

HETEROGENEOUS PHOTOCATALYTIC OXIDATION OF  $\text{NO}_2^-$  IN AQUEOUS SUSPENSION  
OF VARIOUS SEMICONDUCTOR POWDERS

$\text{NO}_2^-$  ion was shown to be oxidized to  $\text{NO}_3^-$  with or without  $\text{O}_2$  under illumination in aqueous suspension of some semiconductor powders. Photoactive substances were  $\text{Ag}_2\text{O}$ ,  $\text{PbO}$ ,  $\text{TiO}_2$  (anatase),  $\text{Si}$ ,  $\text{ZnO}$ ,  $\text{SnO}_2$ ,  $\text{CdS}$ , and  $\text{Bi}_2\text{O}_3$ . The reaction proceeded with band gap illumination of semiconductors.

Acid rain water contains nitric acid as well as sulfuric acid. The concentration of  $\text{NO}_3^-$  in rain water prevails over that of  $\text{NO}_2^-$ . Nitric acid may result from the gaseous oxidation of nitrogen oxides in the atmospheric air as discussed by Calvert and Stockwell.<sup>1)</sup> But  $\text{NO}_2^-$ , most probably stemming from dissolution of  $\text{NO}$  and  $\text{NO}_2$  into water, may possibly be oxidized to  $\text{NO}_3^-$  in water droplets in the atmosphere. The rate of oxidation of  $\text{NO}_2^-$  by  $\text{O}_2$  is very low without any catalyst at ambient temperature.

Heterogeneous photocatalytic reaction has been studied by numerous workers with particular emphasis on utilization of solar energy. Several papers reported photocatalytic reactions of air pollutants.<sup>2-9)</sup> However, heterogeneous photocatalytic reaction of nitrogen oxide species in aqueous media has not yet been published except the photocatalytic reduction of  $\text{NO}$  by Yoneyama et al.<sup>3)</sup> Airborne particulate substance, as is well known, contains semiconductor metal oxides. Thus, the photocatalytic process is interesting in connection with oxidation of  $\text{NO}_2^-$  in water. This preliminary communication reports the oxidation of  $\text{NO}_2^-$  in water under illumination with various metal compounds.

Typical experiments consisted of illuminating 40  $\text{cm}^3$  of  $\text{NaNO}_2$  aqueous solution (ca.  $25 \times 10^{-6}$  mol  $\text{dm}^{-3}$ ) in a quartz tube (25 mm outer diameter) containing ca. 0.05 g of catalyst powder kept in suspension supersonically. The flow gas was bubbled (50  $\text{cm}^3$   $\text{min}^{-1}$ ) through the solution at 1 atm. The tube was positioned 9.5 cm apart from a 150 W xenon lamp.  $\text{NO}_2^-$  in the solution was determined by NEDA colorimetric analysis. The analysis of  $\text{NO}_3^-$  was conducted after decomposition of  $\text{NO}_2^-$  with sulfamic acid.  $\text{NO}_3^-$  was then reduced to  $\text{NO}_2^-$  by a cadmium-copper column, and analyzed by NEDA method.

Catalysts employed were reagent grade powder chemicals as presented below. The surface areas of some catalysts are indicated therewith.  $\text{Ag}_2\text{O}$  (Kanto Kagaku,  $0.7 \text{ m}^2 \text{ g}^{-1}$ ),  $\text{Co}_3\text{O}_4$  (Merck,  $34 \text{ m}^2 \text{ g}^{-1}$ ),  $\text{CuO}$  (Kanto Kagaku,  $0.7 \text{ m}^2 \text{ g}^{-1}$ ),  $\text{MnO}_2$  (Merck,  $3.9 \text{ m}^2 \text{ g}^{-1}$ ),  $\text{NiO}$  (Kanto Kagaku,  $13 \text{ m}^2 \text{ g}^{-1}$ ),  $\text{PbO}$  (Kanto Kagaku,  $0.5 \text{ m}^2 \text{ g}^{-1}$ ),  $\text{PbO}_2$

(Kanto Kagaku,  $0.6 \text{ m}^2 \text{ g}^{-1}$ ),  $\text{TiO}_2$  anatase (Kanto Kagaku,  $111 \text{ m}^2 \text{ g}^{-1}$ ),  $\text{ZnO}$  (Kanto Kagaku,  $4.0 \text{ m}^2 \text{ g}^{-1}$ ),  $\text{Cu}_2\text{O}$  (Kanto Kagaku),  $\text{Al}_2\text{O}_3$  (Junsei Kagaku),  $\text{CdS}$ ,  $\text{CuS}$ ,  $\text{MoS}_2$ ,  $\text{WO}_3$ ,  $\text{SnO}_2$ ,  $\text{SnO}$ ,  $\text{TiO}_2$  (rutile),  $\text{Bi}_2\text{O}_3$ ,  $\text{MoO}_3$  (Wako Junyaku),  $\text{Si}$  (99.99%, -300 mesh, Furuuchi Kagaku),  $\text{SiC}$  (99.5%, -300 mesh, Furuuchi Kagaku). All the catalyst powders were washed twice in doubly distilled water supersonically. The catalysts were centrifugally separated from aqueous suspensions. The flow gas was a mixture of  $\text{N}_2$  and  $\text{O}_2$  (1:1);  $\text{N}_2$  was purified with an activated copper column and a silica-gel column;  $\text{O}_2$  with a silica-gel column. The water was doubly distilled after deionization.

The fraction oxidized was defined as the increase of  $\text{NO}_3^-$  during the reaction time divided by the initial amount of  $\text{NO}_2^-$ . The fraction oxidized was below 0.03 under illumination for 1 h in the presence of the following substances;  $\text{TiO}_2$  (rutile),  $\text{Cu}_2\text{O}$ ,  $\text{CuO}$ ,  $\text{MoS}_2$ ,  $\text{WO}_3$ ,  $\text{MnO}_2$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{NiO}$ ,  $\text{Co}_3\text{O}_4$ , and  $\text{SiC}$ .

Table 1 presents the fraction oxidized for active catalysts under irradiation for 1 h.  $\text{NO}_2^-$  decreased and  $\text{NO}_3^-$  increased during the reaction time. The sum of  $\text{NO}_2^-$  and  $\text{NO}_3^-$  agreed well within the experimental error before and after the reaction. pH values, approximately 6, remained constant within  $\pm 0.5$  during the reaction. Hence, we concluded that the principal reaction was oxidation of  $\text{NO}_2^-$  to  $\text{NO}_3^-$ . The active substances are divided into four groups as described below. (1)  $\text{PbO}$  and  $\text{Ag}_2\text{O}$  showed an appreciable photochemical activity under illumination with or without oxygen. They were not active in the dark. Analysis by atomic absorption revealed that  $\text{Pb}^{2+}$  and  $\text{Ag}^+$  was dissolved into the solution after the reaction. (2)  $\text{TiO}_2$  (anatase),  $\text{ZnO}$ ,  $\text{Si}$ , and  $\text{SnO}_2$  exhibited photocatalytic activity in the oxidation of  $\text{NO}_2^-$  by  $\text{O}_2$ . The fraction oxidized increased with time. The time course and its detailed features will be discussed elsewhere. The catalytic activity virtually disappeared when  $\text{O}_2$  was not supplied to the aqueous suspension. (3)  $\text{Bi}_2\text{O}_3$  and  $\text{CdS}$  are the intermediate between the two groups described above. These substances appreciably oxidized  $\text{NO}_2^-$  with oxygen under illumination. They still exhibited photocatalytic activity to a certain extent even in the absence of oxygen. The fraction oxidized increased with time. These substances were inactive in the dark. (4)  $\text{PbO}_2$  and  $\text{MoO}_3$  oxidized  $\text{NO}_2^-$  with or without oxygen and illumination. These substances appear to work simply as oxidants.

$\text{TiO}_2$  (anatase),  $\text{ZnO}$ ,  $\text{CdS}$ , and  $\text{Bi}_2\text{O}_3$  showed little or no photocatalytic activity, when cut-off filters were placed in the beam to eliminate radiation of wave length shorter than the respective band gap energies (410, 410, 520, 480 nm). Hence, the reactions were obviously initiated by the electron-hole formation in semiconductors by illumination.

$\text{TiO}_2$ ,  $\text{ZnO}$ ,  $\text{Si}$ , and  $\text{SnO}_2$  allow  $\text{NO}_2^-$  to be photochemically oxidized in the presence of  $\text{O}_2$ .  $\text{O}_2$  will react in the following two mechanisms. If the oxidation of  $\text{NO}_2^-$  proceeds in an electrochemical local cell mechanism,  $\text{O}_2$  will scavenge electrons from the conduction band of the semiconductors;  $\text{O}_2$  will simply be reduced to  $\text{OH}^-$  or  $\text{H}_2\text{O}$  (cathodic process).  $\text{NO}_2^-$  will in turn be oxidized by positive holes from the valence band in a reaction such as

Table 1. Oxidized fraction of  $\text{NO}_2^-$  to  $\text{NO}_3^-$  for 1 h.

	Band gap energy eV	Illuminated			Dark	Illuminated through cut-off filters
		with $\text{O}_2$	without $\text{O}_2$	with $\text{Cu}^{2+}$	with $\text{O}_2$	with $\text{O}_2$
$\text{Ag}_2\text{O}$		0.18	0.19	0.79	0.02	
$\text{PbO}$	2.8	0.30	0.25	0.00	0.01	
$\text{TiO}_2$ (anatase)	3.2	0.96 <sup>a)</sup>	0.02	0.04	0.01	0.01
$\text{ZnO}$	3.2	0.50 <sup>a)</sup>	0.02	0.28	0.04	0.03
$\text{Si}$	1.1	0.12	0.02	0.03	0.00	
$\text{SnO}_2$	3.8	0.04	0.02	0.02	0.00	
$\text{CdS}$	2.5	0.28	0.17	0.02	0.01	0.01
$\text{Bi}_2\text{O}_3$	2.6	0.45	0.13	0.07	0.03	0.04
$\text{PbO}_2$		0.17	0.14		0.22	
$\text{MoO}_3$		0.17	0.18		0.14	

a) The reaction time 30 min.

If this is the case, anodic and cathodic processes proceed separately.  $\text{NO}_2^-$  will be oxidized to  $\text{NO}_3^-$  without  $\text{O}_2$ .

Alternatively, oxygen is known to be photoadsorbed on semiconductor surfaces as  $\text{O}_2^-$  and converted to  $\text{HO}_2\cdot$  or  $\text{HO}_2^-$ . Several workers suggested that these intermediate species derived from  $\text{O}_2$  are involved with various photocatalytic reactions.<sup>4,10,11)</sup> These oxygen containing species have been confirmed by ESR in aqueous suspension systems.<sup>12,13)</sup> These species would oxidize  $\text{NO}_2^-$  to  $\text{NO}_3^-$  in the present aqueous suspensions.

$\text{Cu}^{2+}$  was added as an electron scavenger to aqueous suspensions ( $52 \times 10^{-6}$  mol  $\text{dm}^{-3}$ ) under purified  $\text{N}_2$  atmosphere. The oxidation of  $\text{NO}_2^-$  took place in  $\text{ZnO}$  suspension, as presented in Table 1. Thus, the electrochemical local cell mechanism is likely to proceed in  $\text{ZnO}$  suspension to a great extent. However,  $\text{Cu}^{2+}$  does not appear to act as an electron scavenger in  $\text{TiO}_2$  (anatase),  $\text{Si}$ , and  $\text{SnO}_2$  suspensions. The other mechanism via intermediate oxygen containing species will proceed in  $\text{TiO}_2$  (anatase),  $\text{Si}$ , and  $\text{SnO}_2$  systems, although the details of the mechanism are not yet clarified.

The photochemical activity of  $\text{Ag}_2\text{O}$  was enhanced in the presence of  $\text{Cu}^{2+}$ , whereas that of  $\text{PbO}$  disappeared. The activity of  $\text{CdS}$  and  $\text{Bi}_2\text{O}_3$  also dropped with  $\text{Cu}^{2+}$  in the aqueous suspensions. The electrochemical local cell mechanism will substantially proceed in  $\text{Ag}_2\text{O}$  suspension and partially in  $\text{Bi}_2\text{O}_3$  suspension. The detailed reaction mechanisms for the individual catalyst powders are now under investigation in this laboratory.

The authors would like to thank Dr. H. Tatsumoto for his analysis of metallic

ions. This work was partially supported by the Toyota Foundation.
