Received June 10th, 1980

Dedicated to Professor K. Dostál, on the occasion of his 60 th birthday.

#### Abstract

Study of reaction course of trimethylamine with selenium trioxide by conductometric titration and vibration spectra of the products proved that the reaction produces, besides the known donor-acceptor complex $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N} . \mathrm{SeO}_{3}$, also the adduct $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N} . \mathrm{S}_{2} \mathrm{O}_{6}$ similar to that formed in the system pyridine-selenium trioxide. Although the latter adduct could not be isolated in pure state, the results obtained indicate its structural analogy to the compound $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N} \cdot \mathrm{Se}_{2} \mathrm{O}_{6}$. In preparation of the both DA complexes of selenium trioxide and trimethylamine the adduct $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N} . \mathrm{SO}_{2}$ is an important intermediate whose vibration spectra were measured and interpreted, too. Comparison and characterization of bonding relations in the DA complexes $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N}$. . $\mathrm{SeO}_{3}$ and $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N}^{2} \mathrm{SO}_{3}$ were carried out on the basis of results of normal coordinate analysis.

The complex TMA. $\mathrm{SeO}_{3}$ (TMA = trimethylamine) was prepared by reaction ${ }^{1}$ of TMA with the adduct $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N} \cdot \mathrm{SeO}_{3}$ and also by thermal decomposition ${ }^{2}$ of the compound TMA. $\mathrm{O}_{2} \mathrm{Se}\left[\mathrm{OSi}\left(\mathrm{CH}_{3}\right)_{3}\right]_{2}$. Although the donor-acceptor interaction in TMA. $\mathrm{SeO}_{3}$ is obviously greater than that in $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N} . \mathrm{SeO}_{3}$ due to greater basicity of TMA, the adduct TMA. $\mathrm{SeO}_{3}$ is a substantially more labile compound, being decomposed by mere standing at room temperature for several hours ${ }^{2}$. Study of infrared spectra showed ${ }^{3}$ that both TMA. $\mathrm{SeO}_{3}$ and $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N} . \mathrm{SeO}_{3}$ are formed by monomer molecules and not by tetramers, which was incorrectly presumed earlier ${ }^{1,4}$. We have tried to elucidate the reaction course of TMA with selenium trioxide by means of conductometric titration and vibration spectra of the products formed in the same way as earlier in the case of reaction of pyridine with selenium trioxide ${ }^{5}$.

Preparation of the DA complexes of selenium trioxide with TMA involves the adduct TMA. $\mathrm{SO}_{2}$ as an intermediate whose structure was followed predominantly by means of electronic spectra ${ }^{6-9}$. The Raman spectrum of TMA. $\mathrm{SO}_{2}$ was also measured ${ }^{10}$, but the position of the band due to vibration of the donor-acceptor bond SN was only discussed. Therefore, we also tried to discuss in more detail the interpretation of vibration spectra of this compound.

The final part of this paper deals with normal coordinate analysis of the molecules TMA. $\mathrm{SeO}_{3}$ and TMA. $\mathrm{SO}_{3}$ with the aim of verification of the values of quadratic potential constants published ${ }^{11}$ for TMA. $\mathrm{SO}_{3}$ and comparison of bonding relations in the two complexes on the basis of these values.

## EXPERIMENTAL

Reagents. Selenium trioxide was prepared by dehydration of anhydrous selenic acid with diphosphorus pentoxide ${ }^{12}$ and purified by vacuum distillation. TMA was dried by passing over solid potassium hydroxide and sodium wire and purified by distillation. Sulphur trioxide was obtained by distillation from $20 \%$ oleum and purified by distillation. The used solvents were purified and dried by usual methods.

Analytical methods. The hexavalent selenium was determined titrimetrically ${ }^{13}$. TMA was displaced from the samples by $30 \%$ potassium hydroxide solution and distilled into a known amount of $0 \cdot 1 \mathrm{~m}$ hydrochloric acid the excess of which was retitrated with $0 \cdot 1 \mathrm{~m}$ sodium hydroxide. The tetravalent sulphur was determined iodometrically, the hexavalent sulphur was determined gravimetrically as barium sulphate.

The procedure used for the conductometric titration is described in ref. ${ }^{14}$, the methods of determination of melting point, measurement of infrared and Raman spectra, and study of thermical behaviour are described in ref. ${ }^{5}$.

Preparation of TMA. $\mathrm{SO}_{2}$. Gaseous TMA ( 8 g ) was introduced slowly into 50 ml strongly cooled liquid sulphur dioxide to give a light yellow solution. Evaporation of excess sulphur dioxide gave a white crystalline precipitate which was rid of the rest of free sulphur dioxide in vacuum at room temperature. Melting point of this hygroscopic substance is $74-75^{\circ} \mathrm{C}$, its yield was almost quantitative. For TMA. $\mathrm{SO}_{2}$ (123.2) calculated: $47.99 \%$ TMA, $26.03 \%$ S; found: $48.04 \%$ TMA, $25 \cdot 79 \%$ S.

Preparation of TMA. $\mathrm{SeO}_{3} \cdot 2 \cdot 1 \mathrm{~g}$ selenium trioxide was suspended in 50 ml liquid sulphur dioxide at $-50^{\circ} \mathrm{C}$, and 1.95 g TMA. $\mathrm{SO}_{2}$ was added thereto portionwise. After several minutes stirring all the selenium dioxide dissolved, and a clear colourless solution was formed. On evaporation of the solvent in vacuum at about $-15^{\circ} \mathrm{C}$ a white fine crystalline strongly hygroscopic solid separated which was rid of, the rest of solvent in vacuum at room temperature. Yield fast quantitative; m.p. $122-124^{\circ} \mathrm{C}$ with decomposition. For TMA. $\mathrm{SeO}_{3}(186 \cdot 1)$ calculated: $42 \cdot 44 \% \mathrm{Se}$, $31 \cdot 77 \%$ TMA; found: $42 \cdot 60 \% \mathrm{Se}, 31 \cdot 59 \%$ TMA.

Attempts of preparation of TMA. $\mathrm{Se}_{2} \mathrm{O}_{6} \cdot 2 \cdot 2 \mathrm{~g}$ selenium trioxide was suspended in 80 ml liquid sulphur dioxide at $-30^{\circ} \mathrm{C}$, and the suspension obtained was treated portionswise with 1.07 g TMA. $\mathrm{SO}_{2}$. After several minutes stirring a clear solution was formed which became turbid (white turbidity) on slow heating to $-20^{\circ} \mathrm{C}$. After several minutes the reaction mixture separated into two liquid phases: the upper one formed by the solvent used and the lower one formed by the saturated solution of sulphur dioxide in TMA. $\mathrm{Se}_{2} \mathrm{O}_{6}$. After removal of the upper layer of sulphur dioxide in vacuum the lower liquid phase began to separate a solid. Last remainders of sulphur dioxide could not be removed even in vacuum at $40^{\circ} \mathrm{C}$. The obtained very hygroscopical product was not homogeneous and could not be characterized analytically due to its consistency.

Preparation of TMA. $\mathrm{SO}_{3}$. Vacuum sublimation of the product prepared by reaction of TMA. . $\mathrm{SO}_{2}$ with sulphur trioxide in liquid sulphur dioxide medium ${ }^{15}$ gave the product in the form of long needles (up to several cm). Its melting point agreed with refs ${ }^{16,17}\left(240^{\circ} \mathrm{C}\right)$. For TMA. $\mathrm{SO}_{3}$ (139.2) calculated: $42 \cdot 47 \%$ TMA, $57 \cdot 53 \% \mathrm{SO}_{3}$; found: $42 \cdot 39 \%$ TMA, $57 \cdot 92 \% \mathrm{SO}_{3}$.

## RESULTS AND DISCUSSION

## Vibration Spectra and Thermal Behaviour of TMA. $\mathrm{SO}_{2}$

If the stereochemical activity of the free electron pair at tetravalent sulphur atom is considered, then a single space configuration of the TMA. $\mathrm{SO}_{2}$ molecule is possible with the $\mathrm{SO}_{2}$ group located in a plane perpendicular to the symmetry plane of the molecule. It belongs to the $C_{\mathrm{s}}$ point group and is characterized by the following fully reduced vibration representation

$$
\Gamma=23 A^{\prime \mathrm{P}, \alpha}+19 A^{\prime \mathrm{P}, \alpha} .
$$

The vibration spectra of TMA. $\mathrm{SO}_{2}$ are given in Table I. For their interpretation we used the data of refs ${ }^{18,19}$ concerning the assignment of vibration spectra of tri-

[^0]methylamine which was also supported by normal coordinate analysis ${ }^{19}$. The interpretation given in the Table V for valence vibration bands of SO and CN bonds is beyond a doubt. Identification of the band due to valence vibration of the coordination bond SN is more difficult. Hata and Kinumaki ${ }^{10}$ presume that this vibration is connected with a strong band at $186 \mathrm{~cm}^{-1}$ in the Raman spectrum. In the spectrum obtained by us for solid TMA. $\mathrm{SO}_{2}$ we observed in this region a weak band at 167 $\mathrm{cm}^{-1}$ and a strong band (polarized in the spectrum of the solution) at $202 \mathrm{~cm}^{-1}$. In the range of 500 to $400 \mathrm{~cm}^{-1}$ three partially overlapped bands were found altogether, two of which with higher wave numbers ( 473 and $453 \mathrm{~cm}^{-1}$ ) coalesce in the spectrum into a single strong polarized band ( $\varrho=0.27$ ). From comparison of wave numbers of fundamental vibrations of $\mathrm{NC}_{3}$ skeleton in TMA and some complexes of this base ${ }^{20-23}$ (which, according to the findings by Kurze and Paetzold ${ }^{3}$, represents a good measure of magnitude of the donor-acceptor interaction) it can be inferred that magnitude of charge transfer in TMA. $\mathrm{SO}_{2}$ is relatively considerable, and the band due to valence vibration of SN should rather lie in the higher of the two discussed regions. In our opinion it is probable that the bands at 167 and 202 $\mathrm{cm}^{-1}$, belong to deformation vibrations of the molecule, the valence vibration SN being connected with only one of the bands at 453 and $473 \mathrm{~cm}^{-1}$.
Study of thermal behaviour of TMA. $\mathrm{SO}_{2}$ showed that there are two marked endothermic effects at the DTA curve. One of them corresponds to the melting point (at $75^{\circ} \mathrm{C}$ ) and the other (at about $114^{\circ} \mathrm{C}$ ) to decomposition of the complex into its components which escape quantitatively in gaseous form.

## Conductometric Titration of TMA-Selenium Trioxide System

The titration curve of the studied system is given in Fig. 1. The first additions of TMA. $\mathrm{SO}_{2}$ cause the conductivity to increase to a maximum value at the molar

## Fig. 1

Titration curve of the system trimethylamine--selenium trioxide ( $1.35 \mathrm{~g}\left(\mathrm{SeO}_{3}\right)_{4}$ in 140 ml liquid sulphur dioxide)

ratio about $1: 3$. From this point on the conductivity decreases to a minimum at the molar ratio about $1: 2$. This section of the titration curve corresponds to formation of the complex TMA. $\mathrm{Se}_{2} \mathrm{O}_{6}$ the solubility of which in liquid sulphur dioxide is limited; on exceeding a certain concentration it begins to separate from the solution in the form of heavy oily liquid, which results in the observed conductivity decrease. If TMA. $\mathrm{Se}_{2} \mathrm{O}_{6}$ were not separated from the solution, the curve would have monotonous increasing character in the discussed section with the maximum at the molar ratio $1: 2$, as it is seen in Fig. 1 (dashed line), and it would be quite analogous to the titration curve of the system pyridone-selenium trioxide ${ }^{24}$. Reaching of the molar ratio $1: 1$ again is characterized by a minimum at the titration curve. At the molar ratio about $1 \cdot 1: 1$ the curve shows a break corresponding to the moment when a redox reaction proceeds in the system due to excess of TMA, which makes itself felt by the reaction mixture turning slightly red due to reduction of hexavalent selenium down to elementary selenium.

## Vibration Spectra and Structure of TMA.SeO 3 and TMA. $\mathrm{Se}_{2} \mathrm{O}_{6}$

The RA spectra of TMA. $\mathrm{SeO}_{3}$ given in Table II fully confirm the conclusion by Kurze and Paetzold ${ }^{3}$ made on the basis of study of IR spectra, viz. that the compound is formed by monomer molecules with $C_{3 v}$ symmetry. Its fully reduced vibration representation has the following form:

$$
\Gamma=10 A_{1}^{\mathrm{P}, \alpha}+5 A_{2}^{-}+15 E^{\mathrm{P}, \alpha} .
$$

The interpretation of vibration spectra of TMA. $\mathrm{SeO}_{3}$ given in Table II is (except for several points) identical with data of ref. ${ }^{3}$. The bands about 980 and $960 \mathrm{~cm}^{-1}$ are assigned $^{3}$ to the degenerated valence vibrations of the bonds SeO and CN , respectively. The latter band is split in RA spectrum, whereas the former one is not. Splitting of the band due to $v_{\mathrm{e}}\left(\mathrm{NC}_{3}\right)$ has not yet been observed in any spectrum of the TMA complexes studied, whereas the splitting of the band due to $v_{\mathrm{e}}\left(\mathrm{SeO}_{3}\right)$ is very frequent in spectra of solid samples. Hence we judge that the reverse assignment of these bands is more likely, which is confirmed by results of normal coordinate analysis.

In the region $550-400 \mathrm{~cm}^{-1}$ the spectra of $\mathrm{TMA}. \mathrm{SeO}_{3}$ show three bands altogether. The most intensive of them, which in RA spectrum of the solid sample lies at $531 \mathrm{~cm}^{-1}$, belongs obviously to valence vibration of the bond SeN . By this band partially overlapped is the band about $520 \mathrm{~cm}^{-1}$ which is interpreted as $\delta_{\mathrm{e}}\left(\mathrm{NC}_{3}\right)$ in ref. ${ }^{3}$, the band at $435 \mathrm{~cm}^{-1}$ being interpreted as $\delta_{s}\left(\mathrm{NC}_{3}\right)$. However, from polarization measurements it followed that the last of the given bands is depolarized and, in our opionion, belongs to two degenerated vibrations $\delta_{\mathrm{e}}\left(\mathrm{SeO}_{3}\right)$ and $\delta_{\mathrm{c}}\left(\mathrm{NC}_{3}\right)$. Splitting of the band about $530 \mathrm{~cm}^{-1}$ into two components results obviously from the presence of more than one TMA. $\mathrm{SeO}_{3}$ molecule in the elementary cell of the crystal.

[^1]On the basis of the polarization measurement it was necessary also to change the interpretation ${ }^{3}$ of the bands due to the vibrations $\varrho\left(\mathrm{CH}_{3}\right)$. The band at $1257 \mathrm{~cm}^{-1}$ is polarized and, therefore, must belong to $\varrho_{s}\left(\mathrm{CH}_{3}\right)$. Out of the two expected bands for $\varrho_{e}\left(\mathrm{CH}_{3}\right)$ one was only found in RA spectrum at $1114 \mathrm{~cm}^{-1}$. The other with wave number $1259 \mathrm{~cm}^{-1}$ was observed in IR spectrum only.

In the optimum case, molecule of the complex TMA. $\mathrm{Se}_{2} \mathrm{O}_{6}$ can belong to the $C_{\mathrm{s}}$ point group. However, polarization measurement with a liquid sample containing considerable amounts of sulphur dioxide showed that all the bands in RA spectrum are polarized, and TMA. $\mathrm{Se}_{2} \mathrm{O}_{6}$ has the trivial symmetry $C_{1}$. The obtained spectrum is given in Table II wherefrom also follows its interpretation which agrees well with the data obtained ${ }^{5}$ from the vibration spectra of $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N} . \mathrm{Se}_{2} \mathrm{O}_{6}$. On the basis of these results it can be stated that courses of reactions of selenium trioxide with TMA and pyridine are analogous in principle, which was expected. The observed differences are due only to different physico-chemical properties of the formed compounds.

## Raman Spectrum of TMA. $\mathrm{SO}_{3}$

Table III gives RA spectrum of TMA. $\mathrm{SO}_{3}$ along with the known ${ }^{11}$ IR spectrum of this compound. The data confirm the interpretation of IR spectra given by Watari ${ }^{11}$ to be justifiable. The band belonging to the vibration $\varrho_{e}\left(\mathrm{NC}_{3}\right)$ was not observed in the IR spectrum, although the measurement started from $80 \mathrm{~cm}^{-1}$. In RA spectrum of solid TMA. $\mathrm{SO}_{3}$ there are three weak bands in the region $300-150 \mathrm{~cm}^{-1}$, out of which two ones with higher wave number belong obviously to $\varrho_{e}\left(\mathrm{NC}_{3}\right)$ and $\tau_{\mathrm{e}}\left(\mathrm{CH}_{3}\right)$, and the third one belongs to some of the lattice vibrations. The bands at 220 and $259 \mathrm{~cm}^{-1}$ were assigned to $\varrho_{e}\left(\mathrm{NC}_{3}\right)$ and $\tau_{\mathrm{e}}\left(\mathrm{CH}_{3}\right)$. In RA spectrum of the solution these bands could not be observed due to their low intensity.

## Normal Coordinate Analysis of TMA. $\mathrm{SO}_{3}$ and TMA. $\mathrm{SeO}_{3}$ Complexes

The model of the TMA. $\mathrm{ZO}_{3}(\mathrm{Z}=\mathrm{S}, \mathrm{Se})$ complexes used for calculation of quadratic potential constants is given in Fig. 2. If $\mathrm{CH}_{3}$ groups are taken as vibrating units with relative mass 15 , then the following fully reduced vibration representation belongs to the TMA. $\mathrm{ZO}_{3}$ molecules in $C_{3 \mathrm{v}}$ point group:

$$
\Gamma=5 A_{1}^{\mathrm{P}, \boldsymbol{x}}+A_{2}^{-}+6 E^{\mathrm{p}, x} .
$$

The torsion vibration $\tau(\mathrm{ZN})$ belonging to the type $A_{2}$ is inactive in the both types of spectra. For the calculation we used the values of normal vibrations taken from RA spectra of the solutions in sulphur dioxide. Only when some band could not be identified in the spectrum of the solution due to its low intensity, the wave number was taken from RA spectrum of the solid sample.

Fig. 2
Model of the TMA. $\mathrm{ZO}_{3}$ molecules $(\mathbf{Z}=\mathrm{S}$, Se) which was used for normal coordinate analysis

Structural parameters of the both complexes were assessed on the basis of experimental values of cognate compounds $-r_{\mathrm{SN}}=162 \mathrm{pm}, r_{\mathrm{SeN}}=166 \mathrm{pm}, r_{\mathrm{sO}}=$ $=148 \mathrm{pm}, r_{\mathrm{SeO}}=158 \mathrm{pm}, r_{\mathrm{CN}}=155 \mathrm{pm}$, the angle $\mathrm{OZO}=115^{\circ}, \mathrm{OZN}=110 \cdot 9^{\circ}$. Calculation of the quadratic potential constants was carried out by the Wilson GF matrix method using a Tesla 200 computer and a set of programs described in refs ${ }^{25,26}$. For transformation of the $G$ and $F$ matrices arranged in inner coordinates to the block diagonal form we used the following set of symmetrical coordinates:

$$
\begin{aligned}
& S_{1}=\left(\Delta r_{1}+\Delta r_{2}+\Delta r_{3}\right) / \sqrt{ } 3 \\
& S_{2}=\left(\Delta d_{1}+\Delta d_{2}+\Delta d_{3}\right) / \sqrt{ } 3 \\
& S_{3}=R \\
& S_{4}=N_{1}\left[r^{1 / 2}\left(\Delta \alpha_{23}+\Delta \alpha_{13}+\Delta \alpha_{12}\right)-R^{1 / 2}\left(\Delta \beta_{1}+\Delta \beta_{2}+\beta \Delta_{3}\right)\right] \\
& S_{5}=N_{2}\left[d^{1 / 2}\left(\Delta \gamma_{23}+\Delta \gamma_{13}+\Delta \gamma_{12}\right)-R^{1 / 2}\left(\Delta \delta_{1}+\Delta \delta_{2}+\Delta \delta_{3}\right)\right] \\
& S_{6}=N_{1}\left[R^{1 / 2}\left(\Delta \alpha_{23}+\Delta \alpha_{13}+\Delta \alpha_{12}\right)+r^{1 / 2}\left(\Delta \beta_{1}+\Delta \beta_{2}+\Delta \beta_{3}\right)\right] \\
& S_{7}=N_{2}\left[R^{1 / 2}\left(\Delta \gamma_{23}+\Delta \gamma_{13}+\Delta \gamma_{12}\right)+d^{1 / 2}\left(\Delta \delta_{1}+\Delta \delta_{2}+\Delta \delta_{3}\right)\right]
\end{aligned}
$$

for the block $A_{1}\left(N_{1}\right.$ and $N_{2}$ are the normalisation coefficients, $S_{6}$ and $S_{7}$ are the redundant coordinates) and

$$
\begin{aligned}
& S_{8}=\left(2 \Delta r_{1}-\Delta r_{2}-\Delta r_{3}\right) / \sqrt{ } 6 \\
& S_{9}=\left(2 \Delta d_{1}-\Delta d_{2}-{ }_{3}\right) / \sqrt{ } 6 \\
& S_{10}=\left(2 \Delta \alpha_{23}-\Delta \alpha_{13}-\Delta \alpha_{12}\right) / \sqrt{ } 6 \\
& S_{11}=\left(2 \Delta \gamma_{23}-\Delta \gamma_{13}-\Delta \gamma_{12}\right) / \sqrt{ } 6 \\
& S_{12}=\left(2 \Delta \beta_{1}-\Delta \beta_{2}-\Delta \beta_{3}\right) / \sqrt{ } 6 \\
& S_{13}=\left(2 \Delta \delta_{1}-\Delta \delta_{2}-\Delta \delta_{3}\right) / \sqrt{ } 6
\end{aligned}
$$

or

$$
\begin{aligned}
S_{8}^{\prime} & =\left(\Delta r_{2}-\Delta r_{3}\right) / \sqrt{ } 2 \\
S_{9}^{\prime} & =\left(\Delta d_{2}-\Delta d_{3}\right) / \sqrt{ } 2
\end{aligned}
$$

$$
\begin{aligned}
& S_{10}^{\prime}=\left(\Delta \alpha_{13}-\Delta \alpha_{12}\right) / \sqrt{ } 2 \\
& S_{11}^{\prime}=\left(\Delta \gamma_{13}-\Delta \gamma_{12}\right) / \sqrt{ } 2 \\
& S_{12}^{\prime}=\left(\Delta \beta_{2}-\Delta \beta_{3}\right) / \sqrt{ } 2 \\
& S_{13}^{\prime}=\left(\Delta \delta_{2}-\Delta \delta_{3}\right) / \sqrt{ } 2
\end{aligned}
$$

for the blocks $E$.
In the diagonal valence force field approach used for calculation of the potential constants of the TMA. $\mathrm{SO}_{3}$ molecule in ref. ${ }^{11}$ the iteration process for the block $A_{1}$ of the both TMA. $\mathrm{ZO}_{3}$ molecules gave physically meaningless solution presuming assignment of the band with the lowest wave number to valence vibration of the coordination bond ZN. Differences between the calculated and experimental values of wave numbers of the fundamental vibrations also were not negligible. The solu-

[^2]tion obtained in the degenerated blocks $E$ corresponded to the presumed interpretation, but full agreement between the calculated and the measured wave number values was not reached, either. Preliminary calculations showed that the wave number differences in the blocks $E$ can be avoided by considering non-zero values for non--diagonal elements $F_{12}$ and $F_{56}$ (in the case of TMA. $\mathrm{SeO}_{3}$ ) and $F_{34}$ (in the case of TMA. $\mathrm{SO}_{3}$ ). Due to lack of experimental data they had to be fixed in the calculations - the values $5 \mathrm{Nm}^{-1}$ for $F_{12}$ and $F_{56}\left(\mathrm{TMA} . \mathrm{SeO}_{3}\right)$ and $-10 \mathrm{Nm}^{-1}$ for $F_{34}$ (TMA. $\mathrm{SO}_{3}$ ) enabled to reach complete agreement between the calculated and experimental values of wave numbers of the degenerated vibrations of the two complexes. As early as in this calculation phase it was possible to confirm justification of the interpretation of the band at $533 \mathrm{~cm}^{-1}$ in spectrum of TMA. $\mathrm{SeO}_{3}$ to the both deformation vibrations $\delta_{\mathrm{e}}\left(\mathrm{SeO}_{3}\right)$ and $\delta_{\mathrm{e}}\left(\mathrm{NC}_{3}\right)$. The potential constant $f_{\mathrm{CNC}}$ obtained with this presumption was in good agreement with that calculated for the TMA. $\mathrm{SO}_{3}$ molecule, whereas assignment of the partially overlapped band at $520 \mathrm{~cm}^{-1}$ to this vibration led to an almost double $f_{\mathrm{CNC}}$ value.

To obtain physically acceptable solution for the blocks $A_{1}$ it was necessary to introduce further non-diagonal element of the matrices $F_{\mathrm{s}}$ into the calculation. Preliminary calculations showed that the elements $F_{23}, F_{34}, F_{35}$ and the interaction constants $f_{\mathrm{OZO} / \mathrm{OZN}}$ and $f_{\mathrm{CNC} / \mathrm{ZNC}}$ must be considered which are (provided $f_{\mathrm{OZO} / \mathrm{OZN}}=f_{\mathrm{OZO} / \mathrm{OZN}}^{\prime}$ and $\left.f_{\mathrm{CNC} / \mathrm{ZNC}}=f_{\mathrm{CNC} / \mathrm{ZNC}}^{\prime}\right)$ involved in the elements $F_{44}$ and $F_{55}$, respectively, with high numerical coefficient. Therefore, in the final calculation we fixed the deformation potential constants $f_{\mathrm{OZO}}, f_{\mathrm{OZN}}, f_{\mathrm{CNC}}$, and $f_{\mathrm{ZNC}}$ obtained by independent solution of the blocks $E$, which made it possible to adjust all the said elements of matrices $F_{\mathrm{s}}^{\mathrm{A}_{1}}$. Under these conditions the iteration process gave very well-consistent sets of quadratic potential constants for the two molecules TMA. $\mathrm{ZO}_{3}$ (Table IV). Their introduction back into the secular equations made it possible to reproduce the experimental wave number values of fundamental vibrations with errors less than $1 \mathrm{~cm}^{-1}$. Also the distribution of potential energy given in Table $V$ agrees well with the expectation.

Neglecting of some (often important) interaction potential constants (e.g. fozo, $f_{\mathrm{CNC}}^{\prime}$ etc.), fixation of four deformation potential constants, and introduction of the condition $F_{12}=F_{56}$ for TMA. $\mathrm{SeO}_{3}$ in the block $E$ was inevitable due to limited number of experimental data. Therefore, the calculated values of the deformation and interaction quadratic potential constants considered in the calculations will obviously be loaded with a certain error. However, magnitude of the valence potential constants should not be significantly affected, which is documented by the following finding.

There is no qualitative difference between the SO and SeO bonds in structurally analogous compounds. Therefore, there exists a linear relation between their quadratic potential constants ${ }^{27}$. The values calculated for $f_{\mathrm{ZO}}$ in the TMA. $\mathrm{ZO}_{3}$ complexes fulfil this relation very well (with errors below $1 \%$ ) and confirm thus complete struc-
tural analogy between the two compounds. The ZO bond order $\left(N_{\mathrm{sO}}=1 \cdot 83 ; N_{\mathrm{scO}}=\right.$ $=1.58$ according to ref. ${ }^{28}$ ) also agrees with their presumed multiplicity and somewhat different polarity.
The relatively high bond order of the coordination bonds $\mathrm{ZN}\left(N_{\mathrm{ZN}} \approx 0.8\right)$ indicates a strong bonding interaction between the both components of the complexes and an almost equal sharing of electron pair by the atoms $Z$ and $N$. Formation of DA bond affects the bonding relations predominantly in the donor section of the TMA. . $\mathrm{ZO}_{3}$ complexes. These changes are manifested by a relatively low value of the potential constant $f_{\mathrm{CN}}$, which signals an enhanced polarity of CN bonds. If $\mathrm{CH}_{3}$ group is considered to be a vibrating unit with relative mass 15 and if the wave number values ${ }^{29}$ of normal vibrations $\left(v_{\mathrm{s}}\left(\mathrm{NC}_{3}\right) 826 \mathrm{~cm}^{-1}, v_{\mathrm{e}}\left(\mathrm{NC}_{3}\right) 1102 \mathrm{~cm}^{-1}, \delta_{\mathrm{s}}\left(\mathrm{NC}_{3}\right) 364 \mathrm{~cm}^{-1}\right.$, and $\delta_{\mathrm{e}}\left(\mathrm{NC}_{3}\right) 422 \mathrm{~cm}^{-1}$ ) are used, then the value $411 \mathrm{Nm}^{-1}$ is obtained for $f_{\mathrm{CN}}$ in TMA, i.e. by $1 / 3$ higher than that in the two complexes. On the contrary, mutual interaction between CN bonds is markedly greater in TMA. $\mathrm{ZO}_{3}$ ( $f_{\mathrm{CN}}^{\prime}$ about $41 \mathrm{Nm}^{-1}$ ) than in TMA ( $f_{\mathrm{CN}}^{\prime}=13 \mathrm{Nm}^{-1}$ ). Hence it can be judged that the easy redox decomposition of TMA. $\mathrm{SeO}_{3}$ is enabled by intermolecular interaction of the both strongly polar groups of this complex. A smaller tendency to redox decomposition observed ${ }^{5}$

Table V
