Several single and mixed oxides were used as sensors for detection of  $\text{CO}$ ,  $\text{CO}_2$ ,  $\text{NO}$ , and  $\text{NO}_2$ . The conductivity of  $(\text{Cr}_2\text{O}_3)_{1-x}(\text{Nb}_2\text{O}_5)_x$  was greatly changed by a contact with 1-1000 ppm of  $\text{NO}$ , but was unchanged by that with  $\text{CO}$  or  $\text{CO}_2$ . The sensitivity to  $\text{NO}$  was maximum by operating at 573 K using oxide with  $x=0.1$ . The influence of  $\text{CO}$  during detection of  $\text{NO}$  was negligible at  $x=0.5$ .

Oxide semiconductors have been widely used for various chemical sensors.<sup>1-2)</sup> Typical examples in practical use are  $\text{SnO}_2$  or  $\gamma\text{-Fe}_2\text{O}_3$  based oxides for combustible gas sensors.<sup>3)</sup> Recently, the sensors for poisonous gases are requested increasingly for security and to avoid air pollution. A small and cheap nitrogen monoxide sensor is one of the important subjects. Although the chemical luminescence method has been popularly employed for  $\text{NO}$  detection, some materials for  $\text{NO}$  sensor have been proposed for miniaturization or simplification of the detection system. The  $\text{NO}$  sensors proposed so far utilize semiconductive properties of oxides<sup>4)</sup> or organic thin films,<sup>5-6)</sup> a galvanic cell, and a solid electrolyte.<sup>7)</sup> Of these types of sensors, oxide semiconductors are advantageous in their stability and cost but generally lack in selectivity. In the present study, we tried to develop the sensitivity and selectivity of  $\text{NO}$  sensor using several single and mixed oxides. Influences of  $\text{CO}$ ,  $\text{CO}_2$ , and  $\text{NO}_2$  on the detection of  $\text{NO}$  were also studied.

Mixed oxides were prepared by coprecipitation or evaporation of aqueous solutions of corresponding metal nitrates. The powders thus obtained were calcined at 723 K for 5 h, and then pressed into disks (10 mm in diameter and 0.5 mm thick). After heating at 773 K for 2 h, a Pt paste was applied on both faces of the disks and again fired at 873 K for 30 min. Conductivities of the disks were measured in a flow system with a quartz cell in a temperature range of 473 K to 873 K. Various concentrations of  $\text{NO}$ ,  $\text{NO}_2$ ,  $\text{CO}$ , and  $\text{CO}_2$  were obtained by mixing with dry air. Seebeck coefficients of pellet samples (5 mm x 5 mm x 10 mm) were measured at 573 K. The measurement was performed in a controlled partial pressure of oxygen. Partial pressure of oxygen, which was monitored by yttria-stabilized zirconia oxygen sensor, was controlled either by diluting  $\text{O}_2$  with  $\text{N}_2$  ( $1\text{-}10^{-4}$  atm) or by using a gaseous mixture of  $\text{CO}$  and  $\text{CO}_2$  ( $10^{-10}\text{-}10^{-18}$  atm).

Conductivities of various oxides were measured under a flow of air with or without 600 ppm of  $\text{NO}$ ,  $\text{NO}_2$ ,  $\text{CO}$ , and  $\text{CO}_2$ , as summarized in Table 1. The sensitivity of the response is defined as the ratio of the conductivity change of an oxide with gas adsorption to the conductivity in air,  $\sigma/\sigma_{\text{air}}$ , where  $\sigma$  and  $\sigma_{\text{air}}$  stand for conductivities in a sample gas and air, respectively. The selectivity of sensors is

a) Conductivity in air.

b) Sensitivity =  $(\sigma - \sigma_{\text{air}}) / \sigma_{\text{air}}$ .

discussed by comparing the cross sensitivity at a given concentration of each gas. Tin and zinc oxides, which are well-known as sensors for combustible gases, underwent large change in conductivity with adsorption of NO, though the conductivity changes were larger for CO than for NO. All the single metal oxides listed in Table 1 did not achieved a sufficient selectivity for NO detection. The conductivity of every metal oxide examined here was unchanged by introduction of CO<sub>2</sub>. The conductivities of Cr<sub>2</sub>O<sub>3</sub>-ZnO, Nb<sub>2</sub>O<sub>5</sub>-Al<sub>2</sub>O<sub>3</sub>, SnO<sub>2</sub>-TiO<sub>2</sub>, and V<sub>2</sub>O<sub>5</sub>-ZrO<sub>2</sub> were unchanged with an exposure to either NO, NO<sub>2</sub>, CO, or CO<sub>2</sub>. Mixing of oxides sometimes gave rise to enhancement of the sensor

performance. Especially, the sensitivity to CO was six times larger for Al<sub>2</sub>O<sub>3</sub>-ZnO than that for single ZnO. The high sensitivity of Al<sub>2</sub>O<sub>3</sub>-ZnO appears to result from its large surface area, increasing adsorption amount, and low conductivity. Although Al<sub>2</sub>O<sub>3</sub>-ZnO and ZrO<sub>2</sub>-ZnO were sensitive to NO, these oxides are not adequate for a

Fig. 1. Temperature dependence of sensitivity of Cr<sub>2</sub>O<sub>3</sub>-Nb<sub>2</sub>O<sub>5</sub> to NO, NO<sub>2</sub>, CO, and CO<sub>2</sub>. (gas concentration 600 ppm)

selective NO sensor because of their higher sensitivity to CO. The conductivity of  $\text{Cr}_2\text{O}_3\text{-Nb}_2\text{O}_5$  was largely changed with adsorption of NO and  $\text{NO}_2$  at 573 K, but were unaffected with that of CO and  $\text{CO}_2$ . Further study was focused on the  $\text{Cr}_2\text{O}_3\text{-Nb}_2\text{O}_5$  system as a NO sensor.

The sensitivity of the  $\text{Cr}_2\text{O}_3\text{-Nb}_2\text{O}_5$  element depended on the operation temperature as shown in Fig. 1. The sensitivity to NO was maximum at 573 K and decreased with either increasing or decreasing temperature. On the other hands, sensor became sensitive to CO with increasing temperature up to 673 K. It is obvious that the optimum operation temperature of  $\text{Cr}_2\text{O}_3\text{-Nb}_2\text{O}_5$  is about 573 K from the requests of sensitivity and selectivity.

The sensitivity of  $\text{Cr}_2\text{O}_3\text{-Nb}_2\text{O}_5$  is examined as a function of the concentrations of NO,  $\text{NO}_2$ , CO, and  $\text{CO}_2$  at 573 K in Fig. 2. The sensitivity of  $\text{Cr}_2\text{O}_3\text{-Nb}_2\text{O}_5$  decreased with increasing concentrations of NO,  $\text{NO}_2$ , and CO, but the sensitivity to NO was the largest among these gases. Therefore, the  $\text{Cr}_2\text{O}_3\text{-Nb}_2\text{O}_5$  sample is selective and sensitive enough for detection of NO. With introducing 600 ppm of NO abruptly, 80% of the steady response was attained within 50 s. Subsequent purge with air restored 80% of the original level within 90 s.

The Seebeck coefficient of  $\text{Cr}_2\text{O}_3\text{-Nb}_2\text{O}_5$  was obtained from thermoelectromotive force as a function of partial pressure of oxygen (Fig. 3). The equimolar oxide of  $\text{Cr}_2\text{O}_3\text{-Nb}_2\text{O}_5$  possessed positive Seebeck coefficient in the  $P_{\text{O}_2}$  range of  $10^{-17}$  to 1 atm. This agreed with observed p-type response with introduction of a small amount of CO, NO, and

Fig. 2. Dependence of  $\text{Cr}_2\text{O}_3\text{-Nb}_2\text{O}_5$  sensitivity on concentration of NO,  $\text{NO}_2$ , CO, and  $\text{CO}_2$  in air. (operation temperature 573 K)

Fig. 3. Dependence of Seebeck coefficient of  $\text{Cr}_2\text{O}_3\text{-Nb}_2\text{O}_5$  on partial pressure of oxygen. ( $\text{Cr}_2\text{O}_3 : \text{Nb}_2\text{O}_5 = 5 : 5$ )

$\text{NO}_2$ , as mentioned above. Seebeck coefficient decreased monotonously and the sample changed into n-type semiconductor at very low  $P_{\text{O}_2}$  ( $10^{-18}$  atm).

The composition dependence of sensitivity as well as conductivity in air of the system  $(\text{Cr}_2\text{O}_3)_{1-x}(\text{Nb}_2\text{O}_5)_x$  are shown in Fig. 4. The oxide system of  $(\text{Cr}_2\text{O}_3)_{1-x}(\text{Nb}_2\text{O}_5)_x$  was insensitive to  $\text{CO}_2$  over the whole composition range. It is noted that with increasing  $x$ , the sign of sensitivity was reversed at about  $x=0.7$ . Namely, the conductivity of sample decreased by a contact with  $\text{NO}$ ,  $\text{NO}_2$ , or  $\text{CO}$  at  $x=0.5$ , while it increased at  $x=0.7$ . Since pure  $\text{Cr}_2\text{O}_3$  and  $\text{Nb}_2\text{O}_5$  are p- and n-type semiconductors, respectively, the change of the sign occurs at intermediate composition. The sensitivity to  $\text{NO}$  was the highest at  $x=0.9$ , but almost zero at  $x=0.7$ . On the other hand, the sensitivity to  $\text{CO}$  was very small around the equimolar composition. The oxide with  $x=0.9$  was sensitive to  $\text{NO}$ , though this sensor was also sensitive to  $\text{CO}$  and  $\text{NO}_2$ . When the selectivity is required for  $\text{NO}$  detection, one should choose the sample with  $x=0.5$ . The sensitivity and selectivity of sensor elements were greatly enhanced by mixing of  $\text{Cr}_2\text{O}_3$  and  $\text{Nb}_2\text{O}_5$ . This mixed oxide system is excellent in its selectivity for detection of  $\text{NO}$ .

Fig. 4. Effects of oxide composition on the sensitivity of  $(\text{Cr}_2\text{O}_3)_{1-x}(\text{Nb}_2\text{O}_5)_x$  mixed oxides. (operation temperature 573 K, gas concentration 600 ppm)
