

NOVEL REARRANGEMENTS AND FORMATION OF 2,5-DIHYDRO-1,2,5-OXONIASTANNABORATOLES

via METHANOLYSIS OF ZWITTERIONIC

η^2 -(ALKYN-1-YL-BORATE)ALKENYLTIN COMPOUNDS*

Bernd Wrackmeyer, Gerald Kehr, Sabine Willbold, and Roland Boese

Organo-substituted 2,5-dihydro-1,2,5-oxoniastannaboratoles **3** were prepared by methanolysis of zwitterionic η^2 -(alkyn-1-ylborate)alkenyltin compounds **1**. Analogously, the bis[η^2 -(alkyn-1-ylborate)alkenyltin derivative **2** reacts with an excess of methanol to give a dimeric MeO-bridged 2,5-dihydro-1,2,5-oxoniastannaboratole (**10a**)₂. Various intermediates could be identified by NMR spectroscopy, and the molecular structure of (**10a**)₂ was determined by X-ray analysis. The structures of several products of the methanolysis indicate that protolysis of an Sn–C= bond occurs first, followed by an MeO/alkenyl exchange reaction.

1. INTRODUCTION

The reaction of organoboron [1–6] or organotin compounds [7–10] with OH acidic reagents provides a preparative useful route to the synthesis of hydrocarbons, e.g., in the synthesis of alkenes from the reaction of alkenylboranes or stannanes with methanol. However, if both dialkylboryl and trialkylstannyl groups are attached to a C=C bond (**A**), a number of less expected products are formed, e.g., as the result of protolysis of an Sn-alkyl bond and rearrangement and/or addition reactions [11] (bonds are indicated that are likely to be attacked by methanol if a more or less weak O–B coordinative bond has been formed).

This work reports on the reaction of the zwitterionic compounds **1** and **2** with methanol. There are numerous reactive sites in these compounds, even more than in **A**, considering the presence of bridging alkynyl groups and the enhanced Lewis-acidic character of the tin atom in the stannyl group. These compounds **1** [12–17] and **2** [18–20] are intermediates, which could be isolated at low temperature in the course of 1,1-organoboration reactions [21] of bis(alkyn-1-yl)tin and tetrakis(alkyn-1-yl)tin compounds with triorganoboranes. The reactions of **1** and **2** with methanol were studied in a stoichiometric ratio as well as in excess of methanol. The reactivity of compound **2** towards less reactive alcohols such as ethanol, isopropanol, and

* Dedicated to the 100th Anniversary of A. N. Nesmeyanov's birth.

tert-butanol was also studied. NMR spectroscopic measurements between 208–298 K served for monitoring the progress of the reactions and for the characterization of the products (^1H , ^{11}B , ^{13}C , and ^{119}Sn NMR). In the case of one of the final reaction products of **2** with methanol, the molecular structure of a novel dimer was determined by X-ray structural analysis.

2. RESULTS AND DISCUSSION

2.1. Reactions of Compounds **1** with Methanol

All reactions of **1** with one equivalent of methanol lead to the 2,5-dihydro-2-stanna-1-oxonia-5-boratoles **3**, irrespective of the solvent (THF or hexane), accompanied by elimination of one equivalent of the respective terminal alkyne, as shown in Scheme 1 (the corresponding 2,5-dihydro-1,2,5-oxoniaplumbaboratole is formed if the reaction of **1(Pb)** with MeOH is carried out [18]). The selective formation of the heterocycles **3a** and **3c** is observed at 208 K and 263 K, respectively, whereas **3b** is generated together with **6b** at 298 K. It is known that the bridging alkynyl group can readily move back from the boron to the tin atom. Therefore, a nucleophilic attack of MeOH at the boron atom may shift the alkynyl group to the tin atom (corresponding to an S_N2 mechanism) to give an adduct as shown in **A**, followed by protolysis of the Sn–C≡ bond. Since there is an intramolecular coordinative N–Sn bond in **1c**, this mechanism is more likely than primary nucleophilic attack at the tin atom. In the cases of

Scheme 1

1a,b, the present data do not allow one to distinguish it from coordination of MeOH to the formally cationic tin center in **1** in the first step, followed by elimination of the alkyne in consecutive protolysis and exchange reactions.

Addition of an excess of methanol causes further reactions at room temperature only in the case of **3a**. The first product is **4a** and (*Z*)-hept-3-ene **5a** is the final product (Scheme 1). The compounds **3b** and **3c** are not attacked by an excess of methanol.

The formation of **6b** requires a more detailed explanation (Scheme 2). Since the reaction of **1b** with methanol is slow, it competes with intramolecular 1,1-alkylboration [21]. The latter process leads to the 1,4-stannabora-cyclohexa-2,5-diene **7b** [22]. All NMR spectroscopic evidence indicates that **7b** prefers a half-chair conformation [23] in which the boron atom is shifted out of the plane formed by the two C=C units and the tin atom. This conformation facilitates the coordination of methanol to the boron atom in the way shown in **B**, and protolysis of one of the Sn–C= bonds can readily take place.

Scheme 2

The protolysis of the Sn–C= bond is followed by intramolecular O–B coordination to give the cyclic intermediate **C** (see the compounds **3**). The intermediate **C** can rearrange into **6b** by intramolecular exchange of the alkenyl and the methoxy group. This explains the positions of Et and *i*-Pr in one alkenyl group groups in **6b** which differ from those in **7b**.

2.2. Reaction of Compound **2** with Methanol

The reaction of the compound **2** with two equivalents of methanol should lead at first, in analogy to the observation in the case of **1**, by elimination of one equivalent of propyne, to the 2,5-dihydro-2-stanna-1-oxoniaboratoles **D** and **E**, in which the latter contains the second equivalent of MeOH bonded as a Lewis base.

Scheme 3

From **E** a second equivalent of propyne can be eliminated, and **8a** is formed by ring closure. The compound **8a** is detected already at 223 K; it is stable only under these mild reaction conditions, and it contains an undefined amount of coordinated methanol. It decomposes when the reaction mixture is warmed to room temperature to give (*Z*)-pent-2-ene, various methoxyboranes, and tin methoxides. Alternatively, under less mild reaction conditions (in the presence of an excess of MeOH), a product **9a** is formed which gives **10a**, and finally the dimer $(10a)_2$. Thus **8a** could be a precursor of **10a**, and the compounds **8a** and **9a** possess the intermediates **D** and **E** as common precursors.

The comparison of the structures of **8a** and **9a** shows that the positions of Me and Et in one of the alkenyl groups are different. Again it is conceivable that protolysis of an $\text{Sn}-\text{C}=\text{C}$ bond occurs first, followed by exchange reactions, as outlined in the case of **6b** (*vide supra*).

The reaction of **2** with ethanol or 2-propanol gives compounds analogous to **9a**, and dimerization is not observed. In the case of *tert*-butanol, the reaction was extremely slow at room temperature, and defined final products could not be identified.

2.3. NMR Spectroscopic Results

The proposed structures of the products are based on consistent NMR data sets and on data for comparison (Tables 1–5). The ¹H NMR spectra are often fairly complex as a result of overlapping signals. However, the position of the proton at the C=C bond (e.g., in **6b** or in (**10a**)₂) is clearly indicated by the splitting due to ³J(¹H, ¹H). ¹¹B NMR spectra reveal the presence of tri- or tetra-coordinate boron atoms. Thus, the δ ¹¹B = +53.0 for **6b** is typical [24,25] of a diorganoboron-oxygen compound, and the δ ¹¹B data for **3** and **8–12** (δ = 7–9) indicate the coordination number 4 for the boron atoms [24,25]. ¹³C and ¹¹⁹Sn NMR spectra are conclusive since the ^{117/119}Sn satellites owing to J(Sn, ¹³C) yield valuable structural information, and the δ ¹¹⁹Sn values [26] are also typical of certain structural features. In the ¹³C NMR spectra, there are also broad signals owing to partially relaxed ¹³C–¹¹B scalar one-bond coupling [27] which are useful for the assignment. The δ ¹¹⁹Sn value of **6b** (–81.0) is typical of dialkenyltin compounds [26], and δ ¹¹⁹Sn values of **3a,b** (+197.7, 174.3) indicate the neighborhood of the tin atom to an oxonium-type oxygen [28]. In the case of **3c** (δ ¹¹⁹Sn –23.2), the increase in ¹¹⁹Sn nuclear shielding when compared with that in **3a,b** indicates an intramolecular N–Sn coordination, and this is also evident from the relative increase in the magnitude of |¹J(Sn, ¹³C)|, as predicted by Bent's model of rehybridization [29]. Similar effects are always found in the cases of the compounds of type **3** with THF [e.g., **11(THF)** or **12(THF)**] or MeOH, or **8** with MeOH, **9** with THF or MeOH, and in the dimer (**10a**)₂.

2.4. X-Ray Structural Analysis of Compound (10a)₂

The molecular structure of the crystallographically centrosymmetric (10a)₂ is shown in Fig. 1 [30], and selected bond lengths and bond angles are given in the legend. There is a central planar four-membered ring accompanied by two almost planar five-membered rings which are in mutual *trans* positions and in *endo* positions with respect to the central ring. The five-membered rings form an interplanar angle of 58.8° against the plane of the

central ring. The surroundings of the tin atoms are distorted trigonal bipyramidal. The oxygen atom $\text{O}_{(2A)}$ of a bridging methoxy group ($d_{\text{Sn}(1)-\text{O}_{(2A)}} = 205.9\text{ pm}$), $\text{C}_{(1)}$ of the 2,5-dihydro-1,2,5-oxoniastannaboratole fragment, and $\text{C}_{(11)}$ of the alkenyl group (disordered) lie in the equatorial plane (sum of bond angles 359.8°). The axial positions are occupied each by two oxygen atoms $\text{O}_{(1)}$ (oxonia) and the $\text{O}_{(2)}$ from the second bridging methoxy group (angle $\text{O}_{(1)}-\text{Sn}_{(1)}-\text{O}_{(2)} = 160.3^\circ$). This is in agreement with comparable tin oxygen compounds, in which the axial positions are always occupied by oxygen atoms [31–33].

The distance $d_{\text{Sn}(1)-\text{O}_{(2)}} = 224.6\text{ pm}$ is enlarged with respect to $d_{\text{Sn}(1)-\text{O}_{(2A)}}$ (*vide supra*) and indicates a dative O–Sn bond, although it is shorter than for coordinated THF (in **12(THF)**: $d_{\text{Sn}-\text{O}(\text{THF})} = 242.4\text{ pm}$ [34]).

3. CONCLUSIONS

It has been shown that the zwitterionic intermediates from 1,1-organoboration reactions possess numerous reactive sites which can be used to form new heterocyclic compounds. Interestingly, the methanolysis reaction appears to take place first at the Sn–C= bond, assisted by the presence of the boryl group in *cis* position to the stannyl group. This causes novel rearrangements of the boron-bonded alkenyl group.

4. EXPERIMENTAL

4.1. General, Starting Materials, and Instrumentation

All synthetic work and the handling of compounds was carried out in an argon atmosphere, using carefully dried solvents and dry glassware, observing all precautions to exclude oxygen and moisture. Starting materials were prepared following literature procedures: **1a,b** [12], **1c** [13], **2** [14]. EI-Mass spectra (70 eV): Varian MAT-CH-7 with a direct inlet. NMR spectra measured from samples in 5 mm tubes: Jeol FX90Q [^1H (29.7 MHz), ^{119}Sn (33.6 MHz)]; Bruker AC 300 [^1H , ^{11}B (99.0 MHz), ^{13}C (75.5 MHz), ^{119}Sn (111.9 MHz)]; Bruker AM 500 [^1H , ^{13}C (125.8 MHz), ^{119}Sn (186.5 MHz)]; chemical shifts are given with respect to the residual signal of the respective deuterated solvent [δ ^1H (Me_4Si) = 0], to the signal of the deuterated solvent [δ ^{13}C (Me_4Si) = 0], to external $\text{Et}_2\text{O}\text{-BF}_3$ [δ ^{11}B = 0 for $\Xi(^{11}\text{B})$ = 32.983971 MHz], and to external Me_4Sn [δ ^{119}Sn = 0 for $\Xi(^{119}\text{Sn})$ = 37.290665 MHz].

4.2. Synthesis

2,5-Dihydro-3-substituted 4,5,5-Trialkyl-2,2-dimethyl-1,2,5-oxoniastannaboratoles 3a–c. A solution of **1** (0.4 mmol) in CHCl_3 (0.5 ml) is cooled to -78°C , and MeOH (0.4 mmol; 16.2 μl) is injected. After warming to room temperature and removing all volatile material *in vacuo* (0.1 Torr), **3a** and **3c** are left in the pure state as a colorless liquid or a yellow oil, respectively. The compound **3b** is formed in mixture with **6b**.

Compound 3a: ^1H NMR spectrum (CDCl_3): d [$^nJ(^{119}\text{Sn}^1\text{H})$] = 0.50 [49.5] (s, 6H, SnMe_2); 2.11 (br), 0.50 (br) (10H, BEt_2); 1.97 (q), 0.87 (t) (5H, Et); 2.37 (t), 1.29 (m), 0.94 (t) (7H, Pr); 3.23 [9.8] (s, 3H, OMe).

Compound 3b: ^1H NMR spectrum (CDCl_3): d [$^nJ(^{119}\text{Sn}^1\text{H})$] = 0.56 [48.2] (s, 6H, SnMe_2); 0.84 (d), (12H, $\text{B}(\text{CHMe}_2)_2$), 2.59 (m), 1.11 (d) (7H, *i*-Pr); 2.63 (q), 0.84 (t), (5H, Et); 3.39 [11.7] (s, 3H, OMe); some signals were not assigned due to overlap.

Compound 3c: ^1H NMR spectrum (CDCl_3): d [$^nJ(^{119}\text{Sn}^1\text{H})$] = 0.32 [62.7] (s, 6H, SnMe_2); 0.08 (br), 0.43 (t) (10H, BEt_2); 1.98 (q), 0.81 (t) (5H, Et); 3.39 [87.0] (s), 2.29 (s) (8H, CH_2NMe_2); 3.01 [5.5] (s, 3H, OMe).

2,5-Diethyl-1,4-diisopropyl-1-isopropyl(methoxy)boryl-3,3-dimethyl-3-stanna-1,4-pentadiene (6b): ^1H NMR spectrum (CDCl_3): d [$^nJ(^{119}\text{Sn}^1\text{H})$] = 0.21 [49.9] (s, 6H, SnMe_2); 1.06 (d), (12H, $\text{B}(\text{CHMe}_2)_2$), 2.98 (m), 0.97 (d) (7H, *i*-PrC(Sn)=); 2.42 (q), 0.96 (t), (5H, EtC(Sn)=); 2.12 (m), 0.98 (m), (5H, EtC(H)=); 2.95 (m), 0.97 (d) (7H, *i*-PrC(B)=); 5.48 (t) (1H, =CH); 3.67 (s, 3H, OMe); some signals were not assigned due to overlap.

Bis{ μ -(2-methoxy)-4,5,5-triethyl-2,5-dihydro-1,3-dimethyl-2-[3'-(*E*)-pent-2'-enyl]-1,2,5-oxoniastannaboratole} (10a)₂. A solution of **2** (1.0 g; 2.1 mmol) in hexane (50 ml) is cooled to -78°C , and MeOH (3 ml) is added in one portion. After stirring at room temperature for 48 h and removing all volatile material *in vacuo* (10^{-3} Torr), a colorless solid is left. Crystallization from hexane gives 0.4 g (49 %) of **(10a)₂**; mp $119\text{--}122^\circ\text{C}$. EI-Mass spectrum ($\text{C}_{32}\text{H}_{66}\text{O}_4\text{B}_2\text{Sn}_2$ [776]): m/z (%) = 357 (38), 189 (100). ^1H NMR spectrum (C_6D_6 , 298 K): d [$^nJ(^{119}\text{Sn}^1\text{H})$] = 5.85 [128.0] (q, 2H; $\text{HC}_{(3')}=$); 3.38 [25.6] [10.2] (s, 6H, OMe); 3.20 [7.1] (s, 6H, MeO-bridge); 2.08 (m, 4H), 0.94 (t, 3H), 0.86 (t, 3H) (Et); 1.90 [110.1] (6H, $\text{MeC}_{(3')}=$); 1.68 [16.0] (d, 6H; $\text{MeC}_{(3')}=$); 0.59 (t, 12H), 0.19 (m, 8H) (BEt_2).

4,5,5-Triethyl-1,3-dimethyl-2-[3'-(*E*)-pent-2'-enyl]-2-(propyn-1'-yl)-2,5-dihydro-1,2,5-oxoniastannaboratole Adducts 9a(EtOH) and 9a(*i*-PrOH). The adducts **9a(EtOH)** and **9a(*i*-PrOH)** are prepared following the description for (**10a**)₂ by using EtOH or *i*-PrOH instead of MeOH. After removing all readily volatile material *in vacuo*, yellow, viscous liquids are obtained. Attempts at distillation led to decomposition, and crystallization from various solvents failed.

9a(*i*-PrOH): ¹H-NMR (C₆D₆) relevant signals: δ [¹J(¹¹⁹Sn¹H)] = 6.38 (q, 1H, =CH); 4.33, 1.56, 1.36 (s, d, d, 7H, (*i*-Pr)PrO); 1.88 (s, 3H, MeC₄₍₅₎=); 1.53 (s, 3H; ≡CMe); 1.10 (d, 3H; MeC₄₍₃₎₇).

4.3. X-Ray Structural Analysis of the Dimer (10a)₂

Crystal: C₃₂H₆₆B₂O₄Sn₂; colorless plate of dimensions 0.32 × 0.26 × 0.09 mm, monoclinic, space group *P*2₁/*c* with lattice parameters *a* = 1128.3(2), *b* = 1429.3(3), *c* = 1176.1(2) pm, β = 100.95(2)°, *V* = 1862.1(7)·10⁶ pm³, *Z* = 2, absorption coefficient μ = 1.372 mm⁻¹, ρ = 1.384 g/cm⁻³.

Data collection: Siemens P4 diffractometer, Mo-Kα radiation, λ = 71.069 pm (graphite monochromator), 109 K, crystal scaled under nitrogen into glass capillary; 2θ range 3° – 55°, ω-scan type, 4417 reflections collected, 4210 independent (*R*_{merge} = 0.0298), observed 3871 (*F*₀ ≥ 4σ(*F*)), empirical psi-scan absorption correction, min/max transmission factors: 0.90/0.75.

Structure solution and refinement: Patterson Methods, full matrix least squares on *F*² (Siemens-SHELXTL Vers. 5.03, 1994), refinement of 217 parameters, all non-hydrogen atoms with anisotropic temperature factors; the hydrogen atoms were described on calculated positions with the 1.2 (1.5 for methyl groups) fold isotropic temperature factors of the equivalent temperature factors of the corresponding carbon atoms applying the riding model; for the disordered carbon atoms, C₁₂ to C₁₅ occupancies were refined and subsequently fixed at 0.6 and 0.4, respectively. The refinement converged at final *R* indices *R*¹ = 0.0362 and *R*² (all data) = 0.0968, max./min. residual difference electron density 1.2·10⁻⁶ pm⁻³.

Support of this work by the Deutsche Forschungsgemeinschaft and Fonds der Chemischen Industrie is gratefully acknowledged.
