Prussian-blue-modified magnetite (PB-Fe<sub>3</sub>O<sub>4</sub>) was prepared by a simple method. The Cs<sup>+</sup> sorption ability of PB-Fe<sub>3</sub>O<sub>4</sub> was evaluated by batch magnetic separation. As a result, the maximum sorption amount of Cs<sup>+</sup> with PB-Fe<sub>3</sub>O<sub>4</sub> was 16.2 mg g<sup>-1</sup>, and the sorption ability was not greatly changed in the presence of high concentration of NaCl. The recovery of PB-Fe<sub>3</sub>O<sub>4</sub> from water by magnet predicted that it was sufficiently applicable to treatment of water contaminated with radioactive Cs<sup>+</sup>.

Today, Japan is faced with a critical pollution problem with radioactive species such as cesium (Cs), strontium (Sr), and iodine (I) spilled from the Fukushima nuclear power plant (NPP). Therefore, easy and safe methods to treat and analyze radioactive materials in environments of soil and water are required. Prussian blue (PB) is known as a low-cost adsorbent, which has a high selectivity for cesium (Cs) and a high stability for decomposition.<sup>1,2</sup> Therefore, PB has been used as an adsorbent for the removal of Cs<sup>+</sup> uptaken into an organism.<sup>3</sup> The basic structure of PB is a three-dimensional polymeric network with a face-centered cubic cell consisting of alternating iron(III) (coordinated to nitrogen) and iron(II) (coordinated to carbon atom) ions linked via the bridging of cyanide ligands.<sup>4,5</sup> Most of sorbed Cs<sup>+</sup> is introduced in the lattice of PB. However, PB crystal is small, and thus the microcrystalline nature of PB is not adequate to column loading, filtration, and centrifugation after Cs<sup>+</sup> sorption. A magnetic separation using magnetic materials such as hematite (Fe<sub>2</sub>O<sub>3</sub>) and magnetite (Fe<sub>3</sub>O<sub>4</sub>) is an easy and quick method to collect and separate target compounds from water, and recently it has been applied to various fields such as analytical biochemistry, medical science, and biotechnology.<sup>6-8</sup> The magnetic separation has an advantage in the recovery of adsorbent with harmful matter without filtration and centrifugation after adsorption. Several studies on magnetic separation have been reported about the treatment methods for heavy metal ions and organic pollutants by using modified Fe<sub>3</sub>O<sub>4</sub>.<sup>9-12</sup>

The purpose of this study is to develop an easy and safe method for treatment of Cs<sup>+</sup> in water using PB-modified Fe<sub>3</sub>O<sub>4</sub> (PB-Fe<sub>3</sub>O<sub>4</sub>). The column method is used widely for water treatment, and the treatment of coolant containing radioactive species at Fukushima NPP is also performed by the column method. However, use of columns requires the consideration of clogging and water leaks, and sometimes generates back pressure. Furthermore, columns constructed with several pieces of equipment are often complicated systems, and so there is a high probability of mechanical failure. Our proposed method is very simple and has few of the problems described above. Moreover, this method can be applied to turbid solutions containing many kinds of suspended matter. Since only

**Figure 1.** Schematic representation of PB-Fe<sub>3</sub>O<sub>4</sub> and lattice structure of PB.

magnetic sorbents are recovered by the magnet easily, the sorbent can be used again for treatment. So this method can be applied to not only coolant solution but also wastewater in various conditions. Thus, we prepared PB-Fe<sub>3</sub>O<sub>4</sub> as follows and evaluated the magnetic method using PB-Fe<sub>3</sub>O<sub>4</sub>. The image of PB-Fe<sub>3</sub>O<sub>4</sub> is shown in Figure 1.

At first, Fe<sub>3</sub>O<sub>4</sub> was prepared in the following manner.<sup>13</sup> 5.2 g of FeCl<sub>3</sub>·6H<sub>2</sub>O and 2.0 g of FeCl<sub>2</sub>·4H<sub>2</sub>O were dissolved in 25 mL of deionized water (DW), and then 0.85 mL of 12 M HCl was added in the solution. The solution was added to 250 mL of 1.5 M NaOH solution with vigorous stirring at 80 °C. After 60 min with stirring, the mixed solution was cooled by water, and then the Fe<sub>3</sub>O<sub>4</sub> collected by magnet was washed with DW until the pH of supernatant was around 7. DW for preparation of solution was used after purging with N<sub>2</sub>. The surface area of Fe<sub>3</sub>O<sub>4</sub> was measured by Autosorb6 (YUASA), and the result was 7.82 m<sup>2</sup> g<sup>-1</sup>. The modification of PB on the Fe<sub>3</sub>O<sub>4</sub> surface using potassium hexacyanidoferrate(II) (K<sub>4</sub>[Fe(CN)<sub>6</sub>]).<sup>14</sup>

100 mg of Fe<sub>3</sub>O<sub>4</sub> was added into 100 mL of 2.0 mM K<sub>4</sub>[Fe(CN)<sub>6</sub>] solution (pH 2 with HCl), and then the mixture was stirred for 3 h. The PB-Fe<sub>3</sub>O<sub>4</sub> collected by magnet was washed with water three times and then dried in an oven at 40 °C for 24 h. All reagents were provided by Wako, Japan. Scanning electron microscopy (SEM, JSM-7400F JEOL) and transmission electron microscopy (TEM, JEM-2100F JEOL) images of PB-Fe<sub>3</sub>O<sub>4</sub> are shown in Figure 2. Core-shell structure of PB-Fe<sub>3</sub>O<sub>4</sub> and crystal of PB on Fe<sub>3</sub>O<sub>4</sub> can be observed in Figures 2b and 2c, respectively. The size of PB crystal grain on Fe<sub>3</sub>O<sub>4</sub> was about 100 nm, and the thickness of PB layer on Fe<sub>3</sub>O<sub>4</sub> was 200–400 nm from TEM images. The presence of PB modified on Fe<sub>3</sub>O<sub>4</sub> was confirmed by powder X-ray diffraction (XRD) and Fourier transform infrared spectroscopy (FT-IR). The XRD pattern measurements were performed by Miniflex (Rigaku) with Ni filtered Cu Kα radiation (λ = 0.154 nm) at 35 kV, 15 mA. As shown in Figure 3a, the peaks of (220), (311), (222), (400), (422), (511), and (440) were detected as the characteristic

**Figure 2.** SEM (a) and TEM (b, c) images of PB-Fe<sub>3</sub>O<sub>4</sub>.

**Figure 3.** XRD patterns of Fe<sub>3</sub>O<sub>4</sub> (a) and PB-Fe<sub>3</sub>O<sub>4</sub> (b).

peaks of Fe<sub>3</sub>O<sub>4</sub>.<sup>15</sup> After PB modification, some new peaks, marked peaks of Figure 3b, coincided with the characteristic peaks of PB.<sup>16</sup> The FT-IR measurements were carried out with FT/IR-4100 (JASCO) in KBr pellets. In Figure S2,<sup>20</sup> peaks at around 1610 cm<sup>-1</sup> observed in curve (a) and (b) were related to the -OH deformed vibration, and the peaks around 3400 cm<sup>-1</sup> in curve (a) and (b) were assigned to the -OH stretching vibration on the surface of Fe<sub>3</sub>O<sub>4</sub>.<sup>17,18</sup> The peak of 2082 cm<sup>-1</sup> in curve (b) was assigned to the CN stretching in the formed [Fe<sup>II</sup>-CN-Fe<sup>III</sup>] structure.<sup>19</sup> The size and  $\zeta$  potential of Fe<sub>3</sub>O<sub>4</sub> and PB-Fe<sub>3</sub>O<sub>4</sub> were measured by using photon correlation spectroscopy (PCS) and electrophoretic light scattering (ELS), respectively (Delsa™ nano HC, Beckman Coulter). As a result, the average particle sizes of Fe<sub>3</sub>O<sub>4</sub> and PB-Fe<sub>3</sub>O<sub>4</sub> were 6.4 and 6.7  $\mu$ m, respectively. The  $\zeta$  potentials of Fe<sub>3</sub>O<sub>4</sub> and PB-Fe<sub>3</sub>O<sub>4</sub> were 20 and -79 mV at pH 5.5 (Figure S1).<sup>20</sup> The amount of modified PB estimated by gravimetry was 0.29 mmol g<sup>-1</sup> (Figure S2 and Table S1).<sup>20</sup> The sorption ability of PB-Fe<sub>3</sub>O<sub>4</sub> for Cs<sup>+</sup> was evaluated by sorption experiments. The batch experiments were carried out using 10 mL of Cs<sup>+</sup> solution and 10 mg of PB-Fe<sub>3</sub>O<sub>4</sub> at pH 5.5 (uncontrolled) and 25 °C, and then PB-Fe<sub>3</sub>O<sub>4</sub> was collected by Nd-Fe-B magnet (0.4 T, 25 × 10 × 5 mm<sup>3</sup>) after sorption. Cs<sup>+</sup> concentration in supernatant was measured by ICP-MS (SPQ 6500, SEIKO). Figure 4 showed the results of sorption in various concentrations of Cs<sup>+</sup> (0.01–0.5 mM). The results indicated that the sorption amount of Cs<sup>+</sup> onto PB-Fe<sub>3</sub>O<sub>4</sub> was increased with increase in the concentration of Cs<sup>+</sup> in the solution. The sorption results were fitted to a Langmuir model and Freundlich model to obtain the maximum sorption amount of Cs<sup>+</sup> onto PB-Fe<sub>3</sub>O<sub>4</sub>. Both fitting results were favorable to

**Figure 4.** Adsorption isotherm of Cs<sup>+</sup> onto PB-Fe<sub>3</sub>O<sub>4</sub>.

**Figure 5.** Kinetics of Cs<sup>+</sup> sorption onto PB-Fe<sub>3</sub>O<sub>4</sub> on 0.001 (closed circle), 0.01 (closed triangle), and 0.1 mM (closed square) of Cs<sup>+</sup> with NaCl and without NaCl (open square).

these models, but the result of Freundlich was slightly better than that of the Langmuir (the correlation coefficient with Freundlich model: 0.977 and with Langmuir model: 0.975 according to Table S2).<sup>20</sup> The maximum sorption amount from the fitting data of Langmuir model was 16.2 mg g<sup>-1</sup>. Freundlich model is generally said to well fit the sorption on porous material such as activated carbon. On the other hand, the Langmuir model is well fitted to monolayer adsorption. Since the layer of the lattice structure of PB formed on Fe<sub>3</sub>O<sub>4</sub> was relatively thin, the property of PB-Fe<sub>3</sub>O<sub>4</sub> as porous material was not significantly pronounced. As a result, the sorption behavior might also fit well for the Langmuir model. Figure 5 indicated the results of sorption rate of Cs<sup>+</sup> onto PB-Fe<sub>3</sub>O<sub>4</sub> and influence of coexisting salt on sorption of Cs<sup>+</sup>, where concentrations were

0.001, 0.01, and 0.1 mM. The concentration of coexisting NaCl was 3 wt%, the same as that of seawater. According to these results, most of Cs<sup>+</sup> sorbed onto PB-Fe<sub>3</sub>O<sub>4</sub> within the first 60 min in all cases. In 0.01 and 0.1 mM Cs<sup>+</sup> solution, Cs<sup>+</sup> sorbed slowly after 60 min. The presence of two different sorption rates of Cs<sup>+</sup> suggests that the sorption site of Cs<sup>+</sup> in the sorbent is not only the surface of PB layer but also the inside of PB lattice. Moreover, the influence of coexisting salt on the sorption of Cs<sup>+</sup> by PB-Fe<sub>3</sub>O<sub>4</sub> was evaluated by comparison between sorption behaviors of Cs<sup>+</sup> in 0.1 mM Cs<sup>+</sup> solution with and without NaCl. The amount of sorbed Cs<sup>+</sup> from water containing NaCl was 91% of that without NaCl. It was found that the ability of Cs<sup>+</sup> sorption with PB-Fe<sub>3</sub>O<sub>4</sub> was present even with low concentration Cs<sup>+</sup> under the high matrix conditions.

The recovery of PB-Fe<sub>3</sub>O<sub>4</sub> from water by a magnet was evaluated by measuring weight of collected PB-Fe<sub>3</sub>O<sub>4</sub>. The recovery test was performed in the following way. First, 100 mg of PB-Fe<sub>3</sub>O<sub>4</sub> was dispersed in 1 L of water. Then, the PB-Fe<sub>3</sub>O<sub>4</sub> was recovered by magnet at various times with stirring. The recovered PB-Fe<sub>3</sub>O<sub>4</sub> was dried at 40 °C for 24 h in an oven and then the weight measured. According to the results, the recovery ratio of PB-Fe<sub>3</sub>O<sub>4</sub> was almost 100% at 6 min (Figure S3).<sup>20</sup> Thus, the good recovering ability of PB-Fe<sub>3</sub>O<sub>4</sub> was useful in the water treatment process. If the particle size of PB-Fe<sub>3</sub>O<sub>4</sub> is smaller than the case in our study, the sorption amount of Cs<sup>+</sup> will be increased because of increasing surface area and modified amount of PB. However, the decrease in the particle size of PB-Fe<sub>3</sub>O<sub>4</sub> may lead to the reduction of recovery because of weaker magnetic strength.

Based on our study, a full automation system for treatment of contaminated water may be feasible if a hanged electrical magnet is used for collection of PB-Fe<sub>3</sub>O<sub>4</sub> after sorption of Cs<sup>+</sup>. It will make possible to treat the contaminated water with radioactive Cs<sup>+</sup> with few exposure.

We thank Professor F. Matsuda (Hokkaido University) for the IR measurement, Associate Professor Y. Kamiya (Hokkaido University) for the XRD measurement and Dr. H.W. Yu (Hokkaido University) for the TEM. The analysis of surface area, particle size distribution, and ζ potential were carried out with Autosorb6 and Delsa™ nano HC at the OPEN FACILITY, Hokkaido University Sousei Hall.
