The genus *Daphne* (Thymelaeaceae), including 44 species, is widely distributed in the southwest and northwest regions of China [1]. The roots or barks of most plants of this genus have been used to treat wound, bruises, and fauritis as a folk medicine in China [2]. *Daphne marginata* is an ornamental plant whose growth is restricted to the South of China. The barks of *D. marginata* were collected in Dayu (Jiangxi province, China) in March 2005, and were authenticated by Prof. Tan Ceming, Jiangxi Plantation Research Institute, China. A voucher specimen is deposited in the Department of Pharmacognosy, Second Military Medical University.

The air dried barks (7.5 kg) of *D. marginata* were extracted with 75% ethanol at room temperature. The EtOH extract was partitioned with petroleum ether, CHCl₃, EtOAc, and *n*-BuOH. Part of the EtOAc extract (50 g) was subjected to column chromatography on silica gel with gradient elution by CHCl₃–MeOH (100:1–1:1) to afford **1–9**.

The compounds were identified using UV, IR, mass, and NMR spectra, and all these data were in good agreement with the literature data [3–10]. All those compounds were isolated from *D. marginata* for the first time. The ¹³C NMR data of compounds **1, 3, 4, 8, 9** are reported in this paper for the first time.
