A CONVENIENT STEREOSPECIFIC ALKYLATION OF PHENYLACETYLENE BY ELECTROCHEMICAL REACTION OF ORGANOBORANES

Yuzuru TAKAHASHI, Masao TOKUDA, the late Mitsuomi ITOH, and Akira SUZUKI*

Faculty of Engineering, Hokkaido University, Sapporo 060

The electrochemical reaction of phenylacetylene with trialkylboranes in a tetrahydrofuran solution containing tetraalkylammonium halide gives the corresponding alkynes $\underline{\text{via}}$ a retention of configuration with respect to the boron-carbon bonds. The reaction mechanism is also discussed.

We have previously reported that the reaction of iodine with ate-complexes prepared from trialkylboranes and lithium acetylides gives corresponding internal alkynes in good yields, and also reported that the electrochemical reaction of 1-alkynes with trialkylboranes similarly gives corresponding alkynes in excellent yields under mild conditions. Such procedures have been shown to provide new simple, general syntheses of alkynes with a broad range of applicability since they readily permit the introduction of secondary alkyl and aryl groups as easily as primary alkyl groups. In the electrochemical procedure there is an additional advantage that all alkyl groups of trialkylboranes are used as alkylating agents. We wish to report here that the electrochemical alkylation of phenylacetylene proceeds via a complete retention of the configuration of the boron-carbon bond.

Hydroboration of 1-methylcyclohexene at 0°C followed by further reaction with propene or 1-pentene smoothly gives bis($\underline{\text{trans}}$ -2-methylcyclohexyl)propyl- (1a) or bis($\underline{\text{trans}}$ -2-methylcyclohexyl)pentylborane (1b) [Scheme 1]. 3,4 Electrochemical

Scheme 1

reaction of la with phenylacetylene in a tetrahydrofuran solution containing tetran-butylammonium iodide as a supporting electrolyte produced 1-(trans-2-methylcyclohexy1)-2-phenylethyne (2) $[n_D^{20} \ 1.5059; NMR \ (CCl_4) \ \delta 1.12 \ (d, 3H, J=5.7 \ Hz), 0.8-2.3$ (m, 10H), 7.26 ppm (m, 5H); m/e (rel. intensity) 196 (M⁺, 100), 185 (31), 171 (43), 157 (70), 143 (77), 130 (89), 117 (65%) and 1-phenyl-1-pentyne $(3a)^{2,5}$ in good yields [Scheme 1]. Stereochemistry of 2 was confirmed by the following evidence. Reduction 6 of a tetrahydrofuran solution of 2 with lithium aluminum hydride gave (E)-1-(trans-2-methylcyclohexyl)-2-phenylethylene (4) in a 63% yield. Ozonolysis of a methanol solution of 4 followed by treatment with 15% hydrogen peroxide and acetic acid gave benzoic acid and trans-2-methylcyclohexanecarboxylic acid (5). Retention time of 5 on glpc analysis and the NMR spectrum were completely identical with those of the authentic sample prepared by the base-catalyzed isomerization of cis-2-methylcyclohexanecarboxylic acid, which was obtained by hydrogenation of an acetic acid solution of o-toluic acid over platinum oxide. Glpc analysis of the electrolysis product showed only two peaks due to 2 and 3a and glpc of cyclohexanecarboxylic acid derived from 2 gives only the peak of 5. Accordingly, the electrochemical alkylation was found to produce the corresponding alkynes with a complete retention of the configuration with respect to the boroncarbon bond. Similar electrochemical reaction of 1b with phenylacetylene was also shown to undergo stereospecifically to give 2 and $3b^{2,5}$ in good yields. Furthermore, the stereochemistry of the reaction of iodine with the ate-complex formed from 1 and lithium phenylacetylide was also examined, and it was indicated that the reaction also proceeds through a complete retention, as reported before.8 Representative results are summarized in Table 1.

Hydroboration of 1-methylcyclohexene with borane at 65°C followed by refluxing in THF for 10 h gave a mixture of several trialkylboranes, which were converted into trans-2-methylcyclohexanol (70%), 3-methylcyclohexanol (25%) and cyclohexylmethanol (5%) upon oxidation with alkaline hydrogen peroxide. Electrolysis of the organoborane mexture in the presence of phenylacetylene under the conditions mentioned above produced the corresponding alkynes 2 (68%), 1-(3-methylcyclohexyl)-2-phenylethyne (24%) and 1-cyclohexylmethyl-2-phenylethyne (8%). This result shows that the electrochemical alkylation proceeds regionelectively.

We have proposed that the electrochemical alkylation of 1-alkynes goes on <u>via</u> nucleophilic attack of acetylide anion formed at a cathode to alkyl halide formed at an anode [Scheme 2]. However, the stereospecificity and regionselectivity of the present electrochemical alkylation suggest different reaction pathways from those mentioned in Scheme 2. The bromide isolated from an anodic oxidation of <u>la</u> in a tetrahydrofuran solution containing tetra-n-butylammonium bromide using a

Anode:
$$R_3B + X \cdot (or X_2) \longrightarrow RX$$

Cathode: $C_6H_5C \equiv CH \longrightarrow C_6H_5C \equiv C^{-+}NR_4^{--}$

Table 1. Electrochemical Reaction of Phenylacetylene with R_2 BR' and the Reaction of Iodine with Lithium 1-Alkynyltriorganoborates from R_2 BR'

Onerough	Onesanaharana		Yield ^a of Product (%)			
Organoborane R R'		Electrolysisb		Reaction with I2 ^C		
ĸ	K	A	В	A	В	
	n-C ₃ H ₇ (la)	162	79	49	42	
	n-C ₅ H ₁₁ (1b)	128	70	44	39	
	n-C ₃ H ₇	90	76	32	67	

- a) Analyzed by glpc, based on organoborane employed.
- b) Organoborane (1, 1 mmol), phenylacetylene (9 mmol) and tetra-n-butylammonium iodide (2.7 mmol) dissolved in 40 ml of THF was electrolyzed at a constant current (33 mA/cm²) for 3.5 h at 45°C under a nitrogen atmosphere. The electrolyzed mixture was oxidized with alkaline hydrogen peroxide.
- c) The reaction was carried out by the method described in ref. 1.

divided cell was not cis-2-methylcyclohexyl bromide (c-6) alone, but a mixture of c-6 (27%), trans-2-methylcyclohexyl bromide (t-6, 21%) and 3-methylcyclohexyl bromide (7, 52%). Alkynes which might be formed by nucleophilic substitution of the latter two bromides t-6 and 7 were not entirely obtained in the present electrochemical reaction of la with phenylacetylene. Furthermore, it has been found that no reaction occurs when the electrolysis is carried out in a divided cell, the halide ion of a supporting electrolyte plays an important role in the reaction, and the acetylide anion was actually formed at a cathode. 9 Judging from these results, we now propose the following mechanism [Scheme 3]. Anodic oxidation of iodide ion of a supporting electrolyte gives iodine. 10 On the other hand, trialkylboranes react with acetylides formed at a cathode to give corresponding 1-alkynyltrialkylborates. Such complexes react with iodine to induce transfer of an alkyl group from boron to carbon. Chemical reaction of iodine with 1-alkynyltriorganoborate stops at a transfer of one alkyl group. However, in the present electrochemical reaction, acetylide ions are continuously generated at a cathode, and these anions may produce $R_2BC \equiv CC_6H_5$ and $RB(C \equiv CC_6H_5)_2$, which result in the transfer of the second and the third alkyl groups.
