The reaction of the title cyclic complex (1) with sodium amalgam in THF resulted in the expected cleavage of the Fe—Fe bond to afford bis-sodium salt $(\text{Me}_2\text{SiSiMe}_2)[\eta^5\text{-C}_5\text{H}_4\text{Fe}(\text{CO})_2\text{Na}]_2$ (4). The latter was not isolated and was used directly to react with MeI, PhCH₂Cl, CH₃C(O)Cl, PhC(O)Cl, Cy₃SnCl (Cy = cyclohexyl) or Ph₃SnCl to afford corresponding ring-opened derivatives $(\text{Me}_2\text{SiSiMe}_2)[\eta^5\text{-C}_5\text{H}_4\text{Fe}(\text{CO})_2\text{R}]_2$ [5, R = Me; 6, R = PhCH₂; 7, R = CH₃C(O); 8, R = PhC(O); 9, R = Cy₃Sn or 10, R = Ph₃Sn]. The crystal and molecular structures of 10 were determined by X-ray diffraction analysis. The molecule took the desired *anti* conformation around the Si—Si bond. The length of the Si—Si bond is 0.2343(3) nm, which is essentially identical to that in the cyclic structure of 1 [0.2346(4) nm]. This result unambiguously demonstrates that the Si—Si bond in the cyclic structure of 1 is not subject to obvious ring strain.

Keywords silicon, iron, sodium amalgam, X-ray diffraction

Introduction

Considerable attention has recently been paid toward the novel thermal rearrangement reaction of $(\text{Me}_2\text{SiSiMe}_2)[\eta^5\text{-C}_5\text{H}_4\text{Fe}(\text{CO})_2]_2$ (1), which proceeds through metathesis of the Si—Si and Fe—Fe bonds to give $-(\text{Me}_2\text{Si}-\eta^5\text{-C}_5\text{H}_4\text{Fe}(\text{CO})_2\text{SiMe}_2-\eta^5\text{-C}_5\text{H}_4\text{Fe}(\text{CO})_2)-$ (2) containing two Si—Fe bonds (Scheme 1). Since this reaction was first reported in 1993,¹ many efforts in this area have been devoted to explore the scopes of this reaction in related systems. For example, possibilities of the reaction in similar cyclic structures to that of 1 but containing a Ge—Ge bond²⁻⁴ in place of the Si—Si bond or a Ru—Ru bond^{5,6} in place of the Fe—Fe bond have been investigated. Mechanistic details of this reaction have also been under intensive study, which has resulted in recognition of the intramolecular nature and the interesting regioselective character.^{7,8} All results obtained up to now demonstrate that it is the cyclic structure that is responsible for the reaction to take place. But what kind of property of the cyclic structure is the critical factor that leads to the taking place of the reaction is still a question.

Scheme 1

To examine if cyclic structure has any unusual properties, we have recently studied the reaction of 1 with I₂, which unexpectedly revealed the selective cleavage of the Fe—Fe bond with retention of the Si—Si bond to lead to the ring-opened complex $(\text{Me}_2\text{SiSiMe}_2)[\eta^5\text{-C}_5\text{H}_4\text{Fe}(\text{CO})_2\text{I}]_2$ (3).⁹ It was interesting to note that 3 could be a wonderful acyclic model complex suitable for comparison with the cyclic structure of 1. This comparison may hopefully provide the desired information about if there is significant ring strain at the Si—Si bond in the cyclic structure. However, the molecular structure of 3 determined by X-ray diffraction analysis showed an unusual *gauche* conformation rather than the *anti* one around the Si—Si bond. Thus, structural data of acyclic model complexes with the normal *anti* conformation are still desired. Herein, we report an alternative ring-opening method involving reductive cleavage of the Fe—Fe bond with sodium amalgam (Na/Hg), which afforded the ring-opened bis-sodium salt $(\text{Me}_2\text{SiSiMe}_2)[\eta^5\text{-C}_5\text{H}_4\text{Fe}(\text{CO})_2\text{Na}]_2$ (4) as well as a series of its derivatives $(\text{Me}_2\text{SiSiMe}_2)[\eta^5\text{-C}_5\text{H}_4\text{Fe}(\text{CO})_2\text{R}]_2$ (5, R = Me; 6, R = PhCH₂; 7, R = CH₃C(O); 8, R = PhC(O); 9, R = Cy₃Sn or 10, R = Ph₃Sn). A standard *anti* conformation was revealed by study on the molecular structure of 10.

Experimental

All reactions were carried out under an argon atmo-

sphere by using standard Schlenk techniques. ^1H NMR spectra were recorded on a JEOL FX90Q or JNH-60SI spectrometer. IR spectra were recorded on a Nicolet 5DX FT-IR instrument and elemental analyses were performed using a Vario EL instrument. THF and hexane were dried by refluxing with sodium in the presence of benzophenone and distilled just before use. Complex **1** was synthesized using the reported method.¹ Other chemicals were purchased and used without further purification.

Preparation of **4**

To 1% Na/Hg (30 g) in a 100-mL Schlenk flask was added **1** (0.468 g, 1.0 mmol) in THF (40 mL) while stirring magnetically. The reaction was lasted for 30 min after the addition was completed to give an orange THF solution containing a large amount of orange suspension. This solution, along with the suspension of **4**, was used directly in the next reaction.

Preparation of **5**–**10**

A typical experimental procedure is described for the synthesis of **5**. The solution layer obtained above was transferred to another flask using a syringe, to which CH_3I (0.45 g, 3.0 mmol) was added with magnetically stirring at room temperature. The resulting solution, which became green, was stirred for another 30 min to complete the reaction. After removal of the solvent under reduced pressure, the residue was dissolved in a small amount of benzene and purified through a short column (neutral Al_2O_3 , *n*-hexane). Collection of the yellow band gave **5** as yellow crystals. In similar manners, **6**–**10** were obtained as yellow crystals when PhCH_2Cl , $\text{CH}_3\text{C}(\text{O})\text{Cl}$, $\text{PhC}(\text{O})\text{Cl}$, $\text{C}_2\text{H}_5\text{SnCl}$ or Ph_3SnCl were used in place of CH_3I .

5 Yield 70%, m.p. 49–51 °C; ^1H NMR (CDCl_3) δ : 0.31 (s, 12H, SiMe), 0.31 (s, 6H, FeMe), 4.68 (brs, 4H, Cp), 4.86 (brs, 4H, Cp); IR (KBr) ν_{co} : 1996, 1956 cm^{-1} . Anal. calcd for $\text{C}_{20}\text{H}_{26}\text{O}_4\text{Si}_2\text{Fe}_2$: C 48.21, H 5.26; found C 48.22, H 5.40.

9 Yield 79%, m.p. 193–195 °C; ^1H NMR (CDCl_3) δ : 0.41 (s, 12H, SiMe), 1.20–1.95 (m, 66H, Cy), 4.52 (brs, 4H, Cp), 4.89 (brs, 4H, Cp); IR (KBr) ν_{co} : 2026, 1975 cm^{-1} . Anal. calcd for $\text{C}_{54}\text{H}_{86}\text{O}_4\text{Si}_2\text{Fe}_2\text{Sn}_2$: C 53.85, H 7.20; found C 53.87, H 7.47.

10 Yield 61%, m.p. 203–205 °C; ^1H NMR (CDCl_3) δ : 0.37 (s, 12H, SiMe), 4.65 (brs, 8H, Cp), 7.27–7.60 (m, 30H, Ph); IR (KBr) ν_{co} : 1983, 1926 cm^{-1} . Anal. calcd for $\text{C}_{54}\text{H}_{56}\text{O}_4\text{Si}_2\text{Fe}_2\text{Sn}_2$: C 55.53, H 4.32; found C 55.54, H 4.91.

X-Ray crystallography

Crystals of **10** suitable for X-ray diffraction analysis were obtained from a mixed solvent of hexane and benzene. Data collection was performed on an ENRAF-NONIUS CAD-4 diffractometer equipped with graphite monochromated $\text{Mo K}\alpha$ radiation ($\lambda = 0.071037$ nm) using the ω - 2θ scan technique at room temperature. The structure was solved by direct phase determination method. Hydrogen atoms were not found. All non-hydrogen atoms were refined by full-matrix least-squares methods with anisotropic thermal parameters. All calculations were performed on a PDP 11/4 computer using the SDP-PLUS program system. A summary of the crystallographic data is shown in Table 1. Selected bond lengths and angles are shown in Table 2.

Results and discussion

Synthesis of complexes

Na/Hg has been well known to be a mild reducing agent¹⁰ and hopefully to be able to cleave the Fe—Fe bonds with retention of the Si—Si bond of **1**. Thus, the reaction of **1** with Na/Hg was carried out in THF and found to lead to cleavage of the Fe—Fe bond to produce bis-sodium salt **4** as expected (Scheme 2). This reaction proceeded smoothly at room temperature and finished in about 30 min as indicated by disappearance of the dark-red color of **1**. At the end of the reaction, the solution became orange with a large amount of orange suspension present due to that **4** was only slightly soluble in THF. Compound **4** thus formed was not isolated and was used directly to react with a series of alkylating, acylating and stannylating agents to produce the expected ring-opened derivatives **5—10** (Scheme 2).

Compounds **5—10** were all yellow crystalline solids. They were stable enough to be handled in the air at room temperature during the separation and purification processes. But long-term standing in the air, especially in solutions, could cause obvious decomposition. They were characterized by elemental analyses. ¹H NMR spectra of them generally gave an up-field singlet due to the Si—Me protons and two sets of multiplets corresponding to the Cp

groups. Other signals that arose from the alkyl, acyl and stannyl moieties were also observed at the expected chemical shifts. IR spectra of these products generally gave two absorption bands corresponding to the symmetrical and asymmetrical stretching vibration modes of two geminal carbonyl groups. Additional absorption bands were observed in the carbonyl absorption region for **7** and **8** due to the presence of the acyl groups. All of these results are in accord with the molecular structures of **5—10**.

Scheme 2

Molecular structure

The molecular structure of **10** was determined by the X-ray diffraction method. The molecule (Fig. 1) had *C_i* symmetry, in which two triphenylstannyl groups were linked to the iron atoms after the Fe—Fe bond was cleaved, while the Si—Si bond was still retained. Unlike the structure of **3** reported previously,⁹ the molecule of **10** took the desired *anti* conformation around the Si—Si bond. The length of the Si—Si bond in this ring-opened structure was determined to be 0.2343(3) nm, which is essentially identical to that in the cyclic structure of **1** [0.2346(4) nm]¹ within the limits of experimental errors. This result demonstrates that either forming or breaking of the cyclic structure does not affect the length of the Si—Si bond. Therefore, the Si—Si bond in the cyclic structure of **1** must not be subject to obvious ring strain. We have previously reported that the boat-like conformation of the six-membered cyclic structure of **1**, which consists of two silicon, two iron and two bridge-head carbon atoms, might cause certain extent of molecular strain,¹ because groups at two silicon atoms were in eclipsed arrangement. According to the present result, it is likely that this kind of molecular strain is not so serious as to lengthen the Si—Si bond. It is also of interest here to compare the Si—Si bond length of **10** with that of **3** [0.2353(3) nm],⁹ which exhibits a tendency of slightly lengthening the Si—Si bond in the

Fig. 1 Molecular structure of **10**.

case of **3**. This could be caused by the gauche conformation of **3**, which may result in weak repulsively steric effects between the groups at two silicon atoms. Therefore, the unusual gauche conformation should not be due to intramolecular attractive effects but alternatively it most probably was stabilized by intermolecular interactions of crystal packing.⁹ The length of the Fe—Sn bond of **10** was determined to be 0.25441(9) nm, which is nearly the same as that of CpFe(CO)₂SnPh₃ (0.2540 nm).¹¹ Other bond lengths and angles are normal for this complex as shown in Table 2.

Conclusion

The reaction of **1** with Na/Hg was found to be an effective route to cleave the Fe—Fe bond and afford the expected ring-opened products. Various alkyl, acyl and stannyl iron derivatives could be synthesized using this method. Molecular structure of the bis-triphenylstannyl derivative determined by the X-ray diffraction method demonstrated the desired *anti* conformation around the Si—Si bond. The length of its Si—Si bond was found to be identical to that of **1**, unambiguously demonstrating that the cyclic structure of **1** is not subject to obvious ring strain. This can be an evidence for ruling out the possible mechanism involving thermally induced cleavage of the

Si—Si bond as the initial step for the novel rearrangement from **1** to **2**.
