

# STRUCTURE OF THE ISOCOUMARIN ARTEMIDIN

A. Mallabaev, I. M. Saitbaeva,  
and G. P. Sidyakin

UDC 547.588.25

For the substance artemidin (I) isolated previously we proposed an isocoumarin structure with a butylene side chain in position 3 of the  $\alpha$ -pyrone ring [1].

This paper gives a proof of the structure of I on the basis of a chemical study of it.

The IR spectrum of artemidin (Fig. 1) has the absorption band of a trans-disubstituted double bond ( $970\text{ cm}^{-1}$ ), whose presence is confirmed by bromination and hydrogenation reactions. The bromination of I gave dibromoartemidin with the composition  $\text{C}_{13}\text{H}_{12}\text{O}_2\text{Br}_2$  (II). The hydrogenation of artemidin in the presence of platinum oxide forms a dihydro derivative  $\text{C}_{13}\text{H}_{14}\text{O}_2$  (III). The IR spectra of dibromoartemidin and dihydroartemidin lack the absorption band of a double bond. The UV spectrum of III retains the maxima characteristic for isocoumarin [2] (Fig. 2), and in its NMR spectrum the signals of the olefinic protons are shifted upfield [1].

When dihydroartemidin was heated with an aqueous solution of caustic potash, a keto acid (IV) was obtained, which shows that the substance has an isocoumarin, but not a coumarin, skeleton [3]. The IR spectrum of the ketoacid has absorption bands at  $1595$ ,  $1570$ , and  $1490\text{ cm}^{-1}$  (aromatic ring),  $1685\text{ cm}^{-1}$  (C=O of a carboxy group),  $1705\text{ cm}^{-1}$  (C=O of a ketone), and  $2650\text{ cm}^{-1}$  (OH group of a dimerized acid). The presence of a ketone group in the saponification product of dihydroartemidin was confirmed by the formation of the 2,4-dinitrophenylhydrazone (V).

The elementary compositions, melting points, and UV spectra of dihydroartemidin, the ketoacid, and its hydrazone agree with those for the corresponding derivatives of capillarin [4-6] (Table 1).

Fig. 1. IR spectra of: a) artemidin (I); b) dihydroartemidin (III); c) the isocarbostryl (VI); d) the ketoacid (IV).

Fig. 2. UV spectra of: 1) artemidin (I); 2) dihydroartemidin (III); 3) the ketoacid (IV).

TABLE 1.

Artemidin derivatives	mp, °C	Capillarin derivatives	mp, °C
Dihydroartemidin	45- 46	Tetrahydrocapillarin	45.5-46.5
Ketoacid from dihydroartemidin	85- 86	Tetrahydrocapillarin acid	85.5-86.5
2,4-Dinitrophenylhydrazone of ketoacid	174-175	2,4-Dinitrophenylhydrazone of tetrahydrocapillarin acid	174-175

When dihydroartemidin was heated in a sealed tube with ammonia, the oxygen of the pyrone ring was replaced by NH with the formation of an isocarbostyryl [4],  $C_{13}H_{15}ON$  (VI). In the IR spectrum (in  $CHCl_3$ ) of this compound the band of the carbonyl group shifted from  $1725$  to  $1665\text{ cm}^{-1}$  and, in addition, a sharp band of an NH group appeared at  $3400\text{ cm}^{-1}$ .

To establish the position of the double bond in the side chain, artemidin was oxidized with chromic anhydride in acetic acid. Propionic acid and isocoumarin-3-carboxylic acid (VII) were isolated from the oxidation products. The methyl ester of the acid (VIII) had the same melting point as authentic methyl isocoumarin-3-carboxylate [7]. Consequently, the double bond in the butylene chain is present in the 1,2 position.

The spectral and chemical information obtained permits structure I to be proposed for artemidin.

## EXPERIMENTAL

The IR spectra were taken on a UR-10 spectrophotometer, the UV spectra on an SF-4A instrument, and the NMR spectra on a JNM-100 instrument. The analytical results of the compounds corresponded to the calculated figures.

**Isolation of Artemidin.** A 10-kg sample of the epigeal part of *Artemisia dracunculus* was extracted with chloroform. The residue after the chloroform had been distilled off (yield 5%) was dissolved in ether. The ethereal solution was extracted with 0.5% KOH solution to eliminate acidic products and then distilled, and the residue was chromatographed on neutral alumina (activity grade IV, ratio 1:10). The column was eluted successively with petroleum ether, benzene, chloroform, and ether. One-liter fractions were collected. Fractions 2-6 were rechromatographed on silica gel (activity grade I, 1:40) and eluted with petroleum ether and a petroleum ether-ether mixture (9:1). When the petroleum ether-ether eluate was concentrated, a crystalline precipitate of artemidin was obtained. The precipitate was separated preparatively on plates with a fixed layer of silica gel in a petroleum ether-acetone (20:1) system. The zones with  $R_f$  0.45 were eluted with ether, giving colorless needles of artemidin  $C_{13}H_{12}O_2$ , mp  $49-50^\circ\text{C}$  (from petroleum ether), mol. wt. 200 (mass spectrometry).

**Hydrogenation of Artemidin.** One gram of artemidin in solution in 10 ml of absolute ethanol was hydrogenated in the presence of 0.1 g of platinum oxide, 200 ml of hydrogen being absorbed in 30 min. After

removal of the catalyst and the solvent, colorless crystals of dihydroartemidin were obtained with mp 45-46°C (from petroleum ether). A mixture with artemidin showed a depression of the melting point.

Bromination of Artemidin. A 3% solution of bromine in  $\text{CHCl}_3$  was added dropwise to a solution of 0.073 g of artemidin in 2 ml of  $\text{CHCl}_3$  until it was no longer decolorized. The dibromo derivative had mp 139-140°C (from methanol), mol. wt. 360 (mass spectrometry).

Saponification of Dihydroartemidin. A mixture of 0.2 g of dihydroartemidin and 50 ml of 5% KOH solution was boiled for 20 min. When the cooled mixture was acidified with 5% HCl, crystals of the ketoacid of dihydroartemidin deposited with mp 85-86°C (from petroleum ether).

2,4-Dinitrophenylhydrazone of the Ketoacid. The ketoacid (0.05 g) was treated with a saturated HCl solution of 2,4-dinitrophenylhydrazine. On standing, crystals appeared in the form of yellow needles (hydrazone) with mp 174-175°C (from ethanol).

Amination of Dihydroartemidin. A mixture of 0.1 g of dihydroartemidin and 2 ml of conc.  $\text{NH}_3$  was heated in a sealed tube at 130-150°C for 5 h. After cooling, crystals of the isocarbostyryl with mp 137-138°C (from acetone) deposited.

Oxidation of Artemidin. A solution of 0.3 g of artemidin in 8 ml of glacial acetic acid was treated with a solution of 0.4 g of chromic anhydride in 10 ml of 50% acetic acid, and the mixture was left to stand for 3 days. Propionic acid was identified in the reaction mixture on a fixed layer of cellulose [in a tertiary butanol-ammonia-water (25:3:5) system] from its  $R_f$  value of 0.55 (with a marker), being shown up by bromophenol blue as a blue spot on a yellow background. The acetic acid was driven off from the mixture at 40-50°C, the residue was treated with a 5% solution of sodium carbonate, the carbonate extract was washed with ether and acidified with 5% HCl, and the isocoumarin-3-carboxylic acid was extracted with ether. Mp of the acid 236-237°C (from ethyl acetate).

Methylation of Isocoumarin-3-carboxylic Acid. An ethereal solution of diazomethane was added to 0.01 g of the acid in 20 ml of ether. The mixture was left for 24 h, after which the solvent was driven off. The residue consisted of methyl isocoumarin-3-carboxylate with mp 172-173°C (from methanol).

## CONCLUSIONS

Structure I has been proposed for artemidin on the basis of the preparation of a number of derivatives and spectral characteristics.
