding hemiacetal with pyridinium chlorochromate.[20]

Melting points were determined with a capillary apparatus and are uncorrected. Optical rotations were measured at $20 \pm 2^{\circ}$ C in the stated solvent; $[\alpha]_{D}^{20}$ values are given in 10⁻¹ deg cm²g⁻¹. IR spectra were recorded on a Bruker Vector 22 spectrometer. ¹H and ¹³C NMR spectra were recorded on Varian XL-200, Unity 300, Inova 500, Unity Inova 600, and Bruker AMX 300 spectrometers, at room temperature unless otherwise specified; chemical shifts are quoted in ppm (δ) from SiMe4 (TMS) as an internal standard; assignments were aided by homo- and heteronuclear two-dimensional experiments. Signals marked with an asterisk (*) could not be assigned with certainty. In the ¹H NMR data listed below, the n and m values quoted for geminal or vicinal proton-proton coupling constants $J_{n,m}$

denote the number of corresponding sugar protons, where applicable. Mass spectra were measured on a Finnigan MAT 95 spectrometer. MALDI-TOF mass spectra were acquired using α -cyano-4-hydroxycinnamic acid as the matrix. Elemental analysis was carried out in the analytical laboratories of the universities of Göttingen and Ferrara.

4,8-Anhydro-5,6,7,9-tetra-O-benzyl-1,2,3-trideoxy-D-glycero-L-manno-

non-2-ynitol (8): A stirred solution of 1 (549 mg, 1.00 mmol) in anhydrous THF (10 mL) was cooled to $-50\,^\circ\text{C}$, whereupon butyllithium (1.25 mL, 2.00 mmol, 1.6 M solution in hexane) was added dropwise. Stirring was continued at -50 °C for 10 min, and then methyl trifluoromethanesulfonate (340 μ L, 3.00 mmol) was added. After an additional 30 min at -50 °C, the reaction mixture was diluted with 1M phosphate buffer at pH 7 (20 mL), allowed to warm to room temperature, and extracted with Et₂O (2 \times 100 mL). The combined organic phases were dried (Na₂SO₄) and concentrated. The residue was chromatographed on a column of silica gel eluting with cyclohexane/EtOAc (9:1) to give 8 (506 mg, 90%) as a syrup. $[\alpha]_{\rm D}^{20}$ $+1.5^{\circ}$ (*c* = 1.2, CHCl₃); ¹H NMR (300 MHz, C₆D₆): $\delta = 1.42$ (d, 3H; 1-H), 3.24 (ddd, 1H; 8-H), 3.64 (dd, $J_{8,9b} = 2.0$ Hz, 1H; 9b-H), 3.66 (dd, $J_{5,6} =$ 9.0 Hz, 1 H; 5-H), 3.68 (dd, $J_{8,9a} = 3.5$, $J_{9a,9b} = 10.8$ Hz, 1 H; 9a-H), 3.78 (dd, $J_{7,8} = 9.7, J_{6,7} = 8.9$ Hz, 1H; 7-H), 4.06 (dq, $J_{4,5} = 9.5, J_{1,4} = 2.0$ Hz, 1H; 4-H), 4.34 and 4.47 (2d, J = 12.0 Hz, 2H; PhCH₂), 4.60 and 4.86 (2d, J = 11.1 Hz, 2H; PhCH₂), 4.80 and 4.91 (2d, J = 11.5 Hz, 2H; PhCH₂), 4.82 and 5.05 (2d, $J = 11.0 \text{ Hz}, 2\text{ H}; \text{ PhCH}_2), 7.02 - 7.40 \text{ ppm} (m, 20\text{ H}; 4 \text{ Ph}); {}^{13}\text{C} \text{ NMR}$ $(75 \text{ MHz}, C_6 D_6)$: $\delta = 3.2 (C-1), 69.4 (C-9), 70.7 (C-4), 73.6, 74.9, 75.3, and$ 75.5 (4 PhCH₂), 78.2 (C-7), 79.4 (C-8), 77.8 and 82.0 (C-2, C-3), 83.2 (C-5), 86.4 (C-6), 127.6-128.4, 138.9, 139.2, 139.3, and 139.5 ppm (Ph); elemental

1,2-Bis(2',3',4',6'-tetra-O-benzyl-β-D-glucopyranosyl)ethyne (10): A stirred solution of 1 (200 mg, 0.36 mmol) in anhydrous THF (3.6 mL) was cooled to -70 °C, whereupon butyllithium (0.25 mL, 0.40 mmol, 1.6 M solution in hexane) was added dropwise. Stirring was continued at $-\,70\,^\circ\text{C}$ for 15 min, and then a solution of lactone 9 (194 mg, 0.36 mmol) in anhydrous THF (3.6 mL) was added. After a further 1.5 h at -70 °C, the reaction mixture was diluted with 1M phosphate buffer at pH 7 (20 mL), allowed to warm to room temperature, and extracted with CH_2Cl_2 (2 × 100 mL). The combined organic layers were dried (Na2SO4) and concentrated to afford the hemiacetal as a mixture of anomers. A stirred mixture of the crude hemiacetal, activated 4 Å powdered molecular sieves (0.36 g), and triethylsilane (240 mL, 1.49 mmol) in anhydrous CH₃CN (6.5 mL) and CH_2Cl_2 (2.5 mL) was cooled to $-10^{\circ}C$, and then freshly distilled $BF_3 \cdot Et_2O$ (180 μ L, 1.40 mmol) was added dropwise. Stirring was continued at -10° C for 1 h, and then the mixture was diluted with Et₃N (0.6 mL) and CH₂Cl₂ (50 mL), filtered through a pad of Celite, and concentrated. The residue was chromatographed on a column of silica gel eluting with cyclohexane/ EtOAc $(12{:}1\,{\rightarrow}\,5{:}1)$ to give 10 (200 mg, 52 %) as a white solid; m.p. 89– 90°C (cyclohexane/pentane); $[\alpha]_{D}^{20} = -20.5^{\circ}$ (c = 1.3, CHCl₃); ¹H NMR $(300 \text{ MHz}, C_6D_6): \delta = 3.21 \text{ (ddd, 2H; 2 5'-H)}, 3.50 \text{ (dd, 2H; 2 3'-H)}, 3.60$ $(dd, J_{5',6'b} = 1.8 Hz, 2H; 26'b-H), 3.65 (dd, J_{6'a,6'b} = 11.2, J_{5',6'a} = 3.6 Hz, 2H; 2$ 6'a-H), 3.68 (dd, $J_{2',3'} = 9.1$ Hz, 2H; 22'-H), 3.74 (dd, $J_{4',5'} = 9.8$, $J_{3',4'} = 8.7$ Hz, 2H; 2 4'-H), 4.08 (d, $J_{1',2'}$ = 9.2 Hz, 2H; 2 1'-H), 4.30 and 4.42 (2d, J = 12.1 Hz, 4H; 2 PhCH₂), 4.56 and 4.82 (2d, J = 11.4 Hz, 4H; 2 PhCH₂), 4.78 and 4.90 (2 d, J = 11.5 Hz, 4H; 2 PhCH₂), 4.84 and 5.19 (2 d, J = 11.0 Hz, 4H; 2 PhCH₂), 7.03-7.32 and 7.47-7.53 ppm (2m, 40H; 8 Ph); ¹³C NMR (75 MHz, C_6D_6): $\delta = 69.3$ (2 C-6'), 70.4 (2 C-1'), 74.9, 75.4, and 77.9 (8 PhCH₂), 79.6 (2 C-5'), 82.5 (2 C-2'), 84.0 (C-1, C-2), 86.3 (2 C-3'), 127.7 -128.7, 138.8, 138.9, 139.2, and 139.5 ppm (Ph); MS (MALDI-TOF): m/z: 1095.6 [M+H+Na], 1111.8 [M+H+K]; elemental analysis (%) calcd for C₇₀H₇₀O₁₀ (1071.3): C 76.48, H 6.59; found: C 76.31, H 6.74.

8,12-Anhydro-2,3,4,9,10,11,13-hepta-O-benzyl-6,7-dideoxy-D-glycero-Dgulo-D-gluco-tridecopyranolactone (12): A stirred solution of 11 (450 mg, 0.46 mmol) in acetic acid (18 mL) was heated to 100° C and then 1M aqueous H₂SO₄ (1.8 mL) was added dropwise. The solution was stirred at 100 °C for a further 75 min, and then cooled to room temperature, diluted with CH₂Cl₂ (100 mL), and washed with saturated aqueous Na₂CO₃ solution (5 \times 20 mL). The organic phase was dried (Na₂SO₄) and concentrated. The residue was chromatographed on a column of silica gel eluting with cyclohexane/EtOAc $(8:1 \rightarrow 4:1)$ to give the disaccharidic hemiacetal as an approximately 1:1 mixture of anomers (370 mg). A mixture of this product, activated 4 Å powdered molecular sieves (0.38 g), and anhydrous CH₂Cl₂ (3.8 mL) was stirred at room temperature for 15 min, and then pyridinium chlorochromate (410 mg, 1.90 mmol) was added in one portion. The mixture was vigorously stirred at room temperature for 60 min until the starting material had been consumed (TLC analysis), and then diluted with cyclohexane (3.8 mL) and Et₂O (7.6 mL) to precipitate the chromium salts. Stirring was continued for a further 10 min, and then the brown suspension was filtered through a pad of silica gel $(5 \times 4 \text{ cm})$. Further elution with Et₂O/cyclohexane (2:1; ca. 100 mL) gave 12 as a white solid (363 mg, 82%); m.p. $117-119^{\circ}C$ (cyclohexane); $[\alpha]_{D}^{20} = +36.3^{\circ}$ (c = 0.9, CHCl₃); ¹H NMR (300 MHz, C₆D₆): $\delta = 1.52 - 1.62$ (m, 1H; 7b-H), 1.65 -1.75 (m, 1H; 6b-H), 2.12-2.23 (m, 2H; 6a-H, 7a-H), 3.20-3.27 (m, 2H), 3.38 (dd, $J_{4,5} = 8.4$ Hz, 1H; 4-H), 3.34–3.40 (m, 1H), 3.65–3.79 (m, 4H), 3.83 (dd, $J_{3,4} = 5.3$ Hz, 1H; 3-H), 4.10 (d, $J_{2,3} = 5.4$ Hz, 1H; 2-H), 4.38 and 4.46 (2 d, J = 12.1 Hz, 2H; PhCH₂), 4.39-4.45 (m, 1H; 5-H), 4.28 and 4.47 (2d, J = 11.5 Hz, 2H; PhCH₂), 4.32 and 4.51 (2d, J = 11.5 Hz, 2H; PhCH₂), 4.50 and 4.84 (2d, J = 11.3 Hz, 2H; PhCH₂), 4.54 and 4.93 (2d, J = 11.8 Hz, 2H; PhCH₂), 4.65 and 4.90 (2d, J=11.4 Hz, 2H; PhCH₂), 4.90 (s, 2H; PhCH₂), 7.02-7.36 ppm (m, 35H; 7 Ph); elemental analysis (%) calcd for C₆₂H₆₄O₁₀ (969.2): C 76.84, H 6.66; found: C 76.60, H 6.92.

3,7:10,14-Dianhydro-4,5,6,11,12,13,15-hepta-O-benzyl-1,2,8,9-tetradeoxy-D-erythro-L-talo-D-gulo-pentadec-1-ynitol (13): Commercially available $CeCl_3 \cdot 7H_2O$ (261 mg, 0.70 mmol) was heated in a reaction flask at $120 \degree C/0.1$ mbar for 1 h and at $140 \degree C/0.1$ mbar for 1 h, and then cooled to $0\degree C$ under an argon atmosphere. It was taken up in anhydrous THF (2.8 mL), the suspension was stirred at room temperature for 2 h, and then cooled to $-78\degree C$. Meanwhile, a stirred solution of commercially available trimethylsilylacetylene (122 µL, 0.88 mmol) in anhydrous THF (1 mL) was cooled to -78°C, and then butyllithium (0.55 mL, 0.88 mmol, 1.6 M solution in hexane) was slowly added. The resulting solution was stirred at $-78\,^\circ\text{C}$ for 45 min, and then transferred via a cannula into the stirred suspension of CeCl₃ in THF, prepared immediately prior to use as described above. The yellow mixture obtained was stirred at -78°C for 30 min, and then a solution of lactone 12 (336 mg, 0.35 mmol) in anhydrous THF (2.5 mL) was added dropwise. The mixture was stirred at -78°C for an additional 2 h, then diluted with 0.1M HCl (4 mL), allowed to warm to room temperature, and extracted with Et₂O (3×50 mL). The combined organic layers were dried (Na2SO4) and concentrated to give the disaccharidic hemiacetal as an approximately 1:1 mixture of anomers. A stirred mixture of the hemiacetal, activated 4 Å powdered molecular sieves (0.35 g), and triethylsilane (232 µL, 1.45 mmol) in anhydrous CH₃CN (6 mL) and CH₂Cl₂ (2 mL) was cooled to -10° C, and then freshly distilled BF₃·Et₂O (174 µL, 1.37 mmol) was added dropwise. Stirring was continued at -10° C for a further 1 h, and then the mixture was diluted with Et₃N (0.6 mL) and CH2Cl2 (50 mL), filtered through a pad of Celite, and concentrated. A solution of the residue in CH₂Cl₂ (100 mL) was washed with H₂O, dried (Na2SO4), and concentrated. A solution of the crude silvlated C-disaccharide in CH₃OH/THF (1:1; 12 mL) was treated with 1M NaOH (0.7 mL) for 1 h at room temperature, then neutralized with 1M HCl, and concentrated to remove the organic solvents. The residue was diluted with CH2Cl2 (100 mL), and this solution was washed with H_2O_1 , dried (Na₂SO₄), and concentrated. The residue was chromatographed on a column of silica gel eluting with $CH_2Cl_2/Et_2O~(40{:}1\,{\rightarrow}\,30{:}1)$ to afford ${\bf 13}~(213~mg,\,63\,\%)$ as a white solid; m.p. $178 - 180 \degree C$ (EtOAc/cyclohexane); $[\alpha]_{D}^{20} = +7.4^{\circ}$ (c = 1.0, CHCl₃); selected ¹H NMR data (300 MHz, C_6D_6): $\delta = 1.99$ (d, 1 H; 1-H), 1.63-1.69 and 2.25-2.29 (2 m, 4H; 2 8-H, 2 9-H), 3.18-3.29 (m, 4H), 3.34-3.40 (m, 1H), 3.45-3.51 (m, 3H), 3.66-3.72 (m, 3H), 3.76 (dd, J_{4.5}=8.8, $J_{5.6} = 9.7$ Hz, 1H; 5-H), 3.96 ppm (dd, 1H, $J_{1,3} = 2.2$, $J_{3,4} = 9.7$ Hz; 3-H); elemental analysis (%) calcd for C₆₄H₆₆O₉ (979.2): C 78.50, H 6.79; found: C 78.72, H 6.61.

Synthesis of the perbenzylated carboranyl *C*-glycosides: general procedure: Decaborane(14) (B₁₀H₁₄, 1.3–1.4 equivalents with respect to the alkyne as the starting material) was heated in refluxing CH₃CN (2 mL per mmol of the alkyne) for 30 min, in the course of which the solution turned yellow, indicating the formation of the adduct B₁₀H₁₂· 2 CH₃CN. A solution of the alkyne in toluene (2 mL per mmol) was then added and heating was continued for 16–18 h. For work-up, MeOH (1 mL) was added, the mixture was heated to reflux for 30 min, cooled to room temperature, and concentrated in vacuo. Baseline impurities were removed by filtration through a short plug of silica with EtOAc as eluent. The pure products were obtained by column chromatography using *n*-pentane/EtOAc (15:1) as the eluent.

Deprotection of the perbenzylated carboranyl *C*-glycosides: general procedure: The benzylated sugar derivative was dissolved in EtOAc/MeOH (1:5; 1 mL/25 µmol of the *C*-glycoside), Pd(OH)₂/C (10%, 1 mg/µmol of the *C*-glycoside) was added, and the resulting mixture shaken under H₂ atmosphere (up to 3 bar) in a Parr apparatus for 5-8 h. The progress of the reaction was monitored by TLC. The catalyst was carefully filtered off (*danger of spontaneous combustion when dry!*), the solvents were removed, and the residue was washed with Et₂O to obtain the deprotected compound.

decaborane(12) (24): Quantitative from **19**, colorless solid; $R_{\rm f}$ (EtOAc/MeOH, 4:1) = 0.06; $[a]_{20}^{20} = +7.5^{\circ}$ (c = 0.1, MeOH); IR (KBr): $\bar{\nu} = 3385$ (O – H), 2925 (C – H), 2574 (B – H), 1339, 1094 cm⁻¹; UV (CH₃CN): $\lambda_{\rm max}$ (lg ε) = 191.0 (3.847), 248.5 (3.376), 280.0 (2.965), 326.0 nm (3.278); ¹H NMR (500 MHz, CD₃OD): $\delta = 1.50 - 3.00$ (brs, 10H; BH), 3.14 (dd, J = 9.2, 9.2 Hz, 2H; 5a-H, 5b-H), 3.26 (ddd, J = 9.5, 7.3, 2.2 Hz, 2H; 2a-H, 2b-H), 3.33 – 3.39 (m, 4H; 3a-H, 3b-H, 4a-H, 4b-H), 3.58 (dd, J = 12.1, 7.3 Hz, 2H; 2 CH_aH_bOH), 3.67 (d, J = 9.1 Hz, 2H; 6a-H, 6b-H), 3.89 ppm (dd, J = 12.1, 2.2 Hz, 2H; 2 CH_aH_bOH); ¹³C NMR (125 MHz, CD₃OD): $\delta = 63.15$ (2 CH₂OH), 71.17 (C-5a, C-5b), 74.61 (C-3a, C-3b), 77.49 (C-6a, C-6b), 80.49 (C-4a, C-4b), 81.75 (2 carborane-C), 82.47 ppm (C-2a, C-2b); MS (ESI): m/z (%): 960 (100) [2*M*+Na]⁺, 492 (45) [*M*+Na]⁺; C₁₄H₃₂B₁₀O₁₀ (468.5).

Cytotoxicity tests: Adherent cells of the human bronchial carcinoma cell line A 549, of the murine melanoma cell line B-16, of the human pancreas carcinoma cell line PancTu 1, and of the colorectal human adeno carcinoma cell line LoVo were seeded in 96-well plates (TC Microwell 96F, Nunc) and cultivated at 37°C under air with a CO2 content enriched to 7.5% in Dulbecco's modified Eagle's medium (DMEM, Biochrom) supplemented with L-glutamine (4mm, Gibco), NaHCO3 (44mm, Biochrom), and 10% fetal calf serum (FCS, heat-inactivated for 30 min at 56 °C, Gibco). The cells were incubated with compounds 2 and 20-23 at various concentrations for 24 h in a serum-free medium (Ultra Culture, Cambrex) containing 1% DMSO. After five days of cultivation, the cells were treated with MTT (final concentration 0.5 mg mL⁻¹) for 4 h, and with a solubilizing solution (10% SDS in 0.1M HCl) overnight. The optical density of the resulting blue formazane derivative was measured with a photometer (thermo max microplate reader, Molecular Devices) after cell lysis. The measured optical density is proportional to the fraction of the living, metabolically active cells. The experiments were performed in duplicate.

Acknowledgement

This work was generously supported by the Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie. Kind donations of chemicals by Aventis S.A., BASF AG, Bayer AG, Degussa AG, and Wacker AG are gratefully acknowledged. The authors would also like to thank Ms. Maria Grazia Zampolli and Ms. Stefanie Heidrich for their help in the synthesis of ethynyl *C*-glycosides and with the in vitro cytotoxicity tests.
