A Convenient Method for the Preparation of Secondary Propargylic Ethers. The Reaction of Acetals with 1-Trimethylsilylalkynes Promoted by the Combined Use of Catalytic Amounts of Tin(IV) Chloride and Zinc Chloride

Masaji HAYASHI, Atsuro INUBUSHI, and Teruaki MUKAIYAMA

Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162

In the coexistence of catalytic amounts of SnCl<sub>4</sub> and ZnCl<sub>2</sub>, acetals undergo a coupling with 1-trimethylsilylalkynes in good yields to give secondary propargylic ethers, which are also directly produced from aldehydes by the reaction with alkoxytrimethylsilanes and 1-trimethylsilylalkynes under the same conditions.

Recently, trityl cation promoted carbon-carbon bond forming reactions  $^{1}$ ) have been developed in our laboratory, and it becomes apparent that a stoichiometric amount of Lewis acid, such as  ${\rm TiCl}_4$ ,  $^{2}$ ) is not necessarily required in these acid promoted reactions of carbonyl compounds with various silyl nucleophiles. During our continuing work on the development of efficient promotors, a useful carbon-carbon bond forming reaction was studied by the combined use of catalytic amounts of various Lewis acids.  $^{3}$ )

The reaction of 1-trimethylsilylalkynes with acetals generally requires an equimolar amount or a large excess of Lewis acids, such as  ${\rm TiCl_4}$ , <sup>4)</sup> and it was also shown that the above mentioned reaction was hardly promoted by a catalytic amount of the activators. In this communication, we wish to describe that the reaction of 1-trimethylsilylalkynes with acetals takes place smoothly in the coexistence of catalytic amounts of  ${\rm SnCl_4}$  and  ${\rm ZnCl_2}$  to give secondary propargylic ethers. The ethers can be also obtained directly from aldehydes, alkoxytrimethylsilanes and 1-trimethylsilylalkynes under the same conditions.

In the first place, cinnamaldehyde dimethyl acetal was treated with 1-trimethylsilylethynylbenzene( $\underline{1}$ ) in the presence of 10 mol% of  $\mathrm{TrClo_4}^5$ ) to afford the corresponding propargylic ether in 23% yield. But most of other acetals, such as 3-phenylpropanal dimethyl acetal ( $\underline{2}$ ), did not react with  $\underline{1}$ , or only a trace of the desired products were obtained. So, we tried the reaction of  $\underline{2}$  with  $\underline{1}$  in the coexistence of 10 mol% each of  $\mathrm{TiCl_4}$  and  $\mathrm{SnCl_2}$ , and it was found that the reaction took place smoothly in  $\mathrm{CH_2Cl_2}$  at 0 °C to give the product  $\underline{3}$  in 47% yield.

- a) Reactions were carried out in  $CH_2Cl_2$  with 1.0 equivalent of  $\underline{1}$  except for entries 8 and 9.
- In all experiments, 10 mol% catalysts were used. b)
- c) Ref. 6.d) Molar ratio of 1:2=1.5:1.

After screening various combinations of metal salts by taking the reaction of  $\underline{2}$  with  $\underline{1}$  as a probe, it was found that the reaction proceeded smoothly in  $CH_2Cl_2$ at the room temperature by the combined use of SnCl<sub>4</sub> and ZnCl<sub>2</sub> as the catalyst to afford the desired product (3) in an excellent yield (85%) (Table 1).

Next, according to this method, the reaction of various acetals (4) with 1trimethylsilylalkynes (5) was tried (see Table 2), and the corresponding secondary propargylic ethers (6) were obtained in good yields.

It is assumed that \*SnCl3-ZnCl3 species is initially generated from SnCl4 and ZnCl<sub>2</sub>, and while <sup>+</sup>SnCl<sub>3</sub> activates acetals, <sup>-</sup>ZnCl<sub>3</sub> attacks silicon atom of 1trimethylsilylalkynes to form TMS-Cl-ZnCl2 like species which is in turn transformed into  $\mathtt{TMS-OR}^2$  and the original catalytic species as sketched below.

$$R^{1} = \begin{bmatrix} -\frac{1}{2} & -\frac{1}{2} &$$

extracts were dried over MgSO4. After evaporation of the solvent, the residue was purified by preparative TLC (silica gel) to afford 1,5-diphenyl-3-methoxypent -1-yne (0.85 mmol, 85%).

From the synthetic point of view, it is more desirable to prepare secondary propargylic ethers directly from aldehydes instead of acetals in the above reaction. Based on this consideration, the reaction of the hemiacetal-type compounds 7 with 1 was tried. As shown in Table 3, it was found that in the coexistence of 20 mol% of  $SnCl_4$  and  $ZnCl_2$ , adducts  $\underline{7}$  were initially formed from alkoxytrimethylsilanes and aldehydes, and  $\underline{7}$  reacted in turn with  $\underline{1}$  to form the desired secondary propargylic ethers  $(\underline{6})$ .

It was reported from our laboratory that allyl ethers reacted with an allylsilane to afford 1,5-diene derivatives by the use of a catalytic amount of  $TrClO_{4}$ . This result suggests us to develop a convenient method of the two carbon-carbon bonds formation. Secondary propargylic ethers thus obtained have a potentiality of coupling with other nucleophile such as an allylsilane. The desired 1,5-ene-yne derivative ( $\underline{a}$ ) was obtained in good yield when  $\underline{a}$  was treated with allyltrimethylsilane in the coexistence of 20 mol% each of SnCl4 and ZnCl2.8)

$$\xrightarrow{\text{Cat.}}$$
 Ph  $\xrightarrow{\text{Cat.}}$  Ph  $\xrightarrow{\text{Cat.}}$  Ph  $(56\%)$ 

It is noted that the combined use of  $SnCl_4$  and  $ZnCl_2$  effectively promotes the reaction of 1-trimethylsilylalkynes with an acetal, and also secondary propargylic ethers thus obtained are converted into 1,5-ene-yne derivatives by the reaction with allyltrimethylsilane in the presence of the same catalyst. Further studies directed to useful carbon-carbon bond forming reactions utilizing the above mentioned promoter are currently in progress.
