Enantioselective synthesis has been achieved using chiral compounds arising from mono- and dideuterated methyl groups as chiral inducers in conjunction with asymmetric autocatalysis. The absolute configuration of the product was controlled by the small degree of chirality generated by the difference between the partially deuterated methyl groups (CDH₂ and CD₂H) and the non-deuterated methyl group (CH₃) in *N*-benzoyl- α -methylalanine.

It is known that substitution of atoms for their isotopes often generates chiral compounds.^{1,2} However, enantioselective synthesis using chiral compounds arising from isotope substitution is a challenging problem.^{3–5} There have been a few reports on enantioselective synthesis using chiral compounds arising from deuterium substitution.³ However, the enantiomeric excess (ee) of the products induced by the deuterated chiral compounds was very low because the isotopes had almost the same electronic and steric structures.⁶

We studied asymmetric autocatalysis of pyrimidyl alkanols,^{7–9} in which a chiral product acts as the chiral catalyst for its own production with a significant enhancement of the ee.¹⁰ Asymmetric autocatalysis enables an amplification of the ee from extremely low ee values (ca. 0.00005% ee) to >99.5% ee during three consecutive reactions.^{11,12} Chiral compounds act as chiral initiators of asymmetric autocatalysis to afford highly enantioenriched pyrimidyl alkanols with an absolute configuration corresponding to the chirality of the initiator.¹³

We have previously reported on asymmetric autocatalysis using chiral compounds arising from a deuterium substitution of the enantiotopic hydrogen atoms, i.e., for benzyl alcohol- α -*d* and glycine- α -*d*.¹⁴ However, in these cases, the ratio of the exact mass difference between deuterium (D) and hydrogen (H) is relatively large, i.e., 99.8% of the mass of an H atom. On the other hand, the difference in mass ratio between the (partially) deuterated methyl groups (CDH₂, CD₂H, and CD₃) and CH₃ is much smaller, as shown in Figure 1. It is noteworthy that the exact difference in mass is only 6.7% between monodeuterated CDH₂ and CH₃ groups. Thus, asymmetric induction mediated using chiral compounds arising from partially deuterated enantiotopic methyl groups is a challenge. To the best of our knowledge, there have been no reports on enantioselective synthesis induced by chiral compounds arising from partially deuterated enantiotopic methyl groups.

Here, we report on a highly enantioselective synthesis induced by *N*-benzoyl- α -methyl-*d*₁-alanine and *N*-benzoyl- α -methyl-*d*₂-alanine in conjunction with asymmetric autocatalysis (Chart 1 and Scheme 1). We chose *N*-benzoyl- α -methylalanine (1) as our model compound, and chiral (*S*) and (*R*)-*d*_{1–3}-1 having deuterated methyl groups were then synthesized.¹⁵

Figure 1. Generation of asymmetric carbon atom by deuterium substitution of enantiotopic hydrogen atoms and methyl groups.

Scheme 1. Asymmetric autocatalysis triggered by isotopically (D/H) chiral *N*-benzoyl- α -methylalanine (1).

When pyrimidine-5-carbaldehyde **2** and diisopropylzinc (*i*-Pr₂Zn) were reacted in the presence of (*R*)-*N*-benzoyl- α -methyl-*d*₁-alanine **1**, (*R*)-pyrimidyl alkanol **3** with an 87% ee was obtained (Table 1, Entry 1). On the other hand, the reaction using (*S*)-*d*₁-1 afforded (*S*)-**3** with an 85% ee (Entry 2). The correlation between the absolute configurations of the chiral initiator and alkanol **3** produced exhibited a nice reproducibility, i.e., (*R*)- and (*S*)-*d*₁-1 afforded (*R*)- and (*S*)-**3** (84%–90% ee), respectively (Entries 3 and 4). When a smaller amount

^aUnless otherwise noted, asymmetric autocatalysis was performed as follows. A 1 M toluene solution of *i*-Pr₂Zn (0.075 mL) was added to 0.5 mL of (*R*)-*d*₁-**1** (0.025 mmol) in toluene at 0 °C. After the mixture was stirred for a period of 30 min at 0 °C, a toluene solution (0.2 mL) of pyrimidine-5-carbaldehyde **2** (4.7 mg, 0.025 mmol) was added to the mixture over a period of 1.5 h. The mixture was then stirred for 12 h, and toluene (1.1 mL), a 1 M toluene solution of *i*-Pr₂Zn (0.2 mL) and aldehyde **2** (18.8 mg, 0.10 mmol) in toluene (0.5 mL) were added. After a period of 3 h, toluene (7.2 mL), a 1 M toluene solution of *i*-Pr₂Zn (0.80 mL), and **2** (75.3 mg, 0.4 mmol) were then added over a period of 1 h at 0 °C, and the mixture was stirred for a period of 1.5 h. The reaction was quenched using a mixture of 30% aqueous ammonia and a saturated aqueous ammonium chloride (2/1, v/v) solution (10 mL). The mixture was extracted three times using ethyl acetate. The combined organic layers were dried over anhydrous sodium sulfate and evaporated in vacuo. Purification of the residue using silica gel column chromatography (hexane/ethyl acetate = 3/1, v/v) gave (*R*)-5-pyrimidyl alkanol **3** with an 85% ee in an 87% yield. ^bAs to the ee of the initiators, see the Supporting Information and refs. 14b, 15, and 16. ^cIsolated yield. ^dThe ee value was determined by HPLC on a chiral stationary phase (Daicel Chiralcel IB). ^eReduced amount of chiral initiator (0.0025 mmol) was submitted to the reaction. ^fAdditional rounds of asymmetric autocatalysis were performed for the purpose of further amplification of ee. See also ref. 11.

(10 mol %) of (*R*)- or (*S*)-*d*₁-**1** was used as the chiral initiator, the same stereochemical correlation was observed, although the ee of the product was moderate (Entries 5 and 6). It should be noted that further asymmetric autocatalysis amplified the ee to >99.5% ee (Entries 7 and 8).

In the same manner, (*R*)- and (*S*)-*N*-benzoyl- α -methyl-*d*₂-alanine **1** afforded the (*R*)- and (*S*)-pyrimidyl alkanols **3** with a

high ee (80%–88% ee), respectively (Entries 9–12). Again, the ee reached >99.5% after an additional asymmetric autocatalysis (Entries 13 and 14). In addition, *N*-benzoyl- α -methyl-*d*₃-alanines, (*R*)- and (*S*)-*d*₃-**1**, were employed as the chiral initiators. The same correlation was observed as with the *d* and *d*₂ analogs (Entries 15–22).

In summary, we have demonstrated the first example of asymmetric induction, in conjunction with asymmetric autocatalysis, using chiral compounds arising from the partial deuteration of enantiotopic methyl groups.
