Received September 3rd, 1973

Charge-transfer spectra of a series of substituted silacyclopentenes and some related carbon analogues were measured in the visible region in dichloromethane solution. Tetracyanoethylene was used as an electron acceptor with the aim of proving stereoelectronic requirements of hyper-conjugation. The changes of  $\nu_{\rm CT}$  with substitution at silicon are greater in cyclopentenylsilanes, in which the (HC—Si) bond is in a conformation suitable for interaction with  $\pi$ -system. Penning ionization spectra of analogous carbon compounds and of some silicon derivatives were also measured. Reported values of the first vertical ionization potentials correlate well with the wave-numbers of charge-transfer bands,  $\nu_{\rm CT}$ , which is evidence in support of the use of charge-transfer spectra for studying hyperconjugative interaction. Results are interpreted by means of simple orbital diagrams based on CNDO/2 wave functions. Acceptor properties of silicon can be explained by the interaction with the antibonding orbital,  $\Sigma_{\pi}^*$ , (Si—C) or (Si—X) bonds, without assuming the interaction of its *d*-orbitals. The order of acceptor strength of SiX<sub>3</sub>(SiX<sub>2</sub>) group (X = F > Cl > H > CH<sub>3</sub>) is in harmony with this explanation.

As it has already been experimentally and theoretically shown several times<sup>1-3</sup>, manifestations of hyperconjugation are extraordinarily dependent on the conformation of the molecules. Bock<sup>4</sup> showed on the basis of CNDO/2 calculations that the conformation of allylsilane, in which the (H<sub>2</sub>C—Si) bond is parallel to the  $\pi$ -system, is c. 0-43 eV more stable than the conformation in which the (H<sub>2</sub>C—Si) bond lies in the nodal plane of the  $\pi$ -system. Using correlation diagrams for these two conformations, the author illustrates mechanisms of the intermolecular interaction. However, individual conformers do not differ in their stability to the extent that conformational nonrigidity of the system could be neglected.

For that reason series of silacyclopentenes and cyclopentenylsilanes I-III (M = C, X = H; M = Si, X = F, Cl, H, CH<sub>3</sub>) were prepared and studied. The rigid skeleton of the molecule of these compounds ensures a stable conformation, which renders it possible to discuss individual mechanisms of interaction separately on the basis of the perturbation theory and of the symmetry of the molecule.

Part CXII in the series Organosilicon Compounds; Part CXI: This Journal 39, 1169 (1974).

## EXPERIMENTAL

Trimethylsilylcyclopentene-3 was prepared by reaction of chlorocyclopentene<sup>5</sup> with trimethylchlorosilane in tetrahydrofuran<sup>6</sup>. B.p. 142°C,  $n_D^{20}$  1·4472 (ref.<sup>7</sup> b.p. 144°C,  $n_D^{20}$  1·4560; ref.<sup>8</sup> b.p. 99–100°C,  $n_D^{20}$  1·4488; ref.<sup>6</sup> b.p. 135–140°C). For C<sub>8</sub>H<sub>16</sub>Si (140·09) calculated: 68·48% C, 11·49% H; found: 68·35% C, 11·40% H.

Trichlorsilylcyclopentene-3 was prepared by a modified Kumada's procedure<sup>8</sup>. A mixture of 40 ml of trichlorosilane, 10 ml of cyclopentadiene, 10 mg of bis(benzonitrile)palladium dichloride, and 0·1 g of triphenylphosphine was heated in a sealed glass ampoule at 100°C for 48 h. After removal of unreacted compounds by distillation under reduced pressure, the expected derivative was obtained as a sole product in a 60% yield. The use of triphenylphosphine gave only a 15% yield. B.p. 75°C/20 Torr (ref.<sup>7</sup> 43-45°C/5 Torr). For C<sub>5</sub>H<sub>7</sub>SiCl<sub>4</sub> (201·44) calculated: 52-79% Cl; found: 52-28% Cl.

Silylcyclopentene-3 was obtained by reduction of the trichlorosilyl derivative with lithium aluminium hydride in dibutyl ether. The product was distilled directly from the reaction mixture through a short column. Traces of dibutyl ether were removed by preparative gas chromatography. B.p.  $82^{\circ}$ C,  $n_D^{\circ 0}$  1·4595. For  $C_5H_{10}$ Si (98·09) calculated: 61·16°C, 10·19% H; found: 60·62% C, 10·21% H.

1,1-Dichloro-1-silacyclopentene-3 was obtained by pyrolysis of hexachlorodisilane in the presence of 1,3-butadiene in a flow apparatus<sup>12</sup>.

1,1-Dichloro-3-methyl-1-silacyclopentene-3 was obtained by pyrolysis of hexachlorodisilane in the presence of isoprene<sup>12</sup>.

Other derivatives were obtained in the usual way from appropriate chloro-substituted derivatives by their reduction with lithium aluminium hydride, methylation with methylmagnesium bromide or by fluorination with antimony trifluoride. Their physical constants are given in Table I. The carbon analogues were prepared by reported procedures; in the table are therefore recorded only their physical properties and the references to the literature. The purity of all the compounds was checked by gas chromatography; the substances all contained less than 1% of impurities.

Tetracyanoethylene (*purum*, Fluka) was used without further purification. Dichloromethane (analytical purity grade, Lachema) was washed with sodium carbonate solution, dried over calcium chloride and distilled through a 1 m column filled with ceramic rings. The fraction collected at 39-39·5°C was stored in a dark flask over Nalsit 4A molecular sieve.

Charge-transfer spectra of all the compounds mentioned with tetracyanoethylene as an acceptor were measured in dichloromethane solution with a Specord, Zeiss, spectrometer (Jena, DDR) in the 15000-35000 cm<sup>-1</sup> region under the conditions reported in a previous work<sup>13</sup>. As estimated, the maxima of the bands were read with the accuracy of  $\pm 100$  cm<sup>-1</sup>. The results are summarized in Table I. In the case of cyclopentene, the addition of tetracyanoethylene caused a fast dissocoloration of the yellow solution of the complex, presumably due to a consecutive reaction.

Spectra of Penning ionization. Absolute ionization potentials were determined with respect to benzene as a standard (9.24 eV (ref.<sup>14</sup>). The low energy of the exciting particle (Ar  ${}^{3}P_{2} =$

= 11.54 eV) allowed to measure only the first ionization potentials. The measurements were carried out on a high resolution instrument<sup>15,16</sup>. The obtained values of adiabatic and vertical ionization potentials are recorded in Table II.

### RESULTS AND DISCUSSION

The correlation of the wavenumber of the band maxima of charge-transfer complexes with the values of the first ionization potentials taken from the literature<sup>17-19</sup> is graphically represented in Fig. 1. With the aim of complementing the data not available in the literature, the Penning ionization spectra of some carbon analogues were measured. The Penning ionization differs from the photoelectron spectroscopy in the nature of the exciting particles. In place of protons, it makes use of metastable particles, in this case the <sup>3</sup>P<sub>2</sub> metastable state of argon (Fig. 3). Owing to the possibility of fine specific interactions between a molecule and the exciting particle, the spectra differ in some cases from usual photoelectron spectra<sup>16</sup>. This circumstance made it impossible to measure the spectra and ionization potentials of all the silicon derivatives under study. Also due to the above mentioned interactions the values obtained by photoelectron spectroscopy and do not lie on the regression line (Fig. 1). The regression line has the following form:

$$v_{\rm CT}(10^3 \, . \, {\rm cm}^{-1}) = (8.200 \pm 0.570) \, {\rm IP} \, ({\rm eV}) - (50.19 \pm 0.53), \quad r = 0.986 \, .$$

The values of ionization potentials obtained by Penning ionization were not included. When these values are considered, the correlation coefficient is 0.981, but the slope of the regression line is worse ( $8.930 \pm 0.580$ ).

It is worthy of note that the same regression equation also describes the values

#### FIG. 1

Dependence of Wavenumbers of Charge--Transfer Bands of Studied Compounds with Tetracyanoethylene as Electron Acceptor on Values of First Vertical Ionization Potentials

a 2,2-Dimethyl-3-butene, b 2,2-dimethyl-4-pentene, c allylsilane, d allyltrimethylsilane ( $v_{CT}$  taken from ref.<sup>13</sup>). IP<sub>v</sub>'s obtained by photoelectron spectroscopy (O) and Penning ionization ( $\bullet$ ). of ionization potentials of the higher cycloolefins and allylsilanes. Heilbronner has also shown<sup>17</sup> that the first ionization potential of *cis*-cycloolefins corresponds to ionization from the  $\pi$  orbital. This fact, along with the results obtained by Schweig<sup>18</sup> on the basis of a study of photoelectron spectra and quantum chemical calculations by the CNDO/2 method, served in this work as the basis for the interpretation of observed charge-transfer spectra.

Contrary to cyclopentene, silacyclopentenes are planar<sup>20-22</sup>. The highest occupied molecular orbital (HOMO) can be depicted on the basis of CNDO/2 wave functions<sup>18</sup> as the antibonding combination of (HOMO)  $\pi$  orbital of *cis*-butene with the  $\Sigma_{\pi}$  combination of  $\sigma(\text{Si}-X)$  orbitals (Fig. 2). The (H<sub>2</sub>C-Si) bond now lies in the plane of the ring and due to symmetry cannot interact with  $\pi$ -orbitals. The values of  $\Delta v_{\text{CT}} = (\nu(\text{R}-\text{SiCl}_3) - \nu(\text{R}-\text{Si}(\text{CH}_3)_3)$  are quite in harmony with this assumption. Such a possibility exists, however, in substituted allylsilanes<sup>13</sup> and cyclopentenyl-silanes (*III*), which results in higher  $\Delta \nu$  values ( $\Delta \nu$  (allylsilanes) = 6200 \text{ cm}^{-1},

FIG. 2

Schematic Representation of the Highest Occupied Orbital (HOMO) $_{\pi}$  of Cyclopentene and the Corresponding Orbital Diagram of Its Formation

 $\Delta\nu$  (III) = 8000 cm<sup>-1</sup>), compared to silacyclopentenes ( $\Delta\nu$  (I) = 3400 cm<sup>-1</sup>,  $\Delta\nu$  (II) = 2100 cm<sup>-1</sup>). In compounds (I) and (II) only interaction of the HOMO orbital of *cis*-2-butene with the  $\Sigma_{\pi}$  and  $\Sigma_{\pi}^*$ , or  $d_{yz}$  orbital may take place due to symmetry. On the basis of correlation diagrams  $\Sigma_{\pi}^*$  and  $d_{yz}$  orbitals of silicon cannot be distinguished. This could be possible only on the basis of quantum chemical calculations with inclusion of configurational interaction. The arguments of the perturbation theory support, however, the participation of the  $\Sigma_{\pi}^*$  orbital<sup>13</sup>.

The  $\pi - \Sigma_{\pi}$  combination of the highest occupied orbital corresponds to a decrease of ionization potential relative to a  $\pi$ -standard. The participation of  $\Sigma_{\pi}^*$  orbitals, which increases with increasing electronegativity of substituents on silicon, leads on the contrary to an increase of ionization potential, as shown in the correlation diagram.

The values of  $v_{CT}$  for all series studied agree with this assumption. Correlation diagrams show also the effect of the  $\pi$ -system on the resulting values of  $v_{CT}$ . Thus, for example,  $\Delta v = [v(5) - v(13)] = 900 \text{ cm}^{-1}$  is smaller than  $[v(10) - v(14)] = 1700 \text{ cm}^{-1}$ , which is quite understandable from correlation diagrams. The introduction of the methyl group to *cis*-2-butene, giving 2-methyl-2-butene, leads to an increase in HOMO energy (compare ionization potentials of *cis*-2-butene<sup>18</sup> 9.33 eV

and 2-methyl-butene 8.86 eV), which results in a greater interaction of the  $\pi$ - $\Sigma_{\pi}$  orbital with the  $\Sigma_{\pi}^{*}$  orbital, and then to a greater additional decrease in HOMO energy. This effect is even more distinct when comparing  $\Delta v [v(14 - v(9)] = -900 \text{ cm}^{-1}$  and  $\Delta v [v(13) = v(6)] = +600 \text{ cm}^{-1}$ . From the foregoing it is obvious that the order of acceptor strength of silicon depends above all on the substitution on silicon and only to a lesser extent on the type of the attached  $\pi$ -system.

FIG. 3

Penning Ionization Spectra of Some Compounds Studied (12, 13, 14 from the bottom) In the series of silacyclopentenes (I) this order is  $SiF_2 > SiCl_2 > SiH_2 > CH_2 >$ > Si(CH<sub>3</sub>)<sub>2</sub>, while in series II it is SiF<sub>2</sub> > SiCl<sub>2</sub> > SiH<sub>2</sub> > Si(CH<sub>3</sub>)<sub>2</sub> > CH<sub>2</sub>. This seems to indicate that in the latter series silicon affects the order only by its +I effect. A description of this type does not yield any information concerning the mechanism of transfer of substituent effects and, furthermore, it is not able to explain why the influence of the +I effect is not observed *e.g.* in series *I*. Similar problems relating to the +I effect of alkyl groups were discussed *e.g.* by Heilbronner<sup>17</sup>. This clearly demonstrates the limitation of the classical concepts of the different effects and the necessity of their substitution for corresponding orbital equivalents, such as e.g. Hoffmann's concept of "through space" or "through bond" interaction<sup>23,24</sup>. One of the additional reasons in support of Hoffmann's interpretation is the recently studied effect of stereospecificity of  $\sigma$  inductive effect<sup>25</sup>. The participation of d orbitals in the compounds  $(CH_3)_4 X (X = C, Si, Ge, Sn, and$ Pb) has recently been rejected in an excellent work by Lappert<sup>26</sup> only on the basis of symmetry rules. The only important interaction which is exhibited in the photoelectron spectra of these compounds is "through space" interaction.

The importance of low lying antibonding orbitals has convincingly been shown also by Schweig<sup>27</sup> who used the example of interactions in  $H_3Si-CH_2-CH_2^-$ . The author found that these orbitals stabilize syn-clinal conformation so that it is the most stable one, in contradistinction to the rules suggested by Hoffmann<sup>1</sup>. However, it was Hoffmann who pointed out<sup>28</sup> the importance of the interaction with antibonding orbitals and made the suggestion to term this phenomen "superjacent orbital interaction".

The authors thank Dr V. Čermák, The J. Heyrovský Institute of Physical Chemistry and Electrochemistry, Czechoslovak Academy of Sciences, Prague, for kind measurements of Penning ionization spectra and assistance with their interpretation.
