### Facile and Convenient Method of Deuterium Gas Generation Using a Pd/C-Catalyzed  $H_2-D_2$  Exchange Reaction and Its Application to Synthesis of Deuterium-Labeled Compounds

### Takanori Kurita, Fumiyo Aoki, Takuto Mizumoto, Toshihide Maejima, Hiroyoshi Esaki, Tomohiro Maegawa, Yasunari Monguchi, and Hironao Sajiki<sup>\*[a]</sup>

**Abstract:** The Pd/C-catalyzed  $H_2-D_2$ exchange reaction using a  $H_2-D_2O$ combination provided a general, efficient and environmentally friendly route for the preparation of deuterium gas  $(D_2)$ . H<sub>2</sub> sealed in a reaction flask was converted into nearly pure  $D_2$ , which could be used for the Pd/C-catalyzed one-pot reductive deuteration of various reducible functionalities and the chemoselective one-pot deuteroge-

Keywords: chemoselectivity · deuterium gas · heterogeneous catalysis · isotopic labeling · palladium

nation of olefin and acetylene. Additionally, we established the capturing method of the generated  $D_2$  in a balloon, which was successfully applied to the Pd/C-catalyzed reductive mono-Nalkylation of a primary amine using nitrile as the alkylating reagent.

### Introduction

Deuterium gas  $(D_2)$  has been widely utilized as a deuterium source for the deuterium-labeling of a variety of molecules,<sup>[1]</sup> since it is a non-radioactive and stable isotope.<sup>[2]</sup> Deuterium-labeled compounds are finding increasing use as research tools in the life, environmental, and material scien $ces.$ <sup>[3,4]</sup> The catalytic deuterogenation of unsaturated hydrocarbons, deuterodehalogenation of aryl chlorides or bromides, deuterodeoxygenation of benzyl alcohols, and deuterogenolysis (ring-opening reaction) of epoxides using  $D<sub>2</sub>$  frequently offer the best routes to prepare the deuterated compounds with a high deuterium efficiency and regioselectivity.<sup>[5]</sup>  $D_2$  is, however, very expensive since it is commercially produced by the electrolysis of  $D_2O$  using an enormous amount of energy or the fractional distillation of liquid hydrogen under cryogenic conditions (ca.  $-250^{\circ}$ C). The pyrolysis of  $UD_3$  was also reported as a generation method of  $D_2$ , but it is not practical because of the use of radioactive uranium metal.<sup>[6]</sup> As for the preparation methods

of  $D_2$  on a laboratory scale, the reactions of metals such as sodium,<sup>[7]</sup> iron,<sup>[8]</sup> and magnesium<sup>[9]</sup> with D<sub>2</sub>O have been reported in the literature, although a large quantity of metal sludge was produced and drastic reaction conditions (several hundred degrees Celsius) were required. Numerous catalytic  $H_2-D_2$  exchange reactions between  $H_2$  and  $D_2O$  have also been reported in the literature.<sup>[10–18]</sup> However, these methods did not produce high purity  $D_2$  and also required high pressure, the use of a special catalyst, and an excess amount of a strong base or acid. Furthermore, the applications of the generated  $D_2$  to the deuterogenation of unsaturated substrates afforded the corresponding deuterated products with low deuterium efficiencies, depending on the  $D_2$  purity.<sup>[19-21]</sup> Therefore, efficient and catalytic preparation methods of pure  $D_2$  via the H<sub>2</sub>–D<sub>2</sub> exchange reaction between H<sub>2</sub> and D<sub>2</sub>O have not yet been developed. Consequently, the development of an efficient and catalytic generation method of  $D<sub>2</sub>$  in the laboratory has been strongly desired. We have recently reported a Pd/C-catalyzed regioselective H–D exchange reaction at the benzylic site in  $D<sub>2</sub>O$  in the presence of a small amount of  $H_2$  at room temperature,<sup>[22]</sup> and multiple deuterium-labeling methods on aromatic rings and/or alkyl side chains under high temperature conditions (110–  $180^{\circ}$ C).<sup>[23]</sup> During the course of these investigations, we have found that 10% Pd/C effectively catalyzed an isotope exchange reaction between  $H_2$  and  $D_2O$ , and the  $H_2$  in the reaction flask was almost entirely replaced by  $D<sub>2</sub>$  at room temperature within 24 h. We have also developed a conven-

ient and one-pot reductive deuteration method using the generated  $D_2$ <sup>[24]</sup> Herein, we describe the details of the Pd/Ccatalyzed  $H_2-D_2$  exchange reaction, including the one-pot reductive deuteration, chemoselective deuterium-labeling method,  $D_2$ -capturing method, and mechanistic aspects.

### Results and Discussion

Pd/C-catalyzed  $H_2-D_2$  exchange reaction between  $H_2$  and  $D_2O$ : In our first investigation, we conducted a  $H_2-D_2$  exchange reaction using  $D_2O$  (1.0 mL, 55 mmol) and 10% Pd/ C (10 mg, 9.4  $\mu$ mol of Pd metal) in the presence of a large quantity of  $H_2$  (balloon, ca. 2.0 L) (Figure 1, condition A). The course of the reaction over time was monitored by <sup>1</sup>H NMR spectroscopy using  $p$ -methoxybenzoic acid sodium salt as an internal standard. Figure 1 indicates the gradual and continuous increase of the DHO signal intensity based upon Equation (1), whereas no increase in the intensity was observed in the absence of  $H_2$  (under Ar atmosphere, condition B) or 10% Pd/C (condition C). The  $H_2$ -D<sub>2</sub> exchange reaction was found to be a Pd/C-catalyzed reaction, and the source of the hydrogen atom of DHO must be  $H_2$ . D<sub>2</sub> (63 mL, 2.6 mmol) [HD (127 mL, 5.2 mmol)] was generated from D<sub>2</sub>O (1.0 mL, 55 mmol) after 24 h (TON = 276) [HD:  $TON = 552$  by the calculation based upon the increased DHO. The present reaction proceeded relatively slowly, but continuously converted  $H_2$  into  $D_2$  even under atmospheric hydrogen pressure at room temperature.This result motivated us to more extensively examine this Pd/C-catalyzed  $H_2$ –  $D_2$  exchange reaction.

Figure 1. Kinetic plots of DHO ratio in  $D_2O$ .

We chose to explore the utility of heterogeneous transition metal catalysts for the reaction [9.4 µmol of each catalyst in  $D_2O$  (1 mL) under an  $H_2$  atmosphere]. As shown in Figure 2, Rh/C indicates the highest activity and Pd/C, Ir/C, and Pt/C are also effective. From the viewpoints of cost and general versatility, we decided to use Pd/C as the catalyst for the  $H_2$ –D<sub>2</sub> exchange reaction.

Next, we attempted the one-pot deuterogenation of an olefin using the generated  $D_2$  (Table 1). A suspension of

Figure 2. Effect of catalyst toward  $H_2-D_2$  exchange reaction.

10% Pd/C (7.4 mg, 10% of the substrate weight) in  $D_2O$ (1 mL, 55 mmol) in a sealed flask (160 mL: interior volume) was stirred under a hydrogen atmosphere at room temperature for 24 h and then *trans*-cinnamic acid (1) was added through a syringe attached to a needle.After 6 h, an approximately 35% deuterium incorporation into both of the reduced methylene positions (C1 and C2) was observed by <sup>1</sup>H NMR spectroscopy (entry 1, Table 1). The deuterium efficiency was significantly improved using  $3 \text{ mL of } D_2O$  and a nearly quantitative deuterium incorporation was achieved (entry 2, Table 1).The D content at the benzylic site (C1 position) was slightly over 50% using 5 mL of  $D_2O$  probably due to the benzylic site selective Pd/C-catalyzed H–D exchange reaction (entry 3, Table 1).<sup>[22]</sup> These results indicate at least  $3 \text{ mL of } D_2O$  is necessary for the complete conversion of pure  $H_2$  to pure  $D_2$  in the 160-mL flask. On the other hand,  $CH<sub>3</sub>OD$  and  $CD<sub>3</sub>OD$  were not efficient deuterium sources, and even increased amounts of  $CH<sub>3</sub>OD$  up to 13.5 mL never improved the D contents of [D]-2 (entries 4– 7, Table 1). Only acidic deuterium atoms seem to work as deuterium sources in the present reaction since the use of

CH<sub>3</sub>OD led to the nearly equal deuterium efficiency as that of  $CD<sub>3</sub>OD$  (entry 4 vs. 7, Table 1), although no desired [D]-2 was generated when the reaction was carried out in an acidic deuterated solvent such as  $CH<sub>3</sub>CO<sub>2</sub>D$  or 20% DCl in D<sub>2</sub>O (entries 8 and 9, Table 1).

The reaction conditions of the  $H_2-D_2$  exchange were optimized as shown in Table 2. The reductive deuteration of 1 efficiently proceeded by a 24 h pre-stirring of 10% Pd/C in

Table 2. Deuterogenation of 1 using  $D_2$  generated in situ.<sup>[a]</sup>

[a] 10% Pd/C in  $D_2O$  was pre-stirred under  $H_2$  atmosphere for 24 h, trans-cinnamic acid (1) was added as a 0.5 mL MeOH solution, and the reaction was quenched after 6 h. [b] D content was determined by <sup>1</sup>H NMR spectroscopy on the basis of the integration of the aromatic protons. [c] Yield of isolated product. [d] Deuterogenation was performed for 6 h without pre-stirring.

 $D_2O$  (3 mL) under a H<sub>2</sub> atmosphere (160 mL, 6.5 mmol) at room temperature (entry 1, Table 2), while almost no deuterium incorporation was observed without pre-stirring (entry 2, Table 2). The efficiency of the deuterium incorporation was significantly reduced by the decreased use of the 10% Pd/C (3 wt%) (entry 3, Table 2) or an increased amount of  $H_2$  using a larger flask (entries 5 and 6, Table 2). On the other hand, a slightly higher D content was obtained by decreasing the amount of  $H<sub>2</sub>$  (75 mL) in a smaller flask (entry 4, Table 2). Therefore, these results indicate that the  $D_2$  purity is significantly affected by the ratio between the  $H<sub>2</sub>$  volume and  $D<sub>2</sub>O$  amount based upon the efficiency of the  $H_2-D_2$  exchange reaction. The use of a larger amount (1.0 and 2.0 mmol) of the substrate (1), compared with 0.5 mmol in entry 1 of Table 2, brought about the successful deuterogenation (entries 7 and 8, Table 2), but increasing 1 caused more  $D<sub>2</sub>$  to be consumed and induces a reduced inner pressure in the enclosed reaction flask, which would decrease the reaction efficiency.Therefore, the reaction conditions described in entry 1 of Table 2 were used as the standard conditions for the following reactions.

One-pot reductive deuteration using  $D<sub>2</sub>$  generated in situ: A wide variety of internal olefins and acetylenes, including dienes and diynes were employed for the one-pot reduction to give the corresponding deuterated products in excellent deuterium efficiencies (entries 1–4 and 8–11, Table 3). However, the reaction of phenylpropiolic acid produced only a moderate D content (72 and 76%, respectively) (entry 5, Table 3). The displacement of the acidic proton by deuterium or conversion to the corresponding sodium salt slightly

improved the deuterium efficiency (entries 6 and 7, Table 3), and an excellent deuterium incorporation was achieved using the corresponding methyl ester as a substrate (entry 8, Table 3). These reactions were very clean and virtually no competitive deuteration on the aromatic ring or non-reducible positions was observed (confirmed by  ${}^{2}$ H NMR spectroscopy).

The present one-pot reductive deuteration method using the generated  $D_2$  was also applicable to the deuteration based on the dehalogenation of aromatic halides, deoxygenation of benzylic oxygen, the ring-opening reaction of epoxides and catalytic reduction of aromatic nitriles (Table 4). The dehalogenation of aromatic chlorides and bromide efficiently proceeded with an excellent D content by the addition of 1.2 equivalents of triethylamine (entries 1–5, Table 4),<sup>[25]</sup> and the coexisting olefin functionality within the molecule underwent the quantitative deuterogenation (entries 3 and 4, Table 4). The Pd/C-catalyzed ring-opening reaction of epoxides regioselectively proceed $ed^{[26]}$  with an efficient deuterium incorporation (entries 5 and 6, Table 4).The deuterogenolysis of benzyl alcohol and ester smoothly proceeded to provide the corresponding deuterated and deoxygenated products  $([D]-20$  and  $[D]-21$ , respectively; entries 7 and 8, Table 4).In these two cases, the D content at the methyl group (44%, entry 7, Table 4) and benzylic methylene group (69%, entry 8) was higher than the theoretical D content of the deuterogenolysis (33% and 50%, respectively), presumably because the Pd/C-catalyzed H– D exchange reaction proceeded at the newly formed benzylic site after deuterogenolysis.[22]

Table 4. Application to catalytic deuteration of various substrates using Pd/C–D<sub>2</sub>O–H<sub>2</sub> system.<sup>[a]</sup>

[a] 10% Pd/C (10 wt% of the substrate) in D<sub>2</sub>O (3 mL, 166 mmol) was stirred under H<sub>2</sub> atmosphere (160 mL, 6.5 mmol) at room temperature for 24 h, then the substrate (0.5 mmol) was added, and the reaction was quenched after 6–48 h. [b] Yield of isolated product. [c] 0.6 mmol of triethylamine was added together with substrate. [d] D content was determined by <sup>1</sup>H NMR spectroscopy after the conversion of the carboxylic acid into the corresponding methyl ester on the basis of the integration of the methyl protons. [e] 5 mL of  $D_2O$ (276 mmol) was used. [f] D content was determined by  ${}^{1}$ H NMR spectroscopy after the conversion of the alcohol into the corresponding acetate on the basis of the integration of the acetyl protons. [g] D content was determined by <sup>1</sup>H NMR spectroscopy on the basis of the integration of the aromatic protons. [h] 20 wt% of the substrate of 10% Pd/C was used and the deuterogenation of aromatic ketone was performed at  $50^{\circ}$ C. [i] 20 wt% of the substrate of 10% Pd/C was used and 0.75 mmol of DCl (20 wt%, solution in D<sub>2</sub>O) was added together with substrate.[j] 30 wt% of the substrate of 10% Pd/C was used and 0.75 mmol of DCl (20 wt%, solution in  $D_2O$ ) were added together with substrate.

3374 <www.chemeurj.org> © 2008 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim Chem. Eur. J. 2008, 14, 3371 – 3379

By the same token, benzophenone was also successfully employed for the deuterogenation of the aromatic ketone to produce  $[D_2]$ -diphenylmethane ( $[D]$ -22) with a 96% D content (entry 9, Table 4). Furthermore, the efficient deuterogenation of aromatic nitriles cleanly proceeded in the presence of 1.5 equivalents of DCl (as a 20 wt%  $D_2O$  solution) and efficiently deuterated benzylamine derivatives ([D]-23 and [D]-24) were obtained without the formation of any sideproducts, such as secondary and tertiary amines (entries 10 and 11, Table 4).

One-pot deuterogenation of aromatic nuclei using the generated  $D_2$ : We recently reported a mild and neutral hydrogenation method of aromatic nuclei catalyzed by 10% Rh/C in water.<sup>[27]</sup> Next, we applied the present method to the deuterogenation of 5-phenoxy-n-valeric acid since Rh/C indicated the efficient catalyst activity toward the  $H_2-D_2$  exchange reaction (Figure 2). The successfully reduced and efficiently labeled cyclohexane derivative ([D]-25) was obtained as shown in Scheme 1.

Scheme 1. Application to deuterogenation of aromatic nuclei using Rh/  $C-D<sub>2</sub>O-H<sub>2</sub>$  system.

The method of capturing the generated  $D<sub>2</sub>$  and its application to the synthesis of deuterium-labeled compounds: The reaction conditions for the complete conversion of  $H_2$  into  $D_2$  were investigated in a pressure-resistant reaction vessel under medium pressure to establish an efficient capturing method of the generated  $D<sub>2</sub>$  because the one-pot and in situ deuteration method was not applicable to water-sensitive substrates and reactions. The purity of the collected  $D<sub>2</sub>$  in a rubber balloon was assessed by the deuterium efficiency of the Pd/C-catalyzed deuterogenation of ethyl cinnamate in cyclohexane (Table 5). The deuterated product  $(D|-4)$  was obtained with a high D content (entry 1, Table 5, C1: 44%, C2: 44%) under the stated conditions.Although increasing the amounts of Pd/C or  $D_2O$ , the decompression of  $H_2$  and lengthening of the reaction time were each modestly effective for the reaction efficiency (entries 2–7, Table 5), nearly pure  $D_2$  was generated under the combined conditions (10 mL of D<sub>2</sub>O, 50 mg of 10% Pd/C, 3 atm of H<sub>2</sub>, 96 mL of pressure-resistant Hyper-glass cylinder, at room temperature for 48 h) as shown in entry 8, Table 5. Roughly 170 mL of  $D<sub>2</sub>$  under atmospheric pressure was captured in the rubber balloon.

We recently reported the Pd/C-catalyzed reductive mono-N-alkylation of anilines using nitriles as an alkylating regent under an  $H<sub>2</sub>$  atmosphere, and this method is also applicable

[a] Capturing Method: 10% Pd/C in  $D_2O$  was stirred under  $H_2$  pressure at room temperature using a pressure-resistant Hyper-glass cylinder (96 mL), the generated  $D_2$  was captured in a rubber balloon. [b] The purity of the generated  $D_2$  was assessed by the deuterogenation of ethyl cinnamate: a mixture of ethyl cinnamate (0.25 mmol) and 10% Pd/C (4.4 mg, 10 wt% of the substrate weight) in cyclohexane (1 mL) were stirred under a captured  $D_2$  atmosphere (ca. 170 mL) at room temperature for 4 h.  $[c]$  D content was determined by  ${}^{1}$ H NMR on the basis of the integration of the aromatic protons.[d] Yield of isolated product.

to the one-pot synthesis of mono-N-alkylanilines starting from nitrobenzene.<sup>[28]</sup> The reductive N-ethylation of nitrobenzene under a captured  $D_2$  atmosphere was investigated using  $[D_3]$ acetonirile (CD<sub>3</sub>CN, D content: 99.8%) as an alkylating reagent (Scheme 2). The reductive alkylation and

Scheme 2. Application to Pd/C-catalyzed reductive mono-N-alkylation using  $CD_3CN$  in captured  $D_2$ .

simultaneous deuteration derived from the captured  $D<sub>2</sub>$  successfully proceeded to afford the desired N-ethylaniline with a good D content at the  $\alpha$ -methylene position of the nitrogen atom (84%). The process of generation, capture and application of  $D_2$  was, therefore, useful for the synthesis of the secondary amine which is regioselectively deuterated at the a-methylene group.

Chemoselective one-pot reductive deuteration by the addition of diphenyl sulfide: We have recently developed a Pd/ C-catalyzed chemoselective hydrogenation method for olefins and acetylenes without the hydrogenolysis of other reducible functionalities by the addition of a very low loading  $(0.01$  equiv) of diphenyl sulfide  $(Ph_2S)$  as a catalyst poison.[29] The chemoselective one-pot reductive deuterations of olefins and acetylenes in the presence of other re-

ducible functionalities were investigated as follows: a suspension of  $10\%$  Pd/C in D<sub>2</sub>O was stirred at room temperature under an H<sub>2</sub> atmosphere for 24 h followed by the addition of  $Ph<sub>2</sub>S$  (0.01 equiv) and the substrate (Table 6). Selective deuterogenation of the olefin and acetylene functions proceeded with excellent deuterium efficiencies without reduction of the aromatic carbonyl (entries 1, 3 and 6, Table 6), benzyl ester, ether and alcohol (entries 4, 7 and 12, Table 6), aromatic chloride (entry 6, Table 6), N-Cbz (entry 8, Table 6), TBDMS ether (entry 9, Table 6) and nitrile (entries 10 and 11, Table 6), although the complete reduction of the alkene as well as aromatic carbonyl (entry 2, Table 6) and benzyl ester (entry 5, Table 6) functions proceeded in the absence of Ph<sub>2S</sub>. The onepot chemoselective deuterogenation of the alkene and alkyne moieties was achieved with a variety of reducible functionalities, including aromatic nuclei, remaining intact.

Reaction mechanism: A plausible mechanism of the Pd/C-catalyzed  $H_2-D_2$  exchange reaction is illustrated in Scheme 3.We assumed that the oxidative addition of the  $H_2$ -adsorbed (activated)  $Pd^0$  (A) to  $D_2O$  would give a  $Pd<sup>H</sup>$  species (B), and the subsequent exchange reaction between  $D$  derived from  $D_2O$ and  $H$  from  $H_2$  followed by the reductive elimination would afford the corresponding  $Pd^0$ –  $HD$  (C) and DHO. The liberation of  $D_2$  and regeneration of  $Pd<sup>0</sup>$  should be achieved by following a similar process through D and E.

It is noteworthy that the  $H_2$ – D<sub>2</sub> exchange efficiency was drastically decreased using the low-purity  $D_2O$  as the deuterium source (Table 7, see also

[a] 10% Pd/C (10 wt% of the substrate) in D<sub>2</sub>O (3 mL, 166 mmol) was stirred under H<sub>2</sub> atmosphere (160 mL, 6.5 mmol) at room temperature for 24 h, the substrate  $(0.5 \text{ mmol})$  and Ph<sub>2</sub>S  $(0.01 \text{ equiv})$  were added, and the reaction was quenched after 24 h. [b] D content was determined by <sup>1</sup>H NMR spectroscopy on the basis of the integration of the aromatic protons. [c] Yield of isolated product. [d] Without Ph<sub>2</sub>S. [e] 30 wt% of the substrate of 10% Pd/C and 5 mL of D<sub>2</sub>O (276 mmol) were used. [f] 20 wt% of the substrate of 10% Pd/C was used.  $[g] 0.25$  mmol of substrate, 0.02 equivalents of Ph<sub>2</sub>S, 30 wt% of the substrate of 10% Pd/C, and 5 mL of D<sub>2</sub>O (276 mmol) were used. [h] 0.25 mmol of substrate, 30 wt% of the substrate of 10% Pd/C and 5 mL of  $D_2O$ (276 mmol) were used.

## Deuterium-Labeling **Deuterium-Labeling**

Scheme 3. Proposed mechanism.

Scheme 3). Only 30% and 26% deuterium efficiencies were observed at the C1 and C2 positions, respectively, in 90%  $D<sub>2</sub>O$  (entry 2, Table 7), and 50%  $D<sub>2</sub>O$  led to virtually no incorporation of deuterium (entry 4, Table 7). Since a decrease in the purity of  $D_2O$  caused a significant drop in the  $H_2-D_2$ exchange efficiency, an excess amount of  $D_2O$  (3 mL, 166 mmol) might be required to circumvent the drastic degradation of the  $D_2O$  purity.

Table 7. Change of H<sub>2</sub>–D<sub>2</sub> exchange efficiency using low-purity  $D_2O^{[a]}$ 

	$D_2O, H_2O$ 10% Pd/C (7.4 mg) $H2$ (160 mL)	rt. 24 h	$\angle$ CO <sub>2</sub> H Phi $1(0.5 \text{ mmol})$ rt, 6 h	C н Phi $[D]-2$	CO <sub>2</sub> H C2

	[mL]	[mL]	C1	C2	[%]
1	3.0	$\theta$	48	46	93
$\overline{c}$	2.7	0.3	30	26	98
3	2.1	0.9	13	12	94
4	1.5	1.5	5	6	98
5	0.9	2.1	0	0	95

[a]  $10\%$  Pd/C (10 wt% of 1) in mixed solvents (3 mL) of H<sub>2</sub>O and D<sub>2</sub>O was stirred under  $H_2$  atmosphere (160 mL, 6.5 mmol) at room temperature for 24 h, trans-cinnamic acid (1) (0.5 mmol) was added, and the reaction was quenched after 6 h. [b] D content was determined by <sup>1</sup>H NMR spectroscopy on the basis of the integration of the aromatic protons. [c] Yield of isolated product.

These results were also considered from a mechanistic point of view based on the isotope effect between H and D. The oxidative addition of Pd to DHO should proceed preferably and H–Pd–OD would predominantly form via insertion to the O-H bond rather than the O-D bond [Eq.  $(2)$ ]. Similarly, complex B' could be generated by the oxidative addition of the H<sub>2</sub>-activated Pd<sup>0</sup> (**A**, Scheme 3) to DHO and virtually no reaction was observed as a result of the "possible" H–H exchange of  $\mathbf{B}'$  [Eq. (3)]. Therefore, the formation of complex **B** derived from  $D_2O$  and **A** (Scheme 3, **A**  $\rightarrow$  **B**) should be necessary to generate HD [Eq. (4)]. The oxidative addition of the HD-activated Pd $^0$  (C, Scheme 3) with D<sub>2</sub>O (Scheme 3,  $C \rightarrow D$ ) gave the complex D, which would undergo the intramolecular H–D exchange, leading to  $D_2$  generation via complex  $D''$  [Eq. (5)]. On the other hand, the oxidative addition of C to DHO would give the

complex D', but virtually no reaction would proceed by the favorable H–H exchange on  $D'$  [Eq. (6)]. Similarly, the existence of  $H<sub>2</sub>O$  would result in no reaction after the complexation by oxidative addition of Pd species A or/and C followed by the intramolecular H–H exchange. The use of excess  $D_2O$  compared with the  $H_2$  volume should be required for the efficient generation of pure  $D_2$ .

### Conclusion

We have demonstrated the Pd/C-catalyzed  $H_2-D_2$  exchange reaction between  $D_2O$  and  $H_2$  and its application to the preparation of deuterium-labeled compounds.  $H_2$  sealed in the reaction flask was efficiently converted into pure  $D_2$ , which can be used for the one-pot reductive deuteration of a variety of reducible functionalities. Furthermore, the chemoselective deuterogenation of olefins and acetylenes was accomplished by the addition of a trace amount of  $Ph<sub>2</sub>S$ with retention of the various other reducible functionalities. A method of capturing the generated  $D<sub>2</sub>$  gas was also developed. The significant features of the  $H_2-D_2$  exchange reaction are efficiency, inexpensiveness, environmental friendliness and convenience.These novel methodologies related to the  $D<sub>2</sub>$  generation should contribute to many chemistry fields.

### Experimental Section

General: 10% Pd/C was purchased from Sigma-Aldrich Co. (Lot. 05718BC). D<sub>2</sub>O ( $>99.9\%$  D atom) was obtained from Cambridge Isotope Laboratories, Inc. or Spectra Gases, Inc. All other reagents were purchased from commercial sources and used without further purification.Analytical thin-layer chromatography (TLC) was carried out on pre-coated Silica Gel 60  $F_{254}$  plates (Merck, Art 5715) and visualized with

#### **A EUROPEAN JOURNAL**

UV light.Flash column chromatography was accomplished using a Silica Gel 60 (Merck; 230–400 mesh) or Silica Gel 60N (Kanto Chemical Co., Inc.; 63–210  $\mu$ m, spherical, neutral). The <sup>1</sup>H, <sup>2</sup>H and <sup>13</sup>C NMR spectra were recorded by a JEOL AL 400 spectrometer or a JEOL EX 400 spectrometer. The chemical shifts  $(\delta)$  are expressed in ppm and are internally referenced to tetramethylsilane or residual solvents (7.27 ppm/CHCl<sub>3</sub>, 3.30 ppm/CH<sub>3</sub>OH, 4.75 ppm/H<sub>2</sub>O and 1.93 ppm/MeCN for <sup>2</sup>H NMR). Elemental analyses were performed using a YANACO CHN CORDER MT-5 instrument.The EI and FAB mass spectra were taken by a JEOL JMS-SX102 A instrument at the Mass Spectrometry Laboratory of the Gifu Pharmaceutical University. The pressurized reactions were carried out using a Hyper-glass cylinder (purchased from Taiatsu Techno Co.). In the mass spectra data,  $M(D_2)$  indicates the molecular ion peak of deuterated product with two deuterium atoms, and  $M(D_0)$  indicates the peak of non-deuterated product.

The procedure for the one-pot reductive deuteration using the Pd/C– D2O–H2 system: Table 2, entry 1; 10% Pd/C (7.4 mg, 10 wt% of 1) and  $D<sub>2</sub>O$  (3 mL, 166 mmol) were placed in a 100 mL round-bottom flask (actual internal volume of the flask is 160 mL). The system was sealed with a septum and filled with  $H_2$  using five vacuum/ $H_2$  cycles. The mixture was stirred at room temperature for 24 h and trans-cinnamic acid (1) (74.1 mg, 0.5 mmol) as a 0.5 mL MeOH solution was added. The mixture was stirred at room temperature for 6 h, diluted with  $Et<sub>2</sub>O$  (10 mL) and passed through a membrane filter (Millex-LH, 0.45 µm). The filtrate was separated into two layers. The aqueous layer was extracted with  $Et<sub>o</sub>O$  $(2 \times 15 \text{ mL})$  and the combined ethereal layers were washed with brine (30 mL), dried over MgSO<sub>4</sub>, filtered and concentrated in vacuo to give the analytically pure dideuterocinnamic acid ([D]-2; 73.5 mg, 98%) as a colorless oil. The D content was determined by  ${}^{1}H$  NMR spectroscopy on the basis of the integration of the aromatic protons. No deuterium incorporation at the aromatic ring was confirmed by <sup>2</sup>H NMR spectroscopy.

**Data for [D]-2**: <sup>1</sup>H NMR (400 MHz, CD<sub>3</sub>OD):  $\delta$  = 2.47 (m, 1.07 H), 2.79 (m, 1.01 H), 7.05-7.18 ppm (m, 5 H, Ph); <sup>2</sup>H NMR (60.7 MHz, CH<sub>3</sub>OH):  $\delta$  = 2.56 (br s), 2.87 ppm (br s); MS (EI): m/z (%): 152 (50)  $[M(D_2)]^+,$ 151 (15)  $[M(D_1)]^+,$  150 (2)  $[M(D_0)]^+,$  106 (60), 92 (100).

Table 4, entry 1: 10% Pd/C (7.8 mg, 10 wt% of 4-chlorobenzoic acid) and  $D_2O$  (3 mL, 166 mmol) were placed in a 100 mL round-bottom flask (actual internal volume of the flask is  $160$  mL). The system was sealed with a septum and filled with  $H_2$  using five vacuum/ $H_2$  cycles. The mixture was stirred at room temperature for 24 h and 4-chlorobenzoic acid (78.0 mg, 0.5 mmol) as a 0.5 mL MeOH solution and Et<sub>3</sub>N (83.6  $\mu$ L, 0.6 mmol) were added. The mixture was stirred at room temperature for 24 h, diluted with Et<sub>2</sub>O (10 mL), and passed through a membrane filter (Millex-LH, 0.45  $\mu$ m). The filtrate was neutralized using a 5% NaHSO<sub>4</sub> aqueous solution and extracted with Et<sub>2</sub>O  $(2 \times 15 \text{ mL})$ . The ethereal layers were washed successively with water (10 mL) and brine (30 mL), dried over MgSO<sub>4</sub>, filtered, and concentrated in vacuo to give an analytically pure 4-deuterobenzoic acid ([D]-14; 48.4 mg, 79%) as a colorless solid. The D content was determined by  ${}^{1}$ H NMR of the corresponding methyl ester on the basis of the integration of the methyl protons.

**Data for methyl ester of [D]-14:** <sup>1</sup>H NMR (400 MHz, CD<sub>3</sub>OD):  $\delta = 3.93$ (s, 3H), 7.49 (d,  $J=5.9$  Hz, 2H), 7.62 (m, 0.060H), 8.04 ppm (d,  $J=$ 5.9 Hz, 2H); MS (EI):  $m/z$  (%): 137 (42)  $[M(D_1)]^+,$  136 (9)  $[M(D_0)]^+,$ 106 (100), 78 (54).

The method of capturing the generated  $D_2$  in situ and the application to the reductive mono-N-alkylation using nitrile: Scheme 2; A suspension of 10% Pd/C (50.0 mg) in  $D_2O$  (10 mL, 553 mmol) in a 96 mL Hyper-glass cylinder was stirred under 3 atm of  $H_2$  pressure (internal  $H_2$  is ca. 260 mL under atmospheric pressure) at room temperature for 48 h.The generated  $D_2$  gas was captured using a rubber balloon (ca. 170 mL). A mixture of nitrobenzene (61.6 mg, 0.5 mmol) and  $10\%$  Pd/C (12.3 mg, 20 wt% of the nitrobenzene) in CD3CN (D content: 99.8%, 0.75 mL, 14.4 mmol) in a test tube was stirred under the captured  $D_2$  (balloon) at room temperature for 24 h. The reaction mixture was diluted with  $Et<sub>2</sub>O$ (30 mL), and passed through a membrane filter (Millex-LH, 0.45 µm). The filtrate was concentrated in vacuo. The residue was purified by flash silica gel column chromatography (hexane:  $Et<sub>2</sub>O = 20:1$ ) to give  $[D<sub>5</sub>]$ -Nethylaniline ([D]-26; 48.1 mg, 79%) as a colorless oil. The D content was

determined by <sup>1</sup>H NMR spectroscopy on the basis of the integration of the aromatic protons.No deuterium incorporation at the aromatic ring was confirmed by <sup>2</sup>H NMR spectroscopy.

**Data for [D]-26**: <sup>1</sup>H NMR (400 MHz, CD<sub>3</sub>OD):  $\delta$  = 1.15 (m, 0.03 H), 3.06 (d,  $J=7.2$  Hz, 0.33H), 6.59–6.64 (m, 3H), 7.08 ppm (m, 2H); <sup>2</sup>H NMR (60.7 MHz, CH<sub>3</sub>OH):  $\delta$  = 1.15 (br s), 3.04 ppm (br s); MS (EI):  $m/z$  (%): 126 (44)  $[M(D_5)]^+,$  125 (36)  $[M(D_4)]^+,$  124 (12)  $[M(D_3)]^+,$  123 (17)  $[M(D_2)]^+, 122 (8) [M(D_1)]^+, 121 (13) [M(D_0)]^+, 108 (100), 107 (56).$

- [23] We have recently reported the multiple deuterium-labeling methods of inactive alkyl chains, aromatic rings, aliphatic secondary alcohols, ketones, phenylalanine derivatives and nucleosides under high temperature conditions using the Pd/C (and/or Pt/C)-D<sub>2</sub>O-H<sub>2</sub> system, see: a) H. Sajiki, F. Aoki, H. Esaki, T. Maegawa, K. Hirota, [Org.](http://dx.doi.org/10.1021/ol0496374) Lett. 2004, 6, 1485-1487; b) H. Sajiki, N. Ito, H. Esaki, T. Maesawa,
