2,2'-Dihydroxy-1,1'-binaphthyl,  $C_{20}H_{14}O_2$ , forms crystalline inclusion compounds of stoichiometries  $1\frac{1}{2}C_{20}H_{14}O_2 \cdot 3MOH \cdot 8H_2O$  ( $M = Li, Na, K$ ),  $C_{20}H_{14}O_2 \cdot CsOH \cdot 6H_2O$ , and  $2C_{20}H_{14}O_2 \cdot 2NH_3 \cdot CH_3OH$ . In the crystal structure of the  $NH_3$  complex, the three molecular components are interlinked by hydrogen bonds to form a column with a hydrophilic stem and a hydrophobic sheath.

2,2'-Dihydroxy-1,1'-binaphthyl ( $C_{20}H_{14}O_2$ , commonly known as bis- $\beta$ -naphthol), **1**, has been found to be a very effective host compound for the isolation<sup>1)</sup> and optical resolution<sup>2)</sup> of a wide range of organic guest species through the formation of crystalline inclusion complexes.<sup>3)</sup> We now report the preparation and structural characterization of a series of new inclusion compounds (formulas **2** to **6**) of **1** with alkali metal hydroxides and ammonia.

$C_{20}H_{14}O_2$  (**1**)

Typical procedures in preparing the complexes are as follows. When a mixture of **1** (1 g) and 20% aqueous NaOH solution (5 ml) was kept at room temperature for 12 h, colorless prisms (1.5 g, mp not clear) of **3** was obtained.

In a similar manner,  $\overset{\sim}{6}$  was obtained as colorless prisms (1.7 g, mp not clear) when a mixture of  $\overset{\sim}{1}$  (1 g) and 5 ml of methanol saturated with ammonia was kept at room temperature for 12 h.

Compounds  $\overset{\sim}{2}$  -  $\overset{\sim}{5}$  are air-sensitive but may be kept for weeks in a sealed tube without apparent decomposition. The alkali metal contents of  $\overset{\sim}{2}$  -  $\overset{\sim}{5}$  were determined by the flame emission technique using a Varian AA-4 atomic absorption spectrophotometer. In each instance a freshly prepared sample was quickly dried by pressing between filter paper and immediately weighed and dissolved for triplicate analysis. In the determination of cesium, a known excess of potassium was added as an ionization suppressor to enhance its emission intensity in the air-acetylene flame. The experimental results (% by weight: Li, 3.57; Na 9.92; K, 15.72; Cs 24.19) obtained for  $\overset{\sim}{2}$  -  $\overset{\sim}{5}$  were consistent with those (Li, 3.23; Na, 9.94; K, 15.81; Cs 24.42) calculated from the stoichiometric formulas  $1\frac{1}{2}C_{20}H_{14}O_2 \cdot 3MOH \cdot 8H_2O$  ( $M = Li, Na, K$ ) and  $C_{20}H_{14}O_2 \cdot CsOH \cdot 6H_2O$ . The formulation of the isomorphous sodium and potassium complexes was substantiated by X-ray crystallographic analysis, but the lithium and cesium complexes did not yield suitable crystals for unit-cell and density measurements.

X-Ray crystallographic studies of  $\overset{\sim}{3}$ ,  $\overset{\sim}{4}$ , and  $\overset{\sim}{6}$  proceeded in the same manner. Densities were determined by flotation in a mixture of hexane and carbon tetrachloride. A selected crystal was sealed inside a 0.5 mm Lindemann glass capillary, and intensity data were collected on a Nicolet R3m diffractometer using Mo-K $_{\alpha}$  radiation ( $\lambda = 0.71069 \text{ \AA}$ ) as described previously.<sup>4)</sup> For  $\overset{\sim}{3}$  and  $\overset{\sim}{4}$  the intensities declined rapidly with increasing Bragg angle.

Crystal data:  $\overset{\sim}{3}$ , FW = 693.81, tetragonal, space group  $I4_1/a$ ,  $a = 19.298(5)$ ,  $c = 37.357(8) \text{ \AA}$ ,  $V = 13912(6) \text{ \AA}^3$ ,  $Z = 16$ ,  $F(000) = 5839$ ,  $D_m = 1.341$ ,  $D_c = 1.325 \text{ g cm}^{-3}$ , crystal size  $0.40 \times 0.24 \times 0.20 \text{ mm}^3$ ,  $\mu = 1.27 \text{ cm}^{-1}$ ,  $2\theta_{max} = 40^\circ$ , 2401 unique reflections, 1450 observed,  $R = 0.218$ ;  $\overset{\sim}{4}$ , FW = 741.94,  $a = 19.303(6)$ ,  $c = 37.549(8) \text{ \AA}$ ,  $V = 13991(7) \text{ \AA}^3$ ,  $F(000) = 6223$ ,  $D_m = 1.393$ ,  $D_c = 1.409 \text{ g cm}^{-3}$ , crystal size  $0.42 \times 0.40 \times 0.32 \text{ mm}^3$ ,  $\mu = 4.49 \text{ cm}^{-1}$ ,  $2\theta_{max} = 40^\circ$ , 2554 unique data, 1617 observed,  $R = 0.275$ ;  $\overset{\sim}{6}$ , FW = 638.76, monoclinic, space group  $P2_1/c$ ,  $a = 11.136(2)$ ,  $b = 19.853(5)$ ,  $c = 15.314(3) \text{ \AA}$ ,  $\beta = 91.36(1)^\circ$ ,  $V = 3384.7(9) \text{ \AA}^3$ ,  $Z = 4$ ,  $F(000) = 1352$ ,  $D_m = 1.250$ ,  $D_c = 1.254 \text{ g cm}^{-3}$ , crystal size  $0.56 \times 0.52 \times 0.46 \text{ mm}^3$ ,  $\mu = 0.87 \text{ cm}^{-1}$ , 4848 unique reflections, 3671 observed,  $R = 0.059$ . The structures were solved by direct phase determination guided by negative quartets.<sup>5)</sup> All computations were performed on a Data General Nova 3/12 minicomputer with the SHELXTL package.<sup>6,7)</sup>

In the crystal structure of  $\overset{\sim}{3}$  and  $\overset{\sim}{4}$ , one host molecule ( $\overset{\sim}{1}$ ) occupies Wyckoff position 8(e) of site symmetry 2, whereas the other is in a general position. The structure is highly disordered, such that two alkali metal atoms and three of the water/hydroxide oxygen atoms failed to appear in a difference Fourier map. The single ordered metal atom is coordinated to a phenolic oxygen atom and two water/hydroxide oxygen atoms, but other atoms occupying the remaining ligand sites could not be located. The occurrence of liquid-like regions in the solid lattice may be a common structural feature of the newly-discovered crystalline inclusion compounds formed by phenol- and propynol-type hosts with alkali metal and ammonium hydroxides.<sup>8)</sup>

Fig. 1. Stereodrawing of the crystal structure of  $2C_{20}H_{14}O_2 \cdot 2NH_3 \cdot CH_3OH$ ,  $\zeta$ . The origin of the unit cell lies at the upper left corner, with  $\underline{a}$  pointing towards the reader,  $\underline{b}$  downwards, and  $\underline{c}$  from left to right. The blackened, shaded, and open circles represent C, N, and O atoms, respectively. Hydrogen bonds are indicated by broken lines.

The crystal structure of  $\zeta$  is shown in Fig. 1. The phenolic groups, ammonia molecules, and methanol molecules are interlinked by hydrogen bonds to form a column with a hydrophilic stem and a hydrophobic sheath. Geometrical details of the hydrogen bonding in the stem are illustrated in Fig. 2. The crystal lattice is constructed from a lateral packing of such infinite columns, all of which are oriented in the direction of the  $\underline{a}$  axis.

Atom numbering scheme for the asymmetric unit in  $\zeta$ .

Fig. 2. Details of the hydrogen bonding in the hydrophilic stem of a column in the crystal structure of  $\mathbf{6}$ . For clarity the aromatic rings have been omitted, so that molecule  $\mathbf{1}$  [torsion angles  $C(1)-C(10)-C(11)-C(12) = 86.8(3)^\circ$  and  $C(21)-C(30)-C(31)-C(32) = -101.3(3)^\circ$ ] appears like 1,4-butanediol. Symmetry transformations: <sup>a</sup>  $1-x, 1-y, 1-z$ ; <sup>b</sup>  $-x, 1-y, 1-z$ ; <sup>c</sup>  $1+x, y, z$ ; <sup>d</sup>  $-1+x, y, z$ . The standard deviation of each hydrogen bond length is about  $0.007 \text{ \AA}$ .
