

A KINETIC STUDY ON THE PROTON-TRANSFER REACTIONS OF m- AND p-NITRO-PHENYLAZOSALICYLIC ACIDS COUPLED WITH INCLUSION REACTIONS WITH  $\beta$ -CYCLODEXTRIN IN AQUEOUS SOLUTIONS<sup>1)</sup>

Noboru YOSHIDA and Masatoshi FUJIMOTO\*

Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060

A kinetic study on the proton-transfer reactions of the title compounds coupled with inclusion reactions with  $\beta$ -cyclodextrin in aqueous solutions is carried out by means of a temperature-jump method. The forward rate constants for the inclusion reactions are in the order of magnitude  $10^6 \text{ mol}^{-1} \text{ dm}^3 \text{ s}^{-1}$ . The rate constants for the recombination of the title compounds with  $\text{OH}^-$  ion increase in the concentrations of  $\beta$ -cyclodextrin.

$\beta$ -Cyclodextrin forms inclusion compounds in aqueous solution with azo dyes and many other inorganic or organic molecules.<sup>2)</sup> The main binding forces in the inclusion compounds are said to be hydrogen bonding,<sup>3)</sup> van der Waals forces,<sup>4)</sup> and hydrophobic interactions.<sup>5)</sup> In general the acid dissociation of azo dyes is facilitated or retarded by forming inclusion compounds with  $\beta$ -cyclodextrin. This behavior is explained by the Raumalkalität (space alkalinity) of  $\beta$ -CD,<sup>6)</sup> dipole-ion interaction,<sup>7)</sup> and hydrophobic microenvironment of the  $\beta$ -CD cavity.<sup>2)</sup>

On the other hand, the importance of the microenvironment at the periphery of the reaction site has been pointed out from the standpoint of solute-solvent interactions in the proton-transfer reactions of o-hydroxy azo compounds in a mixed solvent system.<sup>8)</sup> In the present study the authors aimed to elucidate the microenvironmental effect in the proton-transfer reactions of m- and p-NPAS.

The absorption maxima ( $\lambda_{\text{max}}^{\text{HA}} = 376$  and  $\lambda_{\text{max}}^{\text{A}} = 495$  nm) of p-NPAS in aqueous solution show a red shift ( $\lambda_{\text{max}}^{\text{HA-}\beta\text{CD}} = 382$  and  $\lambda_{\text{max}}^{\text{A-}\beta\text{CD}} = 507$  nm) in the presence of a large excess of  $\beta$ -CD, and the absorbances  $A_{376}$  and  $A_{495}$  decrease with increasing  $\beta$ -CD concentrations (Fig. 2). Figure 3 shows the absorption spectra of m-NPAS which shows no appreciable red shift ( $\lambda_{\text{max}}^{\text{HA}} = 354$  and  $\lambda_{\text{max}}^{\text{A}} = 453$  nm in water;  $\lambda_{\text{max}}^{\text{HA-}\beta\text{CD}} = 356$  and  $\lambda_{\text{max}}^{\text{A-}\beta\text{CD}} = 453$  nm) in the presence of a large excess of  $\beta$ -CD and  $A_{354}$  and  $A_{453}$  decrease with increasing  $\beta$ -CD concentrations.<sup>1)</sup>

Fig. 1. Structural formulae of m-NPAS (1) and p-NPAS (2).

The formation of 1 : 1 inclusion compounds ( $\text{HA-}\beta\text{CD}^-$  and  $\text{A-}\beta\text{CD}^{2-}$ ) of these azo dyes with  $\beta\text{-CD}$  is confirmed by the presence of isosbestic points in the spectral change (Figs. 2 and 3) and by the plot as shown in Fig. 4. In 50% (v/v) dioxane-water media  $\lambda_{\text{max}}^{\text{HA}}$  of m- and p-NPAS are 365 and 387 nm and  $\lambda_{\text{max}}^{\text{A}}$  464 and 506 nm, respectively.

The equilibria for the acid dissociation and the inclusion are expressed as follows,

where  $K_a = [\text{A}][\text{H}]/[\text{HA}]$ ,  $K'_a = [\text{A-}\beta\text{CD}][\text{H}]/[\text{HA-}\beta\text{CD}]$ ,  $K = [\text{HA}][\beta\text{-CD}]/[\text{HA-}\beta\text{CD}]$  and  $K' = [\text{A}][\beta\text{-CD}]/[\text{A-}\beta\text{CD}]$ . The values of  $K$  and  $K'$  were found to be  $9.22 \times 10^{-4}$  and  $2.16 \times 10^{-3} \text{ mol dm}^{-3}$  for m-NPAS, and  $1.37 \times 10^{-3}$  and  $1.12 \times 10^{-3} \text{ mol dm}^{-3}$  for p-NPAS. The changes in  $K_a$  with increasing  $\beta\text{-CD}$  concentrations are summarized in Table 1. In the case of p-NPAS, the change in  $K_a$  is quite a little.

The kinetic data were obtained under pseudo-first-order conditions using a large excess of  $\beta\text{-CD}$ . The inclusion of  $\text{HA}^-$  proceeds in the time region of  $20\text{-}50 \mu\text{s div}^{-1}$  and that of  $\text{A}^{2-}$   $0.1\text{-}0.5 \text{ ms div}^{-1}$  in the case of m-NPAS. The kinetic data are interpreted in terms of the following scheme

The observed relaxation time,  $\tau$ , for the inclusion reaction can be expressed as

$$\tau^{-1} = k_+[\beta\text{-CD}] + k_- \quad (1)$$

The plot of  $\tau^{-1}$  against  $[\beta\text{-CD}]$  gave a straight line with a slope  $k_+$  and an intercept  $k_-$  (Fig. 5). In Table 2 the rate constants  $k_+$ ,  $k_-$ ,  $k'_+$ , and  $k'_-$  are summarized. The values of  $k_-/k_+$  and  $k'_-/k'_+$  for m- and p-NPAS are in agreement with the equilibrium constants  $K$  and  $K'$  determined spectrally. The values of  $k_+$  or  $k'_+$  for m- and p-NPAS are almost the same, which suggests that the process of inclusion is not hindered by the nitro group (Fig. 1). Cramer et al. have pointed out that the value of  $k_+$  is about 2-3 orders of magnitude larger than that of  $k'_+$  when a hydrophilic group such as a hydroxyl group is included into the  $\alpha\text{-CD}$  cavity.<sup>2)</sup> In the present kinetic study the values of  $k_+$  and  $k'_+$  were found to be in the same orders of magnitude ( $10^6 \text{ mol}^{-1} \text{ dm}^3 \text{ s}^{-1}$ ;  $k_+ > k'_+$ ), which suggests that the process of inclusion takes place at the hydrophobic site i.e. the nitro group.<sup>9)</sup>

The rate constants,  $k_f$  and  $k_r$ , are obtained from the following equation.

$$\tau^{-1} = k_f[\text{OH}^-] + k_r \quad (2)$$

Table 1. Acid-dissociation constants,  $K_a/\text{mol dm}^{-3}$ 

$C_{\beta\text{-CD}}/\text{mol dm}^{-3}$	p-NPAS		m-NPAS	
	obsd	calcd <sup>a)</sup>	obsd	calcd <sup>a)</sup>
0	$2.06 \times 10^{-11}$	—	$1.59 \times 10^{-11}$	—
$6.36 \times 10^{-4}$	$2.14 \times 10^{-11}$	$2.21 \times 10^{-11}$	$1.20 \times 10^{-11}$	$1.21 \times 10^{-11}$
$3.18 \times 10^{-3}$	$2.29 \times 10^{-11}$	$2.38 \times 10^{-11}$	$1.05 \times 10^{-11}$	$8.81 \times 10^{-12}$
$\infty$	—	$2.52 \times 10^{-11}$	—	$6.77 \times 10^{-12}$

Table 2.

Rate constants for the proton-transfer and inclusion reactions

Rate constants	p-NPAS	m-NPAS
$k_+/\text{mol}^{-1} \text{ dm}^3 \text{ s}^{-1}$	$3.2 \times 10^6$	$3.3 \times 10^6$
$k_-/\text{s}^{-1}$	$1.1 \times 10^4$	$4.0 \times 10^3$
$k'_+/\text{mol}^{-1} \text{ dm}^3 \text{ s}^{-1}$	$1.5 \times 10^6$	$1.4 \times 10^6$
$k'_-/\text{s}^{-1}$	$4.0 \times 10^3$	$2.2 \times 10^3$
$k_f/\text{mol}^{-1} \text{ dm}^3 \text{ s}^{-1}$	$2.1 \times 10^7$	$2.0 \times 10^7$
$k_r/\text{s}^{-1}$	$1.9 \times 10^4$	$3.5 \times 10^4$

The plot of  $\tau^{-1}$  against  $[\text{OH}^-]$  gave a straight line at each  $\beta$ -CD concentration. Because of the strong intramolecular hydrogen-bond the values of  $k_f$  are three orders of magnitude smaller as compared with those of diffusion-controlled reactions. If the reaction site of the proton-transfer reaction is included into the hydrophobic  $\beta$ -CD cavity, where the dielectric constant is probably small, the rate constant  $k_f$  should decrease.<sup>8)</sup> However the values of  $k_f$  and  $k_r$  were found to increase with the increase in the  $\beta$ -CD concentrations, i.e., for m-NPAS  $k_f = 2.5 \times 10^7$  and  $2.7 \times 10^7 \text{ mol}^{-1} \text{ dm}^3 \text{ s}^{-1}$  and  $k_r = 4.8 \times 10^4$  and  $5.5 \times 10^4 \text{ s}^{-1}$  at  $[\beta\text{-CD}] = 1.60 \times 10^{-3}$  and  $8.02 \times 10^{-3} \text{ mol dm}^{-3}$ , respectively, and for p-NPAS  $k_f = 3.0 \times 10^7 \text{ mol}^{-1} \text{ dm}^3 \text{ s}^{-1}$  and  $k_r = 2.5 \times 10^4 \text{ s}^{-1}$  at  $[\beta\text{-CD}] = 3.26 \times 10^{-3} \text{ mol dm}^{-3}$ . This fact suggests that the reaction site ( $-\text{COO}^- \cdots \text{HO}-$ ) of m- and p-NPAS in the proton-transfer reaction is situated at the outside of the hydrophobic  $\beta$ -CD cavity.<sup>9)</sup>

Fig. 2. Absorption spectra of  $\text{HA}^-$  (1),  $\text{HA-}\beta\text{-CD}^-$  (2),  $\text{A}^{2-}$  (3), and  $\text{A-}\beta\text{-CD}^{2-}$  (4) of p-NPAS at 25 °C and  $I = 0.1 \text{ mol dm}^{-3}$  ( $\text{KNO}_3$ ).  $C_{\text{dye}} = 4.22 \times 10^{-5} \text{ mol dm}^{-3}$ .  $C_{\beta\text{-CD}} = (0-5.65) \times 10^{-3} \text{ mol dm}^{-3}$  at pH = 7.19 for (1) and (2).  $C_{\beta\text{-CD}} = (0-3.14) \times 10^{-3} \text{ mol dm}^{-3}$  at pH = 11.74 for (3) and (4).

Fig. 4. Plot of  $C/\Delta A$  against  $[\beta\text{-CD}]^{-1}$  at pH = 7.43 for m-NPAS.  $\Delta A$  and  $C$  are the change in absorbance and the total dye concentration, respectively.

Fig. 3. Absorption spectra of  $\text{HA}^-$  (1),  $\text{HA-}\beta\text{-CD}^-$  (2),  $\text{A}^{2-}$  (3), and  $\text{A-}\beta\text{-CD}^{2-}$  (4) of m-NPAS at 25 °C and  $I = 0.1 \text{ mol dm}^{-3}$  ( $\text{KNO}_3$ ).  $C_{\text{dye}} = 4.83 \times 10^{-5} \text{ mol dm}^{-3}$ .  $C_{\beta\text{-CD}} = (0-5.70) \times 10^{-3} \text{ mol dm}^{-3}$  at pH = 7.43 for (1) and (2).  $C_{\beta\text{-CD}} = (0-5.65) \times 10^{-3} \text{ mol dm}^{-3}$  at pH = 11.76 for (3) and (4).

Fig. 5. Plot of Eq. 1 at pH = 11.80 for m-NPAS.
