Ten new dimethine dyes of the quinostyrene type are prepared by condensing α -pyrrole aldehyde with various 1-arylquinaldinium salts. The absorption spectra of the new dyes are observed in the visible region in various neutral solvents. The dyes are shown to exhibit solvatochromism, and the spectroscopic data are analyzed.

Continuing work on the synthesis of styrene dyes based on 1-arylquinaldinium salts, and on investigating their optical and biological properties [1, 2], we

Absorption spectra of dye I:

- 1) in MeOH; 2) in Me₂CO;
- 3) in EtOH; 4) in dioxane;
- 5) in CHCl₃; 6) in dichloroethane; 7) in benzene.

have condensed such salts with α -pyrrole aldehyde, and consequently obtained a series of pyrrole dimethine dyes, analogs of quinostyrenes. Equimolecular quantities of pyrrole aldehyde and the appropriate salt were reacted at 115–120° in dry pyridine, yields being 62–95%, the equation is

| Dye | R | Ar | X |
|------|--------------------|--|------------------|
| I | H | C ₆ H ₅ | ClO ₄ |
| II | 6-CH ₃ | <i>p</i> -CH ₃ C ₆ H ₄ | ClO ₄ |
| III | 5,6-benzo | C ₆ H ₅ | I |
| IV | 5,6-benzo | <i>p</i> -CH ₃ C ₆ H ₄ | ClO ₄ |
| V | 5,6-benzo | <i>p</i> -OCH ₃ C ₆ H ₄ | ClO ₄ |
| VI | 5,8-benzo | <i>o</i> -ClC ₆ H ₄ | ClO ₄ |
| VII | 5,8-benzo | β -C ₆ H ₅ | ClO ₄ |
| VIII | H | α -C ₆ H ₅ | ClO ₄ |
| IX | 6-CH ₃ | α -C ₆ H ₅ | ClO ₄ |
| X | 6-OCH ₃ | α -C ₆ H ₅ | ClO ₄ |

All the new dyes were readily soluble in pyridine, ethanol, methanol, acetone, chloroform, dioxane, and dichloroethane, less soluble in benzene, and insoluble in carbon tetrachloride, hexane, ether, and water.

Solution color depended on the nature of the solvent. All the dyes exhibited negative solvatochromism, i. e., color deepening with decrease in solvent polarity (Table 1). The figure gives the absorption curves for dye I. Like the quinostyrenes, all the dyes give a single absorption maximum independent of the solvent.

Solvatochromism is known to be shown by interionic dyes, which can have two structures—one nonpolar, and the other that of a dipolar ion. The actual structure of the molecule and the color of the dye solution depending on the polarizing ability of the solvent. However a number of authors [4, 5] describe the negative centers, e. g., in the case of 1-alkylpyridinium salts. The authors explain this phenomenon by reversal of the dipole at the instant of excitation by a light quantum. The energy expended on this reversal depends on the polarizing force of the solvent, and affects the light quantum. Mushkalo [6] observed solvatochromism with cyanine dyes of noninterionic structure, with a hydrogen atom instead of a radical on the ring nitrogen atom, and explained this solely by hydrogen bonding between the NH group and the O-containing solvent, as the absorption maximum in all oxygen-containing solvents (EtOH, acetone, formamide) was the same, and higher than in chloroform. A number of other authors [7–9] regard hydrogen bonding as playing a substantial but not basic role in solvatochromism. The dimethine dyes considered in this paper do not have an interionic structure, but are dipolar compounds existing only as betaines. In addition the molecule of each dye contains the NH group of the pyrrole ring, determining the possibility of hydrogen bonding with the solvents. Analysis of the spectroscopic data of Table 1 shows that for all the dyes the deepest coloring is in benzene, and the highest in acetone. On passing from acetone to benzene the bathochromic shift of the absorption maximum is 32–40 nm. However on passing from benzene to dioxane the very small bathochromic shift of the absorption maximum which the decrease in dielectric constant (ϵ) would lead one to expect, is not observed, but instead a hypsochromic shift of 15–20 nm. Furthermore changing from ethanol and methanol to acetone leads to a small (3–10 nm) hypsochromic shift of the absorption maximum compared with the bathochromic shift which ϵ values would lead one to expect. The general relationship between the increase in absorption maximum and decrease in ϵ shows separation of solvents containing O, capable of hydrogen bonding with the NH group of the pyrrole ring of the molecule.

*For part LXXIV see [1].

Table 1
Absorption Maxima of Dyes I-X in Various Solvents
(nm)*

| Solvent | Dielectric constant | Dye | | | | | | | | | |
|----------------|---------------------|-----|-----|-----|-----|-----|-----|-----|------|-----|-----|
| | | I | II | III | IV | V | VI | VII | VIII | IX | X |
| Dioxane | 2 | 503 | 503 | 510 | 511 | 510 | 520 | 506 | 508 | 508 | 508 |
| Benzene | 2.23 | 519 | 518 | 528 | 528 | 524 | — | 527 | 526 | 522 | 523 |
| Chloroform | 5.1 | 514 | 511 | 521 | 520 | 521 | 525 | 515 | 519 | 517 | 518 |
| Dichloroethane | 10.16 | 493 | 490 | 504 | 502 | 498 | 492 | 503 | 502 | 496 | 499 |
| Acetone | 21.45 | 484 | 482 | 490 | 488 | 492 | 493 | 490 | 489 | 490 | 489 |
| Ethanol | 25.8 | 490 | 494 | 497 | 496 | 494 | 503 | 495 | 498 | 493 | 498 |
| Methanol | 33.7 | 488 | 483 | 492 | 494 | 493 | 500 | 491 | 495 | 495 | 496 |

*A SF-2M instrument was used to measure the spectra.

Table 2
Properties of Dyes

| Dye | Heat- ing time, min | Appearance | Mp, °C (decomp.) | Formula | N, % | | Yield, % |
|------|------------------------------|--|---------------------|---|------------|-----------------|-------------|
| | | | | | Found | Calcu- lated | |
| I | 60 | Dark cherry red crystals, with reflex | 204-205 | C ₂₁ H ₁₇ ClN ₂ O ₄ | 7.08, 7.10 | 7.05 | 78.5 |
| II | 60 | Cherry red needles | 234-235 | C ₂₃ H ₂₁ ClN ₂ O ₄ | 6.50, 6.52 | 6.60 | 86 |
| III | 60 | Brown powder | 225-227 | C ₂₅ H ₁₉ IN ₂ | 5.79, 5.90 | 5.91 | 62.6 |
| IV | 60 | Brown crystals | 257-259 | C ₂₆ H ₂₁ IN ₂ | 5.72, 6.05 | 5.75 | 95 |
| V | 50 | Dark green shining needles | 258-260 | C ₂₆ H ₂₁ ClN ₂ O ₅ | 5.87, 5.90 | 5.88 | 88 |
| VI | 60 | Dark red crystals with glitter | >300 | C ₂₅ H ₁₈ Cl ₂ N ₂ O ₄ | 5.74, 5.96 | 5.81 | 62.5 |
| VII | 120 | Brown powder | 211-217 | C ₂₉ H ₂₁ ClN ₂ O ₄ | 5.62, 5.85 | 5.77 | 82.7 |
| VIII | 90 | Dark cherry red crystals, with reflex | 210-215 | C ₂₅ H ₁₉ ClN ₂ O ₄ | 6.15, 6.34 | 6.27 | 95.5 |
| IX | 60 | Dark green shining needles | 221-223 | C ₂₆ H ₂₁ ClN ₂ O ₄ | 5.73, 6.00 | 6.08 | 87 |
| X | 120 | Brown powder | 205-208 | C ₂₇ H ₂₁ ClN ₂ O ₅ | 5.70, 5.98 | 5.88 | 95 |

*Crystallized from iso-BuOH; compounds V and VI can also be crystallized from EtOH, and VI and IX from acetone.

So we are inclined to explain the solvatochromism of the dyes prepared by, on the one hand, reversal of the dipole of the molecule when excited by a light quantum whose value will be less, the smaller the ϵ of the solvent. In other words with decrease in the solvent ϵ , the dye solution absorption maximum is displaced towards the longer wavelengths region. This was also found on passing from methanol to benzene. On the other hand, a considerable part is played by hydrogen bonds requiring for the same ϵ value, expenditures of more energy, i. e., large light quanta, resulting in a hypsochromic shift of the absorption maximum. This is particularly clearly evident in the case of benzene-dioxane, where the dielectric constant is practically the same, but there is a hypsochromic shift of the absorption maximum (Table 1).

EXPERIMENTAL

For the preparation of the 1-arylquinaldinium salts see [10-20].

α -(1-Phenylquinolyl-2)- β -(pyrrolyl-2)ethylene perchlorate (I).

A mixture of 0.3 g (0.001 mole) 1-phenylquinaldinium perchlorate, 0.1 g (0.0011 mole) α -pyrrole aldehyde [13], and 2 ml dry pyridine was refluxed for 1 hr. The dye was precipitated with ether, washed with hot water, and crystallized from EtOH. Recrystallization from isobutanol gave minute dark cherry red crystals exhibiting a glitter, mp 204° (decomp), yield 0.31 g (78.5%).

The other dyes were obtained similarly. Dyes II and VI crystallized out on cooling the reaction products, and were washed with ether to remove traces of aldehyde.

Table 2 gives all the experimental results and dye properties.

The solvents for spectroscopy were purified as described in [14].
