The genus *Litsea* (Lauraceae) comprises nearly 200 species, which are distributed widely throughout tropical and subtropical Asia, North America, and subtropical South America. *Litsea szemaois* is an endangered species endemic to southern Yunnan, China [1]. To the best of our knowledge, no work has been reported on the chemical constituents of *L. szemaois*.

As part of the continuous research on plants of the *Litsea* genus, we studied the leaves and twigs of *L. szemaois* collected from Yunnan. Seven compounds were isolated from this plant for the first time.

The leaves and twigs were collected from a forest near Mengla, Xishuangbanna, Yunnan in August 2005 and were identified by Mr. Yu Chen, senior scientist of Kunming Institute of Botany. The powdered leaves and twigs of *L. szemaois* (5 kg) were repeatedly extracted with EtOH at room temperature. The extract was then concentrated under reduced pressure to give a brown syrup, which was sequentially partitioned between H<sub>2</sub>O and Et<sub>2</sub>O and *n*-BuOH.

The Et<sub>2</sub>O extract (30 g) was subjected to a series of chromatographic techniques using a silica gel column (mesh 200–300) and Sephadex LH-20.

The *n*-BuOH extracts (70 g) were subjected to silica gel column chromatography, eluting with EtOAc–MeOH (10:1–1:1) and MeOH, and the resulting fractions were subjected to additional separation steps using a silica gel column and Sephadex LH-20 (MeOH).

A total of seven compounds was isolated and identified based on UV, IR, and NMR spectra, including 2D NMR, which allowed complete assignment of the <sup>1</sup>H NMR and <sup>13</sup>C NMR data, and by direct comparison with authentic samples and the literature.
