Received April 14th, 1971

A method is presented for determination of best hybrid orbitals of a molecule of the type $\mathrm{MX}_{1} \mathrm{X}_{2} \ldots \mathrm{X}_{\mathrm{K}}$ both on the central atom M and on the ligands $\mathrm{X}_{1}$ through $\mathrm{X}_{\mathrm{k}}$ with the aid of the criterion of maximum overlap introduced by Pauling.

The construction of hybrid orbitals for molecules of the type $\mathrm{MX}_{\mathrm{K}}$ (homogeneous ligand sphere) and interpretation of the properties of a given molecule on their basis has been dealt with by Pauling. ${ }^{1}$ Murrell ${ }^{2}$ elaborated a method for the determination of hybrid orbitals of the central atom in the case of molecules of the type $M X_{K}$ with a small or no symmetry using the condition of maximum overlap between the central atom and ligand orbitals and calculated in this way the best hybrid orbitals of the compound $\mathrm{ClF}_{3}$. This method was modified and simplified ${ }^{3-5}$. (The relation between the method of maximum overlap and the Hückel MO method was pointed out by Lykos and Schmeising ${ }^{6}$.) The method of maximum overlap was further used in calculating the hybridization of cyclopropane and similar molecules ${ }^{7}$, in explaining the differences among measured bond lengths ${ }^{4}$ in $\mathrm{PCl}_{5}, \mathrm{SbCl}_{5}, \mathrm{SF}_{4}$ and $\mathrm{ClF}_{3}$, in calculating various conformations ${ }^{8}$ of $\mathrm{ClF}_{5}$ and the bond angles ${ }^{9-12}$ in $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{NH}_{3}$ and in studying complexes containing both $\sigma$ and $\pi$ bonds $^{13}$. The authors ${ }^{13}$, however, did not take into account the hybridization on ligands even when two atomic orbitals were localized on them, namely one for an bond and the other for a $\pi$ bond. To determine the conformation of a molecule of the type $M X_{K}$ on the basis of the method of maximum overlap, a "steepest descent" method was proposed ${ }^{14}$.

The method of maximum overlap was originally formulated for molecules with a homogeneous ligand sphere while the hybridization of ligand orbitals was disregarded. In the present work the generalization for molecules with a heterogeneous ligand sphere is carried out. We take into account the hybridization on the central atom as well as on the ligands. The criterion of maximum overlap is generalized so that a weighed sum of overlap integrals is considered rather than a simple sum as proposed originally ${ }^{2,3}$. The weights influence the heterogeneity of the ligand sphere.

[^0]
## THEORETICAL

We shall consider a molecule of the type $\mathrm{MX}, \mathrm{X}_{2} \ldots \mathrm{X}_{\mathrm{K}}$, where M denotes central atom and $X_{1}$ through $X_{K}$ ligands, which are generally different. On the central atom, a set of orthonormal real atomic orbitals is localized forming a column vector

$$
\begin{equation*}
\Phi=\left\{\varphi_{i} ; i \in\langle 1, P\rangle\right\} ; \tag{1}
\end{equation*}
$$

we assume that $P \geqq K$. Also on the $i$-th ligand $X_{\mathrm{i}}$, a set of orthonormal real atomic orbitals is localized forming a column vector

$$
\begin{equation*}
\boldsymbol{x}_{\mathrm{i}}=\left\{\chi_{\mathrm{j}}^{(\mathrm{i})} ; j \in\left\langle 1, Q_{\mathrm{i}}\right\rangle\right\}, \tag{2}
\end{equation*}
$$

where $Q_{i} \geqq 1, i \in\langle 1, K\rangle$. From the orthonormality of atomic orbitals it follows that

$$
\begin{equation*}
\Phi \Phi^{\mathrm{T}}=I_{(\mathrm{P})}, \quad X_{\mathrm{i}} X_{\mathrm{i}}^{\mathrm{T}}=\boldsymbol{I}_{(\mathrm{Q})}, \tag{3a,b}
\end{equation*}
$$

where $\boldsymbol{I}_{(\mathrm{x})}$ denotes diagonal matrix, $\boldsymbol{\Phi}^{\mathrm{T}}$ transposed vector of $\boldsymbol{\Phi}$, similarly to $\boldsymbol{X}_{\mathrm{i}}^{\top}$ and $i \in\langle 1, K\rangle$.

In the space of atomic orbitals defined by Eq. (1), we select orthonormal hybrid atomic orbitals forming a column vector

$$
\begin{equation*}
\Psi=\left\{\psi_{\mathrm{i}} ; i \in\langle 1, K\rangle\right\} . \tag{4}
\end{equation*}
$$

Analogously to Eqs (3) we have

$$
\begin{equation*}
\Psi \Psi^{\mathrm{T}}=\mathbf{I}_{(\mathrm{K})} \tag{5}
\end{equation*}
$$

The relation between vectors $\boldsymbol{\Phi}$ and $\boldsymbol{\Psi}$ is

$$
\begin{equation*}
\Psi=A \Phi, \tag{6}
\end{equation*}
$$

or in the component formalism $\psi_{\mathrm{i}}=\sum_{\mathrm{j}=1}^{\mathrm{p}} a_{\mathrm{ij}} \varphi_{\mathrm{j}}$ for $i \in\langle 1, K\rangle$, i.e. A denotestransformation matrix of the type $K \times P$ with elements $a_{\mathrm{ij}}$. On introducing Eq. (6) into (5) and using (3) we obtain a condition for the matrix $A$ :

$$
\begin{equation*}
\boldsymbol{\Psi} \Psi^{\mathrm{T}}=A \Phi \Phi^{\mathrm{T}} \mathbf{A}^{\mathrm{T}}=A \mathbf{I}_{(\mathrm{P})} \mathbf{A}^{\mathrm{T}}=A A^{\mathrm{T}}=\boldsymbol{I}_{(\mathrm{K})} \tag{7}
\end{equation*}
$$

In the $i$-th space defined by Eq. (2) we select a normalized hybrid atomic orbital and denote it as $\vartheta_{i}$. It can be expressed as a linear combination of atomic orbitals localized on the given ligand:

$$
\begin{equation*}
\vartheta_{\mathrm{i}}=\boldsymbol{c}_{\mathrm{i}}^{\mathrm{T}} \boldsymbol{X}_{\mathrm{i}}=\sum_{\mathrm{j}=1}^{Q_{\mathrm{i}}} c_{\mathrm{j}}^{(\mathrm{i})} \chi_{\mathrm{j}}^{(\mathrm{i})}, \quad i \in\langle 1, K\rangle, \tag{8}
\end{equation*}
$$

where $\boldsymbol{c}_{\mathrm{i}}^{\mathrm{T}}$ denotes row vector of coefficients $c_{\mathrm{j}}^{(\mathrm{i})}$. From the condition that $\vartheta_{\mathrm{i}}$ is normalized to one we obtain a condition for vector of coefficients $\boldsymbol{c}_{\mathrm{i}}$

$$
\begin{equation*}
c_{\mathrm{i}}^{\mathrm{T}} c_{\mathrm{i}}=\sum_{\mathrm{j}=1}^{Q_{\mathrm{i}}} c_{\mathrm{j}}^{(\mathrm{i})} c_{\mathrm{j}}^{(\mathrm{i})}=1, \quad i \in\langle 1, K\rangle ; \tag{9}
\end{equation*}
$$

taking into account that the set of atomic orbitals localized on the $i$-th ligand, Eq. (2), is orthonormal. Now, the method of maximum overlap consists in determining such hybrid atomic orbitals (Eqs (4) and (8)) or such transformation matrix $\boldsymbol{A}$ in Eq. (6) and column vectors $\boldsymbol{c}_{\mathrm{i}}$ in (8) that the weighed sum of overlap integrals $\left\langle\psi_{\mathrm{i}} \mid \vartheta_{\mathrm{i}}\right\rangle$ is maximum. We construct the functional

$$
\begin{equation*}
I=\sum_{\mathrm{i}=1}^{\mathrm{K}} k_{\mathrm{i}}\left\langle\psi_{\mathrm{i}} \mid \vartheta_{\mathrm{i}}\right\rangle-\sum_{\mathrm{i}, \mathrm{j}=1}^{\mathrm{K}} \frac{\lambda_{\mathrm{ij}}}{2}\left\langle\psi_{\mathrm{i}} \mid \psi_{\mathrm{j}}\right\rangle-\sum_{\mathrm{i}=1}^{\mathrm{K}} \frac{\varepsilon_{\mathrm{i}}}{2}\left\langle\vartheta_{\mathrm{i}} \mid \vartheta_{\mathrm{i}}\right\rangle, \tag{10}
\end{equation*}
$$

in which the first summation expresses the weighed sum of overlap integrals between the $i$-th hybrid atomic orbital on the central atom and that on the ligard $\boldsymbol{X}_{\mathbf{i}}$. The weight coefficients $k_{\mathrm{i}}$ characterize the inhomogeneity of the ligard sphere. They should be understood as semiempirical parameters which can be, for example, determined from energetic relations between the given ligand and the central atom. The second summation with Lagrange multipliers $\lambda_{\mathrm{ij}}$ expresses the restrictive condition (5) of orthonormality of the hybrid atomic orbitals on the central atom. Similarly, the third summation with Lagrange multipliers $\varepsilon_{\mathrm{i}}$ expresses the restrictive condition (9) for the hybrid atomic orbital on the $i$-th ligand. Introducing Eqs (6) and (8) into (10) we obtain

$$
\begin{equation*}
I=\sum_{\mathrm{i}=1}^{\mathrm{K}} \sum_{\mathrm{j}=1}^{\mathrm{p}} \sum_{\mathrm{l}=1}^{Q_{\mathrm{i}}} a_{\mathrm{ij}} c_{\mathrm{l}}^{\mathrm{i})} k_{\mathrm{i}}\left\langle\varphi_{\mathrm{j}} \mid \chi_{\mathrm{i}}^{(\mathrm{i})}\right\rangle-\sum_{\mathrm{i}, \mathrm{j}=1}^{\mathrm{K}} \sum_{\mathrm{i}=1}^{\mathrm{p}} \frac{\lambda_{\mathrm{ij}}}{2} a_{\mathrm{i} 1} a_{\mathrm{j} 1}-\sum_{\mathrm{i}=1}^{\mathrm{K}} \sum_{\mathrm{j}=1}^{Q_{\mathrm{i}}} \frac{\varepsilon_{\mathrm{i}}}{2}\left(c_{\mathrm{j}}^{\mathrm{i})}\right)^{2}, \tag{11}
\end{equation*}
$$

where $\left\langle\varphi_{j} \mid \chi_{\mathrm{j}}^{(\mathrm{i})}\right\rangle$ denotes overlap integral between the $j$-th atomic orbital of the central atom and $l$-th atomic orbital of the ligand $X_{\mathrm{i}}$. The conditions for the functional (11) to be stationary (i.e. the mathematic expression of the maximum overlap) are

$$
\begin{align*}
& \partial I \mid \partial a_{\mathrm{ij}}=0 \text { for } \quad i \in\langle 1, K\rangle ; j \in\langle 1, P\rangle  \tag{12a}\\
& \partial I / \partial c_{\mathrm{j}}^{(\mathrm{i})}=0 \text { for } \quad i \in\langle 1, K\rangle ; j \in\left\langle 1, Q_{\mathrm{i}}\right\rangle \tag{12b}
\end{align*}
$$

The condition (12a) applied to Eq. (11) gives

$$
\begin{equation*}
\sum_{1=1}^{Q_{i}} k_{\mathrm{i}} c_{1}^{(\mathrm{i})}\left\langle\varphi_{\mathrm{j}} \mid \chi_{\mathrm{i}}^{(\mathrm{i})}\right\rangle=\sum_{\mathrm{j}=1}^{\mathrm{K}} \frac{1}{2}\left(\lambda_{\mathrm{i} 1}+\lambda_{1 \mathrm{i}}\right) a_{1 j}, \tag{13}
\end{equation*}
$$

for $i \in\langle 1, K\rangle$ and $j \in\langle 1, P\rangle$. If we introduce the matrices $B$ and $\Lambda$ with the elements

$$
\begin{equation*}
B_{\mathrm{ij}}=\sum_{i=1}^{Q_{1}} k_{\mathrm{i}} c_{\mathrm{i}}^{(\mathrm{i})}\left\langle\varphi_{\mathrm{j}} \mid \chi_{\mathrm{i}}^{(\mathrm{i})}\right\rangle, \quad \Lambda_{\mathrm{i} 1}=\frac{1}{2}\left(\lambda_{\mathrm{i} 1}+\lambda_{\mathrm{ij}}\right), \tag{14a,b}
\end{equation*}
$$

then Eq. (13) can be rewritten in the matrix form as

$$
\begin{equation*}
B=\Lambda A . \tag{15}
\end{equation*}
$$

Assuming that the matrix $\Lambda$ is not singular we can express from Eq. (15) the transformation matrix

$$
\begin{equation*}
A=\Lambda^{-1} B \tag{16}
\end{equation*}
$$

According to the definition $(14 b), \boldsymbol{\Lambda}$ is a symmetrical matrix: $\boldsymbol{\Lambda}^{\mathrm{T}}=\boldsymbol{\Lambda}$. Introducing Eq. (16) into (7) we obtain

$$
\begin{equation*}
A^{-1} B B^{T} A^{-1}=I_{(K)} \tag{17}
\end{equation*}
$$

which is fulfilled if

$$
\begin{equation*}
A=\left(B B^{\mathrm{T}}\right)^{1 / 2} \tag{18}
\end{equation*}
$$

Combining this equation with (16) we obtain the final expression for the transformation matrix:

$$
\begin{equation*}
A=\left(B B^{\mathrm{T}}\right)^{-1 / 2} \mathbf{B} . \tag{19}
\end{equation*}
$$

It is clear from the derivation of this equation that it is equivalent to the condition for the functional (12a) to be stationary. If the coefficients $c_{1}^{(i)}$ of the expansion (14a) are fixed then the elements of the matrix $\boldsymbol{A}$ defined by Eq. (19) lead to the maximum of the functional (11).

The condition (12b) applied to Eq. (11) gives

$$
\begin{equation*}
\sum_{\mathrm{i}=1}^{\mathrm{P}} a_{\mathrm{i} 1} k_{\mathrm{i}}\left\langle\varphi_{\mathrm{l}} \mid \chi_{\mathrm{j}}^{(\mathrm{i})}\right\rangle=\varepsilon_{\mathrm{i}} c_{\mathrm{j}}^{(\mathrm{i})} \tag{20}
\end{equation*}
$$

for $i \in\langle 1, K\rangle$ and $j \in\left\langle 1, Q_{i}\right\rangle$. We introduce a column vector $\boldsymbol{b}_{\mathbf{i}}$ with the elements

$$
\begin{equation*}
b_{\mathrm{j}}^{(\mathrm{i})}=\sum_{\mathrm{l}=1}^{\mathrm{p}} a_{\mathrm{i} 1} k_{\mathrm{i}}\left\langle\varphi_{\mathrm{l}} \mid \chi_{\mathrm{j}}^{(\mathrm{i})}\right\rangle \tag{2I}
\end{equation*}
$$

Eq. (20) can be then be rewritten in the matrix form as

$$
\begin{equation*}
\boldsymbol{b}_{\mathbf{i}}=\varepsilon_{\mathrm{i}} \boldsymbol{c}_{\mathrm{i}} . \tag{22}
\end{equation*}
$$

This result combined with Eq.(9) gives the actual value of the Lagrange multiplier $\varepsilon_{i}$, from which it follows that

$$
\begin{equation*}
c_{i}=\left(b_{i}^{\mathrm{T}} b_{\mathrm{i}}\right)^{-1 / 2} b_{\mathrm{i}} \tag{23}
\end{equation*}
$$

for $i \in\langle 1, K\rangle$. Eqs (19) and (23) express the necessary condition for the functional (10) or (11) to be stationary. These equations are coupled since it follows from Eq. (14a) that the matrix B depends on the vectors $\boldsymbol{c}_{\mathrm{i}}$; similarly it follows from Eqs (21) and (23) that the vectors $\boldsymbol{c}_{\boldsymbol{i}}$ depend on the matrix $\boldsymbol{A}$. This means that their calculation must be performed by the iteration method, namely the following one: we choose a zero-th approximation $\boldsymbol{c}_{\mathrm{i}}^{(0)}$ of the vectors $\boldsymbol{c}_{\mathrm{i}}$. From Eqs (14a) and (19) we calculate the matrix $\boldsymbol{A}^{(0)}$, from which we calculate with the use of Eqs (21) and (23) the vectors $\boldsymbol{c}_{\mathrm{i}}^{(1)}$. We repeat this procedure until the vectors and the matrix are self-consistent. If $Q_{\mathrm{i}}=1$ and $k_{\mathrm{i}}=1$ for $i \in\langle 1, K\rangle$, the solution of Eq. (23) is not necessary, Eq. (19) being reduced to one known from the simple theory of maximum overlap in which no hybridization on ligands is considered ${ }^{3}$. The first summation in Eq. (11), which represents the total bond strength, can be with the aid of Eqs (14a) and (19) rewritten in the form

$$
\begin{equation*}
E=\operatorname{Sp}\left(\mathbf{A} \boldsymbol{B}^{\mathrm{T}}\right)=\operatorname{Sp}\left\{\left(\mathbf{B} \mathbf{B}^{\mathrm{T}}\right)^{1 / 2}\right\} . \tag{24}
\end{equation*}
$$

If the eigenvalues of the symmetrical matrix $\mathbf{B B}^{\mathrm{T}}$ are denoted as $\mu_{1}$ through $\mu_{\mathrm{K}}$, Eq. (24) can be rewritten in the common form ${ }^{3}$

$$
\begin{equation*}
E=\sum_{i=1}^{K} \mu_{i}^{1 / 2} . \tag{25}
\end{equation*}
$$

From a more detailed analysis of the proposed method it follows that the functional (11) has a maximum if the roots in $\left(B B_{i}^{\top}\right)^{-1 / 2}$ and $\left(b_{i}^{\top} b\right)^{-1 / 2}$ are taken with the positive sign.

## BEST HYBRID ORBITALS FOR CIF 3

The described method was applied to a molecule of chlorine trifluoride. According to experimental data ${ }^{10}, \mathrm{ClF}_{3}$ is a planar molecule with bond angles $\nless \mathrm{F}^{1}-\mathrm{Cl}-\mathrm{F}^{2}=\$ \mathrm{~F}^{1}-\mathrm{Cl}-\mathrm{F}^{3}=87 \cdot 5^{\circ}$, bond lengths $\mathrm{R}\left(\mathrm{Cl}-\mathrm{F}^{1}\right)=1.598 \AA, \mathrm{R}\left(\mathrm{Cl}-\mathrm{F}^{2}\right)=\mathrm{R}\left(\mathrm{Cl}-\mathrm{F}^{3}\right)=1.698 \AA$. For a unique definition of the overlap integrais, we assume that the molecule is situated in the $x-z$ plane, the Cl atom being placed in the origin of coordinates. On this atom, six Slater atomic orbitals are localized: $3 s, 3 p_{z}, 3 p_{x}, 3 d_{z}, 3 d_{x^{2}-y^{2}}$ and $3 d_{x z}$. The local coordinate system on each F atom is oriented so that the $z$ axis is directed towards the Cl atom. Two Slater atomic orbitals are localized on the F atoms: $2 s$ and $3 p_{z}$ (the latter is oriented in the local coordinate system). The exponents of the Slater atomic orbitals were calculated according to the Slater rules. The values of the overlap integrals, $\left\langle\varphi_{\mathrm{j}} \mid \chi_{\mathrm{i}}^{(\mathrm{i})}\right\rangle$, calculated according to Mulliken and coworkers ${ }^{11}$ from Eqs (14a) and (21), are in Table I. The weight coefficients $k_{\mathrm{i}}$ were set equal to one (homogeneous ligand sphere). The
iteration in solving Eqs (19) and (23) begins with $c_{\mathrm{i}}^{(0)}(\mathrm{i}=1,2,3)$ chosen so that $c_{\mathrm{i}}^{(\mathrm{j})}=Q_{\mathrm{i}}^{-1 / 2}$ for $j \in\left\langle 1, Q_{\mathrm{i}}\right\rangle$. We obtained after five iterations the total bond strength $E$ defined by Eqs (24) and (25) with a precision to $10^{-8}$. The calculations were performed on a computer of the type IBM 7040 with a program written in Fortran IV. The transformation matrix $\boldsymbol{A}$ is given in Table II and the vectors $c_{\mathrm{i}}(i=1-3)$ are listed in Table III. The total bond strength $E$ for the $\mathrm{ClF}_{3}$

molecule is equal to 1.42277; the contributions from different bonds are: $E\left(\mathrm{Cl}-\mathrm{F}^{1}\right)=0.504708$, $E\left(\mathrm{Cl}-\mathrm{F}^{2}\right)=E\left(\mathrm{Cl}-\mathrm{F}^{3}\right)=0.459033$ in accord with the fact that the $\mathrm{Cl}-\mathrm{F}^{1}$ bond is shorter than the others. Furthermore, calculations were performed with the assumption that only one atomic orbital is localized on the F atoms, namely either $2 s$ or $2 p_{2}$. For the total bond strength we then obtained $E_{\mathrm{s}}=1.30607$ or $E_{\mathrm{p}}=0.75202$. In these two calculations, the hybridization on ligands was not taken into account, so it was sufficient to solve only Eq. (19), a procedure equivalent to the Golebiewski formalism ${ }^{3}$ of maximum overlap.

## CONCLUSIONS

The problem of computing the hybrid atomic orbital both on the central atom and on the ligand can be formulated for special cases in different ways ${ }^{\prime 2}$. The advantage of our method consists in its generality and clear formulation. Moreover, the weight parameters $k_{\mathrm{i}}$ for distinguishing the heterogeneity of the ligand sphere can be simply introduced, the form of the final equations being preserved. The proposed iteration method of solving the coupled equations (19) and (23) was tested on a model calculation of the molecule of $\mathrm{ClF}_{3}$. After five iterations, self-consistent values for transformation matrix $\boldsymbol{A}$ and vectors $\boldsymbol{c}_{\mathrm{i}}$ were obtained.

The authors are indebted to Dr L Valko and Dr P. Pelikan for making available the overlap integrals for the model calculation and for stimulating discussions.
